1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Roles** and select the Quick Suite service role. The default name is `aws-quicksight-service-role-v0`
3. Choose **Add permissions** and then **Create inline policy**.
4. Select **JSON** to open the JSON policy editor, then add the following policy.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": "glue:GetCatalog",  
            "Resource": "*"  
        }  
    ]  
}
```

5. Choose **Next**, enter a **Policy name** and then **Create policy**.

To configure permissions for the Quick Suite admin user

1. Run the following AWS CLI command to find the ARN of your Quick Suite admin user.

```
aws quicksight list-users --aws-account-id 111122223333 --namespace default --  
region region
```

2. Grant Lake Formation permissions to this ARN. For details, see [Managing access to a table or database with Lake Formation](#).

Using table data in Quick Suite

You can connect to table data using Athena as a data source.

Prerequisites

- [Integrate your table buckets with AWS analytics services.](#)
 - [Create a namespace.](#)
 - [Create a table.](#)
 - [Configure permissions for Quick Suite to access tables.](#)
- [Sign up for Quick Suite.](#)

1. Sign in to your Quick Suite account at <https://quicksight.aws.amazon.com/>
2. In the dashboard, choose **New analysis**.
3. Choose **New dataset**.
4. Select **Athena**.
5. Enter a **Data source name**, then choose **Create data source**.
6. Choose Use custom SQL. You will not be able to select your table from the **Choose your table** pane.
7. Enter an Athena SQL query that captures the columns you want to visualize, then choose **Confirm query**. For example, use the following query to select all columns:

```
SELECT * FROM "s3tablescatalog/table-bucket-name".namespace.table-name
```

8. Choose **Visualize** to analyze data and start building dashboards. For more information, see [Visualizing data in Quick Suite](#) and [Exploring interactive dashboards in Quick Suite](#)

Streaming data to tables with Amazon Data Firehose

Amazon Data Firehose is a fully managed service for delivering real-time [streaming data](#) to destinations such as Amazon S3, Amazon Redshift, Amazon OpenSearch Service, Splunk, Apache Iceberg tables, and custom HTTP endpoints or HTTP endpoints owned by supported third-party service providers. With Amazon Data Firehose, you don't need to write applications or manage resources. You configure your data producers to send data to Firehose, and it automatically delivers the data to the destination that you specified. You can also configure Firehose to transform your

data before delivering it. To learn more about Amazon Data Firehose, see [What is Amazon Data Firehose?](#)

Complete these steps to set up Firehose streaming to tables in S3 table buckets:

1. [Integrate your table buckets with AWS analytics services.](#)
2. Configure Firehose to deliver data into your S3 tables. To do so, you [create an AWS Identity and Access Management \(IAM\) service role that allows Firehose to access your tables.](#)
3. Grant the Firehose service role explicit permissions to your table or table's namespace. For more information, see [Grant Lake Formation permissions on your table resources.](#)
4. [Create a Firehose stream that routes data to your table.](#)

Creating a role for Firehose to use S3 tables as a destination

Firehose needs an IAM [service role](#) with specific permissions to access AWS Glue tables and write data to S3 tables. You need this provide this IAM role when you create a Firehose stream.

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**
3. Choose **Create a policy**, and choose **JSON** in policy editor.
4. Add the following inline policy that grants permissions to all databases and tables in your data catalog. If you want, you can give permissions only to specific tables and databases. To use this policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "S3TableAccessViaGlueFederation",  
            "Effect": "Allow",  
            "Action": [  
                "glue:GetTable",  
                "glue:GetDatabase",  
                "glue:UpdateTable"  
            ],  
            "Resource": [  
                "arn:aws:glue:  
                    <region>:  
                        <account>/table/  
                            <table>  
            ]  
        }  
    ]  
}
```

```
        "arn:aws:glue:us-east-1:111122223333:catalog/s3tablescatalog/*",
        "arn:aws:glue:us-east-1:111122223333:catalog/s3tablescatalog",
        "arn:aws:glue:us-east-1:111122223333:catalog",
        "arn:aws:glue:us-east-1:111122223333:database/*",
        "arn:aws:glue:us-east-1:111122223333:table/*/*"
    ],
},

        "Action": [
            "kms:Decrypt",
            "kms:GenerateDataKey"
        ],
        "Resource": [
            "arn:aws:kms:us-east-1:111122223333:key/KMS-key-id"
        ],
        "Condition": {
            "StringEquals": {
                "kms:ViaService": "s3.us-east-1.amazonaws.com"
            },
            "StringLike": {
                "kms:EncryptionContext:aws:s3:arn": "arn:aws:s3:::error delivery bucket/prefix*"
            }
        }
    },
    {
        "Sid": "LoggingInCloudWatch",
        "Effect": "Allow",
        "Action": [
            "logs:PutLogEvents"
        ],
        "Resource": [
            "arn:aws:logs:us-east-1:111122223333:log-group:log-group-name:log-stream:log-stream-name"
        ]
    },
    {
        "Sid": "RequiredWhenAttachingLambdaToFirehose",
        "Effect": "Allow",
        "Action": [
            "lambda:InvokeFunction",
            "lambda:GetFunctionConfiguration"
        ],
        "Resource": [
            "arn:aws:lambda:us-east-1:111122223333:function:function-name:function-version"
        ]
    }
}
```

```
    }
]
}
```

This policy has statements that allow access to Kinesis Data Streams, invoking Lambda functions and access to AWS KMS keys. If you don't use any of these resources, you can remove the respective statements.

If error logging is enabled, Firehose also sends data delivery errors to your CloudWatch log group and streams. For this, you must configure log group and log stream names. For log group and log stream names, see [Monitor Amazon Data Firehose Using CloudWatch Logs](#).

5. After you create the policy, create an IAM role with **AWS service** as the **Trusted entity type**.
6. For **Service or use case**, choose **Kinesis**. For **Use case** choose **Kinesis Firehose**.
7. Choose **Next**, and then select the policy you created earlier.
8. Give your role a name. Review your role details, and choose **Create role**. The role will have the following trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sts:AssumeRole"
      ],
      "Principal": {
        "Service": [
          "firehose.amazonaws.com"
        ]
      }
    }
  ]
}
```

Creating a Firehose stream to S3 tables

The following procedure shows how to create a Firehose stream to deliver data to S3 tables using the console. The following prerequisites are required to set up a Firehose stream to S3 tables.

Prerequisites

- [Integrate your table buckets with AWS analytics services.](#)
 - [Create a namespace.](#)
 - [Create a table.](#)
- Create the [Role for Firehose to access S3 Tables](#).
- [Grant Lake Formation permissions](#) to the Firehose service role you created to access tables.

To provide routing information to Firehose when you configure a stream, you use your namespace as the database name and the name of a table in that namespace. You can use these values in the Unique key section of a Firehose stream configuration to route data to a single table. You can also use this values to route to a table using JSON Query expressions. For more information, see [Route incoming records to a single Iceberg table](#).

To set up a Firehose stream to S3 tables (Console)

1. Open the Firehose console at <https://console.aws.amazon.com/firehose/>.
2. Choose **Create Firehose stream**.
3. For **Source**, choose one of the following sources:
 - Amazon Kinesis Data Streams
 - Amazon MSK
 - Direct PUT
4. For **Destination**, choose **Apache Iceberg Tables**.
5. Enter a **Firehose stream name**.
6. Configure your **Source settings**.
7. For **Destination settings**, choose **Current account** to stream to tables in your account or **Cross-account** for tables in another account.
 - For tables in the **Current account**, select your S3 Tables catalog from the **Catalog** dropdown.

- For tables in a **Cross-account**, enter the **Catalog ARN** of the catalog you want to stream to in another account.
8. Configure database and table names using **Unique Key configuration**, **JSONQuery** expressions, or in a Lambda function. For more information, refer to [Route incoming records to a single Iceberg table](#) and [Route incoming records to different Iceberg tables](#) in the *Amazon Data Firehose Developer Guide*.
 9. Under **Backup settings**, specify a **S3 backup bucket**.
 10. For **Existing IAM roles** under **Advanced settings**, select the IAM role you created for Firehose.
 11. Choose **Create Firehose stream**.

For more information about the other settings that you can configure for a stream, see [Set up the Firehose stream](#) in the *Amazon Data Firehose Developer Guide*.

Running ETL jobs on Amazon S3 tables with AWS Glue

AWS Glue is a serverless data integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use AWS Glue jobs to run extract, transform, and load (ETL) pipelines to load data into your data lakes. For more information about AWS Glue, see [What is AWS Glue?](#) in the *AWS Glue Developer Guide*.

An AWS Glue job encapsulates a script that connects to your source data, processes it, and then writes it out to your data target. Typically, a job runs extract, transform, and load (ETL) scripts. Jobs can run scripts designed for Apache Spark runtime environments. You can monitor job runs to understand runtime metrics such as completion status, duration, and start time.

You can use AWS Glue jobs to process data in your S3 tables by connecting to your tables through the integration with AWS analytics services, or, connect directly using the Amazon S3 Tables Iceberg REST endpoint or the Amazon S3 Tables Catalog for Apache Iceberg. This guide covers the basic steps to get started using AWS Glue with S3 Tables, including:

Topics

- [Step 1 – Prerequisites](#)
- [Step 2 – Create a script to connect to table buckets](#)
- [Step 3 – Create a AWS Glue job that queries tables](#)

Choose your access method based on your specific AWS Glue ETL job requirements:

- **AWS analytics services integration (Recommended)** – Recommended when you need centralized metadata management across multiple AWS analytics services, need to leverage existing AWS Glue Data Catalog permissions and fine-grained access control with Lake Formation, or are building production ETL pipelines that integrate with other AWS services like Athena or Amazon EMR.
- **Amazon S3 Tables Iceberg REST endpoint** – Recommended when you need to connect to S3 tables from third-party query engines that support Apache Iceberg, build custom ETL applications that need direct REST API access, or when you require control over catalog operations without dependencies on AWS Glue Data Catalog.
- **Amazon S3 Tables Catalog for Apache Iceberg** – Use only for legacy applications or specific programmatic scenarios that require the Java client library. This method is not recommended for new AWS Glue ETL job implementations due to additional JAR dependency management and complexity.

 **Note**

S3 Tables is supported on [AWS Glue version 5.0 or higher](#).

Step 1 – Prerequisites

Before you can query tables from a AWS Glue job you must configure an IAM role that AWS Glue can use to run the job. Choose your method of access to see specific prerequisites for that method.

AWS analytics services integration (Recommended)

Prerequisites required to use the S3 Tables AWS analytics integration to run AWS Glue jobs.

- [Integrate your table buckets with AWS analytics services](#).
- [Create an IAM role for AWS Glue](#).
 - Attach the AmazonS3TablesFullAccess managed policy to the role.
 - Attach the AmazonS3FullAccess managed policy to the role.

Amazon S3 Tables Iceberg REST endpoint

Prerequisites to use the Amazon S3 Tables Iceberg REST endpoint to run AWS Glue ETL jobs.

- [Create an IAM role for AWS Glue.](#)

- Attach the AmazonS3TablesFullAccess managed policy to the role.
- Attach the AmazonS3FullAccess managed policy to the role.

Amazon S3 Tables Catalog for Apache Iceberg

Prerequisites use the Amazon S3 Tables Catalog for Apache Iceberg to run AWS Glue ETL jobs.

- [Create an IAM role for AWS Glue.](#)

- Attach the AmazonS3TablesFullAccess managed policy to the role.
- Attach the AmazonS3FullAccess managed policy to the role.
- To use the Amazon S3 Tables Catalog for Apache Iceberg you need to download the client catalog JAR and upload it to an S3 bucket.

Downloading the catalog JAR

1. Check for the latest version on [Maven Central](#). You can download the JAR from Maven central using your browser, or using the following command. Make sure to replace the *version number* with the latest version.

```
wget https://repo1.maven.org/maven2/software/amazon/s3tables/s3-
tables-catalog-for-iceberg-runtime/0.1.5/s3-tables-catalog-for-iceberg-
runtime-0.1.5.jar
```

2. Upload the downloaded JAR to an S3 bucket that your AWS Glue IAM role can access. You can use the following AWS CLI command to upload the JAR. Make sure to replace the *version number* with the latest version, and the *bucket name* and *path* with your own.

```
aws s3 cp s3-tables-catalog-for-iceberg-runtime-0.1.5.jar s3://amzn-s3-demo-
bucket/jars/
```

Step 2 – Create a script to connect to table buckets

To access your table data when you run an AWS Glue ETL job, you configure a Spark session for Apache Iceberg that connects to your S3 table bucket. You can modify an existing script to connect

to your table bucket or create a new script. For more information on creating AWS Glue scripts, see [Tutorial: Writing an AWS Glue for Spark script](#) in the *AWS Glue Developer Guide*.

You can configure the session to connect to your table buckets through the any of the following S3 Tables access methods:

- S3 Tables AWS analytics services integration (Recommended)
- Amazon S3 Tables Iceberg REST endpoint
- Amazon S3 Tables Catalog for Apache Iceberg

Choose from the following access methods to view setup instructions and configuration examples.

AWS analytics services integration (Recommended)

As a prerequisites to query tables with Spark on AWS Glue using the AWS analytics services integration, you must [Integrate your table buckets with AWS analytics services](#)

You can configure the connection to your table bucket through a Spark session in a job or with AWS Glue Studio magics in an interactive session. To use the following examples, replace the *placeholder values* with the information for your own table bucket.

Using a PySpark script

Use the following code snippet in a PySpark script to configure a AWS Glue job to connect to your table bucket using the integration.

```
spark = SparkSession.builder.appName("SparkIcebergSQL") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
"org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog","s3tables") \
    .config("spark.sql.catalog.s3tables",
"org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tables.catalog-impl",
"org.apache.iceberg.aws.glue.GlueCatalog") \
    .config("spark.sql.catalog.s3tables.glue.id",
"111122223333:s3tablescatalog/amzn-s3-demo-table-bucket") \
    .config("spark.sql.catalog.s3tables.warehouse", "s3://amzn-s3-demo-table-
bucket/warehouse/") \
```

```
.getOrCreate()
```

Using an interactive AWS Glue session

If you are using an interactive notebook session with AWS Glue 5.0, specify the same configurations using the `%%configure` magic in a cell prior to code execution.

```
%%configure
{"conf":
 "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
--conf spark.sql.defaultCatalog=s3tables --conf
spark.sql.catalog.s3tables=org.apache.iceberg.spark.SparkCatalog --conf
spark.sql.catalog.s3tables.catalog-impl=org.apache.iceberg.aws.glue.GlueCatalog
--conf spark.sql.catalog.s3tables.glue.id=111122223333:s3tablescatalog/amzn-s3-
demo-table-bucket --conf spark.sql.catalog.s3tables.warehouse=s3://amzn-s3-demo-
table-bucket/warehouse/"}
```

Amazon S3 Tables Iceberg REST endpoint

You can configure the connection to your table bucket through a Spark session in a job or with AWS Glue Studio magics in an interactive session. To use the following examples, replace the *placeholder values* with the information for your own table bucket.

Using a PySpark script

Use the following code snippet in a PySpark script to configure a AWS Glue job to connect to your table bucket using the endpoint.

```
spark = SparkSession.builder.appName("glue-s3-tables-rest") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
"org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog", "s3_rest_catalog") \
    .config("spark.sql.catalog.s3_rest_catalog",
"org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3_rest_catalog.type", "rest") \
    .config("spark.sql.catalog.s3_rest_catalog.uri", "https://
s3tables.Region.amazonaws.com/iceberg") \
    .config("spark.sql.catalog.s3_rest_catalog.warehouse",
"arn:aws:s3tables:Region:111122223333:bucket/amzn-s3-demo-table-bucket") \
```

```
.config("spark.sql.catalog.s3_rest_catalog.rest.sigv4-enabled", "true") \
.config("spark.sql.catalog.s3_rest_catalog.rest.signing-name", "s3tables") \
.config("spark.sql.catalog.s3_rest_catalog.rest.signing-region", "Region") \
.config('spark.sql.catalog.s3_rest_catalog.io-
impl','org.apache.iceberg.aws.s3.S3FileIO') \
.config('spark.sql.catalog.s3_rest_catalog.rest-metrics-reporting-
enabled','false') \
.getOrCreate()
```

Using an interactive AWS Glue session

If you are using an interactive notebook session with AWS Glue 5.0, specify the same configurations using the `%%configure` magic in a cell prior to code execution. Replace the placeholder values with the information for your own table bucket.

```
%%configure
{"conf":
"spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
--conf spark.sql.defaultCatalog=s3_rest_catalog --conf
spark.sql.catalog.s3_rest_catalog=org.apache.iceberg.spark.SparkCatalog
--conf spark.sql.catalog.s3_rest_catalog.type=rest --conf
spark.sql.catalog.s3_rest_catalog.uri=https://s3tables.Region.amazonaws.com/
iceberg --conf
spark.sql.catalog.s3_rest_catalog.warehouse=arn:aws:s3tables:Region:111122223333:bucket/
amzn-s3-demo-table-bucket --conf spark.sql.catalog.s3_rest_catalog.rest.sigv4-
enabled=true --conf spark.sql.catalog.s3_rest_catalog.rest.signing-name=s3tables
--conf spark.sql.catalog.s3_rest_catalog.rest.signing-region=Region --conf
spark.sql.catalog.s3_rest_catalog.io-impl=org.apache.iceberg.aws.s3.S3FileIO --
conf spark.sql.catalog.s3_rest_catalog.rest-metrics-reporting-enabled=false"}
```

Amazon S3 Tables Catalog for Apache Iceberg

As a prerequisite to connecting to tables using the Amazon S3 Tables Catalog for Apache Iceberg you must first download the latest catalog jar and upload it to an S3 bucket. Then, when you create your job, you add the the path to the client catalog JAR as a special parameter. For more information on job parameters in AWS Glue, see [Special parameters used in AWS Glue jobs](#) in the [AWS Glue Developer Guide](#).

You can configure the connection to your table bucket through a Spark session in a job or with AWS Glue Studio magics in an interactive session. To use the following examples, replace the **placeholder values** with the information for your own table bucket.

Using a PySpark script

Use the following code snippet in a PySpark script to configure a AWS Glue job to connect to your table bucket using the JAR. Replace the placeholder values with the information for your own table bucket.

```
spark = SparkSession.builder.appName("glue-s3-tables") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
"org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog", "s3tablesbucket") \
    .config("spark.sql.catalog.s3tablesbucket",
"org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tablesbucket.catalog-impl",
"software.amazon.s3tables.iceberg.S3TablesCatalog") \
    .config("spark.sql.catalog.s3tablesbucket.warehouse",
"arn:aws:s3tables:Region:111122223333:bucket/amzn-s3-demo-table-bucket") \
    .getOrCreate()
```

Using an interactive AWS Glue session

If you are using an interactive notebook session with AWS Glue 5.0, specify the same configurations using the `%%configure` magic in a cell prior to code execution. Replace the placeholder values with the information for your own table bucket.

```
%%configure
{"conf":
"spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
--conf spark.sql.defaultCatalog=s3tablesbucket --conf
spark.sql.catalog.s3tablesbucket=org.apache.iceberg.spark.SparkCatalog
--conf spark.sql.catalog.s3tablesbucket.catalog-
impl=software.amazon.s3tables.iceberg.S3TablesCatalog --conf
spark.sql.catalog.s3tablesbucket.warehouse=arn:aws:s3tables:Region:111122223333:bucket/
amzn-s3-demo-table-bucket", "extra-jars": "s3://amzn-s3-demo-bucket/jars/s3-
tables-catalog-for-iceberg-runtime-0.1.5.jar"}
```

Sample scripts

The following example PySpark scripts can be used to test querying S3 tables with an AWS Glue job. These scripts connect to your table bucket and runs queries to: create a new namespace, create

a sample table, insert data into the table, and return the table data. To use the scripts, replace the *placeholder values* with the information for your own table bucket.

Choose from the following scripts based on your S3 Tables access method.

S3 Tables integration with AWS analytics services

```
from pyspark.sql import SparkSession

spark = SparkSession.builder.appName("SparkIcebergSQL") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-\
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
"org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog","s3tables")
    .config("spark.sql.catalog.s3tables", "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tables.catalog-impl",
"org.apache.iceberg.aws.glue.GlueCatalog") \
    .config("spark.sql.catalog.s3tables.glue.id",
"111122223333:s3tablescatalog/amzn-s3-demo-table-bucket") \
    .config("spark.sql.catalog.s3tables.warehouse", "s3://amzn-s3-demo-table-bucket/\
bucket/amzn-s3-demo-table-bucket") \
    .getOrCreate()

namespace = "new_namespace"
table = "new_table"

spark.sql("SHOW DATABASES").show()

spark.sql(f"DESCRIBE NAMESPACE {namespace}").show()

spark.sql(f"""
CREATE TABLE IF NOT EXISTS {namespace}.{table} (
    id INT,
    name STRING,
    value INT
)
""")

spark.sql(f"""
INSERT INTO {namespace}.{table}
VALUES
    (1, 'ABC', 100),
    (2, 'XYZ', 200)
""")
```

```

spark.sql(f"SELECT * FROM {namespace}.{table} LIMIT 10").show()
```

Step 3 – Create a AWS Glue job that queries tables

The following procedures show how to setup AWS Glue jobs that connect to your S3 table buckets. You can do this using the AWS CLI or using the console with AWS Glue Studio script editor. For more information, see [Authoring jobs in AWS Glue](#) in the *AWS Glue User Guide*.

Using AWS Glue Studio script editor

The following procedure shows how to use the AWS Glue Studio script editor to create an ETL job that queries your S3 tables.

Prerequisites

- [Step 1 – Prerequisites](#)
- [Step 2 – Create a script to connect to table buckets](#)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. From the Navigation pane, choose **ETL jobs**.
3. Choose **Script editor**, then choose **Upload script** and upload the PySpark script you created to query S3 tables.
4. Select the **Job details** tab and enter the following for **Basic properties**.
 - For **Name**, enter a name for the job.
 - For **IAM Role**, select the role you created for AWS Glue.
5. (Optional) If you are using the Amazon S3 Tables Catalog for Apache Iceberg access method, expand **Advanced properties** and for **Dependent JARs path**, enter the S3 URI of the client

catalog jar you uploaded to an S3 bucket as a prerequisite. For example, s3://*amzn-s3-demo-bucket1/jars*/s3-tables-catalog-for-iceberg-runtime-0.1.5.jar

6. Choose **Save** to create the job.
7. Choose **Run** start the job, and review the job status under the **Runs** tab.

Using the AWS CLI

The following procedure shows how to use the AWS CLI to create an ETL job that queries your S3 tables. To use the commands replace the *placeholder values* with your own.

Prerequisites

- [Step 1 – Prerequisites](#)
- [Step 2 – Create a script to connect to table buckets](#) and upload it to an S3 bucket.

1. Create an AWS Glue job.

```
aws glue create-job \
--name etl-tables-job \
--role arn:aws:iam::111122223333:role/AWSGlueServiceRole \
--command '{
    "Name": "glueetl",
    "ScriptLocation": "s3://amzn-s3-demo-bucket1/scripts/glue-etl-query.py",
    "PythonVersion": "3"
}' \
--default-arguments '{
    "--job-language": "python",
    "--class": "GlueApp"
}' \
--glue-version "5.0"
```

Note

(Optional) If you are using the Amazon S3 Tables Catalog for Apache Iceberg access method, add the client catalog JAR to the --default-arguments using the --extra-jars parameter. Replace the *input placeholders* with your own when you add the parameter.

```
--extra-jars": "s3://amzn-s3-demo-bucket/jar-path/s3-tables-catalog-for-iceberg-runtime-0.1.5.jar"
```

2. Start your job.

```
aws glue start-job-run \
--job-name etl-tables-job
```

3. To review your job status, copy the run ID from the previous command and enter it into the following command.

```
aws glue get-job-run --job-name etl-tables-job \
--run-id jr_ec9a8a302e71f8483060f87b6c309601ea9ee9c1ffc2db56706dfcceeb3d0e1ad
```

Getting started querying S3 Tables with Amazon SageMaker Unified Studio

Amazon SageMaker Unified Studio is a comprehensive analytics service that enables you to query and derive insights from your data using SQL, natural language, and interactive notebooks. It supports team collaboration and analysis workflows across AWS data repositories and third-party sources within a unified interface. SageMaker Unified Studio integrates directly with S3 Tables, providing a seamless transition from data storage to analysis within the Amazon S3 console.

You can integrate S3 Tables with SageMaker Unified Studio through the Amazon S3 console or SageMaker Unified Studio console.

For setup through the SageMaker Unified Studio console, see the [SageMaker Unified Studio documentation](#).

Requirements for querying S3 Tables with SageMaker Unified Studio

Using SageMaker Unified Studio with S3 Tables requires the following:

- Your table buckets have been integrated with AWS analytics services in the current Region. For more information, see [Integrating S3 Tables with AWS analytics services](#).
- You are using an IAM role with permissions to create and view resources in SageMaker Unified Studio. For more information, see [Setup IAM-based domains in SageMaker Unified Studio](#).

- You have a SageMaker domain and project. For more information, see [Domains](#) in the *SageMaker Unified Studio Administrator Guide*, and [Projects](#) in the *SageMaker Unified Studio User Guide*.

If you haven't already performed these actions or created these resources, S3 Tables can automatically complete this set up for you so you can begin querying with SageMaker Unified Studio.

Getting started querying S3 Tables with SageMaker Unified Studio

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that contains the table that you want to query.
4. On the bucket details page, select the table that you want to query.
5. Choose **Query**.
6. Then, choose **Query table in SageMaker Unified Studio**.
 - a. If you've already configured SageMaker Unified Studio for your tables the SageMaker Unified Studio console opens to the query editor with a sample SELECT query loaded for you. Modify this query as needed for your use case.
 - b. If you haven't already configured SageMaker Unified Studio for S3 Tables, a set up page appears with a single step to enable Integration with AWS analytics services which integrates your tables with services like SageMaker Unified Studio. This step will execute automatically then you will be redirected to a page in the SageMaker Unified Studio console with the following options to configure your account for querying S3 Tables:
 - i. In **Setting you up as an administrator**, your current federated IAM role is selected. If your current role does not already have the required permissions, you will need to [setup an IAM-based domain in SageMaker Unified Studio](#) and assign permissions to your role so you can login to SageMaker Unified Studio.
 - ii. In **Project data and administrative control**, select **Auto-create a new role with required permissions** to automatically create a role with the required permissions, or select **Use an existing role** and choose a role. If the chosen role does not already have the required permissions, you will need to [setup an IAM-based domain in SageMaker Unified Studio](#) and assign permissions to your admin execution role so you can access data in SageMaker Unified Studio.

- iii. In **Data encryption** select **Use AWS owned key** to let AWS own and manage a key for you or **Choose a different AWS AWS KMS key (advanced)** to use an existing key or to create a new one.
- iv. Select **Set up SageMaker Unified Studio**.
- v. Next, the SageMaker Unified Studio console opens to the query editor with a sample SELECT query loaded for you. Modify this query as needed for your use case.

In the query editor, the **Catalog** field should be populated with s3tablescatalog/ followed by the name of your table bucket, for example, s3tablescatalog/amzn-s3-demo-table-bucket. The **Database** field is populated with the namespace where your table is stored.

Working with Apache Iceberg V3

Apache Iceberg Version 3 (V3) is the latest version of the Apache Iceberg table format specification, introducing advanced capabilities for building petabyte-scale data lakes with improved performance and reduced operational overhead. V3 addresses common performance bottlenecks encountered with V2, particularly around batch updates and compliance deletes.

AWS provides support for deletion vectors and row lineage as defined in the Apache Iceberg Version 3 (V3) specification. These features are available with Apache Spark on [Amazon EMR 7.12](#), [AWS Glue ETL](#), [Amazon SageMaker Unified Studio Notebooks](#), and Apache Iceberg tables in [AWS Glue Data Catalog](#), including [Amazon S3 Tables](#).

Key Features in V3

Deletion Vectors

Replaces V2's positional delete files with an efficient binary format stored as Puffin files. This eliminates write amplification from random batch updates and GDPR compliance deletes, significantly reducing the overhead of maintaining fresh data. Organizations processing high-frequency updates will see immediate improvements in write performance and reduced storage costs from fewer small files.

Row-lineage

Enables precise change tracking at the row level. Your downstream systems can process changes incrementally, speeding up data pipelines and reducing compute costs for change

data capture (CDC) workflows. This built-in capability eliminates the need for custom change tracking implementations.

Version Compatibility

V3 maintains backward compatibility with V2 tables. AWS services support both V2 and V3 tables simultaneously, allowing you to:

- Run queries across both V2 and V3 tables
- Upgrade existing V2 tables to V3 without data rewrites
- Execute time travel queries that span V2 and V3 snapshots
- Use schema evolution and hidden partitioning across table versions

Important

V3 is a one-way upgrade. Once a table is upgraded from V2 to V3, it cannot be downgraded back to V2 through standard operations.

Getting Started with V3

Prerequisites

Before working with V3 tables, ensure you have:

- An AWS account with appropriate IAM permissions
- Access to one or more AWS analytics services (EMR, Glue, Amazon SageMaker Unified Studio Notebooks, or S3 Tables)
- An S3 bucket for storing table data and metadata
- A table bucket to get started with S3 Tables or a general purpose S3 bucket if you are building your own Iceberg infrastructure
- AWS Glue catalog configured

Creating V3 Tables

Creating New V3 Tables

To create a new Iceberg V3 table, set the format-version table property to 3.

Using Spark SQL:

```
CREATE TABLE IF NOT EXISTS myns.orders_v3 (
    order_id bigint,
    customer_id string,
    order_date date,
    total_amount decimal(10,2),
    status string,
    created_at timestamp
)
USING iceberg
TBLPROPERTIES (
    'format-version' = '3'
)
```

Upgrading V2 Tables to V3

You can upgrade existing V2 tables to V3 atomically without rewriting data.

Using Spark SQL:

```
ALTER TABLE myns.existing_table
SET TBLPROPERTIES ('format-version' = '3')
```

Important

V3 is a one-way upgrade. Once a table is upgraded from V2 to V3, it cannot be downgraded back to V2 through standard operations.

What happens during upgrade:

- A new metadata snapshot is created atomically
- Existing Parquet data files are reused
- Row-lineage fields are added to the table metadata
- The next compaction will remove old V2 delete files
- New modifications will use V3's Deletion Vector files
- The upgrade does not perform a historical backfill of row-lineage change tracking records

Enabling Deletion Vectors

To take advantage of Deletion Vectors for updates, deletes, and merges, configure your write mode.

Using Spark SQL:

```
ALTER TABLE myns.orders_v3
SET TBLPROPERTIES ('format-version' = '3',
                    'write.delete.mode' = 'merge-on-read',
                    'write.update.mode' = 'merge-on-read',
                    'write.merge.mode' = 'merge-on-read'
                  )
```

These settings ensure that update, delete, and merge operations create Deletion Vector files instead of rewriting entire data files.

Leveraging Row-lineage for Change Tracking

V3 automatically adds row-lineage metadata fields to track changes.

Using Spark SQL:

```
# Query with parameter value provided
last_processed_sequence = 47

SELECT
    id,
```

```
data,  
_row_id,  
_last_updated_sequence_number  
FROM myns.orders_v3  
WHERE _last_updated_sequence_number > :last_processed_sequence
```

The `_row_id` field uniquely identifies each row, while `_last_updated_sequence_number` tracks when the row was last modified. Use these fields to:

- Identify changed rows for incremental processing
- Track data lineage for compliance
- Optimize CDC pipelines
- Reduce compute costs by processing only changes

Best Practices for V3

When to Use V3

Consider upgrading to or starting with V3 when:

- You perform frequent batch updates or deletes
- You need to meet GDPR or compliance delete requirements
- Your workloads involve high-frequency upserts
- You require efficient CDC workflows
- You want to reduce storage costs from small files
- You need better change tracking capabilities

Optimizing Write Performance

- Enable Deletion Vectors for update-heavy workloads:

```
SET TBLPROPERTIES (  
'write.delete.mode' = 'merge-on-read',  
'write.update.mode' = 'merge-on-read',
```

```
'write.merge.mode' = 'merge-on-read'  
)
```

- Configure appropriate file sizes:

```
SET TBLPROPERTIES (  
'write.target-file-size-bytes' = '536870912' -- 512 MB  
)
```

Optimizing Read Performance

- Leverage row-lineage for incremental processing
- Use time travel to access historical data without copying
- Enable statistics collection for better query planning

Migration Strategy

When migrating from V2 to V3:

- Test in non-production first - Validate upgrade process and performance
- Upgrade during low-activity periods - Minimize impact on concurrent operations
- Monitor initial performance - Track metrics after upgrade
- Run compaction - Consolidate delete files after upgrade
- Update documentation - Reflect V3 features in team documentation

Compatibility Considerations

- Engine versions - Ensure all engines accessing the table support V3
- Third-party tools - Verify V3 compatibility before upgrading
- Backup strategy - Test snapshot-based recovery procedures
- Monitoring - Update monitoring dashboards for V3-specific metrics

Troubleshooting

Common Issues

Error: "format-version 3 is not supported"

- Verify your engine version supports V3

V3 support for Amazon AWS services is as follows:

Service	V3 Support
EMR Spark	Release 7.12+
AWS Glue ETL	Yes
Amazon SageMaker Unified Studio Notebooks	Yes
AWS Glue: Iceberg REST API, Table Maintenance	Yes
Amazon S3 Tables: Iceberg REST API, Table Maintenance	Yes
Amazon Athena (Trino)	No

- Check catalog compatibility
- Ensure latest AWS service versions

Performance degradation after upgrade

- Verify there are no compaction failures. See [Logging and monitoring for S3 Tables](#) for more details.
- Check if Deletion Vectors are enabled. Ensure the following properties are set:

```
SET TBLPROPERTIES (
  'write.delete.mode' = 'merge-on-read',
  'write.update.mode' = 'merge-on-read',
  'write.merge.mode' = 'merge-on-read'
)
```

- You can verify table properties with the following code:

```
DESCRIBE FORMATTED myns.orders_v3
```

- Review partition strategy. Over partitioning can lead to small files. Run the below query to get the average file size for your table:

```
SELECT avg(file_size_in_bytes) as avg_file_size_bytes
FROM myns.orders_v3.files
```

Incompatibility with third-party tools

- Verify tool supports V3 specification
- Consider maintaining V2 tables for unsupported tools
- Contact tool vendor for V3 support timeline

Getting Help

- AWS Support: Contact AWS Support for service-specific issues
- Apache Iceberg Community: Iceberg Slack
- AWS Documentation: AWS Analytics Documentation

Pricing

- Amazon EMR: [Compute and storage pricing](#)
- [Amazon SageMaker pricing](#)
- AWS Glue: [Job run and Data Catalog pricing](#)
- S3 Tables: [Storage and request pricing](#)

Availability

Apache Iceberg V3 support is available across all AWS regions where Amazon EMR, AWS Glue Data Catalog, AWS Glue ETL, and S3 Tables operate.

Additional Resources

- [Apache Iceberg V3 Documentation](#)

- [Getting Started Guide](#)

Replicating S3 tables

Amazon S3 Tables support automatic replication of Apache Iceberg tables stored in Amazon S3 table buckets. Replication destinations can be within the same AWS Region, across multiple AWS Regions, the same account, or to other AWS accounts. By configuring replication for your tables, you can maintain read-only replicas of your data across multiple locations. You can use replicas to enhance data availability, meet compliance requirements and increase access performance for distributed applications.

S3 Tables replication maintains data consistency by committing all table updates, including snapshots, metadata, and data files, to the destination table in the same order as the source table.

When to use S3 Tables replication

You can use S3 Tables replication for the following purposes:

- **Minimize latency** – If your customers are in two geographic locations, you can minimize latency when accessing tables by maintaining read replicas in AWS Regions that are geographically closer to your users.
- **Regulatory compliance** – You can maintain read replicas in specific geographic locations or AWS accounts, which might help you meet certain regulatory or compliance requirements. You can configure the replication destination table bucket to encrypt tables with different AWS KMS keys than the source.
- **Centralized analytics** – If you have data distributed across multiple AWS Regions, you can replicate Region-specific datasets to a centralized Region for unified reporting, cross-Region

analysis, and machine learning model training. This eliminates the need to query across Regions or build custom data aggregation pipelines.

- **Testing and development environments** – You can create read replicas of production tables in separate AWS accounts or table buckets to provide realistic test data for development and QA teams. This isolates testing workloads from production systems while ensuring test environments have current, production-like data without manual exports or data synchronization processes.

Features

S3 Tables replication offers the following features.

Read-only replicas for S3 Tables

S3 Tables replication creates read-only replicas of your Apache Iceberg tables across table buckets. You can query replicas independently using any Iceberg-compatible engine.

Automatically maintained replicas

The S3 Tables replication service automatically maintains replica tables. Replication typically updates replicas within minutes of updates to the source. S3 Tables commits all updates in the same order as the source table to maintain consistency.

Replication to multiple destinations

You can replicate the same table to multiple destination table buckets. Replication destinations can be within the same AWS Region, across multiple AWS Regions, in the same AWS account, or in other AWS accounts.

Independent snapshot retention

Snapshot expiration for replica tables is independent of the source table, allowing you to set different retention periods on replica tables if needed. For example, you can configure your source table to retain snapshots for 30 days while setting a 90-day retention period for replica tables. If you configure a longer retention period on replicas, snapshots that expire at the source remain available and queryable in replicas. This configuration provides extended time-travel capabilities for historical analysis.

Maintain replica tables in lower-cost storage tiers

You can configure destination table buckets to use the S3 Intelligent-Tiering storage class, which automatically optimizes storage costs based on access patterns without performance impact or operational overhead. S3 Intelligent-Tiering is well-suited for replica tables that may be accessed less frequently.

For more information about S3 Tables replication, see the following topics.

Topics

- [How S3 Tables replication works](#)
- [Setting up S3 Tables replication](#)
- [Managing S3 Tables replication](#)

How S3 Tables replication works

S3 Tables replication creates read-only replicas of your Apache Iceberg tables across Regions and AWS accounts. Replica tables are maintained automatically by the S3 Tables service and contain the complete data, metadata, and snapshot history from your source table, making them queryable using any Iceberg-compatible engine for analytics and time-travel operations.

When you configure replication for a table, S3 Tables:

- Creates a read-only replica table in each destination table bucket with the same name and namespace as the source table.
- Backfills the replica with the latest state of the source table
- Monitors the source table for new updates
- Commits all updates to replicas in the same order as the source to maintain consistency

For more information, see the following sections.

Topics

- [What is replicated](#)
- [How data is replicated](#)
- [Snapshot replication](#)
- [Considerations and limitations](#)

What is replicated

The following table components are replicated:

- **Table snapshots** – All snapshots, including compacted snapshots, are replicated in chronological order, maintaining parent-child relationships and sequence numbers from the source table. This ensures that replica tables provide the same time-travel capabilities as source tables.
- **Table data** – All data files referenced by table snapshots are replicated to the destination Region. This includes:
 - **Metadata files** – Table metadata.json files, manifests, manifest lists, partition statistics and table statistics.
 - **Delete files** – All delete files are replicated to maintain data accuracy in replica tables.
 - **Data files** – All data files referenced by manifests are replicated.
- **Table metadata** – Complete metadata replication, including schema information (current and historical), partition specifications, sort orders, and table properties.
- **Schema Information** – All table schemas are replicated, including the current schema and historical schema versions. This ensures that queries against replica tables use the correct column definitions, data types, and field mappings. The replication process maintains schema evolution history, allowing time travel queries to work correctly on replica tables.
- **Partition Specifications** – Current and historical partition specifications are replicated, ensuring replica tables maintain the same partitioning strategy as source tables.
- **Sort Orders** – Table sort orders are replicated to maintain query performance optimizations.

How data is replicated

Replication determines a valid state for replica tables by comparing Apache Iceberg table metadata between the source and replica tables. Replication processes metadata in three categories to update your replica table.

For table metadata

For versioned metadata fields, replication merges values from the source table into the replica table's arrays for the following fields:

- **snapshots** – Merges all snapshots from the source table into the replica table's snapshots array by snapshot-id.

- **snapshot-log** – Merges snapshot logs from the source table into the replica table's snapshot-log array, sorted by timestamp and snapshot-id.
- **sort-orders** – Merges sort order definitions from the source table into the replica table's sort-orders array by order-id.
- **partition-specs** – Merges partition specifications from the source table into the replica table's partition-specs array by spec-id.

For table configuration

For fields that represent table configuration, replication copies values directly from the source table:

- **properties**
- **partition-statistics**
- **statistics**

Current table state is also transferred from the source table:

- **current-snapshot-id**
- **current-schema-id**
- **last-column-id**
- **last-partition-id**
- **last-sequence-number**
- **default-sort-order-id**
- **next-row-id** (Iceberg V3)
- **encryption-keys** (Iceberg V3)

Replica-specific state

The following fields are calculated from merged data and updated for the replica table:

- **location** is updated during replication to point to the correct file location in the replica table bucket, ensuring that all file references are valid in the destination environment.
- **metadata-log** contains all destination metadata filenames and is updated after every successful replication with the current metadata filename.

- All file paths are modified to point to the replica table locations.

Snapshot replication

S3 Tables replication maintains complete snapshot history across Regions by replicating all table snapshots in the same commit order as the source table. The parent-child relationships from the source table are preserved in the replica table.

Snapshot retention

You can configure a custom snapshot retention period for your replicated tables that differs from the retention period of the source. This means that even if snapshots are expired and no longer available in the source table, they can be preserved in replicas.

For example, if your source table has a 30-day snapshot retention period but your replica table is configured with a 90-day retention period, the replica will maintain snapshots from the previous two months that are no longer available in the source table.

Snapshots that you manually expired at the source table are also preserved in the replica table. For example, if you expired snapshots from February at the source table using a Spark procedure, you can still time travel to the snapshots in the replica table.

Considerations and limitations

The following considerations apply to replicated tables:

- S3 Tables replicates both Iceberg V2 and V3 tables. However, replication of upgraded tables (V2 → V3) is not supported.
- Metadata files larger than 500MB are not supported.
- While table updates are typically replicated within minutes, replication can take longer depending on the size of the table update to be replicated, for example, when replication starts backfilling.
- Tables with tags or branches are not supported.
- Replication is not supported for Amazon S3 Metadata tables or other AWS-generated system tables.
- All table snapshots, including compacted snapshots, are replicated from the source table. As a result, compaction is not supported on replica tables.

Setting up S3 Tables replication

You can set up replication to automatically create table replicas from a source table to up to five destination table buckets. Replication can be configured at the bucket level (applying to all tables in the bucket) or at the table level (for specific tables). This topic explains how to configure replication using the Amazon S3 console or the AWS Command Line Interface (AWS CLI).

For more information about setting up replication, see the following topics.

Topics

- [Prerequisites for setting up replication](#)
- [Understanding replication configurations](#)
- [Choosing between bucket-level and table-level replication](#)
- [Setting up replication by using the Amazon S3 console](#)
- [Setting up replication by using the AWS CLI](#)

Prerequisites for setting up replication

Before you configure replication, ensure you have the following:

Required resources

- **Source table bucket** – The table bucket containing the table(s) you want to replicate
- **Destination table bucket(s)** – One or more table buckets where you want to replicate your tables (up to 5 destination table buckets)
- **Source table(s)** – Existing tables in your source table bucket to replicate
- **IAM role(s)** – An IAM role that grants Amazon S3 permissions to replicate tables on your behalf

Required permissions

The IAM identity that you use to set up replication must have the following permissions:

For bucket-level replication:

- `s3tables:PutTableBucketReplication` on the source table bucket
- `s3tables:GetTableBucketReplication` on the source table bucket
- `iam:PassRole` for the replication IAM role

For table-level replication:

- `s3tables:PutTableReplication` on the source table
- `s3tables:GetTableReplication` on the source table
- `iam:PassRole` for the replication IAM role

For cross-account replication:

- Permissions from the destination account's bucket policy

Additional requirements for cross-account replication

If your source and destination table buckets are in different AWS accounts, you also need:

- A bucket policy on the destination table bucket that grants the source account permissions to replicate tables
- The destination account ID and table bucket Amazon Resource Name (ARN)

Additional requirements for encrypted tables

If you want to encrypt replica tables with AWS KMS:

- A KMS key in the destination Region
- Permissions to use the KMS key in your IAM replication role
- A KMS key policy that allows the replication role to encrypt data

Understanding replication configurations

A replication configuration defines how Amazon S3 replicates tables from your source table bucket. Replication can be configured at two levels:

Bucket-level replication

A bucket-level replication configuration applies to all tables in the source table bucket. When you configure bucket-level replication, Amazon S3 automatically replicates any existing tables and any new tables created in the bucket.

Use bucket-level replication when:

- You want to replicate all tables in a bucket
- You want consistent replication behavior across all tables
- You want to simplify management by having a single configuration

Table-level replication

A table-level replication configuration applies to a specific table. Table-level configurations override bucket-level configurations for that specific table.

Use table-level replication when:

- You want to replicate only specific tables
- You need different replication destinations for different tables
- You want to override a bucket-level configuration for certain tables

Replication configuration elements

Each replication configuration contains:

- **IAM role** – The role that Amazon S3 assumes to perform replication operations
- **Rules** – One or more replication rules (limited to 1 rule at launch). Each rule contains:
 - **Destinations** – List of destination table bucket ARNs (up to 5 destinations)
 - **Status** – Whether the rule is enabled or disabled
- **Version token** – A token used to prevent write conflicts when updating configurations

Choosing between bucket-level and table-level replication

Configuration precedence

When both bucket-level and table-level configurations exist:

- Table-level configuration takes precedence for that specific table.
- Other tables follow the bucket-level configuration.

Setting up replication by using the Amazon S3 console

This procedure shows you how to configure replication using the Amazon S3 console.

To set up bucket-level replication

This procedure shows you how to create a table bucket replication configuration using the Amazon S3 console. A table bucket replication configuration applies to all tables in the source table bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Table buckets**.
3. In the **Table buckets** list, choose the name of the table bucket for which you want to configure replication.
4. Choose the **Management** tab.
5. In the **Table bucket replication configuration** section, choose **Create table bucket replication configuration**.
6. In the **Destination** section, configure your replication destinations:
 - a. In the **Table bucket ARN** field, enter the ARN of the destination table bucket. The format is: `arn:aws:s3tables:<region>:<account-id>:bucket/<table-bucket-name>`
Alternatively, choose **Browse S3** to select a table bucket from your account.
 - b. (Optional) To add additional destinations, choose **Add destination**. You can add up to 4 more table buckets for a total of 5 destinations.
7. In the **IAM role** section, configure the replication role:
 - a. For **IAM role selection method**, choose one of the following options:
 - **Create new IAM role** – Amazon S3 creates a new role with the necessary permissions for replication.
 - **Choose from existing IAM roles** – Select an existing role that has the required replication permissions.
 - **Enter IAM role ARN** – Manually enter the ARN of an existing IAM role.
 - b. If you chose **Choose from existing IAM roles**, select a role from the **IAM role** dropdown list.
 - c. (Optional) Choose **View** to review the selected role's permissions in the IAM console.
8. Choose **Create replication configuration**.

After you create the replication configuration, Amazon S3 begins the initial backfill process. You can monitor the replication status in the **Table replication status** section, which displays

information about each destination including replication status, destination table ARN, and last replicated metadata.

To set up table-level replication

This procedure shows you how to create a table-level replication configuration using the Amazon S3 console. A table replication configuration applies to a specific table and overrides any bucket-level replication configuration for that table.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Table buckets**.
3. In the **Table buckets** list, choose the name of the table bucket that contains the table you want to replicate.
4. Choose the **Tables** tab.
5. In the **Tables** list, choose the name of the table that you want to replicate.
6. Choose the **Management** tab.
7. In the **Table replication configuration** section, choose **Create table replication configuration**.
8. In the **Destination** section, configure your replication destinations:
 - a. In the **Table bucket ARN** field, enter the ARN of the destination table bucket. The format is: `arn:aws:s3tables:<region>:<account-id>:bucket/<table-bucket-name>`
Alternatively, choose **Browse S3** to select a table bucket from your account.
 - b. (Optional) To add additional destinations, choose **Add destination**. You can add up to 4 more table buckets for a total of 5 destinations.
9. In the **IAM role** section, configure the replication role:
 - a. For **IAM role selection method**, choose one of the following options:
 - **Create new IAM role** – Amazon S3 creates a new role with the necessary permissions for replication.
 - **Choose from existing IAM roles** – Select an existing role that has the required replication permissions.
 - **Enter IAM role ARN** – Manually enter the ARN of an existing IAM role.
 - b. If you chose **Choose from existing IAM roles**, select a role from the **IAM role** list.

c. (Optional) Choose **View** to review the selected role's permissions in the IAM console.

10. Choose **Create replication configuration**.

What happens next?

After you create the replication configuration:

- Amazon S3 begins the initial backfill process, creating replica tables in each destination bucket
- The replication status changes to **Replicating** once backfill begins
- You can monitor replication progress on the **Management** tab
- Initial replication time depends on the size of your source table

Setting up replication by using the AWS CLI

This procedure shows you how to configure replication using the AWS CLI. Replace the account IDs, regions, and bucket names with your actual values. Add all destination buckets to the permissions.

Step 1: Create an IAM role for replication

First, create an IAM role that Amazon S3 can assume to replicate your tables.

1. Create a trust policy document that allows S3 Tables to assume the role. Save this as `trust-policy.json`:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "replication.s3tables.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

2. Create the IAM role:

```
aws iam create-role \
--role-name S3TablesReplicationRole \
--assume-role-policy-document file://trust-policy.json \
--description "Role for S3 Tables replication"
```

3. Create a permissions policy that grants replication permissions. Save this as `replication-permissions.json`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3tables:GetTable",
                "s3tables:GetTableMetadataLocation",
                "s3tables:GetTableMaintenanceConfiguration",
                "s3tables:GetTableData"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket-source/table/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3tables>ListTables"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket-source"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3tables>CreateTable",
                "s3tables>CreateNamespace"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:444455556666:bucket/amzn-s3-demo-table-bucket-destination"
        }
    ]
}
```

```
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3tables:PutTableData",
            "s3tables:GetTableData",
            "s3tables:UpdateTableMetadataLocation",
            "s3tables:PutTableMaintenanceConfiguration"
        ],
        "Resource": "arn:aws:s3tables:us-east-2:444455556666:bucket/amzn-s3-demo-table-bucket-destination/table/*"
    }
]
```

4. Attach the permissions policy to the role:

```
aws iam put-role-policy \
--role-name S3TablesReplicationRole \
--policy-name S3TablesReplicationPermissions \
--policy-document file://replication-permissions.json
```

5. (Optional) If using KMS encryption, add KMS permissions to your policy:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey",
        "kms:Encrypt"
    ],
    "Resource": "arn:aws:kms:us-east-1:111122223333:key/SOURCE-KEY-ID"
},
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ]
}
```

```
],
"Resource": [
    "arn:aws:kms:us-west-2:44445556666:key/DESTINATION-KEY-ID-1"
]
}
```

(Cross-account only) Step 2: Configure destination bucket policy

If you are replicating to a different AWS account, the destination account must grant permissions to the source account.

1. In the destination account, create a bucket policy for the destination table bucket. Save this as `destination-bucket-policy.json`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::44445556666:role/cross-account-test"
            },
            "Action": [
                "s3tables:PutTableData",
                "s3tables:GetTableData",
                "s3tables:UpdateTableMetadataLocation",
                "s3tables:PutTableMaintenanceConfiguration"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket-cross-account-destination/table/*"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::44445556666:role/cross-account-test"
            },
            "Action": [
                "s3tables:CreateTable",
                "s3tables:CreateNamespace"
            ],
        }
    ]
}
```

```
        "Resource": "arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket-cross-account-destination"
    }
]
```

2. Apply the policy using the S3 Tables API:

```
aws s3tables put-table-bucket-policy \
--table-bucket-arn arn:aws:s3tables:us-west-2:44445556666:bucket/amzn-s3-demo-table-bucket-cross-account-destination \
--policy file://destination-bucket-policy.json \
--profile destination-account
```

3. Modify your source KMS key to allow S3 Tables replication and maintenance:

```
{
    "Version": "2012-10-17",
    "Id": "key-consolepolicy-3",
    "Statement": [
        {
            "Sid": "allow replication to decrypt",
            "Effect": "Allow",
            "Principal": {
                "AWS": "replication_role_arn"
            },
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/SOURCE-KEY-ID"
        },
        {
            "Sid": "allow maintenance",
            "Effect": "Allow",
            "Principal": {
                "Service": "maintenance.s3tables.amazonaws.com"
            },
            "Action": [
                "kms:Decrypt",
```

```
        "kms:GenerateDataKey"
    ],
    "Resource": "arn:aws:kms:us-east-1:111122223333:key/SOURCE-KEY-ID"
}
]
```

4. Similarly, add permissions in your destination KMS key policy

```
{
    "Version": "2012-10-17",
    "Id": "key-policy-3",
    "Statement": [
        {
            "Sid": "allow maintenance",
            "Effect": "Allow",
            "Principal": {
                "Service": "maintenance.s3tables.amazonaws.com"
            },
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-west-2:444455556666:key/DESTINATION-KEY-ID-1"
        },
        {
            "Sid": "allow replication to encrypt/decrypt",
            "Effect": "Allow",
            "Principal": {
                "AWS": "replication_role_arn"
            },
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-west-2:444455556666:key/DESTINATION-KEY-ID-1"
        }
    ]
}
```

Step 3: Create a replication configuration

You can use the AWS CLI to create a replication configuration at the table bucket-level or the table-level. For more information, see the following procedures.

Create a bucket-level replication configuration

Use this approach to replicate all tables in a bucket.

1. Create a replication configuration file. Save this as bucket-replication-config.json:

Example : Single destination in same account

```
{  
    "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",  
    "rules": [  
        {  
            "destinations": [  
                {  
                    "destinationTableBucketARN": "arn:aws:s3:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket-dr"  
                }  
            ]  
        }  
    ]  
}
```

Example : Multiple destinations across regions

```
{  
    "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",  
    "rules": [  
        {  
            "destinations": [  
                {  
                    "destinationTableBucketARN": "arn:aws:s3:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket-dr"  
                },  
                {  
                    "destinationTableBucketARN": "arn:aws:s3:eu-central-1:111122223333:bucket/amzn-s3-demo-table-bucket-dr"  
                }  
            ]  
        }  
    ]  
}
```

```
        "destinationTableBucketARN": "arn:aws:s3tables:eu-
west-1:111122223333:bucket/amzn-s3-demo-table-bucket-eu"
    },
    {
        "destinationTableBucketARN": "arn:aws:s3tables:ap-
south-1:111122223333:bucket/amzn-s3-demo-table-bucket-apac"
    }
]
}
}
```

Example : Cross-account replication

```
{
    "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",
    "rules": [
        {
            "destinations": [
                {
                    "destinationTableBucketARN": "arn:aws:s3tables:us-
east-1:444455556666:bucket/amzn-s3-demo-table-bucket-partner"
                }
            ]
        }
    ]
}
```

2. Apply the bucket-level replication configuration:

```
aws s3tables put-table-bucket-replication \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket \
--configuration file://bucket-replication-config.json
```

Expected output:

```
{  
  "versionToken": "3HL4kqtJl40Nr8X8gdRQBpUMLUo",  
  "status": "Success"  
}
```

Create a table-level replication configuration

Use this approach to replicate specific tables or to override bucket-level replication.

1. Create a replication configuration file. Save this as `table-replication-config.json`:

Example : Single table replication

```
{  
  "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",  
  "rules": [  
    {  
      "destinations": [  
        {  
          "destinationTableBucketARN": "arn:aws:s3:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket-analytics-bucket"  
        }  
      ]  
    }  
  ]  
}
```

Example : Table with multiple destinations

```
{  
  "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",  
  "rules": [  
    {  
      "destinations": [  
        {  

```

```
        "destinationTableBucketARN": "arn:aws:s3tables:us-
west-2:111122223333:bucket/amzn-s3-demo-table-bucket-dr"
    },
    {
        "destinationTableBucketARN": "arn:aws:s3tables:eu-
west-1:111122223333:bucket/amzn-s3-demo-table-bucket-eu"
    }
]
}
]
```

2. Apply the table-level replication configuration:

```
aws s3tables put-table-replication \
--table-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-
bucket/table/amzn-s3-demo-table-bucket-sales-data \
--configuration file://table-replication-config.json
```

Expected output:

```
{
    "versionToken": "xT2LZkFZ0UuTC2h8XqtGLx2Ak6M",
    "status": "Success"
}
```

Managing S3 Tables replication

After you configure S3 Tables replication, you can monitor replica status to verify what's replicated. You can check replication status in the Amazon S3 console on the source table's **Management** tab, or by using the AWS CLI. For more information, see [Setting up S3 Tables replication](#). This topic explains how to monitor replication and understand the different status values that indicate whether replication is completed, in progress, or has failed.

Monitoring replication status

Replication jobs run continuously for your replicated tables. You can query the status of replication with the GetTableReplicationStatus API or view it in the Amazon S3 console.

To get the status of replication by using the AWS CLI

The following example gets the replication status using the GetTableReplicationStatus API.

```
aws s3tables get-table-replication-status \
--table-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-
bucket/table/sales-data
```

Expected output:

```
{
  "sourceTableARN": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-
bucket/table/sales-data",
  "destinations": [
    {
      "replicationStatus": "COMPLETED",
      "destinationBucketARN": "arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-
demo-table-bucket",
      "destinationTableARN": "arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-
demo-table-bucket/table/sales-data",
      "lastSuccessfulReplicatedUpdate": {
        "metadataLocation": "latest_table_metadata.json",
        "timestamp": "2025-11-15T14:30:00Z"
      }
    },
    {
      "replicationStatus": "PENDING",
      "destinationBucketARN": "arn:aws:s3tables:eu-west-1:111122223333:bucket/amzn-s3-
demo-table-bucket-eu-bucket",
      "destinationTableARN": "arn:aws:s3tables:eu-west-1:111122223333:bucket/amzn-s3-
demo-table-bucket-eu-bucket/table/sales-data",
      "lastSuccessfulReplicatedUpdate": {
        "metadataLocation": "latest_table_metadata.json",
        "timestamp": "2025-11-15T14:25:00Z"
      }
    }
  ]
}
```

```
    }
}
]
}
```

For more information, see [get-table-replication-status](#) in the *AWS CLI Command Reference*.

Understanding the response

The response contains the following elements:

- **sourceTableARN** – The ARN of the source table being replicated.
- **destinations** – An array of destination status objects, one for each configured replication destination. Each destination object contains:
 - **replicationStatus** – The current replication status for this destination (COMPLETED, PENDING, or FAILED).
 - **destinationBucketARN** – The ARN of the destination table bucket.
 - **destinationTableARN** – The ARN of the replica table in the destination bucket.
 - **lastSuccessfulReplicatedUpdate** – Information about the most recent successful replication:
 - **metadataLocation** – The Iceberg metadata file name that was last successfully replicated. Compare this with the source table's current metadata location to determine if replication is up to date.
 - **timestamp** – The time when this metadata file was replicated to the destination.
 - **failureMessage** (only present when status is FAILED) – A detailed error message describing why replication failed.

Replication status values

Replication can have three possible statuses for each destination:

- **COMPLETED** – All source table snapshots have been successfully replicated to the destination. The source table's latest metadata location matches the last replicated metadata location.
- **PENDING** – Replication is in progress or new commits are waiting to be replicated. The source table's latest metadata location differs from the last replicated metadata location.
- **FAILED** – The last replication job for this table failed. No new updates are being replicated.

S3 Tables AWS Regions, endpoints, and service quotas

The following sections include the supported AWS Regions and service quotas for S3 Tables.

Topics

- [S3 Tables AWS Regions and endpoints](#)
- [S3 Tables quotas](#)

S3 Tables AWS Regions and endpoints

For a list of Regions S3 Tables is currently available in, see [Amazon S3 endpoints](#). To connect programmatically to an AWS service, you use an endpoint. For more information, see [AWS service endpoints](#).

S3 Tables supports dual-stack endpoints for public access and AWS PrivateLink. Dual-stack endpoints allow you to access S3 tables buckets using the Internet Protocol version 6 (IPv6), in addition to the IPv4 protocol, depending on what your network supports.

S3 Tables dual-stack endpoints use the following naming convention: s3tables.*aws-region*.api.aws

For a complete list of S3 Tables endpoints, see [Amazon S3 endpoints](#).

S3 Tables quotas

Quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. The following are the quotas for S3 Tables resources. For more Amazon S3 quota information, see [Amazon S3 quotas](#).

Name	Default	Adjustable	Description
Table Buckets	10	To request a quota increase, contact Support .	The number of Amazon S3 table buckets that you can create per AWS Region in an account.

Name	Default	Adjustable	Description
Namespaces	10,000	To request a quota increase, contact Support .	The number of Amazon S3 table namespaces that you can create per table bucket.
Tables	10,000	To request a quota increase, contact Support .	The number of Amazon S3 tables that you can create per table bucket.

Making requests to S3 Tables over IPv6

Amazon S3 supports the ability to access S3 buckets using the Internet Protocol version 6 (IPv6), in addition to the IPv4 protocol, using dual-stack endpoints. Dual-stack endpoints resolve to either an IPv6 endpoint or IPv4 endpoint depending on what your network supports.

The following are some things you should know before trying to access S3 Tables over IPv6:

- The client and the network accessing the table bucket must be enabled to use IPv6.
- Your tables client and your S3 client must both have dual-stack enabled.
- If you use IP address filtering IAM policies they must be updated to handle IPv6 addresses. For more information about managing access permissions with IAM, see [the section called “Identity and Access Management \(IAM\)”](#).
- When using IPv6, server access log files output IP addresses in an IPv6 format. You need to update existing tools, scripts, and software that you use to parse Amazon S3 log files so that they can parse the IPv6 formatted Remote IP addresses. For more information, see [the section called “Logging server access”](#).

Getting started making S3 Tables requests over IPv6

When you make a request to a dual-stack endpoint, the table bucket URL resolves to an IPv6 or an IPv4 address depending on what your network supports. If your network prefers IPv4 requests will automatically use IPv4. If your network prefers IPv6, requests will use IPv6. No

configuration change is required other than updating your client or application to enable the dual-stack endpoint.

When using the REST API, you directly access an Amazon S3 endpoint by using the endpoint name (URI). You can access S3 Tables and table buckets through a dual-stack endpoint using the following naming convention:

s3tables.<region>.api.aws

For a complete list of endpoints for S3 Tables, see [Amazon Simple Storage Service endpoints and quotas](#).

When using the AWS CLI, AWS SDKs, and Iceberg clients, you can use a parameter or flag to change to a dual-stack endpoint. You can also specify the dual-stack endpoint directly as an override of the Amazon S3 endpoint in the config file.

You can enable dual-stack endpoint resolution in SDKs or clients by setting the dual-stack flag using the following command:

```
S3TablesClient client = S3TablesClient.builder()
    .region(Region.US_EAST_1)
    .dualstackEnabled(true)
    .build();
```

To use the dual-stack endpoint in the AWS CLI, see [Using dual-stack endpoints from the AWS CLI](#).

For information on using the dual-stack endpoints for AWS PrivateLink, see, [Using the dual-stack endpoints to access tables and table buckets](#).

Security for S3 Tables

Amazon S3 provides a variety of security features and tools. The following is a list of these features and tools supported by S3 Tables. Proper application of these tools can help ensure that your resources are protected and accessible only to the intended users.

Identity-based policies

[Identity-based policies](#) are attached to an IAM user, group, or role. You can use identity-based policies to grant an IAM identity access to your table buckets or tables. By default, users and roles

don't have permission to create and modify tables and table buckets. They also can't perform tasks by using S3 console, AWS CLI, or Amazon S3 REST APIs. You can create IAM users, groups, and roles in your account and attach access policies to them. You can then grant access to your resources. To create and access table buckets and tables, an IAM administrator must grant the necessary permissions to the AWS Identity and Access Management (IAM) role or users. For more information, see [Access management for S3 Tables](#).

Resource-based policies

[Resource-based policies](#) are attached to a resource. You can create resource-based policies for table buckets and tables. You can use a table bucket policy to control table bucket and namespace-level API access permissions. You can also use a table bucket policy to control table-level API permissions on multiple tables in a bucket. Depending on the policy definition, the permissions attached to the bucket can apply to all or specific tables in the bucket. You can also use a table policy to grant table-level API access permissions to individual tables in the bucket.

When S3 Tables receives a request to perform a table bucket operation or a table operation, it first verifies that the requester has the necessary permissions. It evaluates all the relevant access policies, user policies, and resource-based policies in deciding whether to authorize the request (IAM user policy, IAM role policy, table bucket policy, and table policy). With table bucket policies and table policies, you can personalize access to your resources to ensure that only the identities you have approved can access your resources and perform actions on them. For more information, see [Access management for S3 Tables](#).

AWS Organizations service control policies (SCPs) for S3 Tables.

You can use Amazon S3 Tables in Service Control Policies (SCPs) to manage permissions to users in your organization. Similar to IAM and resource policies, all table and bucket level actions are referenced as part of `s3tables` namespace in the policies. For more information, see [Service control policies \(SCPs\)](#) in the *AWS Organizations User Guide*.

Protecting S3 table data with encryption

Using server-side encryption with AWS KMS keys (SSE-KMS) in table buckets

Topics

- [How SSE-KMS works for tables and table buckets](#)
- [Enforcing and scoping SSE-KMS use for tables and table buckets](#)
- [Monitoring and Auditing SSE-KMS encryption for tables and table buckets](#)
- [Permission requirements for S3 Tables SSE-KMS encryption](#)
- [Specifying server-side encryption with AWS KMS keys \(SSE-KMS\) in table buckets](#)

Table buckets have a default encryption configuration that automatically encrypts tables by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption applies to all tables in your S3 table buckets, and comes at no cost to you.

If you need more control over your encryption keys, such as managing key rotation and access policy grants, you can configure your table buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). The security controls in AWS KMS can help you meet encryption-related compliance requirements. For more information about SSE-KMS, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

How SSE-KMS works for tables and table buckets

SSE-KMS with table buckets differs from SSE-KMS in general purpose buckets in the following ways:

- You can specify encryption settings for table buckets and individual tables.
- You can only use customer managed keys with SSE-KMS. AWS managed keys aren't supported.
- You must grant permissions for certain roles and AWS service principals to access your AWS KMS key. For more information, see [Permission requirements for S3 Tables SSE-KMS encryption](#). This includes granting access to:
 - The S3 maintenance principal – for performing table maintenance on encrypted tables
 - Your S3 Tables integration role – for working with encrypted tables in AWS analytics services
 - Your client access role – for direct access to encrypted tables from Apache Iceberg clients
 - The S3 Metadata principal – for updating encrypted S3 metadata tables

- Encrypted tables use table-level keys that minimize the number of requests made to AWS KMS to make working with SSE-KMS encrypted tables more cost effective.

SSE-KMS encryption for table buckets

When you create a table bucket, you can choose SSE-KMS as the default encryption type and select a specific KMS key that will be used for encryption. Any tables created within that bucket will automatically inherit these encryption settings from their table bucket. You can use the AWS CLI, S3 API, or AWS SDKs to modify or remove the default encryption settings on a table bucket at any time. When you modify the encryption settings on a table bucket those settings apply only to new tables created in that bucket. Encryption settings for pre-existing tables are not changed. For more information, see [Specifying encryption for table buckets](#).

SSE-KMS encryption for tables

You also have an option to encrypt an individual table with a different KMS key regardless of the bucket's default encryption configuration. To set encryption for an individual table, you must specify the desired encryption key at the time of table creation. If you want to change the encryption for an existing table, then you'll need to create a table with desired key and copy data from old table to the new one. For more information, see [Specifying encryption for tables](#).

When using AWS KMS encryption, S3 Tables automatically creates unique table-level data keys that encrypt new objects associated with each table. These keys are used for a limited time period, minimizing the need for additional AWS KMS requests during encryption operations and reducing the cost of encryption. This is similar to [S3 Bucket Keys for SSE-KMS](#).

Enforcing and scoping SSE-KMS use for tables and table buckets

You can use S3 Tables resource-based policies, KMS key policies, IAM identity-based policies, or any combination of these, to enforce the use of SSE-KMS for S3 tables and table buckets. For more information on identity and resource policies for tables, see [Access management for S3 Tables](#). For information on writing key policies, see [Key policies](#) in the *AWS Key Management Service Developer Guide*. The following examples show how you can use policies to enforce SSE-KMS.

Enforcing the use of SSE-KMS for all tables with a table bucket policy

This is an example of table bucket policy that prevents users from creating tables in a specific table bucket unless they encrypt tables with a specific AWS KMS key. To use this policy, replace the *user input placeholders* with your own information:

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "EnforceKMSEncryption",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": [  
                "s3tables:CreateTable"  
            ],  
            "Resource": [  
                "arn:aws:s3tables:us-west-2:111122223333:bucket/example-table-bucket/*"  
            ],  
            "Condition": {  
                "StringNotEquals": {  
                    "s3tables:sseAlgorithm": "aws:kms",  
                    "s3tables:kmsKeyArn": "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
                }  
            }  
        }  
    ]  
}
```

Requiring users to use SSE-KMS encryption with an IAM policy

This IAM identity policy requires users to use a specific AWS KMS key for encryption when creating or configuring S3 Tables resources. To use this policy, replace the *user input placeholders* with your own information:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "RequireKMSKeyOnTables",  
            "Action": [  
                "s3tables:CreateTableBucket",  
                "s3tables:PutTableBucketEncryption",  
                "s3tables:CreateTable"  
            ]  
        }  
    ]  
}
```

```
]
  "Effect": "Deny",
  "Resource": "*",
  "Condition": {
    "StringNotEquals": {
      "s3tables:sseAlgorithm": "aws:kms",
      "s3tables:kmsKeyArn": "<key_arn>"
    }
  }
}
]
```

Restricting the use of a key to a specific table bucket with a KMS key policy

This example KMS key policy allows the key to be used by a specific user only for encryption operations in a specific table bucket. This type of policy is useful for limiting access to a key in cross-account scenarios. To use this policy, replace the *user input placeholders* with your own information:

JSON

```
{
  "Version": "2012-10-17",
  "Id": "Id",
  "Statement": [
    {
      "Sid": "AllowPermissionsToKMS",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
      ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "kms:EncryptionContext:aws:s3:arn": "<table-bucket-arn>/*"
        }
      }
    }
}
```

```
    }  
]  
}
```

Monitoring and Auditing SSE-KMS encryption for tables and table buckets

To audit the usage of your AWS KMS keys for your SSE-KMS encrypted data, you can use AWS CloudTrail logs. You can get insight into your [cryptographic operations](#), such as `GenerateDataKey` and `Decrypt`. CloudTrail supports numerous [attribute values](#) for filtering your search, including event name, user name, and event source.

You can track encryption configuration requests for Amazon S3 tables and table buckets by using CloudTrail events. The following API event names are used in CloudTrail logs:

- `s3tables:PutTableBucketEncryption`
- `s3tables:GetTableBucketEncryption`
- `s3tables>DeleteTableBucketEncryption`
- `s3tables:GetTableEncryption`
- `s3tables CreateTable`
- `s3tables>CreateTableBucket`

 **Note**

EventBridge isn't supported for table buckets.

Permission requirements for S3 Tables SSE-KMS encryption

When you use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) for tables in S3 table buckets you need to grant permissions for different identities in your account. At minimum your access identity and the S3 Tables maintenance principal need access to your key, the other permissions required depend on your use case.

Required Permissions

To access a table encrypted with a KMS key, you need these permissions on that key:

- `kms:GenerateDataKey`

- kms :Decrypt

⚠ Important

To use SSE-KMS on tables the Amazon S3 Tables maintenance service principal (`maintenance.s3tables.amazonaws.com`) needs `kms:GenerateDataKey` and `kms:Decrypt` permissions on the key.

Additional permissions

These additional permissions are required depending on your use case:

- **Permissions for the AWS analytics services integration** – If you work with SSE-KMS encrypted tables in AWS analytics services, your integration role needs permission to use your KMS key.
- **Permissions for direct access** – If you work with SSE-KMS encrypted tables directly, through methods such as the Amazon S3 Tables Iceberg REST endpoint or Amazon S3 Tables Catalog for Apache Iceberg, you need to grant the IAM role your client uses access your key.
- **Permissions for S3 Metadata tables** – If you use SSE-KMS encryption for S3 Metadata tables, you need to provide the S3 Metadata service principal (`metadata.s3.amazonaws.com`) access to your KMS key. This allows S3 Metadata to update encrypted tables so they will reflect your latest data changes.

ⓘ Note

For cross-account KMS keys, your IAM role needs both key access permission and explicit authorization in the key policy. For more information about cross-account permissions for KMS keys, see [Allowing external AWS accounts to use a KMS key](#) in the *AWS Key Management Service Service Developer Guide*.

Topics

- [Granting the S3 Tables maintenance service principal permissions to your KMS key](#)
- [Granting IAM principals permissions to work with encrypted tables in integrated AWS analytics services](#)
- [Granting IAM principals permissions to work with encrypted tables directly](#)

- [Granting the S3 Metadata service principal permissions to use your KMS key](#)

Granting the S3 Tables maintenance service principal permissions to your KMS key

This permission is required to create SSE-KMS encrypted tables and to allow automatic table maintenance like compaction, snapshot management, and unreferenced file removal on the encrypted tables.

Note

Whenever you make a request to create an SSE-KMS encrypted table, S3 Tables checks to make sure the `maintenance.s3tables.amazonaws.com` principal has access to your KMS key. To perform this check, a zero-byte object is temporarily created in your table bucket, this object will be automatically removed by the [unreferenced file removal](#) maintenance operations. If the KMS key you specified for encryption doesn't have maintenance access the `createTable` operation will fail.

To grant maintenance access on SSE-KMS encrypted tables, you can use the following example key policy. In this policy, the `maintenance.s3tables.amazonaws.com` service principal is granted permission to use a specific KMS key for encrypting and decrypting tables in a specific table bucket. To use the policy, replace the `user input placeholders` with your own information:

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "EnableKeyUsage",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "maintenance.s3tables.amazonaws.com"  
            },  
            "Action": [  
                "kms:GenerateDataKey",  
                "kms:Decrypt"  
            ],  
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id",  
            "Condition": {  
                "StringLike": {  
                    "kms:EncryptionContext": "tableArn=arn:aws:s3:::my-table"  
                }  
            }  
        }  
    ]  
}
```

```
        "Condition": {
            "StringLike": {
                "kms:EncryptionContext:aws:s3:arn": "<table-or-table-bucket-
arn>/*"
            }
        }
    ]
}
```

Granting IAM principals permissions to work with encrypted tables in integrated AWS analytics services

To work with S3 tables in AWS analytics services, you integrate your table buckets with Amazon SageMaker Lakehouse. This integration allows AWS analytics services to automatically discover and access table data. For more information on the integration, see [Integrating Amazon S3 Tables with AWS analytics services](#).

When you work with SSE-KMS encrypted tables in those services, the role you use needs to have permission to use your AWS KMS key for encryption operations. You can apply these permissions to the S3TablesRoleForLakeFormation role created during the integration, or to your own IAM role.

The following inline IAM policy example can be used to grant the S3TablesRoleForLakeFormation service role permission to use a specific KMS key in your account for encryption operations. To use the policy replace the *input placeholder values* with your own.

```
{
    "Sid": "AllowTableRoleAccess",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/service-role/S3TablesRoleForLakeFormation"
    },
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
    ],
    "Resource": "<kms-key-arn>"
}
```

Granting IAM principals permissions to work with encrypted tables directly

When you work with encrypted tables using third party or direct access methods, you must grant the role you use access to your KMS key. The following examples shows how to grant access through an IAM policy or a KMS key policy.

IAM policy

Attach this inline policy to your IAM role to allow KMS key access. To use this policy replace the *input placeholder values* with your own KMS key arn.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowKMSKeyUsage",  
            "Effect": "Allow",  
            "Action": [  
                "kms:Decrypt",  
                "kms:GenerateDataKey"  
            ],  
            "Resource": "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
        }  
    ]  
}
```

KMS key policy

Attach this inline policy to a KMS key to allow the specified AWS KMS role to use the key. To use this policy replace the *input placeholder values* with your IAM role.

```
{  
    "Sid": "Allow use of the key",  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": [  
            "arn:aws:iam::<catalog-account-id>:role/<role-name>"  
        ]  
    }  
}
```

```
},
"Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey",
],
"Resource": "*"
}
```

Granting the S3 Metadata service principal permissions to use your KMS key

To allow Amazon S3 to update SSE-KMS encrypted metadata tables, and perform maintenance on those metadata tables, you can use the following example key policy. In this policy, you allow the `metadata.s3.amazonaws.com` and `maintenance.s3tables.amazonaws.com` service principals to encrypt and decrypt tables in a specific table bucket using a specific key. To use the policy, replace the *user input placeholders* with your own information:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnableKeyUsage",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "maintenance.s3tables.amazonaws.com",
                    "metadata.s3.amazonaws.com"
                ]
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
            "Condition": {
                "StringLike": {
                    "kms:EncryptionContext:aws:s3:arn": "<table-or-table-bucket-  

arn>/"
                }
            }
        }
    ]
}
```

```
        }
    }
}
```

Specifying server-side encryption with AWS KMS keys (SSE-KMS) in table buckets

All Amazon S3 table buckets have encryption configured by default, and all new tables created in an table bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every table bucket. If you want to specify a different encryption type, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

You can specify SSE-KMS encryption in your `CreateTableBucket` or `CreateTable` requests, or you can set the default encryption configuration in the table bucket in a `PutTableBucketEncryption` request.

Important

To allow automatic maintenance on SSE-KMS encrypted tables and table buckets you must grant the `maintenance.s3tables.amazonaws.com` service principal permission to use your KMS key. For more information, see [Permission requirements for S3 Tables SSE-KMS encryption](#).

Specifying encryption for table buckets

You can specify SSE-KMS as the default encryption type when you create a new table bucket, for examples, see [Creating a table bucket](#). After creating a table bucket, you can specify the use of SSE-KMS as the default encryption setting using REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI).

Note

When you specify SSE-KMS as the default encryption type, the key you use for encryption must allow access to the S3 Tables maintenance service principal. If the maintenance service principal does not have access, you will be unable to create tables in that table

bucket. For more information, see [Granting the S3 Tables maintenance service principal permissions to your KMS key](#).

Using the AWS CLI

To use the following example AWS CLI command, replace the *user input placeholders* with your own information.

```
aws s3tables put-table-bucket-encryption \
--table-bucket-arn arn:aws:s3tables:us-east-1:11122223333:bucket/amzn-s3-demo-
; \
--encryption-configuration '{
    "sseAlgorithm": "aws:kms",
    "kmsKeyArn": "arn:aws:kms:us-
east-1:11122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}' \
--region us-east-1
```

You can remove the default encryption setting for a table bucket using the [DeleteTableBucketEncryption](#) API operation. When you remove encryption settings new tables created in the table bucket will use the default SSE-S3 encryption.

Specifying encryption for tables

You can apply SSE-KMS encryption to a new table when you create it using query engines, REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI). The encryption settings you specify when creating a table take precedence over the default encryption setting of the table bucket.

Note

When you use SSE-KMS encryption for a table the key you use for encryption must allow the S3 Tables maintenance service principal to access it. If the maintenance service principal does not have access, you will be unable to create the table. For more information, see [Granting the S3 Tables maintenance service principal permissions to your KMS key](#).

Required permissions

The following permissions are required to create encrypted tables

- `s3tables:CreateTable`
- `s3tables:PutTableEncryption`

Using the AWS CLI

The following AWS CLI example creates a new table with a basic schema, and encrypts it with a customer managed AWS KMS key. To use the command, replace the *user input placeholders* with your own information.

```
aws s3tables create-table \
--table-bucket-arn "arn:aws:s3tables:Region:ownerAccountId:bucket/amzn-s3-demo-table-bucket" \
--namespace "mydataset" \

Data protection refers to protecting data while it's in transit (as it travels to and from Amazon S3) and at rest (while it's stored on disks in Amazon S3 data centers). S3 Tables always protects data in transit using Transport Layer Security (1.2 and above) through HTTPS. For protecting data at rest in S3 table buckets, you have the following options:

Server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 table buckets have encryption configured by default. The default option for server-side encryption is with Amazon S3 managed keys (SSE-S3). This encryption comes at no cost to you and applies to all tables in your S3 table buckets unless you specify another form of encryption. Each object is encrypted with a unique key. As an additional safeguard, SSE-S3 encrypts the key itself with a root key that it regularly rotates. SSE-S3 uses one of the strongest block ciphers available, 256-bit Advanced Encryption Standard (AES-256), to encrypt your data.

Server-side encryption with AWS KMS keys (SSE-KMS)

You can choose to configure table buckets or tables to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). The security controls in AWS KMS can help you meet encryption-related compliance requirements. SSE-KMS gives you more control over your encryption keys by allowing you to do the following:

- Create, view, edit, monitor, enable or disable, rotate, and schedule deletion of KMS keys.
- Define the policies that control how and by whom KMS keys can be used.
- Track key usage in AWS CloudTrail to verify your KMS keys are being used correctly.

S3 Tables supports using customer managed keys in SSE-KMS to encrypt tables. AWS managed keys are not supported. For more information on using SSE-KMS for S3 tables and table buckets, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in table buckets](#).

Access management for S3 Tables

In S3 Tables resources include table buckets and the tables that they contain. The root user of the AWS account that created the resource (the resource owner) and AWS Identity and Access

Management (IAM) users within that account that have the necessary permissions can access a resource that they created. The resource owner specifies who else can access the resource and the actions that they are allowed to perform on the resource. Amazon S3 has various access management tools that you can use to grant others access to your S3 resources. If you've integrated your tables with AWS Amazon SageMaker Lakehouse you can also manage fine-grained access to your tables and namespaces with Lake Formation. The following topics provide you with an overview of resources, IAM actions, and condition keys for S3 Tables. They also provide examples for both resource-based and identity-based policies for S3 Tables.

Topics

- [Resources](#)
- [Actions for S3 Tables](#)
- [Condition keys for S3 Tables](#)
- [IAM identity-based policies for S3 Tables](#)
- [Resource-based policies for S3 Tables](#)
- [AWS managed policies for S3 Tables](#)
- [Granting access with SQL semantics](#)
- [Managing access to a table or database with Lake Formation](#)

Resources

S3 Tables resources include table buckets and the tables that they contain.

- Table buckets – Table buckets are specifically designed for tables and provide higher transactions per seconds (TPS) and better query throughput compared to self-managed tables in general purpose S3 buckets. Table buckets deliver the same durability, availability, scalability, and performance characteristics as Amazon S3 general purpose buckets.
- Tables – Tables in your table buckets are stored in Apache Iceberg format. You can query these tables using standard SQL in query engines that support Iceberg.

Amazon Resource Names (ARNs) for tables and table buckets contain the `s3:tables` namespace, the AWS Region, the AWS account ID, and the bucket name. To access and perform actions on your tables and table buckets, you must use the following ARN formats:

- Table ARN format:

`arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-bucket/table/demo-tableID`

Actions for S3 Tables

In an identity-based policy or resource-based policy, you define which S3 Tables actions are allowed or denied for specific IAM principals. Tables actions correspond to bucket and table-level API operations. All actions are part of a unique IAM namespace: `s3tables`.

When you use an action in a policy, you usually allow or deny access to the API operation with the same name. However, in some cases, a single action controls access to more than one API operation. For example, the `s3tables:GetTableData` actions includes permissions for the `GetObject`, `ListParts`, and `ListMultipart` API operations.

The following are supported actions for table buckets. You can specify the following actions in the `Action` element of an IAM policy or resource policy.

Action	Description	Access level	Cross-account access
<code>s3tables:CreateTableBucket</code>	Grants permissions to create a table bucket	Write	No
<code>s3tables:GetTableBucket</code>	Grants permission to retrieve a table bucket ARN, table bucket name, and create date.	Write	Yes
<code>s3tables>ListTableBuckets</code>	Grants permission to list all table	Read	No

Action	Description	Access level	Cross-account access
	buckets in this account.		
s3tables:CreateNamespace	Grants permission to create a name space in a table bucket	Write	Yes
s3tables:GetNamespace	Grants permission to retrieve namespace details	Read	Yes
s3tables>ListNamespaces	Grants permission to list all namespaces on the table bucket.	Read	Yes
s3tables>DeleteNamespace	Grants permission to delete a namespace in a table bucket	Write	Yes
s3tables>DeleteTableBucket	Grants permission to delete the bucket	Write	Yes

Action	Description	Access level	Cross-account access
s3tables:PutTableBucketPolicy	Grants permission to add or replace a bucket policy	Permissions Management	No
s3tables:GetTableBucketPolicy	Grants permission to retrieve the bucket policy	Read	No
s3tables:DeleteTableBucketPolicy	Grants permission to delete the bucket policy	Permissions Management	No
s3tables:GetTableBucketMaintenanceConfiguration	Grants permission to retrieve the maintenance configuration for a table bucket	Read	Yes
s3tables:PutTableBucketMaintenanceConfiguration	Grants permission to add or replace the maintenance configuration for a table bucket	Write	Yes

Action	Description	Access level	Cross-account access
s3tables:PutTableBucketEncryption	Grants permission to add or replace the encryption configuration for a table bucket	Write	No
s3tables:GetTableBucketEncryption	Grants permission to retrieve the encryption configuration for a table bucket	Read	No
s3tables>DeleteTableBucketEncryption	Grants permission to delete the encryption configuration for a table bucket	Write	No

The following actions are supported for tables:

Action	Description	Access level	Cross-account access
s3tables:GetTableMaintenance	Grants permission to retrieve the maintenance	Read	Yes

Action	Description	Access level	Cross-account access
eConfiguration	configuration for a table		
s3tables:PutTableMaintenanceConfiguration	Grants permission to add or replace the maintenance configuration for a table	Write	Yes
s3tables:PutTablePolicy	Grants permission to add or replace a table policy	Permissions Management	No
s3tables:GetTablePolicy	Grants permission to retrieve the table policy	Read	No
s3tables:DeleteTablePolicy	Grants permission to delete the table policy	Permissions management	No
s3tables: CreateTable	Grants permission to create a table in a table bucket	Write	Yes

Action	Description	Access level	Cross-account access
s3tables: GetTable	Grants permission to retrieve a table information	Read	Yes
s3tables: GetTableMetadataLocation	Grants permission to retrieve the table root pointer (metadata file)	Read	Yes
s3tables: ListTables	Grants permission to list all tables in a table bucket	Read	Yes
s3tables: RenameTable	Grant permissions to change the name of a table.	Write	Yes
s3tables: UpdateTableMetadataLocation	Grants permission to update table root pointer (metadata file)	Write	Yes

Action	Description	Access level	Cross-account access
s3tables: GetTableData	Grants permission to read the table metadata and data objects stored in the table bucket	Read	Yes
s3tables: PutTableData	Grants permission to write the table metadata and data objects stored in the table bucket	Write	Yes
s3tables: GetTableEncryption	Grants permission to retrieve the encryption settings for a table	Write	No
s3tables: PutTableEncryption	Grants permission to add encryption to a table	Write	No

Action	Description	Access level	Cross-account access
s3tables:DeleteTable	Grants permission to delete a table from a table bucket	Write	Yes

To perform table-level read and write actions, S3 Tables supports Amazon S3 API operations such as `GetObject` and `PutObject`. The following table provides a list of object-level actions. When granting read and write permissions to your tables, you use the following actions.

Action	S3 object APIs
s3tables:DeleteTable	<code>GetObject</code> , <code>ListParts</code> , <code>HeadObject</code>
s3tables:PutTableData	<code>PutObject</code> , <code>CreateMultipartUpload</code> , <code>CompleteMultipartUpload</code> , <code>UploadPart</code> , <code>AbortMultipartUpload</code>

For example, if a user has `GetTableData` permissions, then they can read all the files associated with the table, such as its metadata file, manifest, manifest list files, and parquet data files.

Condition keys for S3 Tables

S3 Tables supports [AWS global condition context keys](#).

Additionally, S3 Tables defines the following condition keys that you can use in an access policy.

Condition key	Description	Type
<code>s3tables:tableName</code>	<p>Filters access by the name of the tables in the table bucket.</p> <p>You can use the <code>s3tables:tableName</code> condition key to write IAM, or table bucket policies that restrict user or application access to only the tables that meet this name condition.</p> <p>It's important to note that if you use the</p>	String

Condition key	Description	Type
	<p>s3tables: tableName condition key to control access then changes in tables' name could impact these policies.</p> <p>Example</p> <p>value:</p> <pre>"s3tables :tableName e":"department"</pre>	

Condition key	Description	Type	
	<p>s3tables:namespace</p> <p>Filters access by the namespace s created in the table bucket.</p> <p>You can use the s3tables:namespace condition key to write IAM, table, or table bucket policies that restrict user or application access to tables that are part of a specific namespace.</p> <p><i>Example value:</i></p> <pre>"s3tables :namespace": "hr"</pre> <p>It's important to note that if you use the s3tables:namespace condition</p>	<p>String</p>	

Condition key	Description	Type	
	key to control access, then changes in namespace could impact these policies.		

Condition key	Description	Type
s3tables: SSEAlgorithm	<p>Filters access by the server-side encryption algorithm used to encrypt a table.</p> <p>You can use the s3tables:SSEAlgorithm condition key to write IAM, table, or table bucket policies that restrict user or application access to tables that are encrypted with a certain encryption type.</p> <p><i>Example value:</i></p> <pre>"s3tables:SSEAlgorithm": "aws:kms"</pre>	String

Condition key	Description	Type
	<p>It's important to note that if you use the s3tables: SSEAlgorithm condition key to control access, then changes in encryption could impact these policies.</p>	

Condition key	Description	Type	
s3tables: KMSKeyArn	<p>Filters access by the AWS KMS key ARN for the key used to encrypt a table</p> <p>You can use the s3tables:KMSKeyArn condition key to write IAM, table, or table bucket policies that restrict user or application access to tables that are encrypted with a specific KMS key.</p> <p>It's important to note that if you use the s3tables:KMSKeyArn condition key to control</p>	ARN	

Condition key	Description	Type
	access, then changing your KMS key could impact these policies.	

IAM identity-based policies for S3 Tables

By default, users and roles don't have permission to create or modify tables and table buckets. They also can't perform tasks by using the s3 console, AWS Command Line Interface (AWS CLI), or Amazon S3 REST APIs. To create and access table buckets and tables, an AWS Identity and Access Management (IAM) administrator must grant the necessary permissions to the IAM role or users. To learn how to create an IAM identity-based policy by using these example JSON policy documents, see [Creating IAM policies](#) in the *IAM User Guide*.

The following topic includes examples of IAM identity-based policies. To use the following example policies, replace the *user input placeholders* with your own information.

            ]
        }
    ]
}
```

{}

Resource-based policies for S3 Tables

S3 Tables provides resource-based policies for managing access to table buckets and tables: table bucket policies and table policies. You can use a table bucket policy to grant API access permissions at the table bucket, namespace, or table-level. The permissions attached to the table bucket can apply to all tables in the bucket or to specific tables in the bucket, depending on the policy definition. You can use a table policy to grant permissions at the table-level.

When S3 Tables receives a request, it first verifies that the requester has the necessary permissions. It evaluates all the relevant access policies, user policies, and resource-based policies in deciding whether to authorize the request (IAM user policy, IAM role policy, table bucket policy, and table policy). For example, if a table bucket policy grants a user permissions to perform all actions on the tables in the bucket (including `DeleteTable`), but an individual table has a table policy that denies the `DeleteTable` action for all users, then the user cannot delete the table.

The following topic includes examples of table and table bucket policies. To use these policies, replace the *user input placeholders* with your own information.

Note

- Every policy that grants permissions to modify tables should include permissions for `GetTableMetadataLocation` to access the table root file. For more information, see [GetTableMetadataLocation](#).
- Every time that you perform a write or delete activity on your table, include permissions to `UpdateTableMetadataLocation` in your access policy.
- We recommend using a table bucket policy for governing access to bucket-level actions and a table policy for governing access to table-level actions. In cases where you want to define the same set of permissions across multiple tables, then we recommend using a table bucket policy.

Topics

- [Example 1: Table bucket policy allows access to PutBucketMaintenanceConfiguration for buckets in an account](#)

- [Example 2: Table bucket policy to allows read \(SELECT\) access to tables stored in the hrnamespace](#)
- [Example 3: Table policy to allow user to delete a table](#)

Example 1: Table bucket policy allows access to PutBucketMaintenanceConfiguration for buckets in an account

The following example table bucket policy allows the IAM data steward to delete unreferenced objects for all the buckets in an account by allowing access to PutBucketMaintenanceConfiguration.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:role/datasteward"  
            },  
            "Action": [  
                "s3tables:PutTableBucketMaintenanceConfiguration"  
            ],  
            "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/*"  
        }  
    ]  
}
```

Example 2: Table bucket policy to allows read (SELECT) access to tables stored in the hrnamespace

The following an example table bucket policy allows Jane, a user from AWS account ID 123456789012 to access tables stored in the hr namespace in a table bucket.

JSON

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Jane"
        },
        "Action": [
            "s3tables:GetTableData",
            "s3tables:GetTableMetadataLocation"
        ],
        "Resource": "arn:aws:s3tables:us-east-1:11122223333:bucket/amzn-s3-demo-table-bucket/table/*",
        "Condition": {
            "StringLike": {
                "s3tables:namespace": "hr"
            }
        }
    }
]
```

Example 3: Table policy to allow user to delete a table

The following example table policy that allows the IAM role data steward to delete a table.

JSON

```
{
    "Version": "2012-10-17",
    "Id": "DeleteTable",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::11122223333:role/datasteward"
            },
            "Action": [
                "s3tables>DeleteTable",
                "s3tables>UpdateTableMetadataLocation",
                "s3tables>PutTableData",
                "s3tables>GetTableMetadataLocation"
            ]
        }
    ]
}
```

```
        ],
        "Resource": "arn:aws:s3:us-east-1:111122223333:bucket/amzn-s3-
demo-bucket/table/tableUUID"
    }
]
```

AWS managed policies for S3 Tables

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see [AWS managed policies](#) in the *IAM User Guide*.

AWS managed policy: AmazonS3TablesFullAccess

You can attach the AmazonS3TablesFullAccess policy to your IAM identities. This policy grants permissions that allow full access to Amazon S3 Tables. For more information about this policy, see [AmazonS3TablesFullAccess](#).

AWS managed policy: AmazonS3TablesReadOnlyAccess

You can attach the AmazonS3TablesReadOnlyAccess policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon S3 Tables. For more information about this policy, see [AmazonS3TablesReadOnlyAccess](#).

AWS managed policy: AmazonS3TablesLakeFormationServiceRole

You can attach the `AmazonS3TablesLakeFormationServiceRole` policy to your IAM identities. This policy grants permissions that allow the AWS Lake Formation service role access to S3 Tables. AWS KMS permissions are used to allow Lake Formation to access encrypted tables. For more information about this policy, see [AmazonS3TablesLakeFormationServiceRole](#).

Amazon S3 Tables updates to AWS managed policies

View details about updates to AWS managed policies for Amazon S3 Tables since S3 Tables began tracking these changes.

Change	Description	Date
Amazon S3 Tables updated <code>AmazonS3TablesFullAccess</code> .	S3 Tables updated the AWS-managed policy called <code>AmazonS3TablesFullAccess</code> . This update grants permission to pass a role to the S3 Tables Replication service.	December 2, 2025
Amazon S3 Tables added <code>AmazonS3TablesLakeFormationServiceRole</code> .	S3 Tables added a new AWS-managed policy called <code>AmazonS3TablesLakeFormationServiceRole</code> . This policy grants permissions that allows the Lake Formation service role access to S3 Tables.	May 19, 2025
Amazon S3 Tables added <code>AmazonS3TablesFullAccess</code> .	S3 Tables added a new AWS-managed policy called <code>AmazonS3TablesFullAccess</code> . This policy grants permissions that allow full access to Amazon S3 Tables.	December 03, 2024

Change	Description	Date
Amazon S3 Tables added AmazonS3TablesRead OnlyAccess .	S3 Tables added a new AWS-managed policy called AmazonS3TablesRead OnlyAccess . This policy grants permissions to allow read-only access to Amazon S3 Tables.	December 03, 2024
Amazon S3 Tables started tracking changes.	Amazon S3 Tables started tracking changes for its AWS managed policies.	December 03, 2024

Granting access with SQL semantics

You can grant permissions to tables by using SQL semantics in table and table bucket policies. Examples of SQL semantics you can use are CREATE, INSERT, DELETE, UPDATE, and ALTER. The following table provides a list of API actions associated with SQL semantics that you can use to grant permissions to your users.

S3 Tables partially supports permissions using SQL semantics. For example, the `CreateTable` API only creates an empty table in the table bucket. You need additional permissions such as, `UpdateTableMetadata`, `PutTableData`, and `GetTableMetadataLocation` to be able to set the table schema. These additional permissions also mean that you are also granting the user access to insert rows in the table. If you wish to govern access purely based on SQL semantics, then we recommend using [AWS Lake Formation](#) or any third-party solution that is integrated with S3 Tables.

Table-level activity	IAM actions
SELECT	s3tables: GetTableD ata , s3tables: GetTableM

Table-level activity	IAM actions		
	s3:metadataLocation		
CREATE	s3:CreateTable, s3:UpdateTableMetadataLocation, s3:PutTableData, s3:GetTableMetadataLocation,		
INSERT	s3:UpdateTableMetadataLocation, s3:PutTableData, s3:GetTableMetadataLocation		

Table-level activity	IAM actions		
UPDATE	<pre>s3tables: UpdateTab leMetadata aLocation ,</pre> <pre>s3tables: PutTableD ata , s3tables: GetTableM etadataLo cation</pre>		
ALTER,RENAME	<pre>s3tables: UpdateTab leMetadata aLocation ,</pre> <pre>s3tables: PutTableD ata , s3tables: GetTableM etadataLo cation , s3tables: RenameTab le</pre>		

Table-level activity	IAM actions
DELETE, DROP	s3tables:DeleteTable , s3tables:UpdateTableMetadataLocation , s3tables:PutTableData , s3tables:GetTableMetadataLocation

 **Note**

The `s3tables:DeleteTable` permission is required to delete a table from a table bucket. This permission allows you to permanently remove a table and all its associated data and metadata. Use this permission carefully as the delete operation cannot be undone.

Managing access to a table or database with Lake Formation

After your table buckets are integrated with the AWS analytics services, Lake Formation manages access to your tables and requires that each IAM principal (user or role) be authorized to perform actions on them. Lake Formation uses its own permissions model (Lake Formation permissions) that enables fine-grained access control for Data Catalog resources.

For more information, see [Overview of Lake Formation permissions](#) in the *AWS Lake Formation Developer Guide*.

There are two main types of permissions in AWS Lake Formation:

1. Metadata access permissions control the ability to create, read, update, and delete metadata databases and tables in the Data Catalog.
2. Underlying data access permissions control the ability to read and write data to the underlying Amazon S3 locations that the Data Catalog resources point to.

Lake Formation uses a combination of its own permissions model and the IAM permissions model to control access to Data Catalog resources and underlying data:

- For a request to access Data Catalog resources or underlying data to succeed, the request must pass permission checks by both IAM and Lake Formation.
- IAM permissions control access to the Lake Formation and AWS Glue APIs and resources, whereas Lake Formation permissions control access to the Data Catalog resources, Amazon S3 locations, and the underlying data.

Lake Formation permissions apply only in the Region in which they were granted, and a principal must be authorized by a data lake administrator or another principal with the necessary permissions in order to be granted Lake Formation permissions.

 **Note**

If you're the user who performed the table bucket integration, you already have Lake Formation permissions to your tables. If you're the only principal who will access your tables, you can skip this step. You only need to grant Lake Formation permissions on your tables to other IAM principals. This allows other principals to access the table when running queries. For more information, see [Granting Lake Formation permission on a table or database](#).

Granting Lake Formation permission on a table or database

You can grant a principal Lake Formation permissions on a table or database in a table bucket, either through the Lake Formation console or the AWS CLI.

 **Note**

When you grant Lake Formation permissions on a Data Catalog resource to an external account or directly to an IAM principal in another account, Lake Formation uses the

AWS Resource Access Manager (AWS RAM) service to share the resource. If the grantee account is in the same organization as the grantor account, the shared resource is available immediately to the grantee. If the grantee account is not in the same organization, AWS RAM sends an invitation to the grantee account to accept or reject the resource grant. Then, to make the shared resource available, the data lake administrator in the grantee account must use the AWS RAM console or AWS CLI to accept the invitation. For more information about cross-account data sharing, see [Cross-account data sharing in Lake Formation](#) in the [AWS Lake Formation Developer Guide](#).

Console

1. Open the AWS Lake Formation console at <https://console.aws.amazon.com/lakeformation/>, and sign in as a data lake administrator. For more information about how to create a data lake administrator, see [Create a data lake administrator](#) in the [AWS Lake Formation Developer Guide](#).
2. In the navigation pane, choose **Data permissions**, and then choose **Grant**.
3. On the **Grant Permissions** page, under **Principals**, do one of the following:
 - For Amazon Athena or Amazon Redshift, choose **IAM users and roles**, and select the IAM principal you use for queries.
 - For Amazon Data Firehose, choose **IAM users and roles**, and select the service role that you created to stream to tables.
 - For Quick Suite, choose **SAML users and groups**, and enter the Amazon Resource Name (ARN) of your Quick Suite admin user.
 - For AWS Glue Iceberg REST endpoint access, choose **IAM users and roles** then select the IAM role you created for your client. For more information, see [Create an IAM role for your client](#)
4. Under **LF-Tags or catalog resources**, choose **Named Data Catalog resources**.
5. For **Catalogs**, choose the subcatalog that you created when you integrated your table bucket, for example, `account-id:s3tablescatalog/amzn-s3-demo-bucket`.
6. For **Databases**, choose the S3 table bucket namespace that you created.
7. (Optional) For **Tables**, choose the S3 table that you created in your table bucket.

Note

If you're creating a new table in the Athena query editor, don't select a table.

8. Do one of the following:

- If you specified a table in the prior step, for **Table permissions**, choose **Super**.
- If you didn't specify a table in the prior step, go to **Database permissions**. For cross-account data sharing, you can't choose **Super** to grant the other principal all permissions on your database. Instead, choose more fine-grained permissions, such as **Describe**.

9. Choose **Grant**.

CLI

1. Make sure that you're running the following AWS CLI commands as a data lake administrator. For more information, see [Create a data lake administrator](#) in the *AWS Lake Formation Developer Guide*.
2. Run the following command to grant Lake Formation permissions on table in S3 table bucket to an IAM principal to access the table. To use this example, replace the *user input placeholders* with your own information.

```
aws lakeformation grant-permissions \
--region us-east-1 \
--cli-input-json \
'{
    "Principal": {
        "DataLakePrincipalIdentifier": "user or role ARN, for example, arn:aws:iam::account-id:role/example-role"
    },
    "Resource": {
        "Table": {
            "CatalogId": "account-id:s3tablescatalog/amzn-s3-demo-bucket",
            "DatabaseName": "S3 table bucket namespace, for example, test_namespace",
            "Name": "S3 table bucket table name, for example test_table"
        }
    },
    "Permissions": [
        "DESCRIBE"
    ]
}'
```

```
    "ALL"  
]  
}'
```

VPC connectivity for S3 Tables

All tables in S3 Tables are in the Apache Iceberg format and are made up of two types of S3 objects. These two types of objects are data files which store the data and metadata files which track information about the data files at different points in time. All table bucket, namespace, and table operations (for example, `CreateNamespace`, `CreateTable`, and so on) are routed through an S3 Tables endpoint (`s3tables.region.amazonaws.com`) and all object-level operations that read or write the data and metadata files continue to be routed through an S3 service endpoint (`s3.region.amazonaws.com`).

To access S3 Tables, Amazon S3 supports two types of VPC endpoints by using AWS PrivateLink: gateway endpoints and interface endpoints. A gateway endpoint is a gateway that you specify in your route table to access S3 from your VPC over the AWS network. Interface endpoints extend the functionality of gateway endpoints by using private IP addresses to route requests to Amazon S3 from within your VPC, on premises, or from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway.

To access S3 Tables from a VPC, we recommend creating two VPC endpoints (one for S3 and the other for S3 Tables). You can create either a gateway or an interface endpoint to route file (object) level operations to S3 and an interface endpoint to route bucket and table-level operations to S3 Tables. You can create and use VPC endpoints for file-level requests using S3. For more information, see [Gateway endpoints](#) in the *AWS PrivateLink User Guide*.

To learn more about using AWS PrivateLink to create and work with endpoints for S3 Tables, see the following topics. To create a VPC interface endpoint, see [Create a VPC endpoint](#) in the *AWS PrivateLink Guide*.

Topics

- [Creating VPC endpoints for S3 Tables](#)
- [Accessing table buckets and tables through endpoints using the AWS CLI](#)
- [Configuring a VPC network when using query engines](#)
- [Using the dual-stack endpoints to access tables and table buckets](#)
- [Restricting access to S3 Tables within the VPC network](#)

Creating VPC endpoints for S3 Tables

When you create a VPC endpoint, S3 Tables generates two types of endpoint-specific DNS names: Regional and Zonal.

- A Regional DNS name is of the following format:
VPCEndpointID.s3tables.AWSregion.vpce.amazonaws.com. For example, for the VPC endpoint ID vpce-1a2b3c4d, the DNS name generated will be similar to vpce-1a2b3c4d-5e6f.s3tables.us-east-1.vpce.amazonaws.com
- A Zonal DNS name is of the following format: VPCEndpointID-AvailabilityZone.s3tables.AWSregion.vpce.amazonaws.com. For example, For the VPC endpoint ID vpce-1a2b3c4d-5e6f., the DNS name generated will be similar to vpce-1a2b3c4d-5e6f-us-east-1a.s3tables.us-east-1.vpce.amazonaws.com

A Zonal DNS name includes your Availability Zone. You might use Zonal DNS names if your architecture isolates Availability Zones. Endpoint specific S3 DNS names can be resolved from the S3 public DNS domain.

You can also use Private DNS options to simplify routing S3 traffic over VPC endpoints and help you take advantage of the lowest-cost network path available to your application. Private DNS maps the public endpoint of S3 Tables, for instance, s3tables.region.amazonaws.com, to a private IP in your VPC. You can use private DNS options to route Regional S3 traffic without updating your S3 clients to use the endpoint-specific DNS names of your interface endpoints.

Accessing table buckets and tables through endpoints using the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to access table buckets and tables through the interface endpoints. With the AWS CLI, aws s3 commands route traffic through the Amazon S3 endpoint. The aws s3tables AWS CLI commands use the Amazon S3 Tables endpoint.

An example of an s3tables VPC endpoint is vpce-0123456afghjip1jw-nmopsqea.s3tables.region.vpce.amazonaws.com

An s3tables VPC endpoint doesn't include a bucket name. You can access the s3tables VPC endpoint using the aws s3tables AWS CLI commands.

An example of an s3 VPC endpoint is amzn-s3-demo-bucket.vpce-0123456afghjip1jw-nmopsqea.s3.region.vpce.amazonaws.com

You can access the s3 VPC endpoint using the aws s3 AWS CLI commands.

Using the AWS CLI

To access table buckets and tables through interface endpoints using the AWS CLI, use the --region- and --endpoint-url parameters. To perform table bucket and table level actions, use the S3 Tables endpoint URL. To perform object level actions, use the Amazon S3 endpoint URL.

In the following examples, replace the *user input placeholders* with your own information.

Example 1: Use an endpoint URL to list table buckets in your account

```
aws s3tables list-table-buckets --endpoint https://vpce-0123456afghjipljb-aac.s3tables.us-east-1.amazonaws.com --region us-east-1
```

Example 2: Use an endpoint URL to list tables in your bucket

```
aws s3tables list-tables --table-bucket-arn arn:aws:s3tables:us-east-1:123456789301:bucket/amzn-s3-demo-bucket --endpoint https://vpce-0123456afghjipljb-aac.s3tables.us-east-1.amazonaws.com --region us-east-1
```

Configuring a VPC network when using query engines

Use the following steps to configure a VPC network when using query engines.

1. To get started, you can create or update a VPC. For more information, see [Create a VPC](#).
2. For table and table bucket level operations that route to S3 Tables, create a new interface endpoint. For more information, see [Access an AWS service using an interface VPC endpoint](#).
3. For all object level operations that route to Amazon S3, create a gateway endpoint or a interface endpoint. For more information on gateway endpoints, see [Create a gateway endpoint](#).
4. Next, configure your data resources and launch an Amazon EMR cluster. For more information, see [Getting started with Amazon EMR](#).
5. You can then submit a Spark application with an additional configuration by selecting your DNS names from the VPC endpoint. For example, spark.sql.catalog.ice_catalog.s3tables.endpoint and https://interface-endpoint.s3tables.us-east-1.amazonaws.com For more information, see [Submit work to your Amazon EMR cluster](#).

Using the dual-stack endpoints to access tables and table buckets

S3 Tables supports dual-stack connectivity for AWS PrivateLink. Dual-stack endpoints allow you to access S3 tables buckets using the Internet Protocol version 6 (IPv6), in addition to the IPv4 protocol, depending on what your network supports. You can access an S3 bucket through a dual-stack endpoint using the following naming convention:

```
s3tables.<region>.api.aws
```

The following are some things you should know before trying to access S3 tables and table buckets over IPv6 in your VPC:

- The client you use to access tables and your S3 client must both have dual-stack enabled.
- IPv6 inbound is not enabled by default for VPC security groups. To allow IPv6 access you will need to add a new rule allowing HTTPS (TCP port 443) to your security group. For more information, see [Configure security group rules](#) in the *Amazon EC2 user guide*
- If your VPC doesn't have IPv6 CIDRs assigned, you will need to manually add an IPv6 CIDR block to your VPC. For more info, see [Add IPv6 support for your VPC](#) in the *AWS PrivateLink user guide*
- If you use IP address filtering IAM policies they must be updated to handle IPv6 addresses. For more information about managing access permissions with IAM, see [Identity and Access Management for Amazon S3](#).

To create a new VPC endpoint that uses the dual-stack endpoint for S3 Tables use example CLI command:

```
aws ec2 create-vpc-endpoint \
--vpc-id vpc-id \
--service-name com.amazonaws.aws-region.s3tables \
--subnet-ids subnet-1 subnet-2 \
--vpc-endpoint-type Interface \
--ip-address-type dualstack \
--dns-options "DnsRecordIpType=dualstack" \
--security-group-ids sg-id \
--region aws-region
```

For more information on creating VPC endpoints see [Create an interface endpoint](#) in the VPC user guide.

If your network supports IPv6 and you want to update your VPC to enable IPv6 you can use the following CLI command:

```
aws ec2 modify-vpc-endpoint \
--vpc-endpoint-id vpce-id \
--ip-address-type dualstack \
--dns-options "DnsRecordIpType=dualstack" \
--region aws-region
```

Restricting access to S3 Tables within the VPC network

Similar to resource-based policies, you can attach an endpoint policy to your VPC endpoint that controls the access to tables and table buckets. In the following example, the interface endpoint policy restricts access to only specific table buckets.

JSON

```
{
    "Version": "2012-10-17",
    "Id": "Policy141511512309",
    "Statement": [
        {
            "Sid": "Access-to-specific-bucket-only",
            "Principal": "*",
            "Action": "s3tables:*",
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket",  

                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket/*"
            ]
        }
    ]
}
```

Security considerations and limitations for S3 Tables

The following list describes which security and access control features and functionality are unsupported or limited for S3 Tables.

- Public access policies are not supported. Users can't modify bucket or table policies to allow public access.
- Presigned URLs to access objects associated with a table are not supported.
- Requests made over HTTP are not supported. Amazon S3 automatically responds with an HTTP redirect for any requests made via HTTP to upgrade the requests to HTTPS.
- You must use AWS Signature Version 4 when making requests to an access point by using the REST APIs.
- Requests made over the Internet Protocol version 6 (IPv6) are supported only for object-level actions over table storage endpoints, and not for the table- and bucket-level actions.
- Table bucket and table access policies are limited to 20 KB in size.

Logging and monitoring for S3 Tables

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 Tables. We recommend collecting monitoring data from your tables in table buckets so that you can more easily debug a multipoint failure if one occurs.

AWS provides several tools for monitoring your S3 Tables resources and responding to potential incidents.

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon S3. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

Topics

- [Logging with AWS CloudTrail for S3 Tables](#)
- [Monitoring metrics with Amazon CloudWatch](#)

Logging with AWS CloudTrail for S3 Tables

Amazon S3 is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details. When a supported event activity occurs in Amazon S3, that activity is recorded in a CloudTrail event. You can use AWS CloudTrail trail to log management events and data events for S3 Tables. For more information, see [Amazon S3 CloudTrail events](#) and [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

CloudTrail management events for S3 Tables

Management events provide information about management operations that are performed on resources in your AWS account.

By default, CloudTrail logs management events for S3 Tables. The eventsource for CloudTrail management events for S3 Tables is `s3tables.amazonaws.com`. When you set up your AWS account, CloudTrail management events are enabled by default. The following API actions are tracked by CloudTrail and logged as management events.

- [CreateNamespace](#)
- [CreateTable](#)
- [CreateTableBucket](#)
- [DeleteNamespace](#)
- [DeleteTable](#)
- [DeleteTableBucket](#)
- [DeleteTableBucketPolicy](#)
- [DeleteTablePolicy](#)
- [GetNamespace](#)
- [GetTable](#)
- [GetTableBucket](#)

- [GetTableBucketMaintenanceConfiguration](#)
- [GetTableBucketPolicy](#)
- [GetTableMaintenanceConfiguration](#)
- [GetTableMaintenanceJobStatus](#)
- [GetTableMetadataLocation](#)
- [GetTablePolicy](#)
- [ListNamespaces](#)
- [ListTableBuckets](#)
- [ListTables](#)
- [PutTableBucketMaintenanceConfiguration](#)
- [PutTableMaintenanceConfiguration](#)
- [PutBucketPolicy](#)
- [PutTablePolicy](#)
- [RenameTable](#)
- [UpdateTableMetadataLocation](#)

For more information on CloudTrail management events, see [Logging management events](#) in the *AWS CloudTrail User Guide*.

CloudTrail management events for S3 Tables maintenance

S3 logs automatic maintenance operations as TablesMaintenanceEvent management events in CloudTrail. These events occur during operations like compaction and snapshot expiration. For more information about S3 table maintenance, see [Maintenance for tables](#).

How to identify maintenance events

You can identify S3 Tables maintenance events in CloudTrail logs by these attribute values:

- eventSource: s3tables.amazonaws.com
- eventType: AwsServiceEvent
- eventName: TablesMaintenanceEvent
- userAgent: maintenance.s3tables.amazonaws.com
- activityType:

- `IcebergCompaction` (for compaction)
- `IcebergSnapshotManagement` (for snapshot expiration)

For an example of a compaction maintenance event, see [Example – CloudTrail log file for a table maintenance management event](#).

CloudTrail data events for S3 Tables

Data events provide information about the resource operations performed on or in a resource. By default, CloudTrail trails don't log data events, but you can configure trails to log data events.

When you log data events for a trail in CloudTrail, you will choose or specify the resource type. S3 Tables has two resources types, `AWS::S3Tables::Table` and `AWS::S3Tables::TableBucket`.

The following data events are logged to CloudTrail.

- [`AbortMultipartUpload`](#)
- [`CompleteMultipartUpload`](#)
- [`CreateMultipartUpload`](#)
- [`GetObject`](#)
- [`HeadObject`](#)
- [`ListParts`](#)
- [`PutObject`](#)
- [`UploadPart`](#)

For more information on CloudTrail data events, see [Logging data events](#) in the *AWS CloudTrail User Guide*.

For additional information about CloudTrail events for S3 Tables, see the following topics:

            "clientProvidedHostHeader": "tableWarehouseLocation.s3.us-
east-1.amazonaws.com"
        }
    }
```

Monitoring metrics with Amazon CloudWatch

You can use Amazon CloudWatch metrics to track performance, detect anomalies, and monitor the operational health of tables. There are several sets of CloudWatch metrics that you can use with S3 Tables.

Daily storage metrics for tables and table buckets

Monitor the amount of data stored in tables and table buckets, including total size in bytes and number of files. These metrics track total storage bytes per access tier and file counts at the table bucket, table, and namespace level. Storage metrics for S3 Tables are reported once per day and are provided to all customers at no additional cost.

Table maintenance metrics

Monitor automated maintenance operations performed by Amazon S3 on your tables, such as compaction. These metrics track the number of bytes and files processed during maintenance activities. Maintenance metrics for S3 Tables are reported once per day and are provided to all customers at no additional cost.

Request metrics

Monitor S3 Tables requests to quickly identify and act on operational issues. These CloudWatch metrics can be optionally enabled for individual table buckets. Request metrics for S3 Tables are reported once every minute and are billed at the same rate as CloudWatch custom metrics. Request metrics include:

- counts of data plane operations (GET, PUT, HEAD, POST)
- bytes transferred
- latency measurements

- error rates

 **Note**

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests. It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

Metrics and dimensions

The storage metrics and dimensions that S3 Tables sends to Amazon CloudWatch are listed in the following tables.

 **Note**

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests. It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management

Dashboard might include one or more access requests that do not appear in the bucket metrics.

Daily storage metrics for table buckets in CloudWatch

The AWS/S3/Tables namespace includes the following daily storage metrics which are available at no additional cost. You can filter these metrics by table bucket, table, or namespace name.

Daily storage metrics

Metric Name	Description	Units	Statistics	Granularity
Total Bucket Storage	The amount of storage in bytes used by all tables in a table bucket	Bytes	Sum	Daily
Total number of files	The total count of all files stored in a table bucket	Count	Sum	Daily

Table maintenance metrics

The AWS/S3/Tables namespace includes the following table maintenance metrics which are available at no additional cost. You can filter these metrics by table bucket, table, or namespace name.

Table maintenance metrics

Metric Name	Description	Units	Statistics	Granularity
CompactionBytesProcessed	The number of bytes processed during table compaction operations	Bytes	Sum	Daily
CompactionObjectsCount	The number of objects processed during table compaction operations	Count	Sum	Daily

Request metrics for tables and table buckets in CloudWatch

The AWS/S3/Tables namespace includes the following request metrics which are billed at the same rate as CloudWatch custom metrics. You can filter these metrics by table bucket, table, or namespace name.

Request metrics

Metric Name	Description	Units	Statistics	Granularity
All requests count	The total number of HTTP requests made to a table bucket	Count	Sum	1-minute
Get requests count	The number of HTTP GET requests made to retrieve objects from tables	Count	Sum	1-minute
Put requests count	The number of HTTP PUT requests made to add objects to tables	Count	Sum	1-minute
Head requests count	The number of HTTP HEAD requests made to retrieve metadata from tables	Count	Sum	1-minute
Post requests counts	The number of HTTP POST requests made to tables	Count	Sum	1-minute
UpdateTableMetadataLocation requests count	The number of requests made to update table metadata locations	Count	Sum	1-minute
GetTableMetadataLocation requests count	The number of requests made to retrieve table metadata locations	Count	Sum	1-minute

Metric Name	Description	Units	Statistics	Granularity
BytesDownloaded	The number of bytes downloaded for table requests	Bytes	Sum	1-minute
BytesUploaded	The number of bytes uploaded for table requests	Bytes	Sum	1-minute
4xxErrors	The count of HTTP 4xx client error status codes returned	Count	Sum	1-minute
5xxErrors	The count of HTTP 5xx server error status codes returned	Count	Sum	1-minute
FirstByteLatency	The per-request time from the complete request being received to when the response starts being returned	Milliseconds	Sum	1-minute
TotalRequestLatency	The elapsed per-request time from the first byte received to the last byte sent	Milliseconds	Sum	1-minute

S3 Tables dimensions in CloudWatch

The following dimensions are used to filter S3 Tables metrics.

S3 Tables dimensions

Dimension Name	Description	Example Value
TableBucketName	The name of the Amazon S3 table bucket	my-table-bucket
Namespace	The namespace within the table bucket that contains one or more tables	my-department

Dimension Name	Description	Example Value
TableName	The name of a specific table within a namespace	transactions

Accessing CloudWatch metrics

You can monitor S3 Tables metrics using the CloudWatch Console, the AWS CLI, or the CloudWatch API. This section explains how to access your metrics using these different methods.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. In the buckets list, choose the name of the bucket that contains the tables you want to see metrics for.
4. Choose the **Metrics** tab.
5. Choose the **View in CloudWatch** in any metrics pane to navigate to the CloudWatch console and see your available metrics in the AWS/S3/Tables namespace.

Using the AWS CLI

To list metrics for S3 Tables using the AWS CLI, use the `list-metrics` command with the `--namespace` parameter set to AWS/S3/Tables:

```
aws cloudwatch list-metrics --namespace AWS/S3/Tables
```

To get statistics for a specific S3 Tables metric, use the `get-metric-statistics` command. For example:

```
aws cloudwatch get-metric-statistics \
--namespace AWS/S3/Tables \
--metric-name TotalBucketStorage \
--dimensions Name=TableBucketName,Value=MyTableBucket \
--start-time 2025-03-01T00:00:00 \
--end-time 2025-03-02T00:00:00 \
```

```
--period 86400 \
--statistics Average
```

Best Practices

- When retrieving metrics, set the Period value based on the metric's granularity. For daily metrics (like storage metrics), use 86400 seconds (24 hours). For minute-level metrics (like request metrics), use 60 seconds.
- Use dimensions appropriately to filter metrics to the desired scope (table bucket, namespace, or individual table level).
- Consider using metric math to create derived metrics that better match your monitoring needs.

Managing CloudWatch metrics

Storage metrics are enabled by default for all Amazon S3 tables and table buckets. You can enable or disable additional Request metrics through the console, AWS Command Line Interface (AWS CLI), or AWS SDKs.

Prerequisites

- Requires `s3:table:PutTableBucketMetricsConfiguration` IAM permission

Note

S3 Tables Request metrics are billed at the same rate as CloudWatch custom metrics.

Using the AWS Management Console

To enable or disable additional metrics

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Table buckets**.
3. In the buckets list, choose the name of the table bucket that contains the tables you want to request metrics for.
4. Choose the **Metrics** tab.
5. From the Request metrics panel, choose **Edit**.
6. Select **Enabled** or **Disabled**, then **Save changes**.

Using the AWS CLI

These examples show how to enable or disable request metrics for table buckets by using the AWS CLI. To use these commands, replace the *user input placeholders* with your own information.

Example : To enable request metrics for a table bucket:

```
aws s3tables put-table-bucket-metrics-configuration \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

Example : To disable request metrics for a table bucket:

```
aws s3tables delete-table-bucket-metrics-configuration \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

Working with S3 Vectors and vector buckets

What is Amazon S3 Vectors?

Amazon S3 Vectors delivers purpose-built, cost-optimized vector storage for AI agents, inference, RAG, and semantic search. S3 Vectors is designed to provide the same elasticity, durability, and availability as Amazon S3 and delivers subsecond latency for infrequent queries and as low as 100 milliseconds for more frequent queries. You get a dedicated set of API operations to store, access, and query vector data without provisioning any infrastructure. S3 Vectors consists of several key components that work together:

- **Vector buckets** – A new bucket type that's purpose-built to store and query vectors.
- **Vector indexes** – Within a vector bucket, you can organize your vector data within vector indexes. You perform similarity queries on your vector data within vector indexes.
- **Vectors** – You store vectors in your vector index. For similarity search and AI applications, vectors are created as vector embeddings which are numerical representations that preserve semantic relationships between content (such as text, images, or audio) so similar items are positioned closer together. S3 Vectors can perform similarity searches based on semantic meaning rather than exact matching through comparing how close vectors are to each other mathematically. When adding vector data to a vector index, you can also attach metadata for future filtering queries based on a set of conditions (for example, timestamps, categories, and user preferences).

Writes to S3 Vectors are strongly consistent, which means that you can immediately access the most recently added data. As you write, update, and delete vectors over time, S3 Vectors automatically optimizes the vector data to achieve the best possible price performance for vector storage, even as the data sets scale and evolve. You can control access to your vector data with the existing access control mechanisms of Amazon S3, including bucket and IAM policies. For more information about vector index limits per bucket and vector limits per index, see [Limitations and restrictions](#).

Use cases: Similarity searches across large datasets

Similarity searches allow you to find items that are conceptually related to each other based on their vector representations, rather than exact keyword matches. These searches identify content with similar meanings or characteristics, even when the exact words or visual elements differ.

Common use cases for similarity search with S3 Vectors include:

- **Medical imaging** - Find similarities in millions of medical images to assist with diagnosis and treatment planning
- **Copyright infringement** - Identify potentially derivative content across large media libraries
- **Image deduplication** - Detect and remove duplicate or near-duplicate images from large image collections
- **Video understanding** - Search for specific scenes or content within video assets
- **Enterprise document search** - Enable semantic search across corporate documents to find relevant information based on meaning
- **Personalization** - Deliver tailored recommendations by finding similar items

You should use S3 Vectors if you want to build cost-effective vector search and agentic AI applications with sub-second search times. With vector buckets, you only pay for what you use, and could save costs for uploading, storing, and querying vector embeddings. For more information about pricing, see [Amazon S3 pricing](#).

Features of S3 Vectors

Purpose-built storage for vectors

S3 Vectors is the first purpose-built object storage in the cloud to store and query vectors. Vector buckets are designed to provide cost-effective, elastic, and durable storage for vector data.

Vector embeddings are transforming how customers use and retrieve their unstructured data, from detecting similarities across medical images, finding anomalies in thousands of hours of video footage, navigating through large code bases, and identifying the most relevant case law for a given legal matter. These emerging applications combine with embedding models to encode the semantic meaning of data (for example, text, images, video, code) as numerical vector embeddings.

Within a vector bucket, you organize your vector data within vector indexes, without provisioning infrastructure. As you write, update, and delete vectors over time, S3 Vectors automatically optimize the vector data to achieve the best possible price performance for vector storage, even as the data sets scale and evolve. For more information about vector index limits per bucket and vector limits per index, see [Limitations and restrictions](#).

Perform similarity queries

With S3 Vectors, you can perform queries to find the most similar vectors to a query vector, with sub-second response times for infrequent queries and as low as 100 milliseconds for more frequent queries. S3 Vectors is ideal for workloads where queries are less frequent.

Metadata filtering

You can attach metadata (for example, year, author, genre, and location) as key-value pairs to your vectors. By default, all metadata is filterable unless you explicitly specify it as non-filterable. You can use filterable metadata to filter your query results based on specific attributes, enhancing the relevance of your queries. Vector indexes support string, number, boolean, and list types of metadata. For more information about metadata size limits per vector and filterable metadata size limits per vector, see [Limitations and restrictions](#).

Access management and security

You can manage access for resources in vector buckets with IAM and [Service Control Policies](#) in AWS Organizations. S3 Vectors uses a different service namespace than Amazon S3: the `s3vectors` namespace. Therefore, you can design policies specifically for the S3 Vectors service and its resources. You can design policies to grant access to individual vector indexes, all vector indexes within a vector bucket, or all vector buckets in an account. All Amazon S3 Block Public Access settings are always enabled for vector buckets and cannot be disabled.

Integration with AWS services

S3 Vectors integrates with other AWS services to enhance your vector processing capabilities:

- [Amazon OpenSearch Service](#) - Optimize vector storage costs while continuing to use OpenSearch API operations. This is ideal for workloads that need advanced search functionality such as hybrid search, aggregations, advanced filtering, and faceted search. You can also export a snapshot of an S3 vector index to Amazon OpenSearch Serverless for high QPS and low latency vector search.
- [Amazon Bedrock Knowledge Bases](#) - Select a vector index in S3 Vectors as your vector store to save on storage costs for retrieval augmented generation (RAG) applications.
- [Amazon Bedrock in SageMaker Unified Studio](#) - Develop and test knowledge bases using S3 Vectors as your vector store.

Tutorial: Getting started with S3 Vectors

In this tutorial, you create an S3 vector bucket and a vector index in an AWS Region in the Amazon S3 console. Next, you use an Amazon Bedrock embedding model to generate vector embeddings of your data and store them in your vector index to perform semantic searches.

To get started, sign up for an AWS account if you don't already have one. For more information about setting up with an account, see [Getting started with Amazon S3](#).

Topics

- [Step 1: Create a vector bucket with the console](#)
- [Step 2: Create a vector index in a vector bucket with the console](#)
- [Step 3: Insert vectors into a vector index with the SDK for Python \(Boto3\)](#)
- [Step 4. Query vectors in a vector index with the SDK for Python \(Boto3\)](#)
- [\(Optional\) Automate vector embedding creation with the S3 Vectors Embed CLI](#)
- [\(Optional\) Integrate S3 Vectors with Amazon Bedrock Knowledge Bases](#)
- [\(Optional\) Integrate S3 Vectors with Amazon OpenSearch](#)

Step 1: Create a vector bucket with the console

S3 vector buckets are a type of Amazon S3 bucket that's purpose-built to store and query vectors. You use dedicated API operations to write and query vector data. You can control access to your vector data with access control mechanisms such as IAM identity-based policies and resource-based policies.

In this step, you use the Amazon S3 console to create your first vector bucket. For other ways to create a vector bucket, see [Creating a vector bucket](#).

To create a vector bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Vector buckets**.
3. On the **Vector buckets** page, choose **Create vector bucket**.
4. On the **Create vector bucket** page, for the **Vector bucket name** field, enter a name. In this tutorial, we use **media-embeddings** as the vector bucket name. Vector bucket names must be

3 to 63 characters and unique within an AWS Region. Valid characters are lowercase letters (a-z), numbers (0-9), and hyphens (-).

 **Note**

The vector bucket name can't be changed after the bucket is created.

5. Under **Encryption**, choose **Specify encryption type**. You have the option to specify encryption type as **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or the default **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. In this tutorial, we choose **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. For more information about setting encryption configuration for vector buckets, see [Data protection and encryption in S3 Vectors](#).

 **Note**

The encryption type can't be changed after the vector bucket is created.

6. Under **Tags (Optional)**, you can add tags as key-value pairs to help organize and specify permissions for your vector buckets. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector bucket. For more information, see [Using tags with S3 vector buckets](#).
7. Choose **Create vector bucket**.

Step 2: Create a vector index in a vector bucket with the console

 **Note**

Choose your vector index configuration parameters carefully. After you create a vector index, you can't update the vector index name, dimension, distance metric, or non-filterable metadata keys. To change any of these values, you must create a new vector index.

In this step, you create a vector index in your vector bucket. The vector index is used to store and query your vector embeddings. For more information about vector indexes, see [Vector indexes](#).

To create a vector index

1. Navigate to the newly created vector bucket in the **Vector buckets** list on the Amazon S3 console.
2. Choose **Create vector index**.
3. On the **Create vector index** page, enter a name in the **Vector index name** field. In this tutorial, we use *movies* as the vector index name.

Vector index names must be 3 to 63 characters and unique within this vector bucket. Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.).

The vector index name can't be changed after index creation.

4. Under **Dimension**, specify a numeric value between 1 and 4096 that determines how many numbers will be in each vector that's generated by your vector embedding model. Embedding models are specialized machine learning (ML) models that convert data (such as text or images) into numerical vectors. Embedding models typically produce outputs between 500-2000 dimensions, with each dimension being a floating-point number. In this tutorial, we'll use the Titan Text v2 embedding model from Amazon Bedrock. This embedding model uses 1024-dimensional vectors as the default, so we'll set dimension for the vector index to 1024.

The dimension value can't be changed after index creation. Carefully specify the dimension value based on your embedding model's recommendations.

5. Under **Distance metric**, choose either **Cosine** (which measures angular similarity) or **Euclidean** (which measures straight-line distance) as the distance metric to define how similarity between vectors is calculated during queries. In this tutorial, we choose **Cosine**.

The distance metric can't be changed after index creation. Carefully choose the distance metric based on your embedding model's recommendations.

6. Under **Additional settings (optional)**, you can specify non-filterable metadata keys to store supplementary information alongside your vector embeddings.

Note

You can attach filterable metadata as key-value pairs to each vector when you insert vector data after index creation. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata

keys that are specified as non-filterable during vector index creation are excluded from filtering.

Each non-filterable metadata key must be between 1 to 63 characters and unique within the vector index. These keys are useful for storing reference information that you don't need to filter on during similarity queries. For example, when working with text embeddings, you might want to preserve the original text chunks for reference purposes. In this tutorial, we add a non-filterable metadata key that's named `source_text` to store the text data that we want to create vector embeddings for.

You can't update non-filterable metadata keys after index creation. Plan your metadata structure carefully.

7. Under **Encryption**, choose **Specify encryption type**. You have the option to use the bucket level encryption settings or override the encryption settings for the vector index. If you override the bucket-level settings, you have the option to specify encryption type for the vector index as **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or the **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. In this tutorial, we choose to **Use bucket settings for encryption**. For more information about setting encryption configuration for vector buckets and indexes, see [Data protection and encryption in S3 Vectors](#).
8. Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see [Using tags with S3 vector buckets](#).
9. Choose **Create vector index**.

Verify that your new vector index appears inside the bucket.

Step 3: Insert vectors into a vector index with the SDK for Python (Boto3)

To insert, list, and query vectors, use the AWS SDKs, AWS CLI, or Amazon S3 REST API.

This step is to insert vector embeddings to your vector index with the [PutVectors](#) API operation.

You must first generate vector embeddings by using the embedding model of your choice. If you use Amazon Bedrock, generate embeddings by using the [InvokeModel](#) API operation to specify your preferred embedding model. Alternatively, to generate and insert vector embeddings with a single command, see [\(Optional\) Automate vector embedding creation with the S3 Vectors Embed CLI](#).

The following example code generates 1024-dimensional vector embeddings with the Titan Text Embeddings V2 model from Amazon Bedrock by using the AWS SDK for Python (Boto3), and stores them in your vector index by using the PutVectors API. Along with each vector, we attach key-value pairs as filterable metadata. Additionally, we use a non-filterable metadata key that's named *source_text* to preserve the original text from which each vector is derived. To maximize request throughput and optimize for speed and efficiency, we recommend that you insert and delete vectors in batches. For more information, see [S3 Vectors best practices](#).

```
# Populate a vector index with embeddings from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Texts to convert to embeddings.
texts = [
    "Star Wars: A farm boy joins rebels to fight an evil empire in space",
    "Jurassic Park: Scientists create dinosaurs in a theme park that goes wrong",
    "Finding Nemo: A father fish searches the ocean to find his lost son"
]

# Generate vector embeddings.
embeddings = []
for text in texts:
    response = bedrock.invoke_model(
        modelId="amazon.titan-embed-text-v2:0",
        body=json.dumps({"inputText": text})
    )

    # Extract embedding from response.
    response_body = json.loads(response["body"].read())
    embeddings.append(response_body["embedding"])

# Write embeddings into vector index with metadata.
```

```
s3vectors.put_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    vectors=[
        {
            "key": "Star Wars",
            "data": {"float32": embeddings[0]},
            "metadata": {"source_text": texts[0], "genre": "scifi"}
        },
        {
            "key": "Jurassic Park",
            "data": {"float32": embeddings[1]},
            "metadata": {"source_text": texts[1], "genre": "scifi"}
        },
        {
            "key": "Finding Nemo",
            "data": {"float32": embeddings[2]},
            "metadata": {"source_text": texts[2], "genre": "family"}
        }
    ]
)
```

Step 4. Query vectors in a vector index with the SDK for Python (Boto3)

After you store your vectors embeddings in the vector index, you can perform a similarity search by using the [QueryVectors](#) API operation.

You must first generate your query vector embeddings by using the same embedding model that's used during insertion in [Step 3: Insert vectors into a vector index with the SDK for Python \(Boto3\)](#). In this tutorial, use the Titan Text Embeddings V2 model from Amazon Bedrock through the SDK for Python (Boto3).

You can perform a similarity search to return the closest matching vectors. In a similarity search, you can optionally filter by using metadata keys to narrow results based on specific criteria while maintaining semantic relevance.

```
# Query a vector index with an embedding from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
```

```
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Query text to convert to an embedding.
input_text = "adventures in space"

# Generate the vector embedding.
response = bedrock.invoke_model(
    modelId="amazon.titan-embed-text-v2:0",
    body=json.dumps({"inputText": input_text})
)

# Extract embedding from response.
model_response = json.loads(response["body"].read())
embedding = model_response["embedding"]

# Query vector index.
response = s3vectors.query_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=3,
    returnDistance=True,
    returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))

# Query vector index with a metadata filter.
response = s3vectors.query_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=3,
    filter={"genre": "scifi"},
    returnDistance=True,
    returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))
```

(Optional) Automate vector embedding creation with the S3 Vectors Embed CLI

Amazon S3 Vectors Embed CLI is a standalone command line tool that simplifies the process of working with vector embeddings in S3 Vectors. With single commands, you can create vector embeddings for your data by using Amazon Bedrock, and store and query them in your S3 vector index. The tool supports the following commands:

- `s3vectors-embed put`: Generate vector embeddings of text, file content, or S3 objects, and store them as vectors in an S3 vector index.
- `s3vectors-embed query`: Embed a query input and search for similar vectors in an S3 vector index.

For more information about the commands and usage, see the [Amazon S3 Vectors Embed CLI GitHub repository](#).

(Optional) Integrate S3 Vectors with Amazon Bedrock Knowledge Bases

Amazon Bedrock Knowledge Bases integrates with S3 Vectors for cost effective and long-term storage of vector datasets.

Prerequisites

Follow the [prerequisites](#) to ensure you have necessary permissions for creating an Amazon Bedrock knowledge base.

- Appropriate IAM permissions for both S3 Vectors and Amazon Bedrock services. For more information about IAM permissions for S3 Vectors, see [Identity and Access management in S3 Vectors](#).
- Your source documents prepared for ingestion into the knowledge base.
- An understanding of your embedding model requirements.

Create an Amazon Bedrock knowledge base with S3 Vectors in the console

Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow. When you create a knowledge base with S3 Vectors, Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your

vector index. You can then query the knowledge base and generate responses based on chunks retrieved from your source data.

To create an Amazon Bedrock knowledge base with S3 Vectors in the console

1. Sign in to the AWS Management Console using an [IAM role with Amazon Bedrock permissions](#), and open the Amazon Bedrock console at <https://console.aws.amazon.com/bedrock/>.
2. In the left navigation pane, choose **Knowledge Bases**.
3. In the **Knowledge Bases** section, choose **Create**. In the dropdown list, choose **Knowledge Base with vector store**.
4. Keep the **Knowledge Base name**, **Knowledge Base description**, and **IAM permissions** at their default values in this tutorial.
5. For **Choose a data source type**, choose the data source to connect your knowledge base to. In this tutorial, choose **Amazon S3**.
6. (Optional) Provide any **Tags or Application logs**.
7. Choose **Next**.
8. On the **Configure data source** page, keep the **Data source name**, **Data source location**, **Parsing strategy**, and **Chunking strategy** at the default settings in this tutorial.
9. In the **S3 URI**, enter the S3 general purpose bucket that contains your source files, or choose **Browse S3** and choose the S3 general purpose bucket.
10. For encrypted S3 data, select **Add customer-managed KMS key for S3 data** and specify your customer-managed KMS key.
11. Choose **Next** to proceed to the next step that specifies the **Embeddings model** and **Vector store** options.
12. In the **Embeddings model** section, choose **Select model** and choose an embedding model compatible for use with S3 Vectors. You must use floating-point embeddings. Binary type isn't supported.
13. (Optional) Expand the **Additional configurations** section to see the following configuration options (not all models support all configurations):
 - **Embeddings type** – Whether to convert the data to floating-point (float32) vector embeddings (more precise, but more costly) or binary vector embeddings (less precise, but less costly). To integrate with S3 Vectors, you must choose **Floating-point vector embeddings**.
 - **Vector dimensions** – Choose the embedding models recommended dimension size.

14. In the **Vector store** section, choose the recommended method **Quick create a new vector store** for automatic setup of a new vector bucket, or choose **Use an existing vector store** to use an existing vector bucket if available. For information about using an existing vector store flow, see [Prerequisites for using a vector store you created for a knowledge base](#) in the *Amazon Bedrock User Guide*.
15. For **Additional configurations** – By default, your vector bucket uses server-side encryption with Amazon S3 managed keys (SSE-S3). You can choose to use your own KMS key for server-side encryption with AWS Key Management Service keys (SSE-KMS) for enhanced control over encryption settings.
16. Choose **Next** to review the Knowledge Base details and then choose **Create Knowledge Base**.

 **Note**

The time that it takes to create a knowledge base depends on your specific configurations. When the creation of a knowledge base completes, the status of the knowledge base changes to state it is either ready or available. Once your knowledge base is ready and available, sync your data source for the first time or whenever you want to keep your content up to date. To sync your data source, choose your knowledge base in the console and choose **Sync** within the data source overview section.

(Optional) Integrate S3 Vectors with Amazon OpenSearch

[Amazon OpenSearch Service](#) is a fully managed service that simplifies the deployment, scaling, and operation of OpenSearch in the AWS Cloud. There are two integrations between S3 Vectors and OpenSearch. One is to export vector data from S3 Vectors to OpenSearch Serverless for high-performance search capabilities. The other uses S3 Vectors as a cost-effective storage engine within OpenSearch while maintaining access to OpenSearch functionality.

For more information, see [Using S3 Vectors with OpenSearch Service](#).

Vector buckets

Vector buckets are a type of Amazon S3 bucket designed specifically for storing and querying vector data. Vector buckets use dedicated APIs to manage vector data efficiently and reduce costs of upload, storing, and querying vector embeddings. Vector buckets provide the foundation for

organizing your vector data into indexes, enabling you to perform similarity searches across large datasets while benefiting from the availability, durability, scalability, and cost-effectiveness of Amazon S3.

Vector buckets are optimized for long-term vector storage with sub-second search times. You can perform similarity queries on your vector data and optionally attach metadata to filter queries based on specific conditions such as dates, categories, or user preferences.

Each vector bucket has a unique Amazon Resource Name (ARN) and resource policy attached to it. The ARNs of vector buckets follow the following format:

```
arn:aws:s3vectors:Region:OwnerAccountID:bucket/bucket-name
```

Within a vector bucket, you create vector indexes to store and query your data. Each vector bucket exists within a specific AWS Region and you can create multiple vector indexes inside a vector bucket. Vector buckets support security and access control mechanisms, including IAM identity-based policies and bucket policies. You can use bucket policies to grant or restrict access to specific indexes within your vector bucket.

Key characteristics of vector buckets:

- Purpose-built for vector storage and similarity search operations.
- Strongly consistent writes ensure that the vector data is immediately accessible.
- Automatic optimization of vector data for best price-performance as datasets scale.

For more information about vector index limits per bucket and other limitations, see [Limitations and restrictions](#).

Topics

- [Vector bucket naming rules](#)
- [Creating a vector bucket](#)
- [Listing vector buckets](#)
- [Viewing vector bucket attributes](#)
- [Deleting an empty vector bucket](#)
- [Managing vector bucket policies](#)
- [Using tags with S3 vector buckets](#)

Vector bucket naming rules

Vector bucket names must follow specific naming conventions to ensure uniqueness within an AWS Region. Amazon S3 enforces the following bucket naming requirements, and you can't create a vector bucket if these rules aren't followed. Additionally, there are best practices that, while not enforced, help prevent conflicts when working with vector buckets programmatically or through the console.

Vector bucket naming requirements

When creating vector buckets, you must follow these requirements:

- Vector bucket names must be unique in the same AWS account for each AWS Region.
- Vector bucket names must be between 3 and 63 characters long.
- Vector bucket names can consist only of lowercase letters (a-z), numbers (0-9), and hyphens (-).
- Vector bucket names must begin and end with a letter or number.

Best practices for naming

We recommend following these best practices when naming your vector buckets:

- Use descriptive names that reflect the purpose of your vector data (for example, product-recommendations, document-embeddings).
- Avoid using sensitive information in bucket names as they may appear in logs and URLs.
- Keep names concise but meaningful for easier management and identification.

These naming conventions ensure that your vector buckets can be reliably accessed through the AWS Management Console, Amazon S3 REST API, the AWS CLI, and AWS SDKs.

Creating a vector bucket

You can create a vector bucket using the S3 console or the AWS CLI. All data stored in vector buckets are always encrypted at rest. By default, vector buckets use SSE-S3 to encrypt vector data. You can choose to configure buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) instead. The bucket encryption settings can't be changed after a vector bucket is created, so it's important to choose the appropriate encryption method based on

your security requirements and compliance needs. For more information about security in vector buckets, see [Data protection and encryption in S3 Vectors](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.
3. Choose **Create vector bucket**.
4. For **Vector bucket name**, enter a name for your bucket.

The bucket name must follow the naming rules:

- Bucket name must be between 3 and 63 characters long.
- Bucket name can only include lowercase letters, numbers, and hyphens.
- Bucket name must be unique within your AWS account for an AWS Region.

For more information about vector bucket naming rules, see [Vector bucket naming rules](#).

 **Important**

You can't change the vector bucket name after you create the bucket.

5. For **Encryption**, choose one of the following options:

- **Don't specify encryption type** – Amazon S3 automatically applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for new vectors. Choose this option for the simplest setup with no additional configuration.
- **Specify encryption type** – Choose a specific encryption method:
 - **Server-side encryption with Amazon S3 managed keys (SSE-S3)** – Explicitly choose to use SSE-S3. Amazon S3 encrypts your vector data as it writes it to storage and decrypts it when you access it. AWS manages all encryption keys automatically.
 - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** – Uses customer managed keys (CMKs) in AWS KMS, giving you more control over your encryption keys, key rotation, and access policies.

If you select SSE-KMS, you have additional options:

- **Choose from your AWS KMS keys** – Select an existing customer managed key from your account.
- **Enter AWS KMS key ARN** – Specify the full ARN of a KMS key (required format).
- **Create a KMS key** – Opens the AWS KMS console to create a new customer managed key.

KMS key requirements:

- The KMS key must be in the same Region as the vector bucket.
- You must specify the full KMS key ARN (key IDs and aliases aren't supported).
- You must grant the S3 Vectors service principal (`indexing.s3vectors.amazonaws.com`) the `kms:Decrypt` permission to use the key. For more information about an example AWS KMS key policy, see [Data protection and encryption in S3 Vectors](#).

For detailed information about encryption options and KMS key setup, see [Using SSE-KMS encryption](#).

 **Important**

Encryption settings can't be changed after the vector bucket is created. Choose carefully based on your long-term security and compliance requirements.

6. Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see [Using tags with S3 vector buckets](#).
7. Choose **Create vector bucket**.

After creation, you'll see a confirmation message. The new vector bucket appears in your vector buckets list and is ready for creating vector indexes within the bucket.

Using the AWS CLI

You can create a vector bucket with SSE-S3 encryption using the following command. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-vector-bucket \
--vector-bucket-name "amzn-s3-demo-vector-bucket"
```

To create a vector bucket with SSE-KMS encryption using a customer managed KMS key:

```
aws s3vectors create-vector-bucket \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--encryption-configuration '[{"sseType": "aws:kms", "kmsKeyArn": "arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"}'
```

Using the AWS SDKs

SDK for Python

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Create a vector bucket
s3vectors.create_vector_bucket(vectorBucketName="media-embeddings")
```

Listing vector buckets

You can view all your vector buckets using the Amazon S3 console, AWS CLI, or AWS SDKs. The listing operations support prefix-based filtering to help you find specific buckets when you have many vector buckets in your account. For more information about `ListVectorBuckets`, prefix limits, and response limits, see [ListVectorBuckets](#) in the *Amazon S3 API Reference*.

Prefix search capability

Prefix search allows you to list buckets that start with a specific prefix, making it easier to organize and find related vector buckets. This is particularly useful when you use naming conventions that group related buckets together:

- **Environment-based:** `production-vectors-`, `staging-vectors-`, `dev-vectors-`
- **Use case-based:** `ml-model-vectors-`, `document-search-`, `image-similarity-`
- **Team-based:** `data-science-vectors-`, `ml-platform-vectors-`

Using the S3 console

To list vector buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.

The console displays a list of all your vector buckets with the following information:

- **Name** – The unique name of the vector bucket
- **Creation date** – When the bucket was created
- **Amazon Resource Name (ARN)** – The full ARN for programmatic access

To filter the list:

- To find a bucket based on the start of the bucket name, enter a vector bucket name or prefix in the search box above the bucket list.
- Use prefixes to find groups of related buckets (for example, type "prod-" to find all production buckets)

The list updates in real-time as you type

Using the AWS CLI

```
aws s3vectors list-vector-buckets
```

Using the AWS SDKs

SDK for Python

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#List vector buckets
response = s3vectors.list_vector_buckets()
buckets = response["vectorBuckets"]
```

```
print(buckets)
```

Viewing vector bucket attributes

You can view detailed information about a vector bucket, including its properties, encryption settings and creation details using the Amazon S3 REST API, AWS SDKs, S3 Console, or the AWS Command Line Interface (AWS CLI). For more information about GetVectorBucket, see [GetVectorBucket](#) in the *Amazon S3 API Reference*.

Using the S3 console

1. Sign in to the console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.
3. The console displays a list of all your vector buckets. Find a bucket based on the start of the bucket name, enter a vector bucket name or prefix in the search box above the bucket list. Once you locate your vector bucket, you can view detailed information about it, including its encryption settings, tags, and creation details in the **Properties** tab.

Using the AWS CLI

```
aws s3vectors get-vector-bucket --vector-bucket-name "amzn-s3-demo-vector-bucket"
```

Deleting an empty vector bucket

You can delete a vector bucket when you no longer need it. To delete a vector bucket, you must first delete all the vector indexes within the bucket. When you delete a vector index, all vector data within it is deleted. Use the Amazon S3 REST API, AWS SDKs, S3 Console, or the AWS Command Line Interface (AWS CLI) to delete a vector bucket.

Before you can delete a vector bucket, you must:

- Delete all vector indexes in the bucket.
- Ensure no operations are in progress on the bucket or its indexes.

⚠ Important

- Bucket deletion is permanent and can't be undone.
- All data and configuration associated with the bucket is permanently lost.
- The bucket name becomes available for reuse after deletion.
- Any applications or scripts referencing the bucket will receive errors after deletion.

Using the S3 console

1. Sign in to the console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.
3. The console displays a list of all your vector buckets. Find a bucket based on the start of the bucket name, enter a vector bucket name or prefix in the search box above the bucket list. Once you locate and choose your vector bucket, select the **Delete** option.
4. To confirm this deletion, type **delete** and then select **Delete vector bucket**.

Using the AWS CLI

First, check that no vector indexes exist in the bucket. For more information about how to verify the bucket is empty, see [Listing vector indexes](#).

If indexes exist, you must delete all vectors from each index and then delete the indexes. For more information about how to verify the bucket is empty, see [Listing vectors](#), [Deleting vectors from a vector index](#), and [Deleting a vector index](#).

To delete the empty vector bucket, use the following example command and replace the *user input placeholders* with your own information.

```
aws s3vectors delete-vector-bucket \
--vector-bucket-name "amzn-s3-demo-vector-bucket"
```

Using the AWS SDKs

SDK for Python

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Delete a vector bucket
response = s3vectors.delete_vector_bucket(vectorBucketName="media-embeddings")
```

Managing vector bucket policies

Vector bucket policies are resource-based policies that you attach directly to vector buckets to control access to the bucket and its contents. You can add, view, edit, delete vector bucket policies by using the Amazon S3 REST API, AWS SDKs, S3 Console, or the AWS Command Line Interface (AWS CLI). Bucket policies for vector buckets can grant permissions to principals from other AWS accounts, making them useful for cross-account access scenarios.

Policy management operations

- [PutVectorBucketPolicy](#) – Add or update a bucket policy.
- [GetVectorBucketPolicy](#) – Retrieve the current bucket policy.
- [DeleteVectorBucketPolicy](#) – Remove the bucket policy.

Adding a vector bucket policy

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Vector buckets** and select the vector bucket name that you want to add a policy to.
4. Choose the **Permissions** tab.
5. Under **Vector bucket policy**, choose **Edit**.
6. In the policy editor, enter your policy JSON.

7. (Optional) Choose **Policy examples** to see sample policies that you can adapt to your needs.
8. After entering your policy, choose **Save changes**.

Using the AWS CLI

To add or update a bucket policy, use the following example command and replace the *user input placeholders* with your own information.

```
aws s3vectors put-vector-bucket-policy \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--policy '{"Version": "2012-10-17", "Statement": [{"Effect": "Allow", "Principal": "AWS": "arn:aws:iam::111122223333:root"}, {"Action": "s3vectors:*", "Resource": "arn:aws:s3vectors:a region:111122223333:bucket/amzn-s3-demo-vector-bucket"}]}'
```

Viewing a vector bucket policy

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Vector buckets** and select the vector bucket name that you want to view the policy for.
4. Choose the **Permissions** tab.

Using the AWS CLI

To retrieve a bucket policy, use the following example command and replace the *user input placeholders* with your own information.

```
aws s3vectors get-vector-bucket-policy \
--vector-bucket-name "amzn-s3-demo-vector-bucket"
```

Deleting a vector bucket policy

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.

3. Choose **Vector buckets** and select the vector bucket name that you want to delete the policy for.
4. Choose the **Permissions** tab.
5. Under the **Vector bucket policy**, choose **Delete**.

Using the AWS CLI

To delete a bucket policy, use the following example command and replace the *user input placeholders* with your own information.

```
aws s3vectors delete-vector-bucket-policy \
--vector-bucket-name "amzn-s3-demo-vector-bucket"
```

For detailed information about creating and managing bucket policies, including policy examples and best practices, see [S3 Vectors resource-based policy examples](#).

Using tags with S3 vector buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector buckets. You can tag S3 vector buckets when you create them or manage tags on existing vector buckets. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

Note

There is no additional charge for using tags on vector buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with vector buckets

Use tags on your S3 vector buckets for:

- **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 vector buckets based on their tags. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

ABAC for S3 vector buckets

Amazon S3 vector buckets support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and S3 vector bucket policies. For enterprises, ABAC inAmazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 vector buckets based on the vector bucket's tags by using the following global condition keys:

`aws:ResourceTag/key-name`

Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key Dept with the value Marketing. For more information, see [Controlling access to AWS resources](#).

`aws:RequestTag/key-name`

Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key Dept and that it has the value Accounting. For more information, see [Controlling access during AWS requests](#). You can use this condition key to restrict which tag key-value pairs can be passed during the TagResource and CreateVectorBucket API operations.

`aws:TagKeys`

Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see [Controlling access based on tag keys](#). You can create an S3 vector bucket with tags. To allow tagging during the CreateVectorBucket API operation, you must create a policy that includes both the `s3vectors:TagResource` and `s3vectors>CreateVectorBucket` actions. You can then use the `aws:TagKeys` condition key to enforce using specific tags in the CreateVectorBucket request.

`s3vectors:VectorBucketTag/tag-key`

Use this condition key to grant permissions to specific data in vector buckets using tags. This condition key acts on the tags assigned to the vector bucket for all S3 Vectors actions. Even when you create a index with tags, this condition key acts on the tags applied to the vector bucket that contains that index. For example, you could require that access to a bucket is allowed only if the bucket has the attached tag key Dept with the value Marketing. When

accessing indexes, this condition references tags associated with the vector bucket containing that index, while the aws:ResourceTag/tag-key will reference the tags of the index itself.

Example ABAC policies for vector buckets

See the following example ABAC policies for Amazon S3 vector buckets.

1.1 - IAM policy to create or modify vector buckets with specific tags

In this IAM policy, users or roles with this policy can only create S3 vector buckets if they tag the vector bucket with the tag key project and tag value Trinity in the vector bucket creation request. They can also add or modify tags on existing S3 vector buckets as long as the TagResource request includes the tag key-value pair project:Trinity. This policy does not grant read, write, or delete permissions on the vector buckets or its objects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateVectorBucketWithTags",
      "Effect": "Allow",
      "Action": [
        "s3vectors:CreateVectorBucket",
        "s3vectors:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/projectTrinity"
          ]
        }
      }
    }
  ]
}
```

1.2 - Vector bucket policy to restrict operations on the vector bucket using tags

In this vector bucket policy, IAM principals (users and roles) can perform operations using the PutVectorBucketPolicy action on the vector bucket only if the value of the vector bucket's project tag matches the value of the principal's project tag.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "AllowObjectOperations",  
      "Effect": "Allow",  
      "Principal": {  
        "AWS": "111122223333"  
      },  
      "Action": "s3vectors:PutVectorBucketPolicy",  
      "Resource": "arn:aws::s3vectors:us-west-2:111122223333:bucket/amzn-s3-demo-vector-bucket",  
      "Condition": {  
        "StringEquals": {  
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"  
        }  
      }  
    }  
  ]  
}
```

1.3 - IAM policy to modify tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a vector bucket only if the value of the vector bucket's project tag matches the value of the principal's project tag. Only the four tags project, environment, owner, and cost-center specified in the aws:TagKeys condition keys are permitted for these vector buckets. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your vector buckets.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "EnforceTaggingRulesOnModification",  
      "Effect": "Allow",  
      "Action": [  
        "s3vectors:TagResource"  
      ],  
      "Resource": "arn:aws::s3vectors:us-west-2:111122223333:bucket/*",  
      "Condition": {  
        "StringEquals": {  
          "aws:PrincipalTag/project": "the principal's project tag value"  
        }  
      }  
    }  
  ]  
}
```

```
        "aws:ResourceTag/project": "${aws:PrincipalTag/project}"  
    },  
    "ForAllValues:StringEquals": {  
        "aws:TagKeys": [  
            "project",  
            "environment",  
            "owner",  
            "cost-center"  
        ]  
    }  
}  
]  
}  
]
```

1.4 - Using the `s3vectors:VectorBucketTag` condition key

In this IAM policy, the condition statement allows access to the vector bucket's and vector index's operations only if the vector bucket has the tag key Environment and tag value Production.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAccessToTaggedBucket",  
            "Effect": "Allow",  
            "Action": "*",  
            "Resource": "arn:aws::s3vectors:us-west-2:111122223333:bucket/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3vectors:VectorBucketTag/Environment                }  
            }  
        }  
    ]  
}
```

Managing tags for vector buckets

You can add or manage tags for S3 vector buckets using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see:

Topics

- [Creating vector buckets with tags](#)
- [Adding a tag to a vector bucket](#)
- [Viewing vector bucket tags](#)
- [Deleting a tag from a vector bucket](#)

Creating vector buckets with tags

You can tag Amazon S3 vector buckets when you create them. There is no additional charge for using tags on vector buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging vector buckets, see [Using tags with S3 vector buckets](#).

Permissions

To create a vector bucket with tags, you must have the following permissions:

- `s3vectors:CreateVectorBucket`
- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a vector bucket with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the vector bucket and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your vector buckets only with specific tag keys and values. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

Steps

You can create a vector bucket with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create a vector bucket with tags using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector buckets**.
3. Choose **create vector bucket** to create a new vector bucket.
4. Create a vector bucket as you normally would; see [Creating a vector bucket](#).
5. On the **Create vector bucket** page, **Tags** is an option when creating a new vector bucket.
6. Enter a name for the vector bucket.
7. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
8. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
9. After you complete specifying the options for your new vector bucket, choose **Create vector bucket**.

Using the REST API

For information about the Amazon S3 REST API support for creating a vector bucket with tags, see the following section in the *Amazon S3 Vectors API Reference*:

[CreateVectorBucket](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a vector bucket with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create a vector bucket you must provide configuration details and use the following naming convention: example-vector-bucket

```
aws s3vector create-vector-bucket --vector-bucket-name acc-bucket \  
--tags Department=Accounting,Stage=Prod
```

Adding a tag to a vector bucket

You can add tags to Amazon S3 vector buckets and modify these tags. There is no additional charge for using tags on vector buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging vector buckets, see [Using tags with S3 vector buckets](#).

Permissions

To add a tag to a vector bucket, you must have the following permission:

- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a vector bucket, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to a vector bucket.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws : ,` change the tag key and try again.

Steps

You can add tags to vector buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWSSDKs.

Using the S3 console

To add tags to a vector bucket using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector buckets**.
3. Choose the vector bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.

7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a vector bucket, see the following section in the *Amazon S3 Vectors API Reference*:

[TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a vector bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3vectors tag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket \
--tags Stage=Prod,CostCenter=Marketing
```

Viewing vector bucket tags

You can view or list tags applied to Amazon S3 vector buckets. For more information about tagging vector buckets, see [Using tags with S3 vector buckets](#).

Permissions

To view tags applied to a vector bucket, you must have the following permission:

- `s3vectors>ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a vector bucket, you can do the following:

- Verify that you have the required [Permissions](#) to view or list the tags of the vector bucket.

Steps

You can view tags applied to vector buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a vector bucket using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector buckets**.
3. Choose the vector bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the vector bucket.
6. The **Tags** section shows the User-defined tags by default. You can select the AWS-generated tags tab to view tags applied to your vector bucket by AWS services.

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a vector bucket, see the following section in the Amazon Simple Vectors API Reference:

[ListTagsForResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a vector bucket. To use the command replace the *user input placeholders* with your own information.

```
aws s3vectors list-tags-for-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket
```

Deleting a tag from a vector bucket

You can remove tags from S3 vector buckets. An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector buckets. For more information about tagging vector buckets, see [Using tags with S3 vector buckets](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the vector bucket.

Permissions

To delete a tag from a vector bucket, you must have the following permission:

- `s3vectors:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a vector bucket, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from a vector bucket.

Steps

You can delete tags from vector buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from a vector bucket using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector buckets**.
3. Choose the vector bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.

8. Choose **Delete** to confirm.

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a vector bucket, see the following section in the *Amazon S3 Vectors API Reference*:

[UntagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a vector bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3vectors untag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket \
--tag-keys CostCenter Department
```

Vector indexes

Note

Choose your vector index configuration parameters carefully. After you create a vector index, you can't update the vector index name, dimension, distance metric, or non-filterable metadata keys. To change any of these values, you must create a new vector index.

Vector indexes are resources within vector buckets that store and organize vector data for efficient similarity search operations. When you create a vector index, you specify the distance metric (Cosine or Euclidean), the number of dimensions that a vector should have, and optionally a list of metadata fields that you want to exclude from filtering during similarity queries.

For more information about vector index limits per bucket, vector limits per index, and dimension limits per vector, see [Limitations and restrictions](#).

Each vector index has a unique Amazon Resource Name (ARN). The ARNs of vector indexes follow the following format:

arn:aws:s3vectors:*region*:*account-id*:bucket/*bucket-name*/index/*index-name*

Vector index naming requirements

- Vector index names must be unique within the vector bucket.
- Vector index names must be between 3 and 63 characters long.
- Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.).
- Vector index names must begin and end with a letter or number.

Dimension requirements

A dimension is the number of values in a vector. All vectors added to the index must have exactly this number of values.

- A dimension must be an integer between 1 and 4096.
- A larger dimension requires more storage space.

Distance metric options

Distance metric specifies how similarity between vectors is calculated. When creating vector embeddings, choose your embedding model's recommended distance metric for more accurate results.

- **Cosine** – Measures the cosine of the angle between vectors. Best for normalized vectors and when direction matters more than magnitude.
- **Euclidean** – Measures the straight-line distance between vectors. Best when both direction and magnitude are important.

Non-filterable metadata keys

Metadata keys allow you to attach additional information to your vectors as key-value pairs during storage and retrieval. By default, all metadata is filterable, so you can use it to filter query results. However, you can designate specific metadata keys as non-filterable when you want to store information with vectors without using it for filtering.

Unlike default metadata keys, these keys can't be used as query filters. Non-filterable metadata keys can be retrieved but can't be searched, queried, or filtered. You can only access it after finding the index.

Non-filterable metadata keys allow you to enrich vectors with additional context that you want to retrieve with search results but don't need for filtering. A common example of a non-filterable metadata key is when you embed text into vectors and want to include the original text itself as non-filterable metadata. This allows you to return the source text alongside vector search results without increasing your filterable metadata size limits. Other examples include storing creation timestamps, source URLs, or descriptive information purely for reference. Non-filterable metadata keys can be accessed when retrieving vectors but, unlike default metadata keys, these keys can't be used as query filters.

Requirements for non-filterable metadata keys are as follows.

- Non-filterable metadata keys must be unique within the vector index.
- Non-filterable metadata keys must be 1 to 63 characters long.
- Non-filterable metadata keys can't be modified after the vector index is created.
- S3 Vectors support up to 10 non-filterable metadata keys per index.

For more information about non-filterable metadata keys, see [Non-filterable metadata](#).

Topics

- [Creating a vector index in a vector bucket](#)
- [Listing vector indexes](#)
- [Deleting a vector index](#)
- [Using tags with S3 vector indexes](#)

Creating a vector index in a vector bucket

Note

Choose your vector index configuration parameters carefully. After you create a vector index, you can't update the vector index name, dimension, distance metric, or non-filterable metadata keys. To change any of these values, you must create a new vector index.

A vector index is a resource within a vector bucket that stores and organizes vector data for efficient similarity search. When you create a vector index, you define the characteristics that all vectors in that index must share, such as the dimension, the distance metric used for similarity calculations, and optionally non-filterable metadata keys. You can also optionally configure dedicated encryption settings and tags for the vector index at the time of index creation. For more information about vector index naming requirements, dimension requirements, distance metric options, and non-filterable metadata keys, see [Limitations and restrictions](#). For more information about setting encryption configuration for vector indexes, see [Data protection and encryption in S3 Vectors](#). For more information about setting tags, see [Using tags with S3 vector buckets](#).

Vector indexes must be created within an existing vector bucket and require specific configuration parameters that can't be modified after creation.

Using the S3 console

To create a vector index

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket where you want to create a vector index.
4. Choose **Create vector index**.
5. For **Vector index name**, enter a name for your vector index.

Vector index names must be unique within the vector bucket. Index name must be between 3 and 63 characters. Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.). For more information about the vector index naming requirements, see [Limitations and restrictions](#).

6. For **Dimension**, enter the number of values in each vector.

Note

- The value for **Dimension** determines how many numerical values each vector will contain.
- All vectors added to this index must have exactly this number of values.
- Dimension must be between 1 and 4096.
- A larger dimension requires more storage space.

- Choose based on your embedding model's output dimensions.

For more information about the dimension requirements, see [Limitations and restrictions](#).

7. For **Distance metric**, choose one of the following options:

- **Cosine** – Measures the cosine of the angle between vectors. Best for normalized vectors and when direction matters more than magnitude
- **Euclidean** – Measures the straight-line distance between vectors. Best when both direction and magnitude are important.

8. (Optional) Under **Non-filterable metadata**, configure metadata keys that will be stored but not used for filtering:

To add non-filterable metadata keys:

- Choose **Add key**.
- Enter a key name (1-63 characters and unique within this vector index).
- Repeat to add additional keys (maximum 10 keys).

 **Note**

You can attach filterable metadata as key-value pairs to each vector when you insert vector data after you create a vector index. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata keys that are specified as non-filterable during vector index creation are excluded from filtering. For more information about metadata size limits per vector, including both total and filterable metadata constraints, see [Limitations and restrictions](#).

9. Review your configuration carefully.

 **Note**

These settings can't be changed after creation.

10.Under **Encryption**, choose **Specify encryption type**. You have the option to **Use bucket settings for encryption** or override the encryption settings for the vector index. If you override the bucket-level settings, you have the option to specify encryption type for the vector index as **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or the **Server-**

side encryption with Amazon S3 managed keys (SSE-S3). For more information about setting encryption configuration for vector indexes, see [Data protection and encryption in S3 Vectors](#).

11 Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see [Using tags with S3 vector buckets](#).

12 Choose **Create vector index**.

Using the AWS CLI

To create a vector index in a vector bucket, use the following example commands and replace the user input placeholders with your own information.

Example 1: Creating a vector index with non-filterable metadata keys

```
aws s3vectors create-index \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--index-name "idx" \
--data-type "float32" \
--dimension 1 \
--distance-metric "cosine" \
--metadata-configuration '{"nonFilterableMetadataKeys":["nonFilterableKey1"]}'
```

Example 2: Creating a vector index without non-filterable metadata keys

```
aws s3vectors create-index \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--index-name "idx2" \
--data-type "float32" \
--dimension 4096 \
--distance-metric "euclidean"
```

In addition, all metadata (both filterable and non-filterable) is retrieved the same way by using the `GetVectors`, `ListVectors`, or `QueryVectors` API operations. The following CLI command shows how to retrieve vectors with metadata (including non-filterable metadata).

Example request:

```
aws s3vectors get-vectors \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--index-name "idx" \
--keys '['"vec1", "vec3"]' \
--return-data \
--return-metadata \
```

Example response:

```
{
  "vectors": [
    {
      "key": "vec1",
      "data": {
        "float32": [
          0.10000000149011612,
          0.20000000298023224,
          0.30000001192092896,
          0.4000000059604645,
          0.5
        ]
      },
      "metadata": {
        "category": "test",
        "text": "First vector"
      }
    },
    {
      "key": "vec3",
      "data": {
        "float32": [
          0.6000000238418579,
          0.699999988079071,
          0.800000011920929,
          0.8999999761581421,
          1.0
        ]
      },
      "metadata": {
        "text": "Third vector",
        "category": "test"
      }
    }
  ]
}
```

```
        }
    ]
}
```

The response will include all metadata associated with the vector, regardless of whether it was specified as filterable or non-filterable during index creation.

Using the AWS SDKs

SDK for Python

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Create a vector index "movies" in the vector bucket "media-embeddings" without non-
filterable metadata keys
s3vectors.create_index(
    vectorBucketName="media-embeddings",
    indexName="movies",
    dimension=3,
    distanceMetric="cosine",
    dataType = "float32"
)

#Create a vector index "movies" in the vector bucket "media-embeddings" with non-
filterable metadata keys
s3vectors.create_index(
    vectorBucketName="media-embeddings",
    indexName="movies",
    dimension=3,
    distanceMetric="cosine",
    dataType = "float32",
    metadataConfiguration= {"nonFilterableMetadataKeys": [
        "nonFilterableMetadataKey1"
    ]}
)
```

Listing vector indexes

You can view all vector indexes within a vector bucket. The listing operation supports prefix-based filtering to help you find specific indexes when you have many indexes in a bucket. For more information about `ListIndexes`, prefix limits, and response limits, see [ListIndexes](#) in the Amazon Simple Storage Service API Reference.

Prefix search capability

Prefix search allows you to list indexes that start with a specific prefix, making it easier to organize and find related vector indexes. This is particularly useful when you use naming conventions that group related indexes together:

- **By data type:** text-embeddings-, image-features-, audio-vectors-
- **By model:** model1-embeddings-, model2-vectors-, custom-model-
- **By use case:** search-index-, recommendation-, similarity-
- **By environment:** prod-vectors-, staging-vectors-, dev-vectors-

Using the S3 console

To list vector indexes

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket containing the indexes you want to view.
4. The console displays a comprehensive list of all vector indexes in the bucket, including:
 - **Name** – The name for each index.
 - **Create date** – When the index was created.
 - **Amazon Resource Name (ARN)** – Full ARN for each index.

To filter the list

1. Enter an index name or prefix in the search box above the index list. Use prefixes to find groups of related indexes.

2. The list updates in real-time as you type.

Using the AWS CLI

Use the following example commands and replace the *user input placeholders* with your own information.

To list indexes with a specific prefix in a vector bucket

Example request:

```
aws s3vectors list-indexes \
--vector-bucket-name "amzn-s3-demo-bucket" \
--prefix "idx" \
--max-results 1
```

Example response:

```
{
  "nextToken": "10bb29ZkzxMGtBXs97Rkbs26xdtKemu4brsnq2jX8DCocADkILv5cRphemXS3PXXFnQBihQBmESgEeKaGA",
  "indexes": [
    {
      "vectorBucketName": "amzn-s3-demo-bucket",
      "indexName": "idx",
      "indexArn": "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-bucket/index/idx",
      "creationTime": "2025-06-12T15:50:23+00:00"
    }
  ]
}
```

To list indexes with pagination

Example request:

```
aws s3vectors list-indexes \
--vector-bucket-name "amzn-s3-demo-bucket" \
--prefix "idx" \
```

```
--next-token
"10bb29ZkzxMGtBXs97Rkbs26xdtKemu4brsnq2jX8DCocADkILv5cRphemXS3PXXFnQBihQBmESgEeKaGA"
```

Example response:

```
{
    "indexes": [
        {
            "vectorBucketName": "amzn-s3-demo-bucket",
            "indexName": "idx2",
            "indexArn": "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-bucket/index/idx2",
            "creationTime": "2025-06-12T15:45:37+00:00"
        }
    ]
}
```

Using the AWS SDKs

SDK for Python

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#List vector indexes in your vector bucket
response = s3vectors.list_indexes(vectorBucketName="media-embeddings")
indexes = response["indexes"]
print(indexes)
```

Deleting a vector index

You can delete a vector index when you no longer need it. This operation permanently removes the index and all vectors that are stored within it.

Important

When you delete a vector index, you need to know the following:

- You can delete vector indexes even when the indexes contain vectors.

- All vectors stored in the index are permanently deleted
- All metadata associated with those vectors is permanently lost
- The operation can't be undone or reversed
- Any ongoing operations on the index will fail immediately
- Applications querying the index will receive errors
- The index name becomes available for reuse within the bucket

Using the AWS CLI

Before you delete a vector index, verify the vector index. For more information about how to check the index details, see [GetIndex](#) in the *Amazon S3 API Reference*. For more information about how to list vectors inside the index to see what will be deleted, see [Listing vector indexes](#).

To delete a vector index, use the following example commands. Replace the *user input placeholders* with your own information.

```
aws s3vectors delete-index --vector-bucket-name "amzn-s3-demo-vector-bucket" \
    --index-name "idx2"
```

For more information about how to verify whether the index is deleted, see [Listing vector indexes](#).

Using the AWS SDKs

SDK for Python

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Delete a vector index
response = s3vectors.delete_index(
    vectorBucketName="media-embeddings",
    indexName="movies")
```

Using tags with S3 vector indexes

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector indexes. You can tag S3 vector indexes when you create them or manage tags on existing vector indexes. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

 **Note**

There is no additional charge for using tags on vector indexes beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with vector indexes

Use tags on your S3 vector indexes for:

- **Cost allocation** – Track storage costs by vector index tag in AWS Billing and Cost Management. For more information, see [Using tags for cost allocation](#).
- **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 vector indexes based on their tags. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

 **Note**

You can use the same tags for both cost allocation and access control.

ABAC for S3 vector indexes

Amazon S3 vector indexes support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and S3 vector index policies. For enterprises, ABAC inAmazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 vector indexes based on the vector index's tags by using the following global condition keys:

aws:ResourceTag/key-name

Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key Dept with the value Marketing. For more information, see [Controlling access to AWS resources](#).

aws:RequestTag/key-name

Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key Dept and that it has the value Accounting. For more information, see [Controlling access during AWS requests](#). You can use this condition key to restrict which tag key-value pairs can be passed during the TagResource and CreateIndex API operations.

aws:TagKeys

Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the aws:TagKeys condition key to define what tag keys are allowed. For example policies and more information, see [Controlling access based on tag keys](#). You can create an S3 vector index with tags. To allow tagging during the CreateVectorBucket API operation, you must create a policy that includes both the s3vectors:TagResource and s3vectors>CreateVectorBucket actions. You can then use the aws:TagKeys condition key to enforce using specific tags in the CreateVectorBucket request.

Example ABAC policies for vector indexes

See the following example ABAC policies for Amazon S3 vector indexes.

1.1 - IAM policy to create or modify vector indexes with specific tags

In this IAM policy, users or roles with this policy can only create S3 vector indexes if they tag the vector index with the tag key project and tag value Trinity in the vector index creation request. They can also add or modify tags on existing S3 vector indexes as long as the TagResource request includes the tag key-value pair project:Trinity. This policy does not grant read, write, or delete permissions on the vector indexes or its objects.

```
{  
  "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Sid": "CreateVectorIndexWithTags",
        "Effect": "Allow",
        "Action": [
            "s3vectors:CreateIndex",
            "s3vectors:TagResource"
        ],
        "Resource": "*",
        "Condition": {
            "StringEquals": {
                "aws:RequestTag/projectTrinity"
                ]
            }
        }
    }
]
```

1.2 - IAM policy to modify tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a vector index only if the value of the vector index's project tag matches the value of the principal's project tag. Only the four tags project, environment, owner, and cost-center specified in the aws:TagKeys condition keys are permitted for these vector indexes. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your vector indexes.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceTaggingRulesOnModification",
            "Effect": "Allow",
            "Action": [
                "s3vectors:TagResource"
            ],
            "Resource": "arn:aws::s3vectors:us-west-2:111122223333:bucket/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/projectproject}"
                },
            }
        }
]
```

```
"ForAllValues:StringEquals": {  
    "aws:TagKeys": [  
        "project",  
        "environment",  
        "owner",  
        "cost-center"  
    ]  
}  
}  
}  
]  
}
```

Managing tags for vector indexes

You can add or manage tags for S3 vector indexes using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see:

Topics

- [Creating vector indexes with tags](#)
- [Adding a tag to a vector index](#)
- [Viewing vector index tags](#)
- [Deleting a tag from a vector index](#)

Creating vector indexes with tags

You can tag Amazon S3 vector indexes when you create them. There is no additional charge for using tags on vector indexes beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging vector indexes, see [Using tags with S3 vector indexes](#).

Permissions

To create a vector index with tags, you must have the following permissions:

- `s3vectors:CreateIndex`
- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a vector index with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the vector index and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your vector indexes only with specific tag keys and values. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

Steps

You can create a vector index with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create a vector index with tags using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector indexes**.
3. Choose **create vector index** to create a new vector index.
4. Create a vector index as you normally would; see [Creating a vector index in a vector bucket](#).
5. On the **Create vector index** page, **Tags** is an option when creating a new vector index.
6. Enter a name for the vector index.
7. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
8. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
9. After you complete specifying the options for your new vector index, choose **Create vector index**.

Using the REST API

For information about the Amazon S3 REST API support for creating a vector index with tags, see the following section in the *Amazon S3 Vectors API Reference*:

[CreateIndex](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a vector index with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create a vector index you must provide configuration details and use the following naming convention: example-vector-index

```
aws s3vectors create-index --vector-bucket-name acc-bucket --data-type "float32" \
--index-name accounts-index --dimension 1024 --distance-metric euclidean \
--tags Department=Accounting,Stage=Prod
```

Adding a tag to a vector index

You can add tags to Amazon S3 vector indexes and modify these tags. There is no additional charge for using tags on vector indexes beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging vector indexes, see [Using tags with S3 vector indexes](#).

Permissions

To add a tag to a vector index, you must have the following permission:

- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a vector index, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to a vector index.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.

Steps

You can add tags to vector indexes by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWSSDKs.

Using the S3 console

To add tags to a vector index using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector indexes**.
3. Choose the vector index name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a vector index, see the following section in the *Amazon S3 Vectors API Reference*:

[TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a vector index by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3vectors tag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket/
index/accounts-index \
--tags Stage=Prod,CostCenter=Marketing
```

Viewing vector index tags

You can view or list tags applied to Amazon S3 vector indexes. For more information about tagging vector indexes, see [Using tags with S3 vector indexes](#).

Permissions

To view tags applied to a vector index, you must have the following permission:

- `s3vectors>ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a vector index, you can do the following:

- Verify that you have the required [Permissions](#) to view or list the tags of the vector index.

Steps

You can view tags applied to vector indexes by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a vector index using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector indexes**.
3. Choose the vector index name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the vector index.
6. The **Tags** section shows the User-defined tags by default. You can select the AWS-generated tags tab to view tags applied to your vector index by AWS services.

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a vector index, see the following section in the Amazon Simple Vectors API Reference:

[ListTagsforResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a vector index. To use the command replace the *user input placeholders* with your own information.

```
aws s3vectors list-tags-for-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket/
index/accounts-index
```

Deleting a tag from a vector index

You can remove tags from S3 vector indexes. An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector indexes. For more information about tagging vector indexes, see [Using tags with S3 vector indexes](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the vector index.

Permissions

To delete a tag from a vector index, you must have the following permission:

- `s3vectors:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a vector index, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from a vector index.

Steps

You can delete tags from vector indexes by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from a vector index using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **vector indexes**.
3. Choose the vector index name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a vector index, see the following section in the *Amazon S3 Vectors API Reference*:

[UntagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a vector index by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3vectors untag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket/
index/accounts-index \
--tag-keys CostCenter Department
```

Vectors

Each vector consists of a key, which uniquely identifies each vector in a vector index. Additionally, you can attach metadata (for example, year, author, genre, location) as key value pairs to each vector.

Vector data operations include inserting, listing, querying, and deleting vectors. To generate new vector embeddings of your unstructured data, you can use the [InvokeModel](#) API operation from Amazon Bedrock to specify the model ID of the embedding model that you want to use. Additionally, the open-source Amazon S3 Vectors Embed CLI tool provides a simplified way to generate embeddings and perform semantic searches from the command line. For more information about this open source tool that automates both vector embedding generation with Amazon Bedrock foundation models and semantic search operations within your S3 vector indexes, see [Creating vector embeddings and performing semantic searches with s3vectors-embed-cli](#).

Vector concepts

Vector keys: Each vector is identified by a unique vector key within the index. Vector keys can be up to 1,024 characters long and must be unique within the vector index. Keys are case-sensitive and can contain any UTF-8 characters.

Vector dimension: A dimension is the number of values in a vector. Larger dimensions require more storage space. All vectors in an index must have the same number of dimensions, which is specified when you create the index. A dimension must be an integer between 1 and 4096.

Metadata: You can attach metadata to vectors as key-value pairs to provide additional context and enable filtering during queries. Metadata includes both filterable and non-filterable metadata keys. Filterable metadata is used for query filtering. Non-filterable metadata keys are specified during a vector index creation and provides additional context but can't be used for filtering. Metadata supports string, number, and boolean types. For more information about filterable and non-filterable metadata, see [Metadata filtering](#). For more information about metadata limits, including size limits per vector and maximum metadata keys per vector, see [Limitations and restrictions](#).

Topics

- [Inserting vectors into a vector index](#)
- [Listing vectors](#)
- [Querying vectors](#)

- [Deleting vectors from a vector index](#)
- [Metadata filtering](#)

Inserting vectors into a vector index

You can add vectors to a vector index with the [PutVectors](#) API operation. Each vector consists of a key, which uniquely identifies each vector in a vector index. If you put a vector with a key that already exists in the index, it will overwrite the existing vector completely, which makes the previous vector no longer searchable. To maximize write throughput and optimize for costs, it's recommended that you insert vectors in large batches, up to the maximum batch size for `PutVectors`. However, for workloads that need to use smaller batches - such as when live, incoming vector data must become immediately searchable - you can achieve higher write throughput by using a higher number of concurrent `PutVectors` requests, up to the maximum allowed requests per second limit. For more information about the maximum batch size for `PutVectors`, which is the limit of vectors per `PutVectors` API call, and the maximum requests and vectors per second limit, see [Limitations and restrictions](#). Additionally, you can attach metadata (for example, year, author, genre, location) as key-value pairs to each vector. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata keys that are specified as non-filterable during vector index creation are excluded from filtering. S3 vector indexes support string, number, boolean, and list types of metadata. For more information about the total metadata size limit per vector and the filterable metadata size limit per vector, see [Limitations and restrictions](#). If the metadata size exceeds these limits, the `PutVectors` API operation will return a `400 Bad Request` error.

Before adding vector data to your vector index with the `PutVectors` API operation, you need to convert your raw data into vector embeddings, which are numerical representations of your content as arrays of floating-point numbers. The vector embeddings capture the semantic meaning of your content, enabling similarity searches once they're stored in your vector index through the `PutVectors` operation. You can generate vector embeddings using various methods depending on your data type and use case. These methods include using machine learning frameworks, specialized embedding libraries, or AWS services such as Amazon Bedrock. For example, if you're using Amazon Bedrock, you can generate embeddings with the [InvokeModel](#) API operation and your preferred embedding model.

Additionally, Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow where Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your vector index. You can

then query the knowledge base and generate responses based on chunks retrieved from your source data.

Furthermore, the open-source Amazon S3 Vectors Embed CLI tool provides a simplified way to generate embeddings and perform semantic searches from the command line. For more information about this open source tool that automates both vector embedding generation with Amazon Bedrock foundation models and semantic search operations within your S3 vector indexes, see [Creating vector embeddings and performing semantic searches with s3vectors-embed-cli](#).

Note

When inserting vector data into your vector index, you must provide the vector data as `float32` (32-bit floating point) values. If you pass higher-precision values to an AWS SDK, S3 Vectors converts the values to 32-bit floating point before storing them, and [GetVectors](#), [ListVectors](#), and [QueryVectors](#) operations return the `float32` values. Different AWS SDKs may have different default numeric types, so ensure your vectors are properly formatted as `float32` values regardless of which SDK you're using. For example, in Python, use `numpy.float32` or explicitly cast your values.

Using the AWS SDKs

SDK for Python

```
# Populate a vector index with embeddings from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Texts to convert to embeddings.
texts = [
    "Star Wars: A farm boy joins rebels to fight an evil empire in space",
    "Jurassic Park: Scientists create dinosaurs in a theme park that goes wrong",
    "Finding Nemo: A father fish searches the ocean to find his lost son"
]

# Generate vector embeddings.
embeddings = []
```

```
for text in texts:
    response = bedrock.invoke_model(
        modelId="amazon.titan-embed-text-v2:0",
        body=json.dumps({"inputText": text})
    )

    # Extract embedding from response.
    response_body = json.loads(response["body"].read())
    embeddings.append(response_body["embedding"])

# Write embeddings into vector index with metadata.
s3vectors.put_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    vectors=[
        {
            "key": "Star Wars",
            "data": {"float32": embeddings[0]},
            "metadata": {"source_text": texts[0], "genre": "scifi"}
        },
        {
            "key": "Jurassic Park",
            "data": {"float32": embeddings[1]},
            "metadata": {"source_text": texts[1], "genre": "scifi"}
        },
        {
            "key": "Finding Nemo",
            "data": {"float32": embeddings[2]},
            "metadata": {"source_text": texts[2], "genre": "family"}
        }
    ]
)
```

Listing vectors

You can list vectors in a vector index with the [ListVectors](#) API operation. For more information about the maximum number of vectors that can be returned per page, see [Limitations and restrictions](#). The response includes a pagination token when results are truncated. For more information about the response elements of ListVectors, see [ListVectors](#) in the *Amazon S3 API Reference*. You can also use ListVectors to export vector data from a specified vector index.

`ListVectors` is strongly consistent. After a `WRITE` operation, you can immediately list vectors with all changes reflected.

Using the AWS CLI

To list vectors, use the following example commands. Replace the *user input placeholders* with your own information.

The `segment-count` and `segment-index` parameters allow you to partition your listing operations across multiple parallel requests. When you specify a `segment-count` value (such as 2), you divide the index into that many segments. The `segment-index` parameter (starting from 0) determines which segment to list. This approach helps improve performance when listing large vector indexes by enabling parallel processing. For more information about `segment-count` and `segment-index`, see [ListVectors](#) in the *Amazon S3 API Reference*.

To list all vectors in an index

Example request:

```
aws s3vectors list-vectors \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--index-name "idx" \
--segment-count 2 \
--segment-index 0 \
--return-data \
--return-metadata
```

Example response:

```
{
  "vectors": [
    {
      "key": "vec3",
      "data": {
        "float32": [0.4000000059604645]
      },
      "metadata": {
        "nonFilterableKey": "val4",
        "filterableKey": "val2"
      }
    }
  ]
}
```

```
}
```

To list vectors with pagination

Example request:

```
aws s3vectors list-vectors \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--index-name "idx" \
--segment-count 2 \
--segment-index 0 \
--return-data \
--return-metadata \
--next-token
"zWfh7e57H2jBfBtRRmC70fMwl209G9dg3j2qM6kM4t0rps6C1YzJykgM0il9eGqU5nhf_gTq53If0UdTnsg"
```

Example response:

```
{
  "vectors": [
    {
      "key": "vec1",
      "data": {
        "float32": [0.5]
      },
      "metadata": {
        "nonFilterableKey": "val2",
        "filterableKey": "val1"
      }
    }
  ]
}
```

Using the AWS SDKs

SDK for Python

Example: List vectors in a vector index

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
```

```
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#List vectors in your vector index

response = s3vectors.list_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    maxResults = 600,
    returnData = True,
    returnMetadata = True
)

vectors = response["vectors"]

print(vectors)
```

Example: List all vectors in a vector index in parallel

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#List vectors in the 1st half of vectors in the index.
response = s3vectors.list_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    segmentCount=2,
    segmentIndex=1,
    maxResults = 600,
    returnData = True,
    returnMetadata = True
)

vectors = response["vectors"]

#List vectors starting from the 2nd half of vectors in the index.
# This can be ran in parallel with the first `list_vectors` call.
response = s3vectors.list_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    segmentCount=2,
    segmentIndex=1,
```

```
    maxResults = 600,  
    returnData = True,  
    returnMetadata = True  
)  
  
vectors = response["vectors"]  
  
print(vectors)
```

Querying vectors

You can run a similarity query with the [QueryVectors](#) API operation, where you specify the query vector, the number of relevant results to return (the top K nearest neighbors), and the index ARN. Additionally, you can use metadata filters in a query, to search only the vectors that match the filter. If you make a request to filter on a non-filterable metadata field, the request will return a `400 Bad Request` error. For more information about metadata filtering, see [Metadata filtering](#).

In the response, the vector keys are returned by default. You can optionally include the distance and metadata in the response.

When generating the query vector, you should use the same vector embedding model that was used to generate the initial vectors that are stored in the vector index. For example, if you use the Amazon Titan Text Embeddings V2 model in Amazon Bedrock to generate vector embeddings of your documents, use the same embedding model to convert a question to a query vector. Additionally, Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow where Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your vector index. You can then query the knowledge base and generate responses based on chunks retrieved from your source data. For more information about how to query vectors from an Amazon Bedrock knowledge base in the console, see [\(Optional\) Integrate S3 Vectors with Amazon Bedrock Knowledge Bases](#).

Furthermore, the open-source Amazon S3 Vectors Embed CLI tool provides a simplified way to perform semantic searches from the command line. This open source tool streamlines the query process by handling both the vector embedding generation with Amazon Bedrock foundation models and executing semantic search operations against your S3 vector indexes. For more information about using this tool for querying your vector data, see [Creating vector embeddings and performing semantic searches with s3vectors-embed-cli](#).

S3 Vectors delivers sub-second response times for cold queries, leveraging Amazon S3 elastic throughput to efficiently search across millions of vectors. This makes it highly cost-effective for workloads with infrequent queries. For warm queries, S3 Vectors can deliver response times as low as 100ms, benefiting workloads with repeated or frequent query patterns.

For performing similarity queries for your vector embeddings, several factors can affect average recall performance, including the vector embedding model, the size of the vector dataset (the number of vectors and dimensions), and the distribution of queries. S3 Vectors delivers 90%+ average recall for most datasets. Average recall measures the quality of query results. A 90% average recall means that the response contains 90% of the actual closest vectors (ground truth) that are stored in the vector index relative to the query vector. However, because actual performance may vary depending on your specific use cases, we recommend conducting your own tests with representative data and queries to validate that S3 Vectors meet your recall requirements.

Using the AWS SDKs

SDK for Python

```
# Query a vector index with an embedding from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Query text to convert to an embedding.
input_text = "adventures in space"

# Generate the vector embedding.
response = bedrock.invoke_model(
    modelId="amazon.titan-embed-text-v2:0",
    body=json.dumps({"inputText": input_text})
)

# Extract embedding from response.
model_response = json.loads(response["body"].read())
embedding = model_response["embedding"]

# Query vector index.
response = s3vectors.query_vectors(
```

```
vectorBucketName="media-embeddings",
indexName="movies",
queryVector={"float32": embedding},
topK=3,
returnDistance=True,
returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))

# Query vector index with a metadata filter.
response = s3vectors.query_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=3,
    filter={"genre": "scifi"},
    returnDistance=True,
    returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))
```

Deleting vectors from a vector index

You can delete specific vectors from a vector index by specifying their vector keys using the [DeleteVectors](#) API. This operation is useful for removing outdated or incorrect data while preserving the rest of your vector data.

Using the AWS CLI

To delete vectors, use the following example commands. Replace the *user input placeholders* with your own information.

```
aws s3vectors delete-vectors \
--vector-bucket-name "amzn-s3-demo-vector-bucket" \
--index-name "idx" \
--keys '["vec2","vec3"]'
```

Using the AWS SDKs

SDK for Python

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Delete vectors in a vector index
response = s3vectors.delete_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    keys=["Star Wars", "Finding Nemo"])
```

Metadata filtering

Metadata filtering allows you to filter query results based on specific attributes attached to your vectors. You can use metadata filters with query operations to find vectors that match both similarity criteria and specific metadata conditions.

S3 Vectors supports two types of metadata: filterable metadata and non-filterable metadata. The key difference is that filterable metadata can be used in query filters but has stricter size limitations, while non-filterable metadata can't be used in filters but can store larger amounts of data within its size limits. For more information about metadata limits, including size limits per vector and maximum metadata keys per vector, see [Limitations and restrictions](#).

S3 Vectors performs vector search and filter evaluation in tandem. S3 Vectors searches through candidate vectors in the index to find the top K similar vectors while simultaneously validating if each candidate vector matches your metadata filter conditions. For example, if you search for similar movie embeddings and you filter by genre='mystery', S3 Vectors only returns similar movie embeddings where the genre metadata matches 'mystery'. In contrast to applying the metadata filter after the vector search, this filtering approach is more likely to find matching results. Note: queries with filters may return fewer than top K results when the vector index contains very few matching results.

Topics

- [Filterable metadata](#)
- [Examples of valid filterable metadata](#)

- [Non-filterable metadata](#)

Filterable metadata

Filterable metadata allows you to filter query results based on specific metadata values. By default, all metadata fields are filterable in a similarity query unless explicitly specified as non-filterable during vector index creation. S3 Vectors supports string, number, boolean, and list types of metadata with a size limit per vector. The metadata type is ideal for attributes that you want to filter on, such as categories, timestamps, or status values.

If the metadata size exceeds the supported limits, the [PutVectors](#) API operation will return a `400 Bad Request` error. For more information about the filterable metadata size limit per vector, see [Limitations and restrictions](#).

The following operations can be used with filterable metadata.

Operator	Valid Input Types	Description
\$eq	String, Number, Boolean	Exact match comparison for single values.
		When comparing with an array metadata value, returns true if the input value matches any element in the array. For example, <code>{"category": {"\$eq": "documentary"}}</code> would match a vector with metadata <code>"category": ["documentary", "romance"]</code> .
\$ne	String, Number, Boolean	Not equal comparison
\$gt	Number	Greater than comparison
\$gte	Number	Greater than or equal comparison

Operator	Valid Input Types	Description
\$lt	Number	Less than comparison
\$lte	Number	Less than or equal comparison
\$in	Non-empty array of primitives	Match any value in array
\$nin	Non-empty array of primitives	Match none of the values in array
\$exists	Boolean	Check if field exists
\$and	Non-empty array of filters	Logical AND of multiple conditions
\$or	Non-empty array of filters	Logical OR of multiple conditions

Examples of valid filterable metadata

Simple equality

```
{"genre": "documentary"}
```

This filter matches vectors where the genre metadata key equals "documentary". When you don't specify an operator, S3 Vectors automatically uses the \$eq operator.

Explicit equality

```
// Example: Exact match
{"genre": {"$eq": "documentary"}}
```

```
// Example: Not equal to
{"genre": {"$ne": "drama"}}
```

Numeric comparison

```
{"year": {"$gt": 2019}}
```

```
{"year": {"$gte": 2020}}
```

```
{"year": {"$lt": 2020}}
```

```
{"year": {"$lte": 2020}}
```

Array operations

```
{"genre": {"$in": ["comedy", "documentary"]}}
```

```
{"genre": {"$nin": ["comedy", "documentary"]}}
```

Existence check

```
{"genre": {"$exists": true}}
```

The `$exists` filter matches vectors that have a "genre" metadata key, regardless of the value that's stored for that metadata key.

Logical operations

```
{"$and": [{"genre": {"$eq": "drama"}}, {"year": {"$gte": 2020}}]}
```

```
{"$or": [{"genre": {"$eq": "drama"}}, {"year": {"$gte": 2020}}]}
```

Price range (Multiple conditions on the same field)

```
{"price": {"$gte": 10, "$lte": 50}}
```

For more information about how to query vectors with metadata filtering, see [Metadata filtering](#).

Non-filterable metadata

Non-filterable metadata can't be used in query filters but can store larger amounts of contextual data than filterable metadata. It's ideal for storing large text chunks, detailed descriptions, or other contextual information that doesn't need to be searchable but can be returned with query results. For example, you might store full document text, image descriptions, or detailed product specifications as non-filterable metadata.

Non-filterable metadata keys must be explicitly configured during vector index creation. Once a metadata key is designated as non-filterable during index creation, it can't be changed to filterable later. You can configure multiple metadata keys as non-filterable per vector index, with each metadata key name limited to 63 characters. For more information about the maximum number of non-filterable metadata keys that's allowed per vector index, see [Limitations and restrictions](#).

While you can't filter on non-filterable metadata, you can retrieve it alongside query results using the `return-metadata` parameter. You can use non-filterable metadata for some use cases as follows.

- Use it to provide context for your application without parsing separate data sources.
- Store larger text chunks that would exceed the filterable metadata size limits.
- Include it in vector exports by using the [ListVectors](#) API operation.

For more information about configuring non-filterable metadata, see [Creating a vector index in a vector bucket](#).

Limitations and restrictions

Amazon S3 Vectors has certain limitations and restrictions that you should be aware of when planning your vector storage and search applications.

- Vector buckets per AWS Region in an account: 10,000
- Vector indexes per vector bucket: 10,000
- Vectors per vector index: Up to 2 billion
- Dimension value per vector: 1 to 4,096
- Total metadata per vector: Up to 40 KB (filterable + non-filterable)
- Total metadata keys per vector: Up to 50

- Filterable metadata per vector: Up to 2 KB
- Non-filterable metadata keys per vector index: Up to 10
- Combined PutVectors and DeleteVectors requests per second per vector index: Up to 1,000
- Combined vectors inserted and deleted per second per vector index: Up to 2,500
- Request payload size: Up to 20 MiB
- Vectors per [PutVectors](#) API call: Up to 500
- Vectors per [DeleteVectors](#) API call: Up to 500
- Vectors per [GetVectors](#) API call: Up to 100
- Top-K results per [QueryVectors](#) request: Up to 100
- Vectors listed per page in a [ListVectors](#) response: Up to 1,000
- Vector buckets listed per page in a [ListVectorBuckets](#) response: Up to 500.
- Vector indexes listed per page in a [ListIndexes](#) response: Up to 500.
- Segment count for parallel listing in a ListVectors API call: Up to 16

S3 Vectors best practices

Amazon S3 Vectors delivers purpose-built, cost-optimized vector storage for use by AI-enabled applications and semantic search of your content stored in Amazon S3. Designed to provide S3 level elasticity and durability for storing vector datasets with sub-second query performance for cold queries and as low as 100 milliseconds for warm queries, S3 Vectors is ideal for applications that need to build and grow vector indexes. With S3 Vectors you can use a dedicated set of API operations to store, access, and perform similarity queries on vector data without provisioning any infrastructure. For more information, see [Working with S3 Vectors and vector buckets](#).

To ensure the maximum benefit from S3 Vectors, we recommend that you perform the following best practices.

Inserting and deleting vectors

Your application can achieve up to one thousand [PutVectors](#) or [DeleteVectors](#) requests per second per vector index, or can insert or delete up to two thousand five hundred vectors per second per vector index — whichever limit is reached first. If you exceed the request rates, you might receive a 429 `TooManyRequestsException` error.

To optimize costs, we recommend inserting and deleting vectors in large batches, up to the maximum batch size of 500 vectors per API request. If your workload requires smaller batches, you can send concurrent requests up to the 1,000 requests per second limit. To reach maximum throughput of 2,500 vectors per second, you can send 5 batches per second with 500 vectors each, or 1,000 batches per second with an average of 2.5 vectors each.

Accessing and querying vectors in an S3 vector index

Your application can achieve hundreds of [QueryVectors](#), [GetVectors](#), or [ListVectors](#) requests per second per S3 vector index. If you exceed the request rates, you might receive a 429 `TooManyRequestsException` error. We recommend you use a retry mechanism and configure your application to send fewer requests.

Scaling across vector indexes

To improve query performance per vector index, consider configuring your application to divide vectors across multiple vector indexes when possible. For example, if you have multi-tenant workloads and your application queries each tenant independently, consider storing each tenant's vectors in a separate vector index. For more information, see [Vector indexes](#).

Implementing multi-tenancy with separate vector indexes

You can achieve multi-tenancy by organizing your vector data using a single vector index for each tenant. You can use IAM and bucket policies to restrict each tenant's access to only their designated vector index. This approach helps maintain data isolation and simplifies management by removing the need to create separate buckets for each tenant. For more information, see [Identity and Access management in S3 Vectors](#).

Configuring non-filterable metadata fields for vector indexes

When creating a vector index, configure metadata fields that don't require filtering as non-filterable metadata keys. For example, store text chunks for vector embeddings as non-filterable metadata fields when you need them only for reference. For more information, see [Non-filterable metadata](#).

Creating vector embeddings and performing semantic searches with s3vectors-embed-cli

Amazon S3 Vectors provides a standalone open-source tool called Amazon S3 Vectors Embed CLI (`s3vectors-embed-cli`) that simplifies working with vector data by combining embedding generation with vector operations in single commands. This CLI tool helps you get started with S3 Vectors quickly by automating vector embedding generation with Amazon Bedrock foundation models and semantic search operations within your vector indexes.

The S3 Vectors Embed CLI provides two main commands for integrating Amazon Bedrock embedding models with S3 Vectors operations:

- `s3vectors-embed put`: Generate and insert vector embeddings into an vector index. Specifically, convert text and images into vector embeddings through Amazon Bedrock models and automatically store them in your vector index.
- `s3vectors-embed query`: Generate vector embeddings from your query input through Amazon Bedrock models and query vectors in your vector index.

The Amazon S3 Vectors Embed CLI is available in the [Amazon Web Services - Labs GitHub repository](#). For detailed installation instructions, command parameters, examples, and best practices, see the [Amazon S3 Vectors Embed CLI GitHub repository](#).

For the lower-level S3 Vectors API operations that provide more control and customization, see [Amazon S3 Vectors](#) in the *Amazon Simple Storage Service API Reference*.

Using S3 Vectors with other AWS services

S3 Vectors integrates with other AWS services to enhance your vector processing capabilities and provide comprehensive solutions for AI and machine learning workloads. These integrations allow you to leverage the cost-effective storage of S3 Vectors alongside the specialized capabilities of other AWS services.

Available integrations

S3 Vectors provides native integrations with the following AWS services:

- [Amazon OpenSearch Service](#) - You can export a snapshot of a vector index to Amazon OpenSearch Service for high queries per second (QPS) and low latency vector search. Additionally, Amazon OpenSearch Service adds Amazon S3 Vectors as a new low-cost engine for customers who want to optimize cost while continuing to use Amazon OpenSearch Service API operations for advanced search functionality including hybrid search, aggregations, advanced filtering, faceted search, and more.
- [Amazon Bedrock Knowledge Bases](#) - Use S3 Vectors as your vector store for Retrieval Augmented Generation (RAG) applications, reducing storage costs while maintaining query performance for knowledge base operations. You can access this integration through the Amazon Bedrock console or [Amazon SageMaker AI Unified Studio](#).

Integration benefits

These integrations provide several key advantages:

- **Cost optimization:** Store large vector datasets cost-effectively in S3 Vectors while using specialized services for specific workloads, such as using Amazon OpenSearch for advanced search functionality.
- **Performance flexibility:** Choose the right integration for your performance requirements: S3 Vectors for lower throughput storage and sporadic querying, and other services for high-throughput, low-latency operations.
- **Workflow integration:** Seamlessly incorporate vector operations into existing AWS based AI and ML pipelines.

- **Simplified management:** Reduce operational complexity by using managed integrations rather than building custom solutions.

Topics

- [Using S3 Vectors with OpenSearch Service](#)
- [Using S3 Vectors with Amazon Bedrock Knowledge Bases](#)

Using S3 Vectors with OpenSearch Service

Amazon S3 Vectors integrates with OpenSearch to provide flexible vector storage and search capabilities. This integration allows you to optimize costs by storing vectors in S3 Vectors while leveraging the advanced search features of OpenSearch.

There are two integrations between S3 Vectors and OpenSearch. One is to export vector data from S3 Vectors to OpenSearch Serverless for high-performance search capabilities. The other uses S3 Vectors as a cost-effective storage engine within OpenSearch while maintaining access to OpenSearch functionality.

Export to OpenSearch Serverless

You can export vector indexes from S3 Vectors to OpenSearch Serverless collections for high-performance search operations, hybrid search, aggregations, advanced filtering, and faceted search. When you export, the data is copied to OpenSearch Serverless while remaining in S3 Vectors, which means you'll be paying for both services during this time.

When to use this integration

Consider exporting to OpenSearch Serverless from S3 Vectors when you need the following:

- **Hybrid search capabilities** that combine vector similarity with keyword search.
- **High query throughput** for demanding workloads.
- **Low-latency responses** for real-time applications that require millisecond response times.
- **Advanced analytics** that include aggregations, faceted search, and complex filtering.

Prerequisites

Before using S3 Vectors with OpenSearch, ensure you have the following:

- An existing S3 vector bucket with vector indexes containing your data.
- Appropriate IAM permissions for both S3 Vectors and OpenSearch Service.
- An understanding of your performance requirements to choose the appropriate integration method.

Getting started

Using the AWS Management Console

To export vector data to OpenSearch

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket containing the vector data that you want to export.
4. For **Vector indexes**, choose the radio button next to the vector index that you want to export.
5. Choose **Advanced search export**, then choose **Export to OpenSearch**.

Important

- **Point-in-time export:** The export captures data up to the initiation of the export. If you make updates to your vector data during the ingestion to OpenSearch, not all updates will be reflected in OpenSearch.
- **One-time operation:** This is a one-time export and will not stay in sync with your S3 Vectors data. You must manually re-export to capture any subsequent changes.

Then, to configure and manage the integration of S3 Vectors with Amazon OpenSearch Service, you'll work primarily through the OpenSearch console.

To view exports to OpenSearch

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.

3. In the list of vector buckets, choose the name of the bucket containing the vector data that you want to export.
4. For **Vector indexes**, choose **Advanced search export**, then choose **View exports to OpenSearch**.

Then, you'll view exports to OpenSearch through the OpenSearch console.

For more information about creating and managing OpenSearch Serverless collections, see [Creating and managing Amazon OpenSearch Service Serverless collections](#) in the *Amazon OpenSearch Service Developer Guide*.

OpenSearch with S3 Vectors engine

You can use S3 Vectors as the underlying storage engine for [Amazon OpenSearch Managed clusters](#), providing cost-optimized vector storage while maintaining OpenSearch functionality.

When to use this integration

Consider using OpenSearch with the S3 Vectors engine when you need the following:

- **Hybrid search capabilities** that combine vector similarity with keyword search.
- **Lower query throughput** that may have less frequent or sporadic usage patterns.
- **Higher latency tolerance** for applications that can accept longer response times in exchange for cost savings.
- **Advanced analytics** that include aggregations, faceted search, and complex filtering.
- **Existing OpenSearch workflows** that you want to extend with cost-effective vector storage.

Prerequisites

Before using OpenSearch with S3 Vectors engine, ensure you have:

- An existing OpenSearch managed domain. For more information, see [Creating and managing Amazon OpenSearch Service domains](#) in the *Amazon OpenSearch Service Developer Guide*.
- An understanding of your performance requirements to choose the appropriate integration method.

Getting Started

To use OpenSearch with S3 Vectors engine, set your engine to `S3_Vectors` during index creation in OpenSearch. For more information about the template that you use when creating an index in OpenSearch Service, including where to specify the engine type, see [Methods and engines](#). For more information about the integration between OpenSearch and S3 Vectors engine, see [Advanced search capabilities with an S3 Vectors engine](#) in the *Amazon OpenSearch Service Developer Guide*.

Using S3 Vectors with Amazon Bedrock Knowledge Bases

S3 Vectors integrates with [Amazon Bedrock Knowledge Bases](#) and [Amazon SageMaker AI Unified Studio](#) to simplify and reduce the cost of vector storage for retrieval augmented generation (RAG) applications.

For more information about high-level CLI commands that integrate Amazon Bedrock embedding models with S3 Vectors operations, see .

Topics

- [Integration overview](#)
- [When to use this integration](#)
- [Supported embedding models](#)
- [Prerequisites and permissions](#)
- [Creating a knowledge base with S3 Vectors](#)
- [Managing and querying your knowledge base](#)
- [Limitations](#)

Integration overview

When creating a knowledge base in Amazon Bedrock, you can select S3 Vectors as your vector store. This integration provides the following:

- **Cost savings** for RAG applications with large vector datasets.
- **Seamless integration** with the fully managed RAG workflow of Amazon Bedrock.
- **Automatic vector management** handled by the Amazon Bedrock service.

- **Sub-second cold query latency and as low as 100 millisecond warm query latency** for knowledge base retrieval operations.

Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow. When you create a knowledge base with S3 Vectors, Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your vector index. You can then query the knowledge base and generate responses based on chunks retrieved from your source data.

When to use this integration

Consider using S3 Vectors with Amazon Bedrock Knowledge Bases when you need the following:

- **Cost-effective vector storage** for large datasets where sub-second query latency meets your application requirements.
- **Text and image-based document retrieval** for use cases like searching through manuals, policies, and visual content.
- **RAG applications** that prioritize storage cost optimization over ultra-low latency responses.
- **Managed vector operations** without needing to learn S3 Vectors API operations directly - you can continue using familiar Amazon Bedrock interfaces.
- **Long-term vector storage** with the durability and scalability of Amazon S3

This integration is ideal for organizations building RAG applications that need to search through and extract insights from written content and images, where the cost benefits of S3 Vectors align with acceptable query performance requirements.

Supported embedding models

Refer to [supported models for vector embeddings](#) in the *Amazon Bedrock User Guide*.

Prerequisites and permissions

Before creating a knowledge base with S3 Vectors, ensure you have the following:

- Appropriate IAM permissions for both S3 Vectors and Amazon Bedrock services. For more information about IAM permissions for S3 Vectors, see [the section called “Identity and Access management in S3 Vectors”](#). For more information about IAM permissions for your Amazon

Bedrock Knowledge Bases service role to access S3 Vectors, see [Permissions to access your vector store in Amazon S3 Vectors](#) in the *Amazon Bedrock User Guide*.

- Your source documents prepared for ingestion into the knowledge base.
- An understanding of your embedding model requirements.

When setting up security configurations, you can choose an IAM role that provides Amazon Bedrock permission to access required AWS services. You can let Amazon Bedrock create the service role or use your own custom role. If you use a custom role, configure a vector bucket policy that restricts access to the vector bucket and vector index to the custom role.

For detailed information about required permissions and IAM roles, see [Create a service role for Amazon Bedrock Knowledge Bases](#) in the *Amazon Bedrock User Guide*. The service role must also have permissions for S3 Vectors and AWS KMS API operations.

Creating a knowledge base with S3 Vectors

You can create a knowledge base that uses S3 Vectors through two methods.

Method one: Using the Amazon Bedrock console

When creating a knowledge base in the Amazon Bedrock console, you can choose "S3 vector bucket" as your vector store option. You have two setup options:

- **Quick create a new vector store** - Amazon Bedrock creates an S3 vector bucket and vector index and configures them with the required settings for you. By default, the vector bucket is encrypted using server-side encryption with Amazon S3 managed keys (SSE-S3). You can optionally encrypt the bucket using AWS KMS. For more information about **Quick create a new vector store** in the console, see [Create a knowledge base by connecting to a data source in Amazon Bedrock Knowledge Bases](#) in the *Amazon Bedrock User Guide*.
- **Choose a vector store you have created** - Choose an existing S3 vector bucket and vector index from your account that you've previously created. For more information about creating an S3 vector bucket and vector index in the Amazon Bedrock Knowledge Bases console, see the S3 Vectors tab in [Prerequisites for using a vector store you created for a knowledge base](#) in the *Amazon Bedrock User Guide*.

For detailed step-by-step instructions, see [Create a knowledge base by connecting to a data source in Amazon Bedrock Knowledge Bases](#) in the *Amazon Bedrock User Guide*.

Method two: Using Amazon SageMaker Unified Studio

You can also create and manage knowledge bases with S3 Vectors through Amazon Bedrock in [Amazon SageMaker AI Unified Studio](#). This provides a unified development environment for building and testing AI applications that use knowledge bases.

[Amazon Bedrock in SageMaker AI Unified Studio](#) is designed for users who need integrated notebook capabilities and work across multiple AWS ML and analytics services. You can quickly create an S3 vector bucket and configure it as the vector store for your knowledge bases when you build generative AI applications.

For information about using S3 Vectors with Amazon Bedrock in SageMaker AI Unified Studio, see [Add a data source to your Amazon Bedrock app](#) in the *SageMaker AI Unified Studio User Guide*.

Managing and querying your knowledge base

Data synchronization and management

Amazon Bedrock Knowledge Bases offers ingestion job operations to keep your data source and vector embeddings synchronized. When you sync your data source, Amazon Bedrock scans each document and verifies whether it has been indexed into the vector store. You can also directly index documents into the vector store using the [IngestKnowledgeBaseDocuments](#) operation. Best practice is to create a separate vector store for each knowledge base to ensure data synchronization.

When you delete a knowledge base or data source resource, Amazon Bedrock offers two data deletion policies: Delete (default) and Retain. If you choose the Delete policy, vectors in the vector index and vector bucket are automatically deleted.

Querying and retrieval

After your knowledge base is set up, you can do the following:

- **Retrieve chunks** from your source data using the [Retrieve](#) API operation.
- **Generate responses** based on retrieved chunks using the [RetrieveAndGenerate](#) API operation.
- **Test queries** directly in the Amazon Bedrock console.

Responses are returned with citations to the original source data.

Limitations

When using S3 Vectors with Amazon Bedrock Knowledge Bases, you should know the following limitations:

- **Semantic search only:** S3 Vectors supports semantic search but not hybrid search capabilities.
- **S3 Vectors size limits:** Each vector has a total metadata size limit and a size limit for filterable metadata, which may limit custom metadata and filtering options. When using S3 Vectors as your vector store with Amazon Bedrock Knowledge Bases, you can attach up to 1KB of custom metadata and 35 metadata keys per vector.
- **Chunking strategy constraints:** When using very high token counts with hierarchical chunking in Amazon Bedrock Knowledge Bases, you can exceed the maximum metadata size limits as parent-child chunk relationships and hierarchical context are stored as non-filterable metadata in S3 Vectors. For more information about metadata size limits per vector, see [Limitations and restrictions](#).
- **Floating-point vectors only:** Binary vector embeddings aren't supported.

For comprehensive guidance on working with Amazon Bedrock Knowledge Bases, see [Retrieve data and generate AI responses with Amazon Bedrock Knowledge Bases](#) in the *Amazon Bedrock User Guide*.

AWS Regions, endpoints, and quotas for S3 Vectors

The following sections include the supported AWS Regions and service quotas for Amazon S3 Vectors.

S3 Vectors AWS Regions and endpoints

Amazon S3 Vectors is currently available in the following AWS Regions. To connect programmatically to an AWS service, you use an endpoint. For more information about AWS service endpoints, see [AWS service endpoints](#) in the AWS General Reference. For more Amazon S3 endpoint information, see [Amazon S3 endpoints and quotas](#) in the AWS General Reference.

S3 Vectors endpoints are dual-stack endpoints that support requests over IPv6 and IPv4.

S3 Vectors supports private connectivity with AWS PrivateLink interface endpoints. For more information, see [VPC endpoints for S3 Vectors](#).

S3 Vectors AWS Regions and endpoints

Region Name	Region	Endpoint	Protocol	Signature Version(s) Support
US East (N. Virginia)	us-east-1	s3vectors.us-east-1.api.aws	HTTPS	4
US East (Ohio)	us-east-2	s3vectors.us-east-2.api.aws	HTTPS	4
US West (Oregon)	us-west-2	s3vectors.us-west-2.api.aws	HTTPS	4
EU Central 1 (Frankfurt)	eu-central-1	s3vectors.eu-central-1.api.aws	HTTPS	4
Asia Pacific (Sydney)	ap-southeast-2	s3vectors.ap-southeast-2.api.aws	HTTPS	4
Asia Pacific (Mumbai)	ap-south-1	s3vectors.ap-south-1.api.aws	HTTPS	4
Asia Pacific (Singapore)	ap-southeast-1	s3vectors.ap-southeast-1.api.aws	HTTPS	4

Region	Region Name	Endpoint	Protocol	Signature Version(s) Support
Asia Pacific (Seoul)	ap-northeast-2	s3vectors.ap-north-east-2.api.aws	HTTPS	4
Asia Pacific (Tokyo)	ap-northeast-1	s3vectors.ap-north-east-1.api.aws	HTTPS	4
Canada Central	ca-central-1	s3vectors.ca-central-1.api.aws	HTTPS	4
Europe (Ireland)	eu-west-1	s3vectors.eu-west-1.api.aws	HTTPS	4
Europe (London)	eu-west-2	s3vectors.eu-west-2.api.aws	HTTPS	4
Europe (Paris)	eu-west-3	s3vectors.eu-west-3.api.aws	HTTPS	4
Europe (Stockholm)	eu-north-1	s3vectors.eu-north-1.api.aws	HTTPS	4

S3 Vectors service quotas

Quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. The limits are the service quotas for S3 Vectors resources.

For detailed limits that apply to S3 Vectors, see [Limitations and restrictions](#).

Unless otherwise noted, each quota is per AWS Region. You can request increases for some quotas, and other quotas can't be increased. For more information about requesting a quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*. For more Amazon S3 quota information, see [Amazon S3 endpoints and quotas](#) in the *AWS General Reference*.

Security in S3 Vectors

Amazon S3 Vectors offers highly durable vector storage. Data written to S3 Vectors is stored on S3, which is designed for 99.99999999% (11 nines) of data durability.

S3 Vectors implements a security approach that includes encryption at rest and secure data transmission. Whether you're storing millions of vectors for machine learning applications or building semantic search systems, S3 Vectors provides the security controls necessary to meet your organization's compliance and data protection requirements.

Topics

- [Identity and Access management in S3 Vectors](#)
- [Data protection and encryption in S3 Vectors](#)
- [VPC endpoints for S3 Vectors](#)

Identity and Access management in S3 Vectors

Access management in S3 Vectors follows AWS security best practices, providing multiple layers of control to ensure that only authorized users and applications can access your vector data. The service integrates with IAM and supports both identity-based and resource-based policies, giving you flexibility in how you structure and manage permissions across your organization.

Authenticating and authorizing requests

S3 Vectors uses AWS standard authentication and authorization mechanisms to secure access to vector buckets and their contents. Every request to S3 Vectors must be authenticated using valid AWS credentials, and the service evaluates permissions based on the combination of identity-based policies, resource-based policies, and any applicable service control policies.

The authentication process begins when a client makes a request to S3 Vectors using AWS credentials (access keys, temporary credentials from AWS STS, or IAM roles). The service validates these credentials and then evaluates the permissions associated with the authenticated identity against the requested action and target resource. This evaluation process considers multiple policy types and applies the principle of least privilege to determine whether the request should be allowed or denied.

Authorization in S3 Vectors operates at multiple levels of granularity. You can control access at the vector bucket level, individual vector index level, or even specific operations within an index. This

hierarchical permission model allows you to implement sophisticated access control schemes that align with your organizational structure and data governance requirements.

Resource types defined for vector buckets

S3 Vectors defines specific resource types that can be referenced in IAM policies and resource-based policies. Understanding these resource types is essential for creating effective access control policies that provide the right level of access to the right users and applications.

The following table describes the resource types available in S3 Vectors.

Resource types available in S3 Vectors

Resource type	ARN format	Description
VectorBucket	arn:aws:s3vectors: <i>region:123456789 012</i> :bucket/ <i>bucket-name</i>	Represents a vector bucket and is used for bucket-level operations such as creating, deleting, or configuring the bucket
Index	arn:aws:s3vectors: <i>region:123456789 012</i> :bucket/ <i>bucket-na me</i> /index/ <i>index-name</i>	Represents a vector index within a bucket and is used for index-specific operations such as querying vectors or managing index contents

Policy actions for vector buckets

S3 Vectors provides a comprehensive set of policy actions that correspond to the various operations you can perform on vector buckets and indexes. These actions are designed to provide fine-grained control over who can perform specific operations, allowing you to implement the principle of least privilege effectively.

The following table lists all available policy actions for S3 Vectors resources.

Policy actions for S3 Vectors resources

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Account	ListVectorBuckets	s3vectors :ListVectorBuckets	Grants permission to list all vector buckets in the account and region	List	
VectorBucket	CreateVectorBucket	s3vectors :CreateVectorBucket	Grants permission to create a new vector bucket with specified configuration	Write	s3vectors :sseType, s3vectors :kmsKeyArn
VectorBucket	GetVectorBucket	s3vectors :GetVectorBucket	Grants permission to retrieve vector bucket attributes and configuration	Read	
VectorBucket	DeleteVectorBucket	s3vectors :DeleteVectorBucket	Grants permission to delete an empty vector bucket	Write	
VectorBucket	ListIndexes	s3vectors :ListIndexes	Grants permission to list	List	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
			all indexes within a vector bucket		
VectorBucket	PutVectorBucketPolicy	s3vectors :PutVectorBucketPolicy	Grants permission to apply or update a resource-based policy on a vector bucket	Permissions management	
VectorBucket	GetVectorBucketPolicy	s3vectors :GetVectorBucketPolicy	Grants permission to retrieve the resource-based policy attached to a vector bucket	Read	
VectorBucket	DeleteVectorBucketPolicy	s3vectors :DeleteVectorBucketPolicy	Grants permission to remove the resource-based policy from a vector bucket	Permissions management	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	CreateIndex	s3vectors :CreateIndex	Grants permission to create a new vector index with specified dimensions and metadata configuration	Write	
Index	GetIndex	s3vectors :GetIndex	Grants permission to retrieve vector index attributes and configuration	Read	
Index	DeleteIndex	s3vectors :DeleteIndex	Grants permission to delete a vector index and all its contents	Write	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	QueryVectors	(Required) s3vectors :QueryVectors	<p>Grants permission to perform similarity queries against vectors in an index.</p> <p>With s3vectors :QueryVectors only, you can retrieve vector keys of approximate nearest neighbors and their computed distances from the query vector. This permission is sufficient only when you don't set any metadata filters and don't request</p>	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
			vector data or metadata (by keeping the <code>returnMetadata</code> parameter set to false or not specified).		

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
			<p>(Conditionally required): <code>s3vectors :GetVectors</code></p> <p>Required if you set metadata filters, set <code>returnMetadata</code> to true in your request.</p> <p>With both <code>s3vectors :QueryVectors</code> and <code>s3vectors :GetVectors</code>, you can filter results by using metadata criteria and retrieve vector keys along with their associated data, metadata, and computed distances from the query vector.</p>	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	<u>PutVectors</u>	s3vectors :PutVectors	Grants permission to add or update vectors in an index	Write	
Index	<u>GetVectors</u>	s3vectors :GetVectors	Grants permission to retrieve specific vectors and their metadata by vector key	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	ListVectors	(Required) s3vectors :ListVectors	Grants permission to list vector keys in an index. With s3vectors :ListVectors only, you can list vector keys when both returnData and returnMetadata parameters are false or not specified.	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
			<p>(Conditionally required): <code>s3vectors :GetVectors</code></p> <p>Required if you set either <code>returnData</code> or <code>returnMetadata</code> parameter to <code>true</code> in your request.</p> <p>With both <code>s3vectors :ListVectors</code> and <code>s3vectors :GetVectors</code>, you can retrieve vector keys along with their associate d data and metadata by setting <code>returnData</code> and <code>returnMetadata</code> to <code>true</code>.</p>	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	DeleteVectors	s3vectors :DeleteVectors	Grants permission to delete specific vectors from an index	Write	

These actions can be combined in various ways to create policies that match your specific access requirements. For example, you might create a read-only policy that includes s3vectors:GetVectorBucket, s3vectors>ListIndexes, s3vectors:QueryVectors, and s3vectors:GetVectors actions, or a policy that includes query and vector retrieval permissions but excludes administrative actions like creating or deleting indexes.

Condition keys for vector buckets

Condition keys for vector buckets

	Condition keys	Description	Type
1	s3vectors:sseType	Filters access by server-side encryption type Valid values: AES256 aws:kms	String
2	s3vectors:kmsKeyArn	Filters access by the AWS AWS KMS key ARN for the key used to encrypt a vector bucket	ARN

S3 Vectors identity-based policy examples

IAM identity-based policies are JSON documents that you attach to IAM users, groups, or roles to define what actions they can perform on S3 Vectors resources. These policies are evaluated in the context of the identity making the request and provide a centralized way to manage permissions across your AWS environment. Identity-based policies provide a clear audit trail of who has what permissions and can be easily modified as your access requirements evolve.

When designing identity-based policies for S3 Vectors, consider the different types of users and applications that will interact with your vector data. Common patterns include data scientists who need to query vectors, data engineers who need to load and manage vector data, administrators who need full control over bucket configuration, and applications that need specific read or write access to particular vector indexes.

Example policies

Administrative access policy

This policy provides full administrative access to S3 Vectors resources, suitable for platform administrators or DevOps teams:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAdministrativeAccess",
            "Effect": "Allow",
            "Action": [
                "s3vectors:CreateVectorBucket",
                "s3vectors:PutVectorBucketPolicy",
                "s3vectors:DeleteVectorBucket",
                "s3vectors:DeleteVectorBucketPolicy",
                "s3vectors:GetVectorBucket",
                "s3vectors:GetVectorBucketPolicy",
                "s3vectors>ListVectorBuckets",
                "s3vectors>CreateIndex",
                "s3vectors>DeleteIndex",
                "s3vectors:GetIndex",
                "s3vectors>ListIndexes",
                "s3vectors>DeleteVectors",
                "s3vectors:GetVectors",
                "s3vectors>ListVectors",
                "s3vectors:DescribeVectorBucket"
            ]
        }
    ]
}
```

```
        "s3vectors:PutVectors",
        "s3vectors:QueryVectors"
    ],
    "Resource": "*"
}
]
```

Application-specific access policy

This policy is designed for applications that need to perform specific operations on designated vector indexes:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowApplicationVectorAccess",
            "Effect": "Allow",
            "Action": [
                "s3vectors:QueryVectors",
                "s3vectors:GetVectors",
                "s3vectors:PutVectors",
                "s3vectors>ListVectors"
            ],
            "Resource": [
                "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-vector-
bucket/index/product-recommendations",
                "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-vector-
bucket/index/content-similarity"
            ]
        },
        {
            "Sid": "AllowGetIndex",
            "Effect": "Allow",
            "Action": "s3vectors:GetIndex",
            "Resource": "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-
vector-bucket/index/*"
        },
        {
            "Sid": "AllowIndexInspection",
            "Effect": "Allow",
            "Action": "s3vectors>ListIndexes",
```

```
"Resource": "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-vector-bucket"
}
]
}
```

S3 Vectors resource-based policy examples

Resource-based policies are attached to a resource. You can create resource-based policies for vector buckets. Resource-based policies for S3 Vectors use the standard AWS policy format in JSON that you attach directly to vector buckets to control access to the bucket and its contents.

Unlike identity-based policies that are attached to users, groups, or roles, resource-based policies are attached to the resource itself (the vector bucket) and can grant permissions to principals from other AWS accounts. This makes them ideal for scenarios where you need to share vector data across organizational boundaries or implement fine-grained access controls based on the specific resource being accessed.

Resource-based policies are evaluated in combination with identity-based policies, and the effective permissions are determined by the union of all applicable policies. This means that a principal needs permission from both the identity-based policy (attached to their user/role) and the resource-based policy (attached to the bucket) to perform an action, unless the resource-based policy explicitly grants the permission.

Example 1: Cross-account access policy

This policy demonstrates how to grant specific permissions to users from different AWS accounts:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CrossAccountBucketAccess",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam:123456789012:role/Admin"
      },
      "Action": [
        "s3vectors>CreateIndex",
        "s3vectors>ListIndexes",
        "s3vectors>QueryVectors",
      ]
    }
  ]
}
```

```
        "s3vectors:PutVectors",
        "s3vectors>DeleteIndex"
    ],
    "Resource": [
        "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-
bucket/*",
        "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-
bucket"
    ]
}
]
```

Example 2: Deny vector index level actions

This policy demonstrates how to deny specific vector index level actions to an IAM role:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyIndexLevelActions",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam:123456789012:role/External-Role-Name"
            },
            "Action": [
                "s3vectors:QueryVectors",
                "s3vectors:PutVectors",
                "s3vectors>DeleteIndex",
                "s3vectors:GetVectors",
                "s3vectors:GetIndex",
                "s3vectors>DeleteVectors",
                "s3vectors>CreateIndex",
                "s3vectors>ListVectors"
            ],
            "Resource": "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-
vector-bucket/*"
        }
    ]
}
```

Example 3: Deny modification operations at both vector index and bucket levels

This policy demonstrates how to deny modification requests for both vector index and bucket-level actions by specifying multiple resources:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyModificationActionsAtBucketandIndexLevels",  
            "Effect": "Deny",  
            "Principal": {  
                "AWS": "arn:aws:iam:123456789012:role/External-Role-Name"  
            },  
            "Action": [  
                "s3vectors:CreateVectorBucket",  
                "s3vectors:DeleteVectorBucket",  
                "s3vectors:PutVectorBucketPolicy",  
                "s3vectors:DeleteVectorBucketPolicy",  
                "s3vectors:CreateIndex",  
                "s3vectors:DeleteIndex",  
                "s3vectors:PutVectors",  
                "s3vectors:DeleteVectors"  
            ],  
            "Resource": [  
                "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-  
bucket/*",  
                "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-  
bucket"  
            ]  
        }  
    ]  
}
```

Data protection and encryption in S3 Vectors

Amazon S3 Vectors provides 99.999999999% (11 9s) of durability for your vector data, which ensures exceptional reliability for your vector storage needs. This durability is backed by the proven infrastructure of Amazon S3, which is designed to maintain data integrity and availability even in the face of hardware failures or other disruptions.

Data protection in S3 Vectors encompasses multiple layers of security controls designed to protect your vector data both at rest and in transit.

By default, all new vectors in Amazon S3 Vectors vector buckets use server-side encryption with Amazon S3 managed keys (SSE-S3). When you create a vector bucket with SSE-S3 encryption, all subsequent operations on the bucket automatically use encryption.

S3 Vectors also integrates with AWS Key Management Service (KMS) to provide flexible encryption key management options, allowing you to choose customer-managed keys for permission control and auditability.

When creating a vector index within a vector bucket, you can optionally override the vector bucket level encryption settings and provide an encryption configuration (SSE-S3 or KMS) at the vector index level. If no specific encryption is specified upon vector index creation, the index will inherit the encryption configuration from the vector bucket it belongs to.

Setting server-side encryption behavior for Amazon S3 vector buckets and indexes

Encryption configuration in S3 Vectors is a fundamental security setting to specify when you create a vector bucket. This design ensures that all vector data stored in the bucket is encrypted from the moment of creation. By default, the encryption configuration applies to all vectors, vector indexes, and metadata within the bucket, providing consistent protection across your entire vector dataset in a vector bucket. You can also optionally override the vector bucket level encryption settings and provide a dedicated encryption configuration (SSE-S3 or AWS KMS) at the vector index level.

Important

Encryption settings for a vector bucket can't be changed after the vector bucket is created. You must carefully consider your encryption requirements during the bucket creation process, including compliance requirements, key management preferences, and integration with existing security infrastructure.

When you set the SSE-S3 or SSE-KMS encryption type at the vector bucket level, by default it applies to all vector indexes and vectors within the bucket. The encryption configuration applies to not only the vector data itself but also all associated metadata.

You can also optionally override the vector bucket level encryption settings and provide a dedicated encryption configuration (SSE-S3 or KMS) at the vector index level. Encryption settings for a vector index can't be changed after the vector index is created.

Using SSE-S3 encryption

Server-side encryption with Amazon S3 managed keys (SSE-S3) provides a simple and effective encryption solution for vector buckets where AWS manages all aspects of the encryption process. This encryption method uses AES-256 encryption and is designed to provide strong security with minimal operational overhead, providing organizations with robust encryption without the complexity of the needs to manage encryption keys.

With SSE-S3, Amazon S3 handles the generation, rotation, and management of encryption keys automatically. SSE-S3 provides strong security with no additional configuration or ongoing management requirements. The encryption and decryption processes are handled automatically by the service, and there are no additional charges for using SSE-S3 encryption beyond the standard S3 Vectors pricing.

Using SSE-KMS encryption

Server-side encryption with AWS Key Management Service keys (SSE-KMS) provides enhanced control over encryption keys and enables detailed audit logging of key usage. This encryption method is ideal for organizations with strict compliance requirements, those that need to implement custom key rotation policies, or environments where detailed audit trails of data access are required.

SSE-KMS allows you to use customer managed keys (CMKs) for encrypting your vector data. Customer managed keys provide the highest level of control, allowing you to define key policies, enable or disable keys, and monitor key usage through AWS CloudTrail. This level of control makes SSE-KMS particularly suitable for regulated industries or organizations with specific data governance requirements.

When using SSE-KMS with customer managed keys, you have complete control over who can use the keys to encrypt and decrypt data. You can create detailed key policies that specify which users, roles, or services can access the keys.

Important considerations for SSE-KMS

- **KMS key format requirements:** S3 Vectors requires that you specify KMS keys using the full Amazon Resource Name (ARN) format. Key IDs or key aliases aren't supported.

- Service principal permissions:** When you use customer managed keys with S3 Vectors, you must explicitly grant permissions to the S3 Vectors service principal to use your KMS key. This requirement ensures that the service can encrypt and decrypt your data on your behalf. The service principal that requires access is `indexing.s3vectors.amazonaws.com`.

Example: KMS key policy for S3 Vectors

To use a customer managed KMS key with S3 Vectors, you must update your key policy to include permissions for the S3 Vectors service principal. Here's a comprehensive key policy example.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowS3VectorsServicePrincipal",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "indexing.s3vectors.amazonaws.com"  
            },  
            "Action": "kms:Decrypt",  
            "Resource": "*",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3vectors:aws-region:123456789012:bucket/  
*"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "123456789012"  
                },  
                "ForAnyValue:StringEquals": {  
                    "kms:EncryptionContextKeys": ["aws:s3vectors:arn",  
"aws:s3vectors:resource-id"]  
                }  
            }  
        },  
        {  
            "Sid": "AllowApplicationAccess",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam:123456789012:role/VectorApplicationRole",  
                    "arn:aws:lambda:123456789012:function:VectorLambdaFunction"  
                ]  
            },  
            "Action": "kms:Encrypt",  
            "Resource": "arn:aws:kms:aws-region:123456789012:key/1234567890123456789012",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3vectors:aws-region:123456789012:bucket/  
*"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "123456789012"  
                },  
                "ForAnyValue:StringEquals": {  
                    "kms:EncryptionContextKeys": ["aws:s3vectors:arn",  
"aws:s3vectors:resource-id"]  
                }  
            }  
        }  
    ]  
}
```

```
        "arn:aws:iam:123456789012:user/DataScientist"
    ],
},
"Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey"
],
"Resource": "*",
"Condition": {
    "StringEquals": {
        "kms:ViaService": "s3vectors.aws-region.amazonaws.com"
    },
    "ForAnyValue:StringEquals": {
        "kms:EncryptionContextKeys": ["aws:s3vectors:arn",
"aws:s3vectors:resource-id"]
    }
}
]
}
```

- **Required KMS permissions:**

- S3 Vectors service principal permission:
 - kms:Decrypt – Required by the S3 Vectors service principal (indexing.s3vectors.amazonaws.com) on your customer managed key to maintain and optimize the index in background operations
- IAM principal permissions:
 - kms:Decrypt – Required for all vector-level operations ([PutVectors](#), [GetVectors](#), [QueryVectors](#), [DeleteVectors](#), [ListVectors](#))
 - kms:GenerateDataKey – Required to create a vector bucket by using the customer managed key
- **Cross-account access considerations:** When implementing cross-account access patterns with SSE-KMS, you must ensure that the KMS key policy allows access from the appropriate principals in other accounts. The key ARN format becomes particularly important in cross-account scenarios, as it provides an unambiguous reference to the key regardless of the account context from which it's being accessed.

Setting encryption in S3 Vectors

This topic explains how to set the encryption configuration for your S3 vector buckets and indexes.

Before you begin, make sure you have the following:

- Appropriate permissions to view bucket and index properties.

Using the S3 console

To configure encryption for a vector bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.
3. Choose **Create vector bucket**.
4. For **Bucket name**, enter a name for your bucket.

The bucket name must:

- Be unique within your account for this AWS Region
- Be between 3 and 63 characters long
- Consist only of lowercase letters, numbers, and hyphens (-)

5. For **Encryption**, choose

- **Specify encryption type** – Choose a specific encryption method:
 - **Server-side encryption with Amazon S3 managed keys (SSE-S3)** – With SSE-S3, Amazon S3 handles the generation, rotation, and management of encryption keys automatically.
 - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** – Similar to SSE-S3, but uses customer managed keys (CMKs) in AWS KMS, giving you more control over your keys. For more information about customer managed keys, see [Customer managed keys](#) in the [AWS Key Management Service Developer Guide](#).

If you select this option, under **AWS KMS key**, choose one of the following options:

- **Choose from your AWS KMS keys** – Select an existing KMS key from the dropdown list
- **Enter AWS KMS key ARN** – Enter the Amazon Resource Name (ARN) of a KMS key

- **Create a KMS key** – Create a new customer managed key in the AWS KMS console. For more information, see [Creating symmetric customer managed keys](#) in the *AWS Key Management Service Developer Guide*.

 **Note**

The following requirements apply to the KMS key:

- AWS KMS key ID must not be empty
- Your KMS key must be in the same Region where this bucket is being created
- AWS KMS key ARN must start with "arn:aws:kms:"

 **Important**

Encryption settings can't be changed after the vector bucket is created.

6. If you chose **Enter AWS KMS key ARN**, enter the ARN in the text field provided.
7. If you chose **Create a KMS key**, the console opens the AWS KMS console in a new tab. For instructions on creating a KMS key, see [Creating symmetric customer managed keys](#) in the *AWS Key Management Service Developer Guide*.
8. Choose **Create vector bucket**.

 **Important**

When using KMS encryption, ensure that the IAM principals that need to access objects in the bucket have the necessary KMS permission (kms:Decrypt) for the selected KMS key.

To configure encryption for a vector index

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket where you want to create a vector index.

4. Choose **Create vector index**.
5. For **Vector index name**, enter a name for your vector index.

Vector index names must be unique within the vector bucket. Index name must be between 3 and 63 characters. Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.). For more information about the vector index naming requirements, see [Vector bucket naming rules](#).

6. For **Dimension**, enter the number of values in each vector.

 **Note**

- The value for **Dimension** determines how many numerical values each vector will contain.
- All vectors added to this index must have exactly this number of values.
- Dimension must be between 1 and 4096.
- A larger dimension requires more storage space.
- Choose based on your embedding model's output dimensions.

For more information about the dimension requirements, see [Limitations and restrictions](#).

7. For **Distance metric**, choose one of the following options:
 - **Cosine** – Measures the cosine of the angle between vectors. Best for normalized vectors and when direction matters more than magnitude
 - **Euclidean** – Measures the straight-line distance between vectors. Best when both direction and magnitude are important.
8. (Optional) Under **Non-filterable metadata**, configure metadata keys that will be stored but not used for filtering:

To add non-filterable metadata keys:

- a. Choose **Add key**.
- b. Enter a key name (1-63 characters and unique within this vector index).
- c. Repeat to add additional keys (maximum 10 keys).

Note

You can attach filterable metadata as key-value pairs to each vector when you insert vector data after you create a vector index. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata keys that are specified as non-filterable during vector index creation are excluded from filtering. For more information about metadata size limits per vector, including both total and filterable metadata constraints, see

[Amazon S3 Vectors has certain limitations and restrictions that you should be aware of when planning your vector storage and search applications.](#)

- Vector buckets per AWS Region in an account: 10,000
- Vector indexes per vector bucket: 10,000
- Vectors per vector index: Up to 2 billion
- Dimension value per vector: 1 to 4,096
- Total metadata per vector: Up to 40 KB (filterable + non-filterable)
- Total metadata keys per vector: Up to 50
- Filterable metadata per vector: Up to 2 KB
- Non-filterable metadata keys per vector index: Up to 10
- Combined PutVectors and DeleteVectors requests per second per vector index: Up to 1,000
- Combined vectors inserted and deleted per second per vector index: Up to 2,500
- Request payload size: Up to 20 MiB
- Vectors per [PutVectors](#) API call: Up to 500
- Vectors per [DeleteVectors](#) API call: Up to 500
- Vectors per [GetVectors](#) API call: Up to 100
- Top-K results per [QueryVectors](#) request: Up to 100
- Vectors listed per page in a [ListVectors](#) response: Up to 1,000
- Vector buckets listed per page in a [ListVectorBuckets](#) response: Up to 500.

- Vector indexes listed per page in a [ListIndexes](#) response: Up to 500.

-
- Segment count for parallel listing in a [ListVectors](#) API call: Up to 16
-

.

9. For **Encryption**, choose **Specify encryption type** and then choose one of the following options:

- **Use bucket settings for encryption** – Amazon S3 applies the vector bucket encryption settings to encrypt vector data in the vector index.
- **Override bucket settings for encryption** – Specify a specific encryption type for the vector index:
 - **Server-side encryption with Amazon S3 managed keys (SSE-S3)** – With SSE-S3, Amazon S3 handles the generation, rotation, and management of encryption keys automatically.
 - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** – Similar to SSE-S3, but uses customer managed keys (CMKs) in AWS KMS, giving you more control over your keys. For more information about customer managed keys, see [Customer managed keys](#) in the *AWS Key Management Service Developer Guide*.

If you select this option, under **AWS KMS key**, choose one of the following options:

- **Choose from your AWS KMS keys** – Select an existing KMS key from the dropdown list
- **Enter AWS KMS key ARN** – Enter the Amazon Resource Name (ARN) of a KMS key
- **Create a KMS key** – Create a new customer managed key in the AWS KMS console. For more information, see [Creating symmetric customer managed keys](#) in the *AWS Key Management Service Developer Guide*.

 **Note**

The following requirements apply to the KMS key:

- AWS KMS key ID must not be empty.
- Your KMS key must be in the same Region where this bucket is being created.
- AWS KMS key ARN must start with "arn:aws:kms:"

⚠️ Important

- Encryption settings can't be changed after the vector index is created.
- If you chose **Enter AWS KMS key ARN**, enter the ARN in the text field provided.
- If you chose **Create a KMS key**, the console opens the AWS KMS console in a new tab. For instructions on creating a KMS key, see *Creating symmetric customer managed keys* in the *AWS Key Management Service Developer Guide*.

⚠️ Important

When using KMS encryption, ensure that the IAM principals that need to access objects in the bucket have the necessary KMS permission (`kms:Decrypt`) for the selected KMS key.

10. Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see [Using tags with S3 vector buckets](#).
11. Review your configuration carefully.

ⓘ Note

These settings can't be changed after creation.

12. Choose **Create vector index**.

Using the AWS CLI

The following example shows how to create a vector bucket with the SSE-S3 encryption configuration by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-vector-bucket \
    --vector-bucket-name "amzn-s3-demo-vector-bucket" \
```

```
--encryption-configuration '{"sseType": "AES256"}'
```

The following examples shows how to create a vector bucket that uses the SSE-KMS encryption configuration with a customer managed key. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-vector-bucket \
    --vector-bucket-name "amzn-s3-demo-vector-bucket" \
    --encryption-configuration '{"sseType": "aws:kms", "kmsKeyArn": "arn:aws:kms:us-east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"}'
```

The following example shows how to create a vector index with the SSE-S3 encryption configuration by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-index \
    --vector-bucket-name "amzn-s3-demo-vector-bucket" \
    --index-name "amzn-s3-demo-vector-index" \
    --encryption-configuration '{"sseType": "AES256"}'
```

The following examples shows how to create a vector index that uses the SSE-KMS encryption configuration with a customer managed key. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-index \
    --vector-bucket-name "amzn-s3-demo-vector-bucket" \
    --index-name "amzn-s3-demo-vector-index" \
    --encryption-configuration '{"sseType": "aws:kms", "kmsKeyArn": "arn:aws:kms:us-east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890abc"}'
```

The following examples shows will create a vector index using the encryption settings of the vector bucket. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-index \
    --vector-bucket-name "amzn-s3-demo-vector-bucket" \
    --index-name "amzn-s3-demo-vector-index" \
```

Viewing encryption configuration in S3 Vectors

After creating your vector bucket, you can verify the encryption configuration using the console. Alternatively, you can use the `GetVectorBucket` and `GetIndex` API operations via the AWS REST API, AWS CLI, or AWS SDKs.

Using the AWS CLI

Use the `get-vector-bucket` command to retrieve detailed bucket information, including encryption configuration. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors get-vector-bucket \
--vector-bucket-name amzn-s3-demo-vector-bucket
```

Use the `get-index` command to retrieve detailed vector index information, including encryption configuration. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors get-index \
--vector-bucket-name amzn-s3-demo-vector-bucket
--index-name amzn-s3-demo-vector-index
```

VPC endpoints for S3 Vectors

To access S3 Vectors from your virtual private cloud (VPC), Amazon S3 supports interface VPC endpoints by using AWS PrivateLink (PrivateLink). PrivateLink provides private connectivity between your VPC and S3 Vectors without requiring an internet gateway or NAT device. Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your VPC. Requests to S3 Vectors over interface endpoints stay on the AWS network.

You can also access interface endpoints in your VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your VPC with your on-premises network, see the [AWS Direct Connect User Guide](#) and the [AWS Site-to-Site VPN User Guide](#). For general information about interface endpoints, see [Access an AWS service using an interface VPC endpoint](#) in the [AWS PrivateLink Guide](#).

Benefits of using PrivateLink with S3 Vectors

Using PrivateLink with S3 Vectors provides several security and operational benefits:

- **Enhanced security:** Traffic between your VPC and S3 Vectors remains within the AWS network and doesn't traverse the internet.
- **Simplified network architecture:** Access S3 Vectors without configuring internet gateways, NAT devices, or VPN connections.
- **Granular access control:** Use VPC endpoint policies to control which vector buckets and vector indexes can be accessed through the endpoint.
- **Compliance support:** Meet regulatory requirements that mandate private network connectivity for sensitive data.

VPC endpoint DNS names and resolution

When you create a VPC endpoint, S3 Vectors generates two types of endpoint-specific DNS names: Regional and Zonal.

The Regional and Zonal DNS names of interface VPC endpoints for S3 Vectors are as follows:

- **Regional DNS name:** `vpce-1a2b3c4d-5e6f.s3vectors.region.vpce.amazonaws.com` - The regional VPC endpoint DNS name. Always resolve to private IP addresses.
- **Zonal DNS name:** `vpce-1a2b3c4d-5e6f-availability_zone_code.s3vectors.region.vpce.amazonaws.com` - Zone-specific VPC endpoint DNS names. Always resolve to private IP addresses.

You can also use the DNS name of the public endpoint `s3vectors.region.api.aws` as the private DNS name of the endpoint service if you have private DNS enabled for the VPC endpoint.

IP addressing for interface endpoints

S3 Vectors regional, zonal, and private DNS endpoints support IPv4, IPv6, and dualstack IP types for AWS PrivateLink. For more information, see [IP address types](#) and [DNS record IP type for AWS services](#) in the *AWS PrivateLink Guide*.

The following are some things you should know before trying to access S3 Vectors vector indexes and vector buckets over IPv6 in your VPC:

- The client you use to access vectors and your S3 Vectors client must both have dual-stack enabled.
- If your VPC security group doesn't have IPv6 set up, you'll need to configure a rule to allow IPv6 traffic. For more information, see [Step 3: Update your security group rules](#) in the *VPC User Guide* and [Configure security group rules](#) in the *Amazon EC2 User Guide*.
- If your VPC doesn't have IPv6 CIDRs assigned, you will need to manually add an IPv6 CIDR block to your VPC. For more information, see [Add IPv6 support for your VPC](#) in the *AWS PrivateLink Guide*.
- If you use IP address filtering IAM policies, they must be updated to handle IPv6 addresses. For more information about managing access permissions with IAM, see [Identity and Access management in S3 Vectors](#).

Creating a VPC interface endpoint for S3 Vectors

You can create a VPC interface endpoint for S3 Vectors using the VPC console, AWS CLI, AWS SDKs, or AWS API.

Using the S3 console

1. Open the VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**.
4. For **Service category**, choose **AWS services**.
5. For **Services**, search for s3vectors and select com.amazonaws.*region*.s3vectors.
6. For **VPC**, select the VPC where you want to create the endpoint.
7. (Optional) Under **Additional settings**, for **Enable DNS name**, choose whether to enable the private DNS feature. When enabled, requests that use the public service endpoint (s3vectors.*region*.api.aws), such as requests made through AWS SDKs, resolve to your VPC endpoint instead of the public endpoint.
8. For **Subnets**, select the subnets where you want to create the endpoint network interfaces.
9. For **IP address type**, choose the IP address type for the endpoint:
 - **IPv4**: Assign IPv4 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have IPv4 address ranges.

- **IPv6:** Assign IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets are IPv6 only subnets.
 - **Dualstack:** Assign both IPv4 and IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have both IPv4 and IPv6 address ranges.
10. For **Security groups**, select the security groups to associate with the endpoint network interfaces.
11. (Optional) For **Policy**, you can attach a VPC endpoint policy to control access to S3 Vectors through the endpoint. To allow all operations by all principals on all S3 Vectors resources over the interface endpoint, choose **Full access**. To restrict access, choose **Custom** and enter a policy. For more information, see [Control access to VPC endpoints using endpoint policies](#) in the AWS PrivateLink Guide. If you don't attach a policy, the default policy allows full access.
12. Choose **Create endpoint**.

Using the AWS CLI

To create a new VPC endpoint that returns both IPv4 and IPv6 for S3 Vectors, use the following example CLI command. For more information, see [create-vpc-endpoint](#).

```
aws ec2 create-vpc-endpoint \  
  --vpc-id vpc-12345678 \  
  --service-name com.amazonaws.region.s3vectors \  
  --vpc-endpoint-type Interface \  
  --subnet-ids subnet-12345678 subnet-87654321 \  
  --security-group-ids sg-12345678 \  
  --ip-address-type dualstack \  
  --private-dns-enabled
```

The `--private-dns-enabled` parameter enables the private DNS feature. When enabled, requests to `s3vectors.region.api.aws` will route through your VPC endpoint.

For more information about creating VPC endpoints, see [Create a VPC endpoint](#) in the *VPC User Guide*.

VPC endpoint policies for S3 Vectors

Similar to resource-based policies, you can attach an endpoint policy to your VPC endpoint to control access to vector indexes and vector buckets. For more information about the endpoint policies, see [Control access to VPC endpoints using endpoint policies](#) in the AWS PrivateLink Guide.

Example VPC endpoint policies

The following example VPC endpoint policy allows access to all S3 Vectors operations for all principals:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3vectors:*"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

The following example VPC endpoint policy restricts access to a specific vector bucket:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3vectors:GetVectorBucket",  
                "s3vectors>ListIndexes",  
                "s3vectors:GetIndex",  
                "s3vectors:QueryVectors",  
                "s3vectors:GetVectors"  
            ],  
            "Resource": [  
                "arn:aws:s3vectors:us-west-2:111122223333:bucket/amzn-s3-demo-vector-bucket",  
                "arn:aws:s3vectors:us-west-2:111122223333:bucket/amzn-s3-demo-vector-bucket/*"  
            ]  
        }  
    ]  
}
```

The following example VPC endpoint policy allows access only during business hours using the `aws:CurrentTime` condition key:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": "s3vectors:*",  
            "Resource": "*",  
            "Condition": {  
                "DateGreaterThan": {  
                    "aws:CurrentTime": "08:00Z"  
                },  
                "DateLessThan": {  
                    "aws:CurrentTime": "18:00Z"  
                }  
            }  
        }  
    ]  
}
```

Configuring S3 Vectors clients for VPC endpoints

When using VPC endpoints with S3 Vectors, you can configure your S3 Vectors clients to use either the service DNS name or the VPC endpoint DNS name.

Using the AWS SDKs

SDK for Python

The following example shows how to configure the S3 Vectors client in SDK for Python (Boto3) to use a VPC endpoint:

```
import boto3  
  
# Using service DNS name (requires private DNS feature enabled on VPC endpoint)  
s3vectors_client = boto3.client(  
    's3vectors',  
    region_name='us-west-2',  
    endpoint_url='https://s3vectors.us-west-2.api.aws'  
)
```

```
# Using VPC endpoint DNS name
s3vectors_client = boto3.client(
    's3vectors',
    region_name='us-west-2',
    endpoint_url='https://vpce-12345678.s3vectors.us-west-2.vpce.amazonaws.com'
)
```

Troubleshooting VPC endpoints

If you're experiencing issues with your interface VPC endpoint, consider the following troubleshooting steps:

- **DNS resolution:** Verify that DNS queries for the endpoint resolve to private IP addresses within your VPC CIDR range when using private DNS.
- **Security groups:** Ensure that the security group associated with the VPC endpoint allows inbound HTTPS traffic (port 443) from your VPC resources.
- **Route tables:** Verify that your subnet route tables don't have conflicting routes that might redirect traffic away from the VPC endpoint.
- **VPC endpoint policy:** Check that your VPC endpoint policy allows the necessary S3 Vectors actions and resources.
- **Client configuration:** If the private DNS feature is disabled, configure your S3 Vectors client to use the VPC endpoint DNS name instead of the service DNS name.

Monitoring VPC endpoint usage

You can monitor your S3 Vectors VPC endpoint usage through CloudTrail [NetworkActivity](#) events logs.

For more information about S3 Vectors logging, see [Logging with AWS CloudTrail for S3 Vectors](#).

Logging with AWS CloudTrail for S3 Vectors

Amazon S3 Vectors is integrated with AWS CloudTrail, a service that provides a record of actions that are taken by a user, role, or an AWS service. CloudTrail captures all API calls for S3 Vectors as events. Using the information that's collected by CloudTrail, you can determine the request that was made to S3 Vectors, the IP address from which the request was made, when it was made, and

additional details. When a supported event activity occurs in S3 Vectors, that activity is recorded in a CloudTrail event. You can use CloudTrail trail to log management events and data events for S3 Vectors.

To learn more about CloudTrail, see the [CloudTrail User Guide](#).

S3 Vectors information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in S3 Vectors, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for S3 Vectors, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see [Overview for Creating a Trail](#), [Configuring Amazon SNS Notifications for CloudTrail](#), [Receiving CloudTrail Log Files from Multiple Regions](#), and [Receiving CloudTrail Log Files from Multiple Accounts](#) in the *CloudTrail User Guide*.

All S3 Vectors API actions are logged by CloudTrail and are documented in the [Amazon S3 Vectors API Reference](#). For example, calls to the [CreateVectorBucket](#), [CreateIndex](#), and [QueryVectors](#) actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](#) in the *CloudTrail User Guide*.

CloudTrail management events for S3 Vectors

Management events provide information about management operations that are performed on resources in your AWS account. These are also known as control plane operations. By default, CloudTrail logs management events.

For S3 Vectors, CloudTrail logs the following management events:

- [CreateVectorBucket](#)
- [DeleteVectorBucket](#)
- [GetVectorBucket](#)
- [ListVectorBuckets](#)
- [PutVectorBucketPolicy](#)
- [GetVectorBucketPolicy](#)
- [DeleteVectorBucketPolicy](#)
- [CreateIndex](#)
- [DeleteIndex](#)
- [GetIndex](#)
- [ListIndexes](#)

The eventSource for S3 Vectors management events and data events is `s3vectors.amazonaws.com`.

For more information about management events, see [Logging management events](#) in the *CloudTrail User Guide*.

CloudTrail data events for S3 Vectors

Data events provide information about the resource operations performed on or in a resource. These are also known as data plane operations. By default, CloudTrail doesn't log data events. However, you can configure trails to log data events for S3 Vectors resources.

When you configure your trail to log data events, you can specify the S3 Vectors resource type. S3 Vectors supports the following resource types for data events:

- `AWS::S3Vectors::VectorBucket` – Logs data events for all vector indexes in the specified vector buckets

- `AWS::S3Vectors::Index` - Logs data events for specific vector indexes

For S3 Vectors, CloudTrail logs the following data events:

Vector data operations:

- [PutVectors](#) - Logs when vectors are added to a vector index
- [GetVectors](#) - Logs when vectors are retrieved from a vector index
- [DeleteVectors](#) - Logs when vectors are deleted from a vector index
- [ListVectors](#) - Logs when vectors in a vector index are listed
- [QueryVectors](#) - Logs when similarity queries are performed on a vector index

The eventSource for S3 Vectors data events is `s3vectors.amazonaws.com`.

Enabling data event logging for S3 Vectors

You can enable data event logging for S3 Vectors resources when you create or update a CloudTrail trail. You can specify logging for all vector buckets and vector indexes in your account, or you can specify individual vector buckets or vector indexes. For detailed steps about creating a trail, see [Creating a trail](#) in the *CloudTrail User Guide*.

To enable data event logging for all S3 Vectors resources:

- When creating or updating a trail, choose **Data events**.
- For **Resource type**, choose `AWS::S3Vectors::VectorBucket`.
- For **Resource ARN**, enter `arn:aws:s3vectors:_:_:bucket/*` to log events for all vector buckets, or specify individual vector bucket ARNs (for example, `arn:aws:s3vectors:us-east-1:123456789012:bucket/amzn-s3-demo-vector-bucket`).

To enable data event logging for specific vector indexes:

- When creating or updating a trail, choose **Data events**.
- For **Resource type**, choose `AWS::S3Vectors::Index`.
- For **Resource ARN**, enter the ARN of the specific vector index, such as:
`arn:aws:s3vectors:us-east-1:123456789012:bucket/amzn-s3-demo-vector-bucket/index/my-index`.

For more information about data events, see [Logging data events](#) in the *CloudTrail User Guide*.

}  
}
```

Understanding S3 Vectors log file entries

CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

S3 Vectors CloudTrail log entries contain the following key elements:

- **eventSource** - Always `s3vectors.amazonaws.com` for S3 Vectors events.
- **eventName** - The S3 Vectors API operation that was performed.
- **eventCategory** - Either Management for control plane operations or Data for data plane operations.
- **readOnly**: true for read operations (for examples, [GetVectors](#), [QueryVectors](#), [ListVectors](#)) and false for write operations ([PutVectors](#), [DeleteVectors](#)).
- **resources** - The S3 Vectors resources involved in the operation, including vector buckets and vector indexes.
- **requestParameters** - The parameters that were sent with the request.

- **responseElements** - The response elements returned by the S3 Vectors service.

Access control in Amazon S3

In AWS, a resource is an entity that you can work with. In Amazon Simple Storage Service (S3), *buckets* and *objects* are the original Amazon S3 resources. Every S3 customer likely has buckets with objects in them. As new features were added to S3, additional resources were also added, but not every customer uses these feature-specific resources. For more information about Amazon S3 resources, see [S3 resources](#).

By default, all Amazon S3 resources are private. Also by default, the root user of the AWS account that created the resource (resource owner) and IAM users within that account with the necessary permissions can access a resource that they created. The resource owner decides who else can access the resource and the actions that others are allowed to perform on the resource. S3 has various access management tools that you can use to grant others access to your S3 resources.

The following sections provide you with an overview of S3 resources, the S3 access management tools available, and the best use cases for each access management tool. The lists in these sections aim to be comprehensive and include all S3 resources, access management tools, and common access management use cases. At the same time, these sections are designed to be directories that lead you to the technical details you want. If you have a good understanding of some of the following topics, you can skip to the section that applies to you.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Topics

- [S3 resources](#)
- [Identities](#)
- [Access management tools](#)
- [Actions](#)
- [Access management use cases](#)
- [Access management troubleshooting](#)

S3 resources

The original Amazon S3 resources are buckets and the objects that they contain. As new features are added to S3, new resources are also added. The following is a complete list of S3 resources and their respective features.

Resource type	Amazon S3 feature	Description
bucket	Core features	A bucket is a container for objects. To store an object in S3, create a bucket and then upload one or more objects to the bucket. For more information, see Creating, configuring, and working with Amazon S3 general purpose buckets .
object		An object can be a file and any metadata that describes that file. When an object is in the bucket, you can open it, download it, and move it. For more information, see Working with objects in Amazon S3 .
accesspoint	Access Points	Access Points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 object operations, such as <code>GetObject</code> and <code>PutObject</code> . Each access point has distinct permissions, network controls, and a customized <i>access point policy</i> that works in conjunction with the bucket policy that is attached to the underlying bucket. You can configure any access point to accept requests only from a virtual private cloud (VPC) or configure custom block public access settings for each access point. For more information, see Managing access to shared datasets with access points .
objectlambdaaccesspoint		An Object Lambda Access Point is an access point for a bucket that is also associated with a Lambda function. With Object Lambda Access Point, you can add your own code to Amazon S3 GET, LIST, and HEAD requests to modify and process data as it's returned to an application.

Resource type	Amazon S3 feature	Description
		<p>For more information, see Creating Object Lambda Access Points.</p>
multiregionaccesspoint		<p>Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from Amazon S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, application requests made to a Multi-Region Access Point global endpoint automatically route through the AWS global network to the closest proximity Amazon S3 bucket. For more information, see Managing multi-Region traffic with Multi-Region Access Points.</p>
job	S3 Batch Operations	<p>A job is a resource of the S3 Batch Operations feature. You can use S3 Batch Operations to perform large-scale batch operations on lists of Amazon S3 objects that you specify. Amazon S3 tracks the progress of the batch operation job, sends notifications, and stores a detailed completion report of all actions, providing you with a fully managed, auditable, and serverless experience. For more information, see Performing object operations in bulk with Batch Operations.</p>

Resource type	Amazon S3 feature	Description
storageLensConfiguration	S3 Storage Lens	<p>An S3 Storage Lens configuration collects organization-wide storage metrics and user data across accounts. S3 Storage Lens provides admins with a single view of object storage usage and activity across hundreds, or even thousands, of accounts in an organization, with details to generate insights at multiple aggregation levels. For more information, see Monitoring your storage activity and usage with Amazon S3 Storage Lens.</p>
storageLensGroup		<p>An S3 Storage Lens group aggregates metrics by using custom filters based on object metadata. S3 Storage Lens groups help you investigate characteristics of your data, such as distribution of objects by age, your most common file types, and more. For more information, see Working with S3 Storage Lens groups to filter and aggregate metrics.</p>
accessGrantsInstance	S3 Access Grants	<p>An S3 Access Grants instance is a container for the S3 grants that you create. With S3 Access Grants, you can create grants to your Amazon S3 data for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants.</p>

Resource type	Amazon S3 feature	Description
accessgrantslocation		<p>An Access Grants Location is a bucket, prefix within a bucket, or an object that you register in your S3 Access Grants instance. You must register locations within the S3 Access Grants instance before you can create a grant to that location. Then, with S3 Access Grants, you can grant access to the bucket, prefix, or object for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants</p>
accessgrant		<p>An Access Grant is an individual grant to your Amazon S3 data. With S3 Access Grants, you can create grants to your Amazon S3 data for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants</p>

Buckets

There are two types of Amazon S3 buckets: *general purpose buckets* and *directory buckets*.

- **General purpose buckets** are the original S3 bucket type and are recommended for most use cases and access patterns. General purpose buckets also allow objects that are stored across all storage classes, except S3 Express One Zone. For more information about S3 storage classes, see [Understanding and managing Amazon S3 storage classes](#).
- **Directory buckets** use the S3 Express One Zone storage class, which is recommended if your application is performance-sensitive and benefits from single-digit millisecond PUT and GET latencies. For more information, see [Working with directory buckets](#), [S3 Express One Zone](#), and [Authorizing Regional endpoint API operations with IAM](#).

Categorizing S3 resources

Amazon S3 provides features to categorize and organize your S3 resources. Categorizing your resources is not only useful for organizing them, but you can also set access management rules based on the resource categories. In particular, prefixes and tagging are two storage organization features that you can use when setting access management permissions.

Note

The following information applies to general purpose buckets. Directory buckets do not support tagging, and they have prefix limitations. For more information, see [Authorizing Regional endpoint API operations with IAM](#).

- **Prefixes** — A prefix in Amazon S3 is a string of characters at the beginning of an object key name that's used to organize the objects that are stored in your S3 buckets. You can use a delimiter character, such as a forward slash (/), to indicate the end of the prefix within the object key name. For example, you might have object key names that start with the engineering/ prefix or object key names that start with the marketing/campaigns/ prefix. Using a delimiter at the end of your prefix, such as as a forward slash character / emulates folder and file naming conventions. However, in S3, the prefix is part of the object key name. In general purpose S3 buckets, there is no actual folder hierarchy.

Amazon S3 supports organizing and grouping objects by using their prefixes. You can also manage access to objects by their prefixes. For example, you can limit access to only the objects with names that start with a specific prefix.

For more information, see [Organizing objects using prefixes](#). S3 Console uses the concept of *folders*, which, in general purpose buckets, are essentially prefixes that are pre-pended to the object key name. For more information, see [Organizing objects in the Amazon S3 console by using folders](#).

- **Tags** — Each tag is a key-value pair that you assign to resources. For example, you can tag some resources with the tag topicCategory=engineering. You can use tagging to help with cost allocation, categorizing and organizing, and access control. Bucket tagging is only used for cost allocation. You can tag objects, S3 Storage Lens, jobs, and S3 Access Grants for the purposes of organizing or for access control. In S3 Access Grants, you can also use tagging for cost-allocation. As an example of controlling access to resources by using their tags, you can share only the objects that have a specific tag or a combination of tags.

For more information, see [Controlling access to AWS resources by using resource tags](#) in the *IAM User Guide*.

Identities

In Amazon S3, the resource owner is the identity that created the resource, such as a bucket or an object. By default, only the root user of the account that created the resource and IAM identities within the account that have the required permission can access the S3 resource. Resource owners can give other identities access to their S3 resources.

Identities that don't own a resource can request access to that resource. Requests to a resource are either authenticated or unauthenticated. Authenticated requests must include a signature value that authenticates the request sender, but unauthenticated requests do not require a signature. We recommend that you grant access only to authenticated users. For more information about request authentication, see [Making requests](#) in the *Amazon S3 API Reference*.

Important

We recommend that you don't use the AWS account root user credentials to make authenticated requests. Instead, create an IAM role and grant that role full access. We refer to users with this role as *administrator users*. You can use credentials assigned to the administrator role, instead of AWS account root user credentials, to interact with AWS and perform tasks, such as create a bucket, create users, and grant permissions. For more information, see [AWS account root user credentials and IAM user credentials](#) in the *AWS General Reference*, and see [Security best practices in IAM](#) in the *IAM User Guide*.

Identities accessing your data in Amazon S3 can be one of the following:

AWS account owner

The AWS account that created the resource. For example, the account that created the bucket. This account owns the resource. For more information, see [AWS account root user](#).

IAM identities in the same account of the AWS account owner

When setting up accounts for new team members who require S3 access, the AWS account owner can use AWS Identity and Access Management (IAM) to create [users](#), [groups](#), and [roles](#). The AWS

account owner can then share resources with these IAM identities. The account owner can also specify the permissions to give the IAM identities, which allow or deny the actions that can be performed on the shared resources.

IAM identities provide increased capabilities, including the ability to require users to enter login credentials before accessing shared resources. By using IAM identities, you can implement a form of IAM multi-factor authentication (MFA) to support a strong identity foundation. An IAM best practice is to create roles for access management instead of granting permissions to each individual user. You assign individual users to the appropriate role. For more information, see [Security best practices in IAM](#).

Other AWS account owners and their IAM identities (cross-account access)

The AWS account owner can also give other AWS account owners, or IAM identities that belong to another AWS account, access to resources.

Note

Permission delegation — If an AWS account owns a resource, it can grant those permissions to another AWS account. That account can then delegate those permissions, or a subset of them, to users in the same account. This is referred to as permission delegation. But an account that receives permissions from another account cannot delegate those permissions "cross-account" to another AWS account.

Anonymous users (public access)

The AWS account owner can make resources public. Making a resource public technically shares the resource with *the anonymous user*. Buckets created since April 2023 block all public access by default, unless you change this setting. We recommend that you set your buckets to block public access, and that you only grant access to authenticated users. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

AWS services

The resource owner can grant another AWS service access to an Amazon S3 resource. For example, you can grant the AWS CloudTrail service s3:PutObject permission to write log files to your bucket. For more information, see [Providing access to an AWS service](#).

Corporate directory identities

The resource owner can grant users or roles from your corporate directory access to an S3 resource by using [S3 Access Grants](#). For more information about adding your corporate directory to AWS IAM Identity Center, see [What is IAM Identity Center?](#).

Bucket or resource owners

The AWS account that you use to create buckets and upload objects owns those resources. A bucket owner can grant cross-account permissions to another AWS account (or users in another account) to upload objects.

When a bucket owner permits another account to upload objects to a bucket, the bucket owner, by default, owns all objects uploaded to their bucket. However, if both the *Bucket owner enforced* and *Bucket owner preferred* bucket settings are turned off, the AWS account that uploads the objects owns those objects, and the bucket owner does not have permissions on the objects owned by another account, with the following exceptions:

- The bucket owner pays the bills. The bucket owner can deny access to any objects, or delete any objects in the bucket, regardless of who owns them.
- The bucket owner can archive any objects or restore archived objects, regardless of who owns them. Archival refers to the storage class used to store the objects. For more information, see [Managing the lifecycle of objects](#).

Access management tools

Amazon S3 provides a variety of security features and tools. The following is a comprehensive list of these features and tools. You do not need all of these access management tools, but you must use one or more to grant access to your Amazon S3 resources. Proper application of these tools can help make sure that your resources are accessible only to the intended users.

The most commonly used access management tool is an *access policy*. An access policy can be a *resource-based policy* that is attached to an AWS resource, such as a bucket policy for a bucket. An access policy can also be an *identity-based policy* that is attached to an AWS Identity and Access Management (IAM) identity, such as an IAM user, group, or role. Write an access policy to grant AWS accounts and IAM users, groups, and roles permission to perform operations on a resource. For example, you can grant PUT Object permission to another AWS account so that the other account can upload objects to your bucket.

An access policy describes who has access to what things. When Amazon S3 receives a request, it must evaluate all of the access policies to determine whether to authorize or deny the request. For more information about how Amazon S3 evaluates these policies, see [How Amazon S3 authorizes a request](#).

The following are the access management tools available in Amazon S3.

Bucket policy

An Amazon S3 bucket policy is a JSON-formatted [AWS Identity and Access Management \(IAM\) resource-based policy](#) that is attached to a particular bucket. Use bucket policies to grant other AWS accounts or IAM identities permissions for the bucket and the objects in it. Many S3 access management use cases can be met by using a bucket policy. With bucket policies, you can personalize bucket access to help make sure that only the identities that you have approved can access resources and perform actions within them. For more information, see [Bucket policies for Amazon S3](#).

The following is an example bucket policy. You express the bucket policy by using a JSON file. This example policy grants an IAM role read permission to all objects in the bucket. It contains one statement named BucketLevelReadPermissions, which allows the s3:GetObject action (read permission) on objects in a bucket named amzn-s3-demo-bucket1. By specifying an IAM role as the Principal, this policy grants access to any IAM user with this role. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "BucketLevelReadPermissions",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789101:role/s3-role"  
            },  
            "Action": ["s3:GetObject"],  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/*"]  
        }  
    ]  
}
```

Note

When creating policies, avoid the use of wildcard characters (*) in the Principal element because using a wildcard character allows anyone to access your Amazon S3 resources. Instead, explicitly list users or groups that are allowed to access the bucket, or list conditions that must be met by using a condition clause in the policy. Also, rather than including a wildcard character for the actions of your users or groups, grant them specific permissions when applicable.

Identity-based policy

An identity-based or IAM user policy is a type of [AWS Identity and Access Management \(IAM\) policy](#). An identity-based policy is a JSON-formatted policy that is attached to IAM users, groups, or roles in your AWS account. You can use identity-based policies to grant an IAM identity access to your buckets or objects. You can create IAM users, groups, and roles in your account and attach access policies to them. You can then grant access to AWS resources, including Amazon S3 resources. For more information, see [Identity-based policies for Amazon S3](#).

The following is an example of an identity-based policy. The example policy allows the associated IAM role to perform six different Amazon S3 actions (permissions) on a bucket and the objects in it. If you attach this policy to an IAM role in your account and assign the role to some of your IAM users, the users with this role will be able to perform these actions on the resources (buckets) specified in your policy. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AssignARoleActions",  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject",  
                "s3:GetObject",  
                "s3>ListBucket",  
                "s3>DeleteObject",  
                "s3:DeleteObjectVersion",  
                "s3:PutObjectAcl"  
            ]  
        }  
    ]  
}
```

```
"s3:GetBucketLocation"
],
"Resource": [
"arn:aws:s3::::amzn-s3-demo-bucket/*",
"arn:aws:s3::::amzn-s3-demo-bucket"
]
},
{
"Sid": "AssignARoleActions2",
"Effect": "Allow",
"Action": "s3>ListAllMyBuckets",
"Resource": "*"
}
]
}
```

S3 Access Grants

Use S3 Access Grants to create access grants to your Amazon S3 data for both identities in corporate identity directories, such as Active Directory, and to AWS Identity and Access Management (IAM) identities. S3 Access Grants helps you manage data permissions at scale. Additionally, S3 Access Grants logs end-user identity and the application used to access the S3 data in AWS CloudTrail. This provides a detailed audit history down to the end-user identity for all access to the data in your S3 buckets. For more information, see [Managing access with S3 Access Grants](#).

Access Points

Amazon S3 Access Points simplifies managing data access at scale for applications that use shared datasets on S3. Access Points are named network endpoints that are attached to a bucket. You can use access points to perform S3 object operations at scale, such as uploading and retrieving objects. A bucket can have up to 10,000 access points attached, and for each access point, you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. S3 Access Points can be associated with buckets in the same account or in another trusted account. Access Points policies are resource-based policies that are evaluated in conjunction with the underlying bucket policy. For more information, see [Managing access to shared datasets with access points](#).

Access control list (ACL)

An ACL is a list of grants identifying the grantee and the permission granted. ACLs grant basic read or write permissions to other AWS accounts. ACLs use an Amazon S3–specific XML schema. An ACL is a type of [AWS Identity and Access Management \(IAM\) policy](#). An object ACL is used to manage access to an object, and a bucket ACL is used to manage access to a bucket. With bucket policies, there is a single policy for the entire bucket, but object ACLs are specified for each object. We recommend that you keep ACLs turned off, except in circumstances where you must individually control access for each object. For more information about using ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Warning

The majority of modern use cases in Amazon S3 do not require the use of ACLs.

The following is an example bucket ACL. The grant in the ACL shows a bucket owner that has full control permission.

```
<?xml version="1.0" encoding="UTF-8"?>
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>Owner-Canonical-User-ID</ID>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="CanonicalUser">
        <ID>Owner-Canonical-User-ID</ID>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
</AccessControlPolicy>
```

Object Ownership

To manage access to your objects, you must be the owner of the object. You can use the Object Ownership bucket-level setting to control ownership of objects uploaded to your bucket. Also, use Object Ownership to turn on ACLs. By default, Object Ownership is set to the *Bucket owner*

enforced setting and all ACLs are turned off. When ACLs are turned off, the bucket owner owns all of the objects in the bucket and exclusively manages access to data. To manage access, the bucket owner uses policies or another access management tool, excluding ACLs. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Object Ownership has three settings that you can use both to control ownership of objects that are uploaded to your bucket and to turn on ACLs:

ACLs turned off

- **Bucket owner enforced (default)** – ACLs are turned off, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs do not affect permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

ACLs turned on

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the bucket-owner-full-control canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Additional best practices

Consider using the following bucket settings and tools to help protect data in transit and at rest, both of which are crucial in maintaining the integrity and accessibility of your data:

- **Block Public Access** — Do not turn off the default bucket-level setting *Block Public Access*. This setting blocks public access to your data by default. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).
- **S3 Versioning** — For data integrity, you can implement the S3 Versioning bucket setting, which versions your objects as you make updates, instead of overwriting them. You can use S3 Versioning to preserve, retrieve, and restore a previous version, if needed. For information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).
- **S3 Object Lock** — S3 Object Lock is another setting that you can implement for achieving data integrity. This feature can implement a write-once-read-many (WORM) model to store objects immutably. For information about Object Lock, see [Locking objects with Object Lock](#).

- **Object encryption** — Amazon S3 offers several object encryption options that protect data in transit and at rest. *Server-side encryption* encrypts your object before saving it on disks in its data centers and then decrypts it when you download the objects. If you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted objects. For more information, see [Protecting data with server-side encryption](#). S3 encrypts newly uploaded objects by default. For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). *Client-side encryption* is the act of encrypting data before sending it to Amazon S3. For more information, see [Protecting data by using client-side encryption](#).
- **Signing methods** — Signature Version 4 is the process of adding authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) and [Signature Version 4 signing process](#).

Actions

For a complete list of S3 permissions and condition keys, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Actions

The AWS Identity and Access Management (IAM) actions for Amazon S3 are the possible actions that can be performed on an S3 bucket or object. You grant these actions to identities so they can act on your S3 resources. Examples of S3 actions are `s3:GetObject` to read objects in a bucket, and `s3:PutObject` to write objects to a bucket.

Condition keys

In addition to actions, IAM condition keys are limited to granting access to only when a condition is met. Condition keys are optional.

Note

In a resource-based access policy, such as a bucket policy, or in an identity-based policy, you can specify the following:

- An action or an array of actions in the Action element of the policy statement.
- In the Effect element of the policy statement, you can specify Allow to grant the actions listed, or you can specify Deny to block the listed actions. To further maintain the practice of least privileges, Deny statements in the Effect element of the access policy should be as broad as possible, and Allow statements should be as narrow as possible. Deny effects paired with the s3: * action are another good way to implement opt-in best practices for the identities that are included in policy condition statements.
- A condition key in the Condition element of a policy statement.

Access management use cases

Amazon S3 provides resource owners with a variety of tools for granting access. The S3 access management tool that you use depends on the S3 resources that you want to share, the identities that you are granting access to, and the actions that you want to allow or deny. You might want to use one or a combination of S3 access management tools to manage access to your S3 resources.

In most cases, you can use an access policy to manage permissions. An access policy can be a resource-based policy, which is attached to a resource, such as a bucket, or another Amazon S3 resource ([S3 resources](#)). An access policy can also be an identity-based policy, which is attached to an AWS Identity and Access Management (IAM) user, group, or role in your account. You might find that a bucket policy works better for your use case. For more information, see [Bucket policies for Amazon S3](#). Alternatively, with AWS Identity and Access Management (IAM), you can create IAM users, groups, and roles within your AWS account and manage their access to buckets and objects through identity-based policies. For more information, see [Identity-based policies for Amazon S3](#).

To help you navigate these access management options, the following are common Amazon S3 customer use cases and recommendations for each of the S3 access management tools.

The AWS account owner wants to share buckets only with users within the same account

All access management tools can fulfill this basic use case. We recommend the following access management tools for this use case:

- **Bucket policy** – If you want to grant access to one bucket or a small number of buckets, or if your bucket access permissions are similar from bucket to bucket, use a bucket policy. With bucket policies, you manage one policy for each bucket. For more information, see [Bucket policies for Amazon S3](#).
- **Identity-based policy** – If you have a very large number of buckets with different access permissions for each bucket, and only a few user roles to manage, you can use an IAM policy for users, groups, or roles. IAM policies are also a good option if you are managing user access to other AWS resources, as well as Amazon S3 resources. For more information, see [Example 1: Bucket owner granting its users bucket permissions](#).
- **S3 Access Grants** – You can use S3 Access Grants to grant access to your S3 buckets, prefixes, or objects. S3 Access Grants allows you to specify varying object-level permissions at scale; whereas, bucket policies are limited to 20 KB in size. For more information, see [Getting started with S3 Access Grants](#).
- **Access Points** – You can use Access Points, which are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see [Managing access to shared datasets with access points](#).

The AWS account owner wants to share buckets or objects with users from another AWS account (cross-account)

To grant permission to another AWS account, you must use a bucket policy or one of the following recommended access management tools. You cannot use an identity-based access policy for this use case. For more information about granting cross-account access, see [How do I provide cross-account access to objects that are in Amazon S3 buckets?](#)

We recommend the following access management tools for this use case:

- **Bucket policy** – With bucket policies, you manage one policy for each bucket. For more information, see [Bucket policies for Amazon S3](#).

- **S3 Access Grants** – You can use S3 Access Grants to grant cross-account permissions to your S3 buckets, prefixes, or objects. You can use S3 Access Grants to specify varying object-level permissions at scale; whereas, bucket policies are limited to 20 KB in size. For more information, see [Getting started with S3 Access Grants](#).
- **Access Points** – You can use Access Points, which are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see [Managing access to shared datasets with access points](#).

The AWS account owner or bucket owner must grant permissions at the object-level or prefix-level, and these permissions vary from object to object or prefix to prefix

In a bucket policy, for example, you can grant access to the objects within a bucket that share a specific [key name prefix](#) or have a specific tag. You can grant read permission on objects starting with the key name prefix logs/. However, if your access permissions vary by object, granting permissions to individual objects by using a bucket policy might not be practical, especially since bucket policies are limited to 20 KB in size.

We recommend the following access management tools for this use case:

- **S3 Access Grants** – You can use S3 Access Grants to manage object-level or prefix-level permissions. Unlike bucket policies, you can use S3 Access Grants to specify varying object-level permissions at scale. Bucket policies are limited to 20 KB in size. For more information, see [Getting started with S3 Access Grants](#).
- **Access Points** – You can use access points to manage object-level or prefix-level permissions. Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see [Managing access to shared datasets with access points](#).
- **ACLs** – We do not recommend using Access Control Lists (ACLs), especially because ACLs are limited to 100 grants per object. However, if you choose to turn on ACLs, in your Bucket Settings, set *Object Ownership* to *Bucket owner preferred* and *ACLs enabled*. With this setting, new objects that are written with the *bucket-owner-full-control* canned ACL are automatically owned by the bucket owner rather than the object writer. You can then use object ACLs, which is an

XML-formatted access policy, to grant other users access to the object. For more information, see [Access control list \(ACL\) overview](#).

The AWS account owner or bucket owner wants to limit bucket access only to specific account IDs

We recommend the following access management tools for this use case:

- **Bucket policy** – With bucket policies, you manage one policy for each bucket. For more information, see [Bucket policies for Amazon S3](#).
- **Access Points** – Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see [Managing access to shared datasets with access points](#).

The AWS account owner or bucket owner wants distinct endpoints for every user or application that accesses their data

We recommend the following access management tool for this use case:

- **Access Points** – Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For more information, see [Managing access to shared datasets with access points](#).

The AWS account owner or bucket owner must manage access from Virtual Private Cloud (VPC) endpoints for S3

Virtual Private Cloud (VPC) endpoints for Amazon S3 are logical entities within a VPC that allow connectivity only to S3. We recommend the following access management tools for this use case:

- **Buckets in a VPC setting** – You can use a bucket policy to control who is allowed to access your buckets and which VPC endpoints they can access. For more information, see [Controlling access from VPC endpoints with bucket policies](#).

- **Access Points** – If you choose to set up access points, you can use an access point policy. You can configure any access point to accept requests only from a virtual private cloud (VPC) to restrict Amazon S3 data access to a private network. You can also configure custom block public access settings for each access point. For more information, see [Managing access to shared datasets with access points](#).

The AWS account owner or bucket owner must make a static website publicly available

With S3, you can host a static website and allow anyone to view the content of the website, which is hosted from an S3 bucket.

We recommend the following access management tools for this use case:

- **Amazon CloudFront** – This solution allows you to host an Amazon S3 static website to the public while also continuing to block all public access to a bucket's content. If you want to keep all four S3 Block Public Access settings enabled and host an S3 static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Also, Amazon S3 static websites that do not use this solution can only support HTTP endpoints. CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks.

For more information, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

- **Making your Amazon S3 bucket publicly accessible** – You can configure a bucket to be used as a publicly accessed static website.

Warning

We do not recommend this method. Instead, we recommend you use Amazon S3 static websites as a part of Amazon CloudFront. For more information, see the previous option, or see [Getting started with a secure static website](#).

To create an Amazon S3 static website, without Amazon CloudFront, first, you must turn off all Block Public Access settings. When writing the bucket policy for your static website, make sure that you allow only s3:GetObject actions, not ListObject or PutObject permissions. This

helps make sure that users cannot view all the objects in your bucket or add their own content. For more information, see [Setting permissions for website access](#).

The AWS account owner or bucket owner wants to make the content of a bucket publicly available

When creating a new Amazon S3 bucket, the *Block Public Access* setting is enabled by default. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

We do not recommend allowing public access to your bucket. However, if you must do so for a particular use case, we recommend the following access management tool for this use case:

- **Disable Block Public Access setting** – A bucket owner can allow unauthenticated requests to the bucket. For example, unauthenticated [PUT Object](#) requests are allowed when a bucket has a public bucket policy, or when a bucket ACL grants public access. All unauthenticated requests are made by other arbitrary AWS users, or even unauthenticated, anonymous users. This user is represented in ACLs by the specific canonical user ID 65a011a29cdf8ec533ec3d1ccaae921c. If an object is uploaded to a WRITE or FULL_CONTROL, then this specifically grants access to the All Users group or the anonymous user. For more information about public bucket policies and public access control lists (ACLs), see [The meaning of "public"](#).

The AWS account owner or bucket owner has exceeded access policy size limits

Both bucket policies and identity-based policies have a 20 KB size limit. If your access permission requirements are complex, you might exceed this size limit.

We recommended the following access management tools for this use case:

- **Access Points** – Use access points if this works with your use case. With access points, each bucket has multiple named network endpoints, each with its own access point policy that works with the underlying bucket policy. However, access points can only act on objects, not buckets, and does not support cross-Region replication. For more information, see [Managing access to shared datasets with access points](#).
- **S3 Access Grants** – Use S3 Access Grants, which supports a very large number of grants that give access to buckets, prefixes, or objects. For more information, see [Getting started with S3 Access Grants](#).

The AWS account owner or admin role wants to grant bucket, prefix, or object access directly to users or groups in a corporate directory

Instead of managing users, groups, and roles through AWS Identity and Access Management (IAM), you can add your corporate directory to AWS IAM Identity Center. For more information, see [What is IAM Identity Center?](#)

After you add your corporate directory to AWS IAM Identity Center, we recommend that you use the following access management tool to grant corporate directory identities access to your S3 resources:

- **S3 Access Grants** – Use S3 Access Grants, which supports granting access to users or roles in your corporate directory. For more information, see [Getting started with S3 Access Grants](#).

The AWS account owner or bucket owner wants to give the AWS CloudFront service access to write CloudFront logs to an S3 bucket

We recommended the following access management tool for this use case:

- **Bucket ACL** – The only recommended use case for bucket ACLs is to grant permissions to certain AWS services, such as the Amazon CloudFront awslogsdelivery account. When you create or update a distribution and turn on CloudFront logging, CloudFront updates the bucket ACL to give the awslogsdelivery account FULL_CONTROL permissions to write logs to your bucket. For more information, see [Permissions required to configure standard logging and to access your log files](#) in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the *Bucket owner enforced* setting for S3 Object Ownership to turn off ACLs, CloudFront cannot write logs to the bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

You, as the bucket owner, want to maintain full control of objects that are added to the bucket by other users

You can grant other accounts access to upload objects to your bucket by using a bucket policy, access point, or S3 Access Grants. If you have granted cross-account access to your bucket, you can make sure that any objects uploaded to your bucket remain under your full control.

We recommended the following access management tool for this use case:

- **Object Ownership** – Keep the bucket-level setting *Object Ownership* at the default *Bucket owner enforced* setting.

Access management troubleshooting

The following resources can help you troubleshoot any issues with S3 access management:

Troubleshooting Access Denied (403 Forbidden) errors

If you encounter access denial issues, check the account-level and bucket-level settings. Also, check the access management feature that you are using to grant access to make sure that the policy, setting, or configuration is correct. For more information about common causes of Access Denied (403 Forbidden) errors in Amazon S3, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#).

IAM Access Analyzer for S3

If you do not want to make any of your resources publicly available, or if you want to limit public access to your resources, you can use IAM Access Analyzer for S3. On the Amazon S3 console, use IAM Access Analyzer for S3 to review all buckets that have bucket access control lists (ACLs), bucket policies, or access point policies that grant public or shared access. IAM Access Analyzer for S3 alerts you to buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings that report the source and level of public or shared access.

In IAM Access Analyzer for S3, you can block all public access to a bucket with a single action. We recommend that you block all public access to your buckets, unless you require public access to support a specific use case. Before you block all public access, make sure that your applications will continue to work correctly without public access. For more information, see [Blocking public access to your Amazon S3 storage](#).

You can also review your bucket-level permission settings to configure detailed levels of access. For specific and verified use cases that require public or shared access, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket. You can revisit and modify these bucket configurations at any time. You can also download your findings as a CSV report for auditing purposes.

IAM Access Analyzer for S3 is available at no extra cost on the Amazon S3 console. IAM Access Analyzer for S3 is powered by AWS Identity and Access Management (IAM) IAM Access Analyzer.

To use IAM Access Analyzer for S3 on the Amazon S3 console, you must visit the [IAM Console](#) and create an account-level analyzer in IAM Access Analyzer for each individual Region.

For more information about IAM Access Analyzer for S3, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

Logging and monitoring

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon S3 solutions so that you can more easily debug an access failure. Logging can provide insight into any errors users are receiving, and when and what requests are made. AWS provides several tools for monitoring your Amazon S3 resources, such as the following:

- AWS CloudTrail
- Amazon S3 Access Logs
- AWS Trusted Advisor
- Amazon CloudWatch

For more information, see [Logging and monitoring in Amazon S3](#).

Identity and Access Management for Amazon S3

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon S3 resources. IAM is an AWS service that you can use with no additional charge.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How Amazon S3 works with IAM](#)
- [How Amazon S3 authorizes a request](#)
- [Required permissions for Amazon S3 API operations](#)
- [Policies and permissions in Amazon S3](#)
- [Bucket policies for Amazon S3](#)
- [Identity-based policies for Amazon S3](#)
- [Walkthroughs that use policies to manage access to your Amazon S3 resources](#)
- [Using service-linked roles for Amazon S3 Storage Lens](#)
- [Troubleshooting Amazon S3 identity and access](#)
- [AWS managed policies for Amazon S3](#)

Audience

How you use AWS Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see [Troubleshooting Amazon S3 identity and access](#))
- **Service administrator** - determine user access and submit permission requests (see [How Amazon S3 works with IAM](#))
- **IAM administrator** - write policies to manage access (see [Identity-based policies for Amazon S3](#))

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see [How to sign in to your AWS account](#) in the [AWS Sign-In User Guide](#).

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see [AWS Signature Version 4 for API requests](#) in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An [*IAM user*](#) is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see [Require human users to use federation with an identity provider to access AWS using temporary credentials](#) in the *IAM User Guide*.

An [*IAM group*](#) specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see [Use cases for IAM users](#) in the *IAM User Guide*.

IAM roles

An [*IAM role*](#) is an identity with specific permissions that provides temporary credentials. You can assume a role by [switching from a user to an IAM role \(console\)](#) or by calling an AWS CLI or AWS API operation. For more information, see [Methods to assume a role](#) in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see [Choose between managed policies and inline policies](#) in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must [specify a principal](#) in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see [Service control policies](#) in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see [Resource control policies \(RCPs\)](#) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see [Session policies](#) in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

How Amazon S3 works with IAM

Before you use IAM to manage access to Amazon S3, learn what IAM features are available to use with Amazon S3.

IAM features you can use with Amazon S3

IAM feature	Amazon S3 support
Identity-based policies	Yes
Resource-based policies	Yes
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	Yes

IAM feature	Amazon S3 support
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Forward access sessions (FAS)	Yes
Service roles	Yes
Service-linked roles	Partial

To get a high-level view of how Amazon S3 and other AWS services work with most IAM features, see [AWS services that work with IAM](#) in the *IAM User Guide*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Identity-based policies for Amazon S3

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

Identity-based policy examples for Amazon S3

To view examples of Amazon S3 identity-based policies, see [Identity-based policies for Amazon S3](#).

Resource-based policies within Amazon S3

Supports resource-based policies: Yes

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that

support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

The Amazon S3 service supports *bucket policies*, *access points policies*, and *access grants*:

- Bucket policies are resource-based policies that are attached to an Amazon S3 bucket. A bucket policy defines which principals can perform actions on the bucket.
- Access point policies are resource-based policies that are evaluated in conjunction with the underlying bucket policy.
- Access grants are a simplified model for defining access permissions to data in Amazon S3 by prefix, bucket, or object. For information about S3 Access Grants, see [Managing access with S3 Access Grants](#).

Principals for bucket policies

The `Principal` element specifies the user, account, service, or other entity that is either allowed or denied access to a resource. The following are examples of specifying `Principal`. For more information, see [Principal](#) in the *IAM User Guide*.

Grant permissions to an AWS account

To grant permissions to an AWS account, identify the account using the following format.

```
"AWS": "account-ARN"
```

The following are examples.

```
"Principal": {"AWS": "arn:aws:iam::AccountIDWithoutHyphens:root"}
```

```
"Principal": {"AWS": ["arn:aws:iam::AccountID1WithoutHyphens:root", "arn:aws:iam::AccountID2WithoutHyphens:root"]}}
```

Note

The examples above grant permissions to the root user, which delegates permissions to the account level. However, IAM policies are still required on the specific roles and users in the account.

Grant permissions to an IAM user

To grant permission to an IAM user within your account, you must provide an "AWS" :"*user-ARN*" name-value pair.

```
"Principal": {"AWS": "arn:aws:iam::account-number-without-hyphens:user/username"}}
```

For detailed examples that provide step-by-step instructions, see [Example 1: Bucket owner granting its users bucket permissions](#) and [Example 3: Bucket owner granting permissions to objects it does not own](#).

Note

If an IAM identity is deleted after you update your bucket policy, the bucket policy will show a unique identifier in the principal element instead of an ARN. These unique IDs are never reused, so you can safely remove principals with unique identifiers from all of your policy statements. For more information about unique identifiers, see [IAM identifiers](#) in the *IAM User Guide*.

Grant anonymous permissions

Warning

Use caution when granting anonymous access to your Amazon S3 bucket. When you grant anonymous access, anyone in the world can access your bucket. We highly recommend that you never grant any kind of anonymous write access to your S3 bucket.

To grant permission to everyone, also referred as anonymous access, you set the wildcard ("*") as the Principal value. For example, if you configure your bucket as a website, you want all the objects in the bucket to be publicly accessible.

"Principal": "*"

```
"Principal": {"AWS": "*"}  
}
```

Using "Principal": "*" with an Allow effect in a resource-based policy allows anyone, even if they're not signed in to AWS, to access your resource.

Using "Principal" : { "AWS" : "*" } with an Allow effect in a resource-based policy allows any root user, IAM user, assumed-role session, or federated user in any account in the same partition to access your resource.

For anonymous users, these two methods are equivalent. For more information, see [All principals](#) in the *IAM User Guide*.

You cannot use a wildcard to match part of a principal name or ARN.

⚠️ Important

In AWS access control policies, the Principals "*" and {"AWS": "*"} behave identically.

Restrict resource permissions

You can also use resource policy to restrict access to resources that would otherwise be available to IAM principals. Use a Deny statement to prevent access.

The following example blocks access if a secure transport protocol isn't used:

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "DenyBucketAccessIfSTPNotUsed",  
      "Effect": "Deny",  
      "Principal": "*",  
      "Action": "s3:*",  
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",  
      "Condition": {"StringLike": {"aws:SourceVPC": "10.0.0.0/16"},  
        "StringNotLike": {"aws:SourcePrefix": "10.0.0.0/16"}},  
      "NotAction": "s3:GetObject",  
      "NotResource": "arn:aws:s3:::amzn-s3-demo-bucket/*"  
    }  
  ]  
}
```

```
"Condition": {  
    "Bool": {  
        "aws:SecureTransport": "false"  
    }  
}  
}  
]  
}
```

Using "Principal": "*" so that this restriction applies to everyone is a best practice for this policy, instead of attempting to deny access only to specific accounts or principals using this method.

Require access through CloudFront URLs

You can require that your users access your Amazon S3 content only by using CloudFront URLs instead of Amazon S3 URLs. To do this, create a CloudFront origin access control (OAC). Then, change the permissions on your S3 data. In your bucket policy, you can set CloudFront as the Principal as follows:

```
"Principal": {"Service": "cloudfront.amazonaws.com"}
```

Use a Condition element in the policy to allow CloudFront to access the bucket only when the request is on behalf of the CloudFront distribution that contains the S3 origin.

```
"Condition": {  
    "StringEquals": {  
        "AWS:SourceArn":  
            "arn:aws:cloudfront::111122223333:distribution/CloudFront-distribution-ID"  
    }  
}
```

For more information about requiring S3 access through CloudFront URLs, see [Restricting access to an Amazon Simple Storage Service origin](#) in the *Amazon CloudFront Developer Guide*. For more information about the security and privacy benefits of using Amazon CloudFront, see [Configuring secure access and restricting access to content](#).

Resource-based policy examples for Amazon S3

- To view policy examples for Amazon S3 buckets, see [Bucket policies for Amazon S3](#).
- To view policy examples for access points, see [Configuring IAM policies for using access points](#).

Policy actions for Amazon S3

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

The following shows different types of mapping relationship between S3 API operations and the required policy actions.

- One-to-one mapping with the same name. For example, to use the PutBucketPolicy API operation, the s3:PutBucketPolicy policy action is required.
- One-to-one mapping with different names. For example, to use the ListObjectsV2 API operation, the s3>ListBucket policy action is required.
- One-to-many mapping. For example, to use the HeadObject API operation, the s3:GetObject is required. Also, when you use S3 Object Lock and want to get an object's Legal Hold status or retention settings, the corresponding s3:GetObjectLegalHold or s3:GetObjectRetention policy actions are also required before you can use the HeadObject API operation.
- Many-to-one mapping. For example, to use the ListObjectsV2 or HeadBucket API operations, the s3>ListBucket policy action is required.

To see a list of Amazon S3 actions for use in policies, see [Actions defined by Amazon S3](#) in the *Service Authorization Reference*. For a complete list of Amazon S3 API operations, see [Amazon S3 API Actions](#) in the *Amazon Simple Storage Service API Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Policy actions in Amazon S3 use the following prefix before the action:

```
s3
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [  
    "s3:action1",  
    "s3:action2"  
]
```

Bucket operations

Bucket operations are S3 API operations that operate on the bucket resource type. For example, CreateBucket, ListObjectsV2, and PutBucketPolicy. S3 policy actions for bucket operations require the Resource element in bucket policies or IAM identity-based policies to be the S3 bucket type Amazon Resource Name (ARN) identifier in the following example format.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
```

The following bucket policy grants the user *Akua* with account *12345678901* the s3>ListBucket permission to perform the [ListObjectsV2](#) API operation and list objects in an S3 bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Allow Akua to list objects in the bucket",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Akua"  
            },  
            "Action": [  
                "s3>ListBucket"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"  
        }  
    ]  
}
```

```
    }
]
}
```

Bucket operations in policies for access points for general purpose buckets

Permissions granted in an access point for general purpose buckets policy are effective only if the underlying bucket allows the same permissions. When you use S3 Access Points, you must delegate access control from the bucket to the access point or add the same permissions in the access point policies to the underlying bucket's policy. For more information, see [Configuring IAM policies for using access points](#). In access point policies, S3 policy actions for bucket operations require you to use the access point ARN for the Resource element in the following format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point"
```

The following access point policy grants the user *Akua* with account *12345678901* the s3>ListBucket permission to perform the [ListObjectsV2](#) API operation through the S3 access point named *example-access-point*. This permission allows *Akua* to list the objects in the bucket that's associated with *example-access-point*.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAkuaToListObjectsInBucketThroughAccessPoint",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:user/Akua"
      },
      "Action": [
        "s3>ListBucket"
      ],
      "Resource": "arn:aws:s3:us-west-2:111122223333:accesspoint/example-access-point"
    }
  ]
}
```

Note

Not all bucket operations are supported by access points for general purpose buckets. For more information, see [Access points compatibility with S3 operations](#).

Bucket operations in policies for access points for directory buckets

Permissions granted in an access points for directory buckets policy are effective only if the underlying bucket allows the same permissions. When you use S3 Access Points, you must delegate access control from the bucket to the access point or add the same permissions in the access point policies to the underlying bucket's policy. For more information, see [Configuring IAM policies for using access points for directory buckets](#). In access point policies, S3 policy actions for bucket operations require you to use the access point ARN for the Resource element in the following format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point--usw2-az1--xa-s3"
```

The following access point policy grants the user *Akua* with account *12345678901* the s3:ListBucket permission to perform the [ListObjectsV2](#) API operation through the access point named *example-access-point--usw2-az1--xa-s3*. This permission allows *Akua* to list the objects in the bucket that's associated with *example-access-point--usw2-az1--xa-s3*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAkuaToListObjectsInTheBucketThroughAccessPoint",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Akua"  
            },  
            "Action": [  
                "s3>ListBucket"  
            ],  
            "Resource": "arn:aws:s3express:us-east-1:111122223333:accesspoint/  
example-access-point-usw2-az1-xa-s3"
```

```
    }  
]  
}
```

Note

Not all bucket operations are supported by access points for directory buckets. For more information, see [Object operations for access points for directory buckets](#).

Object operations

Object operations are S3 API operations that act upon the object resource type. For example, GetObject, PutObject, and DeleteObject. S3 policy actions for object operations require the Resource element in policies to be the S3 object ARN in the following example formats.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
```

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/*"
```

Note

The object ARN must contain a forward slash after the bucket name, as seen in the previous examples.

The following bucket policy grants the user **Akua** with account **12345678901** the s3:PutObject permission. This permission allows **Akua** to use the [PutObject](#) API operation to upload objects to the S3 bucket named **amzn-s3-demo-bucket**.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Allow Akua to upload objects",
```

```
        "Effect": "Allow",
        "Principal": [
            "AWS": "arn:aws:iam::111122223333:user/Akua"
        ],
        "Action": [
            "s3:PutObject"
        ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
    }
]
```

Object operations in access point policies

When you use S3 Access Points to control access to object operations, you can use access point policies. When you use access point policies, S3 policy actions for object operations require you to use the access point ARN for the Resource element in the following format: `arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource`. For object operations that use access points, you must include the /object/ value after the whole access point ARN in the Resource element. Here are some examples.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point/object/*
"
```

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point/
object/prefix/*"
```

The following access point policy grants the user *Akua* with account *12345678901* the `s3:GetObject` permission. This permission allows *Akua* to perform the [GetObject](#) API operation through the access point named *example-access-point* on all objects in the bucket that's associated with the access point.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to get objects through access point",
"
```

```
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::111122223333:user/Akua"
        },
        "Action": [
            "s3:GetObject"
        ],
        "Resource": "arn:aws:s3:us-east-1:111122223333:accesspoint/example-
access-point/object/*"
    }
]
```

Note

Not all object operations are supported by access points. For more information, see [Access points compatibility with S3 operations](#).

Object operations in policies for access points for directory buckets

When you use access points for directory buckets to control access to object operations, you can use access point policies. When you use access point policies, S3 policy actions for object operations require you to use the access point ARN for the Resource element in the following format: `arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource`. For object operations that use access points, you must include the /object/ value after the whole access point ARN in the Resource element. Here are some examples.

```
"Resource": "arn:aws:s3express:us-west-2:123456789012:accesspoint/example-access-
point--usw2-az1--xa-s3/object/*"
```

```
"Resource": "arn:aws:s3express:us-west-2:123456789012:accesspoint/example-access-
point--usw2-az1--xa-s3/object/prefix/*"
```

The following access point policy grants the user *Akua* with account *12345678901* the s3:GetObject permission. This permission allows *Akua* to perform the [GetObject](#) API operation through the access point named *example-access-point--usw2-az1--xa-s3* on all objects in the bucket that's associated with the access point.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Allow Akua to get objects through access point",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::12345678901:user/Akua"  
            },  
            "Action": "s3express>CreateSession", "s3:GetObject"  
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point--usw2-az1--xa-s3/object/*"  
        }  
    ]  
}
```

Note

Not all object operations are supported by access points for directory buckets. For more information, see [Object operations for access points for directory buckets](#).

Access point for general purpose bucket operations

Access point operations are S3 API operations that operate on the `accesspoint` resource type. For example, `CreateAccessPoint`, `DeleteAccessPoint`, and `GetAccessPointPolicy`. S3 policy actions for access point operations can only be used in IAM identity-based policies, not in bucket policies or access point policies. Access points operations require the `Resource` element to be the access point ARN in the following example format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point"
```

The following IAM identity-based policy grants the `s3:GetAccessPointPolicy` permission to perform the [GetAccessPointPolicy](#) API operation on the S3 access point named `example-access-point`.

JSON

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Sid": "GrantPermissionToRetrieveTheAccessPointPolicyOfAccessPointExampleAccessPoint",
        "Effect": "Allow",
        "Action": [
            "s3:GetAccessPointPolicy"
        ],
        "Resource": "arn:aws:s3:::123456789012:accesspoint/example-access-point"
    }
]
```

When you use Access Points, to control access to bucket operations, see [Bucket operations in policies for access points for general purpose buckets](#); to control access to object operations, see [Object operations in access point policies](#). For more information about how to configure access point policies, see [Configuring IAM policies for using access points](#).

Access point for directory buckets operations

Access point for directory buckets operations are S3 API operations that operate on the accesspoint resource type. For example, CreateAccessPoint, DeleteAccessPoint, and GetAccessPointPolicy. S3 policy actions for access point operations can only be used in IAM identity-based policies, not in bucket policies or access point policies. Access points for directory buckets operations require the Resource element to be the access point ARN in the following example format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point--usw2-az1--xa-s3"
```

The following IAM identity-based policy grants the s3express:GetAccessPointPolicy permission to perform the [GetAccessPointPolicy](#) API operation on the access point named **example-access-point--usw2-az1--xa-s3**.

JSON

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Sid": "GrantPermissionToRetrieveTheAccessPointPolicyOfAccessPointExampleAccessPointUsw2Az1XaS3",
        "Effect": "Allow",
        "Action": [
            "s3express:CreateSession", "s3express:GetAccessPointPolicy"
        ],
        "Resource": "arn:aws:s3:::111122223333:accesspoint/example-access-point"
    }
]
```

The following IAM identity-based policy grants the s3express:CreateAccessPoint permission to create an access points for directory buckets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Grant CreateAccessPoint.",
            "Principal": "*",
            "Action": "s3express:CreateSession",
            "s3express:CreateAccessPoint": "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

The following IAM identity-based policy grants the s3express:PutAccessPointScope permission to create access point scope for access points for directory buckets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Grant PutAccessPointScope",

```

```
        "Principal": "*",
        "Action": "s3express>CreateSession",
        "s3express>CreateAccessPoint",
        "S3Express:PutAccessPointScope""Effect": "Allow",
        "Resource": "*",
    }
]
}
```

When you use access points for directory buckets to control access to bucket operations, see [Bucket operations in policies for access points for directory buckets](#); to control access to object operations, see [Object operations in policies for access points for directory buckets](#). For more information about how to configure access points for directory buckets policies, see [Configuring IAM policies for using access points for directory buckets](#).

Object Lambda Access Point operations

With Amazon S3 Object Lambda, you can add your own code to Amazon S3 GET, LIST, and HEAD requests to modify and process data as it is returned to an application. You can make requests through an Object Lambda Access Point, which works the same as making requests through other access points. For more information, see [Transforming objects with S3 Object Lambda](#).

For more information about how to configure policies for Object Lambda Access Point operations, see [Configuring IAM policies for Object Lambda Access Points](#).

Multi-Region Access Point operations

A Multi-Region Access Point provides a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Region. You can use a Multi-Region Access Point to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. For more information, see [Managing multi-Region traffic with Multi-Region Access Points](#).

For more information about how to configure policies for Multi-Region Access Point operations, see [Multi-Region Access Point policy examples](#).

Batch job operations

(Batch Operations) job operations are S3 API operations that operate on the job resource type. For example, `DescribeJob` and `CreateJob`. S3 policy actions for job operations can only be used

in IAM identity-based policies, not in bucket policies. Also, job operations require the Resource element in IAM identity-based policies to be the job ARN in the following example format.

```
"Resource": "arn:aws:s3:::123456789012:job/*"
```

The following IAM identity-based policy grants the s3:DescribeJob permission to perform the [DescribeJob](#) API operation on the S3 Batch Operations job named *example-job*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowDescribingBatchOperationJob",  
            "Effect": "Allow",  
            "Action": [  
                "s3:DescribeJob"  
            ],  
            "Resource": "arn:aws:s3:::111122223333:job/example-job"  
        }  
    ]  
}
```

S3 Storage Lens configuration operations

For more information about how to configure S3 Storage Lens configuration operations, see [Setting Amazon S3 Storage Lens permissions](#).

Account operations

Account operations are S3 API operations that operate on the account level. For example, GetPublicAccessBlock (for account). Account isn't a resource type defined by Amazon S3. S3 policy actions for account operations can only be used in IAM identity-based policies, not in bucket policies. Also, account operations require the Resource element in IAM identity-based policies to be "*".

The following IAM identity-based policy grants the s3:GetAccountPublicAccessBlock permission to perform the account-level [GetPublicAccessBlock](#) API operation and retrieve the account-level Public Access Block settings.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowRetrievingTheAccountLevelPublicAccessBlockSettings",  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetAccountPublicAccessBlock"  
            ],  
            "Resource": [  
                "*"  
            ]  
        }  
    ]  
}
```

Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see [Identity-based policies for Amazon S3](#).
- To view examples of Amazon S3 resource-based policies, see [Bucket policies for Amazon S3](#) and [Configuring IAM policies for using access points](#).

Policy resources for Amazon S3

Supports policy resources: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Some Amazon S3 API actions support multiple resources. For example, `s3:GetObject` accesses `example-resource-1` and `example-resource-2`, so a principal must have permissions to access both resources. To specify multiple resources in a single statement, separate the ARNs with commas, as shown in the following example.

```
"Resource": [  
    "example-resource-1",  
    "example-resource-2"]
```

Resources in Amazon S3 are buckets, objects, access points, or jobs. In a policy, use the Amazon Resource Name (ARN) of the bucket, object, access point, or job to identify the resource.

To see a complete list of Amazon S3 resource types and their ARNs, see [Resources defined by Amazon S3](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions defined by Amazon S3](#).

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Wildcard characters in resource ARNs

You can use wildcard characters as part of the resource ARN. You can use the wildcard characters (*) and (?) within any ARN segment (the parts separated by colons). An asterisk (*) represents any combination of zero or more characters, and a question mark (?) represents any single character. You can use multiple * or ? characters in each segment. However, a wildcard character can't span segments.

- The following ARN uses the * wildcard character in the `relative-ID` part of the ARN to identify all objects in the `amzn-s3-demo-bucket` bucket.

```
arn:aws:s3:::amzn-s3-demo-bucket/*
```

- The following ARN uses * to indicate all S3 buckets and objects.

```
arn:aws:s3:::*
```

- The following ARN uses both of the wildcard characters, * and ?, in the `relative-ID` part. This ARN identifies all objects in buckets such as `amzn-s3-demo-example1bucket`, `amzn-s3-demo-example2bucket`, `amzn-s3-demo-example3bucket`, and so on.

```
arn:aws:s3:::amzn-s3-demo-example?bucket/*
```

Policy variables for resource ARNs

You can use policy variables in Amazon S3 ARNs. At policy-evaluation time, these predefined variables are replaced by their corresponding values. Suppose that you organize your bucket as a collection of folders, with one folder for each of your users. The folder name is the same as the username. To grant users permission to their folders, you can specify a policy variable in the resource ARN:

```
arn:aws:s3:::bucket_name/developers/${aws:username}/
```

At runtime, when the policy is evaluated, the variable \${aws:username} in the resource ARN is substituted with the username of the person who is making the request.

Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see [Identity-based policies for Amazon S3](#).
- To view examples of Amazon S3 resource-based policies, see [Bucket policies for Amazon S3](#) and [Configuring IAM policies for using access points](#).

Policy condition keys for Amazon S3

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Condition element specifies when statements execute based on defined criteria. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

Each Amazon S3 condition key maps to the same name request header allowed by the API on which the condition can be set. Amazon S3-specific condition keys dictate the behavior of the same

name request headers. For example, the condition key `s3:VersionId` used to grant conditional permission for the `s3:GetObjectVersion` permission defines behavior of the `versionId` query parameter that you set in a GET Object request.

To see a list of Amazon S3 condition keys, see [Condition keys for Amazon S3](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions defined by Amazon S3](#).

Example: Restricting object uploads to objects with a specific storage class

Suppose that Account A, represented by account ID **123456789012**, owns a bucket. The Account A administrator wants to restrict **Dave**, a user in Account A, so that **Dave** can upload objects to the bucket only if the object is stored in the `STANDARD_IA` storage class. To restrict object uploads to a specific storage class, the Account A administrator can use the `s3:x-amz-storage-class` condition key, as shown in the following example bucket policy.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Dave"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-storage-class": [  
                        "STANDARD_IA"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

In the example, the Condition block specifies the `StringEquals` condition that is applied to the specified key-value pair, `"s3:x-amz-acl": ["public-read"]`. There is a set of predefined keys that you can use in expressing a condition. The example uses the `s3:x-amz-acl` condition key. This condition requires the user to include the `x-amz-acl` header with value `public-read` in every PutObject request.

Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see [Identity-based policies for Amazon S3](#).
- To view examples of Amazon S3 resource-based policies, see [Bucket policies for Amazon S3](#) and [Configuring IAM policies for using access points](#).

ACLs in Amazon S3

Supports ACLs: Yes

In Amazon S3, access control lists (ACLs) control which AWS accounts have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

 **Important**

A majority of modern use cases in Amazon S3 no longer require the use of ACLs.

For information about using ACLs to control access in Amazon S3, see [Managing access with ACLs](#).

ABAC with Amazon S3

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the `condition element` of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [Define permissions with ABAC authorization](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

For information about resources that support ABAC in Amazon S3, see [Using tags for attribute-based access control \(ABAC\)](#).

To view example identity-based policies for limiting access to S3 Batch Operations jobs based on tags, see [Controlling permissions for Batch Operations using job tags](#).

ABAC and object tags

In ABAC policies, objects use s3 : tags instead of aws : tags. To control access to objects based on object tags, you provide tag information in the [Condition element](#) of a policy using the following tags:

- s3:ExistingObjectTag/*tag-key*
- s3:RequestObjectTagKeys
- s3:RequestObjectTag/*tag-key*

For information about using object tags to control access, including example permission policies, see [Tagging and access control policies](#).

Using temporary credentials with Amazon S3

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#) and [AWS services that work with IAM](#) in the *IAM User Guide*.

Forward access sessions for Amazon S3

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see [Forward access sessions](#).

- FAS is used by Amazon S3 to make calls to AWS KMS to decrypt an object when SSE-KMS was used to encrypt it. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).
- S3 Access Grants also uses FAS. After you create an access grant to your S3 data for a particular identity, the grantee requests a temporary credential from S3 Access Grants. S3 Access Grants obtains a temporary credential for the requester from AWS STS and vends the credential to the requester. For more information, see [Request access to Amazon S3 data through S3 Access Grants](#).

Service roles for Amazon S3

Supports service roles: Yes

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

 **Warning**

Changing the permissions for a service role might break Amazon S3 functionality. Edit service roles only when Amazon S3 provides guidance to do so.

Service-linked roles for Amazon S3

Supports service-linked roles: Partial

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

Amazon S3 supports service-linked roles for Amazon S3 Storage Lens. For details about creating or managing Amazon S3 service-linked roles, see [Using service-linked roles for Amazon S3 Storage Lens](#).

Amazon S3 Service as a Principal

How Amazon S3 authorizes a request

When Amazon S3 receives a request—for example, a bucket or an object operation—it first verifies that the requester has the necessary permissions. Amazon S3 evaluates all the relevant access policies, user policies, and resource-based policies (bucket policy, bucket access control list (ACL), and object ACL) in deciding whether to authorize the request.

Note

If the Amazon S3 permission check fails to find valid permissions, an Access Denied (403 Forbidden) permission denied error is returned. For more information, see [Troubleshoot Access Denied \(403 Forbidden\) errors in Amazon S3](#).

To determine whether the requester has permission to perform the specific operation, Amazon S3 does the following, in order, when it receives a request:

1. Converts all the relevant access policies (user policy, bucket policy, and ACLs) at run time into a set of policies for evaluation.
2. Evaluates the resulting set of policies in the following steps. In each step, Amazon S3 evaluates a subset of policies in a specific context, based on the context authority.
 - a. **User context** – In the user context, the parent account to which the user belongs is the context authority.

Amazon S3 evaluates a subset of policies owned by the parent account. This subset includes the user policy that the parent attaches to the user. If the parent also owns the resource in the request (bucket or object), Amazon S3 also evaluates the corresponding resource policies (bucket policy, bucket ACL, and object ACL) at the same time.

A user must have permission from the parent account to perform the operation.

This step applies only if the request is made by a user in an AWS account. If the request is made by using the root user credentials of an AWS account, Amazon S3 skips this step.

- b. **Bucket context** – In the bucket context, Amazon S3 evaluates policies owned by the AWS account that owns the bucket.

If the request is for a bucket operation, the requester must have permission from the bucket owner. If the request is for an object, Amazon S3 evaluates all the policies owned by the

bucket owner to check if the bucket owner has not explicitly denied access to the object. If there is an explicit deny set, Amazon S3 does not authorize the request.

- c. **Object context** – If the request is for an object, Amazon S3 evaluates the subset of policies owned by the object owner.

Following are some example scenarios that illustrate how Amazon S3 authorizes a request.

Example – Requester is an IAM principal

If the requester is an IAM principal, Amazon S3 must determine if the parent AWS account to which the principal belongs has granted the principal necessary permission to perform the operation. In addition, if the request is for a bucket operation, such as a request to list the bucket content, Amazon S3 must verify that the bucket owner has granted permission for the requester to perform the operation. To perform a specific operation on a resource, an IAM principal needs permission from both the parent AWS account to which it belongs and the AWS account that owns the resource.

Example – Requester is an IAM principal – If the request is for an operation on an object that the bucket owner doesn't own

If the request is for an operation on an object that the bucket owner doesn't own, in addition to making sure the requester has permissions from the object owner, Amazon S3 must also check the bucket policy to ensure the bucket owner has not set explicit deny on the object. A bucket owner (who pays the bill) can explicitly deny access to objects in the bucket regardless of who owns it. The bucket owner can also delete any object in the bucket.

By default, when another AWS account uploads an object to your S3 general purpose bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through access control lists (ACLs). You can use Object Ownership to change this default behavior so that ACLs are disabled and you, as the bucket owner, automatically own every object in your general purpose bucket. As a result, access control for your data is based on policies, such as IAM user policies, S3 bucket policies, virtual private cloud (VPC) endpoint policies, and AWS Organizations service control policies (SCPs). For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

For more information about how Amazon S3 evaluates access policies to authorize or deny requests for bucket operations and object operations, see the following topics:

- [How Amazon S3 authorizes a request for an object operation](#)

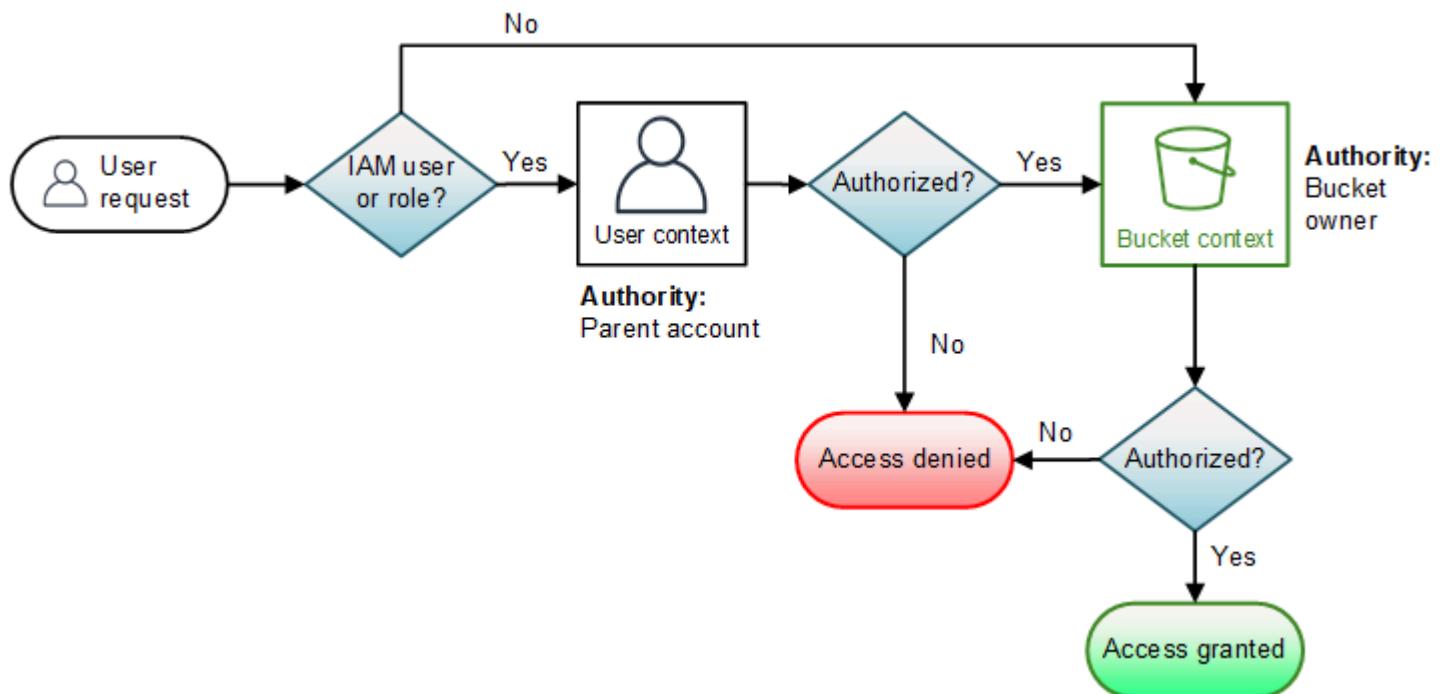

How Amazon S3 authorizes a request for a bucket operation

When Amazon S3 receives a request for a bucket operation, Amazon S3 converts all the relevant permissions into a set of policies to evaluate at run time. Relevant permissions include resource-based permissions (for example, bucket policies and bucket access control lists) and user policies if the request is from an IAM principal. Amazon S3 then evaluates the resulting set of policies in a series of steps according to a specific context—user context or bucket context:

1. **User context** – If the requester is an IAM principal, the principal must have permission from the parent AWS account to which it belongs. In this step, Amazon S3 evaluates a subset of policies owned by the parent account (also referred to as the context authority). This subset of policies includes the user policy that the parent account attaches to the principal. If the parent also owns the resource in the request (in this case, the bucket), Amazon S3 also evaluates the corresponding resource policies (bucket policy and bucket ACL) at the same time. Whenever a request for a bucket operation is made, the server access logs record the canonical ID of the requester. For more information, see [Logging requests with server access logging](#).
2. **Bucket context** – The requester must have permissions from the bucket owner to perform a specific bucket operation. In this step, Amazon S3 evaluates a subset of policies owned by the AWS account that owns the bucket.

The bucket owner can grant permission by using a bucket policy or bucket ACL. If the AWS account that owns the bucket is also the parent account of an IAM principal, then it can configure bucket permissions in a user policy.

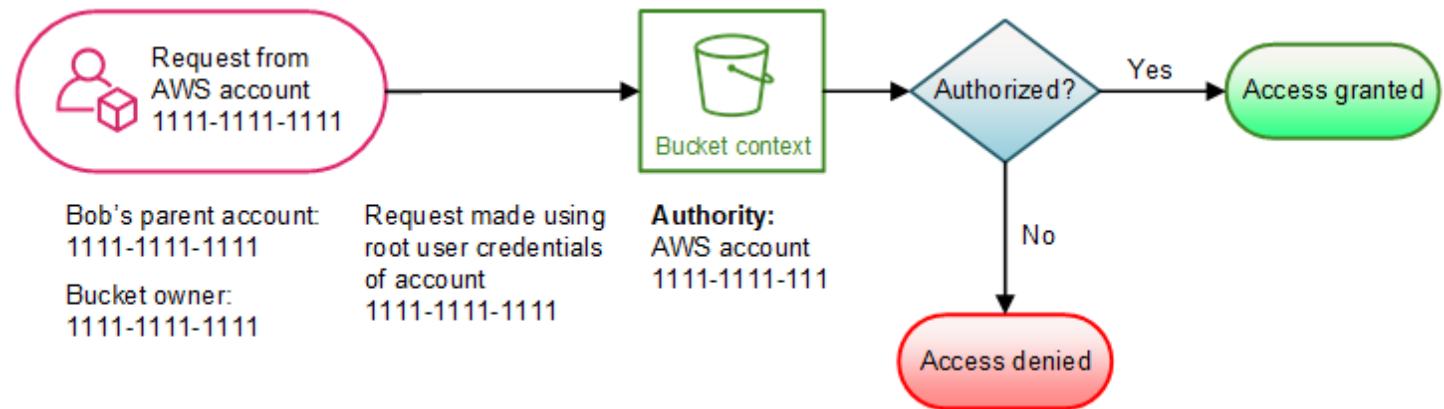

The following is a graphical illustration of the context-based evaluation for bucket operation.

The following examples illustrate the evaluation logic.

Example 1: Bucket operation requested by bucket owner

In this example, the bucket owner sends a request for a bucket operation by using the root credentials of the AWS account.

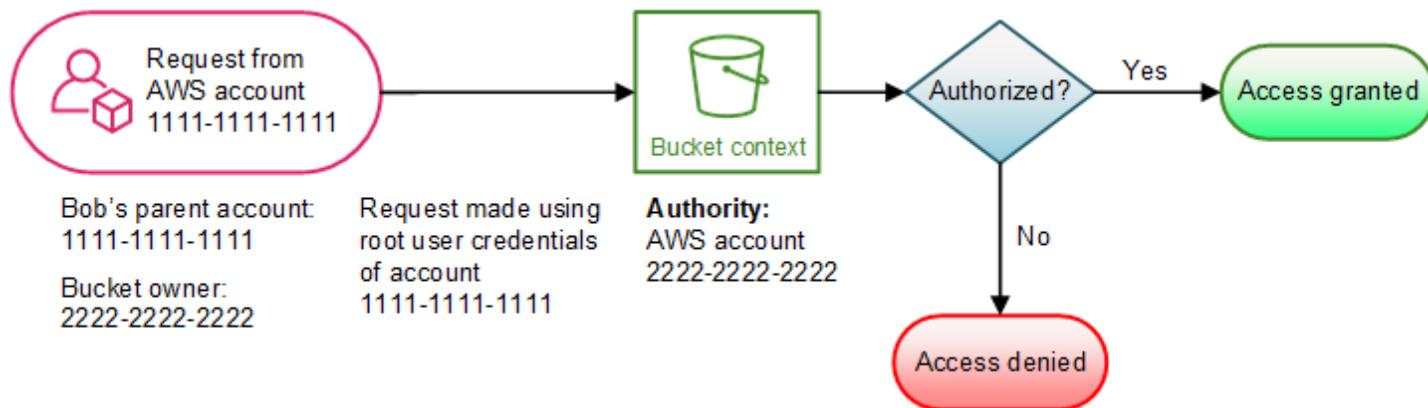

Amazon S3 performs the context evaluation as follows:

1. Because the request is made by using the root user credentials of an AWS account, the user context is not evaluated.
2. In the bucket context, Amazon S3 reviews the bucket policy to determine if the requester has permission to perform the operation. Amazon S3 authorizes the request.

Example 2: Bucket operation requested by an AWS account that is not the bucket owner

In this example, a request is made by using the root user credentials of AWS account 1111-1111-1111 for a bucket operation owned by AWS account 2222-2222-2222. No IAM users are involved in this request.

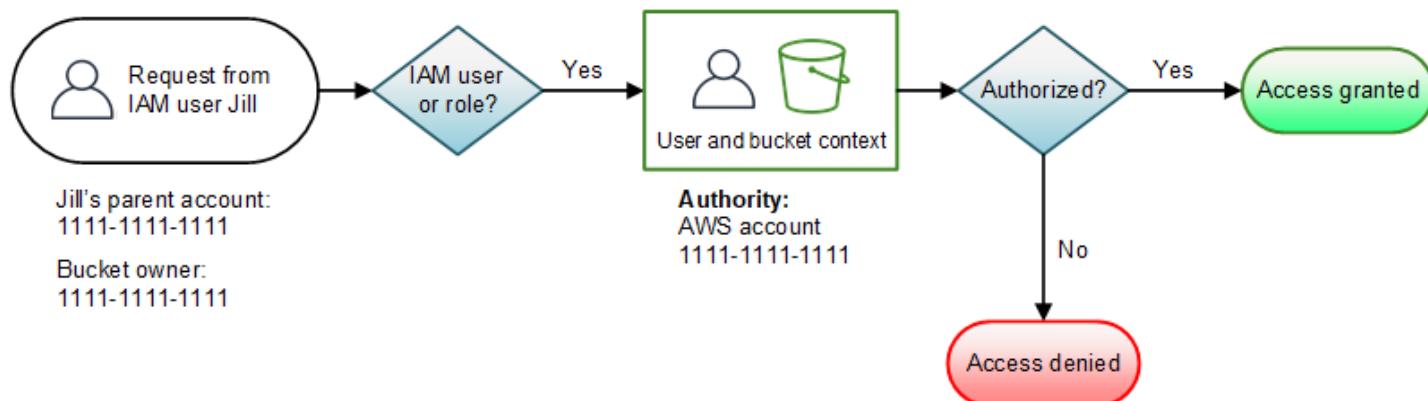

In this example, Amazon S3 evaluates the context as follows:

1. Because the request is made by using the root user credentials of an AWS account, the user context is not evaluated.
2. In the bucket context, Amazon S3 examines the bucket policy. If the bucket owner (AWS account 2222-2222-2222) has not authorized AWS account 1111-1111-1111 to perform the requested operation, Amazon S3 denies the request. Otherwise, Amazon S3 grants the request and performs the operation.

Example 3: Bucket operation requested by an IAM principal whose parent AWS account is also the bucket owner

In the example, the request is sent by Jill, an IAM user in AWS account 1111-1111-1111, which also owns the bucket.

Amazon S3 performs the following context evaluation:

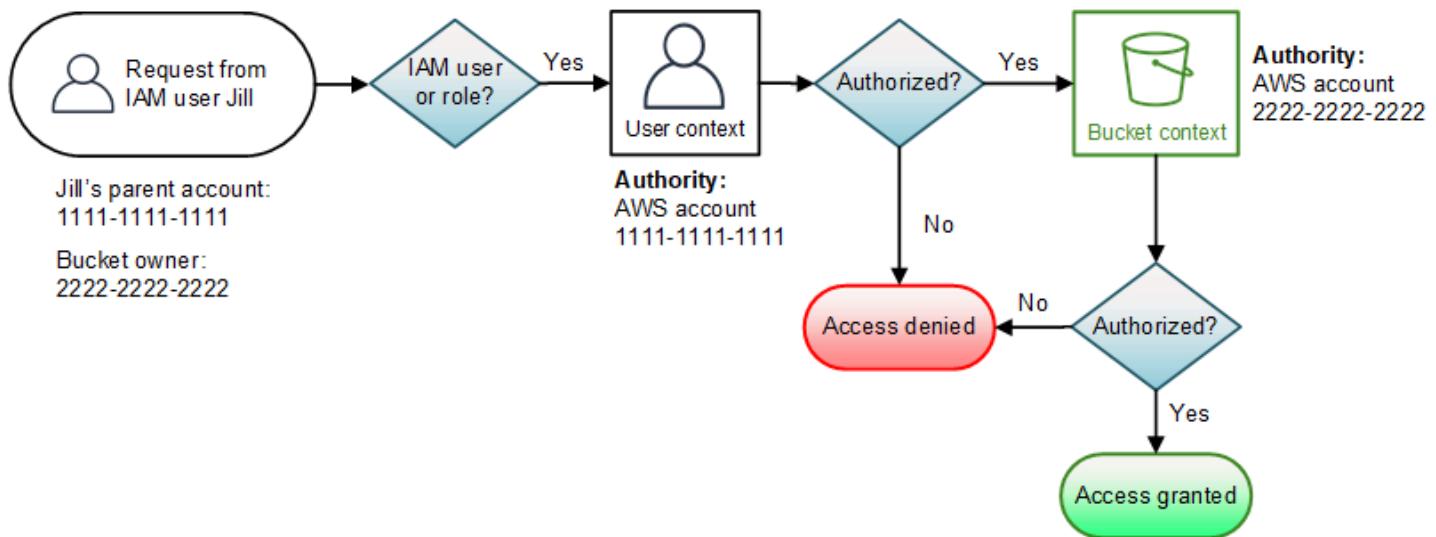

1. Because the request is from an IAM principal, in the user context, Amazon S3 evaluates all policies that belong to the parent AWS account to determine if Jill has permission to perform the operation.

In this example, parent AWS account 1111-1111-1111, to which the principal belongs, is also the bucket owner. As a result, in addition to the user policy, Amazon S3 also evaluates the bucket policy and bucket ACL in the same context because they belong to the same account.

2. Because Amazon S3 evaluated the bucket policy and bucket ACL as part of the user context, it does not evaluate the bucket context.

Example 4: Bucket operation requested by an IAM principal whose parent AWS account is not the bucket owner

In this example, the request is sent by Jill, an IAM user whose parent AWS account is 1111-1111-1111, but the bucket is owned by another AWS account, 2222-2222-2222.

Jill will need permissions from both the parent AWS account and the bucket owner. Amazon S3 evaluates the context as follows:

1. Because the request is from an IAM principal, Amazon S3 evaluates the user context by reviewing the policies authored by the account to verify that Jill has the necessary permissions. If Jill has permission, then Amazon S3 moves on to evaluate the bucket context. If Jill doesn't have permission, it denies the request.

2. In the bucket context, Amazon S3 verifies that bucket owner 2222-2222-2222 has granted Jill (or her parent AWS account) permission to perform the requested operation. If she has that permission, Amazon S3 grants the request and performs the operation. Otherwise, Amazon S3 denies the request.

How Amazon S3 authorizes a request for an object operation

When Amazon S3 receives a request for an object operation, it converts all the relevant permissions—resource-based permissions (object access control list (ACL), bucket policy, bucket ACL) and IAM user policies—into a set of policies to be evaluated at run time. It then evaluates the resulting set of policies in a series of steps. In each step, it evaluates a subset of policies in three specific contexts—user context, bucket context, and object context:

1. **User context** – If the requester is an IAM principal, the principal must have permission from the parent AWS account to which it belongs. In this step, Amazon S3 evaluates a subset of policies owned by the parent account (also referred as the context authority). This subset of policies includes the user policy that the parent attaches to the principal. If the parent also owns the resource in the request (bucket or object), Amazon S3 evaluates the corresponding resource policies (bucket policy, bucket ACL, and object ACL) at the same time.

 **Note**

If the parent AWS account owns the resource (bucket or object), it can grant resource permissions to its IAM principal by using either the user policy or the resource policy.

2. **Bucket context** – In this context, Amazon S3 evaluates policies owned by the AWS account that owns the bucket.

If the AWS account that owns the object in the request is not same as the bucket owner, Amazon S3 checks the policies if the bucket owner has explicitly denied access to the object. If there is an explicit deny set on the object, Amazon S3 does not authorize the request.

3. **Object context** – The requester must have permissions from the object owner to perform a specific object operation. In this step, Amazon S3 evaluates the object ACL.

 **Note**

If bucket and object owners are the same, access to the object can be granted in the bucket policy, which is evaluated at the bucket context. If the owners are different, the

object owners must use an object ACL to grant permissions. If the AWS account that owns the object is also the parent account to which the IAM principal belongs, it can configure object permissions in a user policy, which is evaluated at the user context. For more information about using these access policy alternatives, see [Walkthroughs that use policies to manage access to your Amazon S3 resources](#).

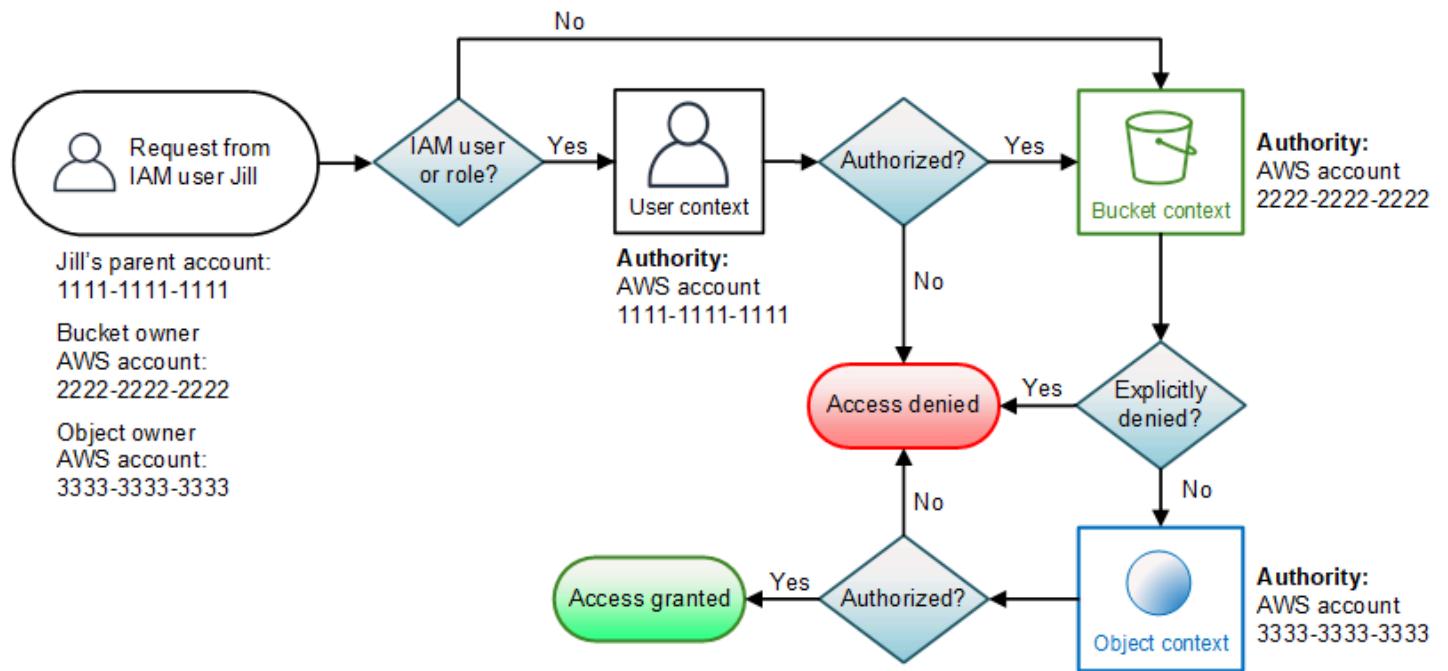

If you as the bucket owner want to own all the objects in your bucket and use bucket policies or policies based on IAM to manage access to these objects, you can apply the bucket owner enforced setting for Object Ownership. With this setting, you as the bucket owner automatically own and have full control over every object in your bucket. Bucket and object ACLs can't be edited and are no longer considered for access. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

The following is an illustration of the context-based evaluation for an object operation.

Example of an object operation request

In this example, IAM user Jill, whose parent AWS account is 1111-1111-1111, sends an object operation request (for example, `GetObject`) for an object owned by AWS account 3333-3333-3333 in a bucket owned by AWS account 2222-2222-2222.

Jill will need permission from the parent AWS account, the bucket owner, and the object owner. Amazon S3 evaluates the context as follows:

1. Because the request is from an IAM principal, Amazon S3 evaluates the user context to verify that the parent AWS account 1111-1111-1111 has given Jill permission to perform the requested operation. If she has that permission, Amazon S3 evaluates the bucket context. Otherwise, Amazon S3 denies the request.
2. In the bucket context, the bucket owner, AWS account 2222-2222-2222, is the context authority. Amazon S3 evaluates the bucket policy to determine if the bucket owner has explicitly denied Jill access to the object.
3. In the object context, the context authority is AWS account 3333-3333-3333, the object owner. Amazon S3 evaluates the object ACL to determine if Jill has permission to access the object. If she does, Amazon S3 authorizes the request.

Required permissions for Amazon S3 API operations

Note

This page is about Amazon S3 policy actions for general purpose buckets. To learn more about Amazon S3 policy actions for directory buckets, see [Actions for directory buckets](#).

To perform an S3 API operation, you must have the right permissions. This page maps S3 API operations to the required permissions. To grant permissions to perform an S3 API operation, you must compose a valid policy (such as an S3 bucket policy or IAM identity-based policy), and specify corresponding actions in the Action element of the policy. These actions are called policy actions. Not every S3 API operation is represented by a single permission (a single policy action), and some permissions (some policy actions) are required for many different API operations.

When you compose policies, you must specify the Resource element based on the correct resource type required by the corresponding Amazon S3 policy actions. This page categorizes permissions to S3 API operations by the resource types. For more information about the resource types, see [Resource types defined by Amazon S3](#) in the *Service Authorization Reference*. For a full list of Amazon S3 policy actions, resources, and condition keys for use in policies, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*. For a complete list of Amazon S3 API operations, see [Amazon S3 API Actions](#) in the *Amazon Simple Storage Service API Reference*.

For more information on how to address the HTTP 403 Forbidden errors in S3, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#). For more information on the IAM features to use with S3, see [How Amazon S3 works with IAM](#). For more information on S3 security best practices, see [Security best practices for Amazon S3](#).

Bucket operations and permissions

Bucket operations are S3 API operations that operate on the bucket resource type. You must specify S3 policy actions for bucket operations in bucket policies or IAM identity-based policies.

In the policies, the Resource element must be the bucket Amazon Resource Name (ARN). For more information about the Resource element format and example policies, see [Bucket operations](#).

Note

To grant permissions to bucket operations in access point policies, note the following:

- Permissions granted for bucket operations in an access point policy are effective only if the underlying bucket allows the same permissions. When you use an access point, you must delegate access control from the bucket to the access point or add the same permissions in the access point policy to the underlying bucket's policy.
- In access point policies that grant permissions to bucket operations, the Resource element must be the accesspoint ARN. For more information about the Resource element format and example policies, see [Bucket operations in policies for access points for general purpose buckets](#). For more information about access point policies, see [Configuring IAM policies for using access points](#).
- Not all bucket operations are supported by access points. For more information, see [Access points compatibility with S3 operations](#).

The following is the mapping of bucket operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateBucket	(Required) s3:CreateBucket	Required to create a new s3 bucket.
	(Conditionally required) s3:PutBucketAcl	Required if you want to use access control list (ACL) to specify permissions on a bucket when you make a CreateBucket request.

API operations	Policy actions	Description of policy actions
	(Conditionally required) s3:PutBucketObjectLockConfiguration , s3:PutBucketVersioning	Required if you want to enable Object Lock when you create a bucket.
	(Conditionally required) s3:PutBucketOwnershipControls	Required if you want to specify S3 Object Ownership when you create a bucket.

API operations	Policy actions	Description of policy actions
<p>CreateBucketMetadataConfiguration (V2 API operation. The IAM policy action name is the same for the V1 and V2 API operations.)</p>	<p>(Required) s3>CreateBucketMetadataConfiguration , s3tables>CreateTableBucket , s3tables:CreateNamespace , s3tables>CreateTable , s3tables:GetTable , s3tables:PutTablePolicy , s3tables:PutTableEncryption , kms:DescribeKey</p>	<p>Required to create a metadata table configuration on a general purpose bucket.</p> <p>To create your AWS managed table bucket and the metadata tables that are specified in your metadata table configuration, you must have the specified s3tables permissions.</p> <p>If you want to encrypt your metadata tables with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you need additional permissions in your KMS key policy. For more information, see the section called “Permissions for metadata tables”.</p> <p>If you also want to integrate your AWS managed table bucket with AWS analytics services so that you can query your metadata table, you need additional permissions. For more information, see Integrating Amazon S3 Tables with AWS analytics services.</p>

API operations	Policy actions	Description of policy actions
CreateBucketMetadataTableConfiguration (V1 API operation)	(Required) s3>CreateBucketMetadataTableConfiguration , s3tables>CreateNamespace , s3tables>CreateTable , s3tables:GetTable , s3tables:PutTablePolicy	<p>Required to create a metadata table configuration on a general purpose bucket.</p> <p>To create the metadata table in the table bucket that's specified in your metadata table configuration, you must have the specified s3tables permissions.</p> <p>If you want to encrypt your metadata tables with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you need additional permissions. For more information, see the section called "Permissions for metadata tables".</p> <p>If you also want to integrate your table bucket with AWS analytics services so that you can query your metadata table, you need additional permissions. For more information, see Integrating Amazon S3 Tables with AWS analytics services.</p>
DeleteBucket	(Required) s3>DeleteBucket	Required to delete an S3 bucket.

API operations	Policy actions	Description of policy actions
DeleteBucketAnalyticsConfiguration	(Required) s3:PutAnalyticsConfiguration	Required to delete an S3 analytics configuration from an S3 bucket.
DeleteBucketCors	(Required) s3:PutBucketCORS	Required to delete the cross-origin resource sharing (CORS) configuration for an bucket.
DeleteBucketEncryption	(Required) s3:PutEncryptionConfiguration	Required to reset the default encryption configuration for an S3 bucket as server-side encryption with Amazon S3 managed keys (SSE-S3).
DeleteBucketIntelligentTieringConfiguration	(Required) s3:PutIntelligentTieringConfiguration	Required to delete the existing S3 Intelligent-Tiering configuration from an S3 bucket.
DeleteBucketInventoryConfiguration	(Required) s3:PutInventoryConfiguration	Required to delete an S3 Inventory configuration from an S3 bucket.
DeleteBucketLifecycle	(Required) s3:PutLifecycleConfiguration	Required to delete the S3 Lifecycle configuration for an S3 bucket.
DeleteBucketMetadataConfiguration (V2 API operation. The IAM policy action name is the same for the V1 and V2 API operations.)	(Required) s3:DeleteBucketMetadataTableConfiguration	Required to delete a metadata table configuration from a general purpose bucket.

API operations	Policy actions	Description of policy actions
DeleteBucketMetadataTableConfiguration (V1 API operation)	(Required) s3:DeleteBucketMetadataTableConfiguration	Required to delete a metadata table configuration from a general purpose bucket.
DeleteBucketMetricsConfiguration	(Required) s3:PutMetricsConfiguration	Required to delete a metrics configuration for the Amazon CloudWatch request metrics from an S3 bucket.
DeleteBucketOwnershipControls	(Required) s3:PutBucketOwnershipControls	Required to remove the Object Ownership setting for an S3 bucket. After removal, the Object Ownership setting becomes Object writer.
DeleteBucketPolicy	(Required) s3:DeleteBucketPolicy	Required to delete the policy of an S3 bucket.
DeleteBucketReplication	(Required) s3:PutReplicationConfiguration	Required to delete the replication configuration of an S3 bucket.
DeleteBucketTagging	(Required) s3:PutBucketTagging	Required to delete tags from an S3 bucket.
DeleteBucketWebsite	(Required) s3:DeleteBucketWebsite	Required to remove the website configuration for an S3 bucket.
DeletePublicAccessBlock (Bucket-level)	(Required) s3:PutBucketPublicAccessBlock	Required to remove the block public access configuration for an S3 bucket.

API operations	Policy actions	Description of policy actions
GetBucketAccelerateConfiguration	(Required) s3:GetAccelerateConfiguration	Required to use the accelerate subresource to return the Amazon S3 Transfer Acceleration state of a bucket, which is either Enabled or Suspended.
GetBucketAcl	(Required) s3:GetBucketAcl	Required to return the access control list (ACL) of an S3 bucket.
GetBucketAnalyticsConfiguration	(Required) s3:GetAnalyticsConfiguration	Required to return an analytics configuration that's identified by the analytics configuration ID from an S3 bucket.
GetBucketCors	(Required) s3:GetBucketCORS	Required to return the cross-origin resource sharing (CORS) configuration for an S3 bucket.
GetBucketEncryption	(Required) s3:GetEncryptionConfiguration	Required to return the default encryption configuration for an S3 bucket.
GetBucketIntelligentTieringConfiguration	(Required) s3:GetIntelligentTieringConfiguration	Required to get the S3 Intelligent-Tiering configuration of an S3 bucket.
GetBucketInventoryConfiguration	(Required) s3:GetInventoryConfiguration	Required to return an inventory configuration that's identified by the inventory configuration ID from the bucket.

API operations	Policy actions	Description of policy actions
GetBucketLifecycle	(Required) s3:GetLifecycleConfiguration	Required to return the S3 Lifecycle configuration of the bucket.
GetBucketLocation	(Required) s3:GetBucketLocation	Required to return the AWS Region that an S3 bucket resides in.
GetBucketLogging	(Required) s3:GetBucketLogging	Required to return the logging status of an S3 bucket and the permissions that users have to view and modify that status.
GetBucketMetadataConfiguration (V2 API operation. The IAM policy action name is the same for the V1 and V2 API operations.)	(Required) s3:GetBucketMetadataTableConfiguration	Required to retrieve a metadata table configuration for a general purpose bucket.
GetBucketMetadataTableConfiguration (V1 API operation)	(Required) s3:GetBucketMetadataTableConfiguration	Required to retrieve a metadata table configuration for a general purpose bucket.
GetBucketMetricsConfiguration	(Required) s3:GetMetricsConfiguration	Required to get a metrics configuration that's specified by the metrics configuration ID from the bucket.
GetBucketNotificationConfiguration	(Required) s3:GetBucketNotification	Required to return the notification configuration of an S3 bucket.

API operations	Policy actions	Description of policy actions
GetBucketOwnershipControls	(Required) s3:GetBucketOwnershipControls	Required to retrieve the Object Ownership setting for an S3 bucket.
GetBucketPolicy	(Required) s3:GetBucketPolicy	Required to return the policy of an S3 bucket.
GetBucketPolicyStatus	(Required) s3:GetBucketPolicyStatus	Required to retrieve the policy status for an S3 bucket, indicating whether the bucket is public.
GetBucketReplication	(Required) s3:GetReplicationConfiguration	Required to return the replication configuration of an S3 bucket.
GetBucketRequestPayment	(Required) s3:GetBucketRequestPayment	Required to return the request payment configuration for an S3 bucket.
GetBucketVersioning	(Required) s3:GetBucketVersioning	Required to return the versioning state of an S3 bucket.
GetBucketTagging	(Required) s3:GetBucketTagging	Required to return the tag set that's associated with an S3 bucket.
GetBucketWebsite	(Required) s3:GetBucketWebsite	Required to return the website configuration for an S3 bucket.
GetObjectLockConfiguration	(Required) s3:GetBucketObjectLockConfiguration	Required to get the Object Lock configuration for an S3 bucket.

API operations	Policy actions	Description of policy actions
GetPublicAccessBlock (Bucket-level)	(Required) s3:GetBucketPublicAccessBlock	Required to retrieve the block public access configuration for an S3 bucket.
HeadBucket	(Required) s3>ListBucket	Required to determine if a bucket exists and if you have permission to access it.
ListBucketAnalyticsConfigurations	(Required) s3:GetAnalyticsConfiguration	Required to list the analytics configurations for an S3 bucket.
ListBucketIntelligentTieringConfigurations	(Required) s3:GetIntelligentTieringConfiguration	Required to list the S3 Intelligent-Tiering configurations of an S3 bucket.
ListBucketInventoryConfigurations	(Required) s3:GetInventoryConfiguration	Required to return a list of inventory configurations for an S3 bucket.
ListBucketMetricsConfigurations	(Required) s3:GetMetricsConfiguration	Required to list the metrics configurations for an S3 bucket.
ListObjects	(Required) s3>ListBucket	Required to list some or all (up to 1,000) of the objects in an S3 bucket.
	(Conditionally required) s3:GetObjectAcl	Required if you want to display object owner information.
ListObjectsV2	(Required) s3>ListBucket	Required to list some or all (up to 1,000) of the objects in an S3 bucket.

API operations	Policy actions	Description of policy actions
	(Conditionally required) s3:GetObjectAcl	Required if you want to display object owner information.
ListObjectVersions	(Required) s3>ListBucketVersions	Required to get metadata about all the versions of objects in an S3 bucket.
PutBucketAccelerateConfiguration	(Required) s3:PutAccelerateConfiguration	Required to set the accelerate configuration of an existing bucket.
PutBucketAcl	(Required) s3:PutBucketAcl	Required to use access control lists (ACLs) to set the permissions on an existing bucket.
PutBucketAnalyticsConfiguration	(Required) s3:PutAnalyticsConfiguration	Required to set an analytics configuration for an S3 bucket.
PutBucketCors	(Required) s3:PutBucketCORS	Required to set the cross-origin resource sharing (CORS) configuration for an S3 bucket.
PutBucketEncryption	(Required) s3:PutEncryptionConfiguration	Required to configure the default encryption for an S3 bucket.
PutBucketIntelligentTieringConfiguration	(Required) s3:PutIntelligentTieringConfiguration	Required to put the S3 Intelligent-Tiering configuration to an S3 bucket.
PutBucketInventoryConfiguration	(Required) s3:PutInventoryConfiguration	Required to add an inventory configuration to an S3 bucket.

API operations	Policy actions	Description of policy actions
PutBucketLifecycle	(Required) s3:PutLifecycleConfiguration	Required to create a new S3 Lifecycle configuration or replace an existing lifecycle configuration for an S3 bucket.
PutBucketLogging	(Required) s3:PutBucketLogging	Required to set the logging parameters for an S3 bucket and specify permissions for who can view and modify the logging parameters.
PutBucketMetricsConfiguration	(Required) s3:PutMetricsConfiguration	Required to set or update a metrics configuration for the Amazon CloudWatch request metrics of an S3 bucket.
PutBucketNotificationConfiguration	(Required) s3:PutBucketNotification	Required to enable notifications of specified events for an S3 bucket.
PutBucketOwnershipControls	(Required) s3:PutBucketOwnershipControls	Required to create or modify the Object Ownership setting for an S3 bucket.
PutBucketPolicy	(Required) s3:PutBucketPolicy	Required to apply an S3 bucket policy to a bucket.
PutBucketReplication	(Required) s3:PutReplicationConfiguration	Required to create a new replication configuration or replace an existing one for an S3 bucket.
PutBucketRequestPayment	(Required) s3:PutBucketRequestPayment	Required to set the request payment configuration for a bucket.

API operations	Policy actions	Description of policy actions
PutBucketTagging	(Required) s3:PutBucketTagging	Required to add a set of tags to an S3 bucket.
PutBucketVersioning	(Required) s3:PutBucketVersioning	Required to set the versioning state of an S3 bucket.
PutBucketWebsite	(Required) s3:PutBucketWebsite	Required to configure a bucket as a website and set the configuration of the website.
PutObjectLockConfiguration	(Required) s3:PutBucketObjectLockConfiguration	Required to put Object Lock configuration on an S3 bucket.
PutPublicAccessBlock (Bucket-level)	(Required) s3:PutBucketPublicAccessBlock	Required to create or modify the block public access configuration for an S3 bucket.
UpdateBucketMetadataInventoryTableConfiguration	(Required) s3:UpdateBucketMetadataInventoryTableConfiguration , s3tables: CreateTableBucket , s3tables>CreateNamespace , s3tables:CreateTable , s3tables:GetTable , s3tables:PutTablePolicy , s3tables:PutTableEncryption , kms:DescribeKey	<p>Required to enable or disable an inventory table for a metadata table configuration on a general purpose bucket.</p> <p>If you want to encrypt your inventory table with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you need additional permissions in your KMS key policy. For more information, see the section called “Permissions for metadata tables”.</p>

API operations	Policy actions	Description of policy actions
UpdateBucketMetadataJournalTableConfiguration	(Required) s3:UpdateBucketMetadataJournalTableConfiguration	Required to enable or disable journal table record expiration for a metadata table configuration on a general purpose bucket.

Object operations and permissions

Object operations are S3 API operations that operate on the object resource type. You must specify S3 policy actions for object operations in resource-based policies (such as bucket policies, access point policies, Multi-Region Access Point policies, VPC endpoint policies) or IAM identity-based policies.

In the policies, the `Resource` element must be the object ARN. For more information about the `Resource` element format and example policies, see [Object operations](#).

Note

- AWS KMS policy actions (`kms:GenerateDataKey` and `kms:Decrypt`) are only applicable for the AWS KMS resource type and must be specified in IAM identity-based policies and AWS KMS resource-based policies (AWS KMS key policies). You can't specify AWS KMS policy actions in S3 resource-based policies, such as S3 bucket policies.
- When you use access points to control access to object operations, you can use access point policies. To grant permissions to object operations in access point policies, note the following:
 - In access point policies that grant permissions to object operations, the `Resource` element must be the ARNs for objects accessed through an access point. For more information about the `Resource` element format and example policies, see [Object operations in access point policies](#).
 - Not all object operations are supported by access points. For more information, see [Access points compatibility with S3 operations](#).
 - Not all object operations are supported by Multi-Region Access Points. For more information, see [Multi-Region Access Point compatibility with S3 operations](#).

The following is the mapping of object operations and required policy actions.

API operations	Policy actions	Description of policy actions
AbortMultipartUpload	(Required) s3:AbortMultipartUpload	Required to abort a multipart upload.
CompleteMultipartUpload	(Required) s3:PutObject	Required to complete a multipart upload.
	(Conditionally required) kms:Decrypt	Required if you want to complete a multipart upload for an AWS KMS customer managed key encrypted object.
CopyObject	For source object:	For source object:
	(Required) Either s3:GetObject or s3:GetObjectVersion	<ul style="list-style-type: none"> • s3:GetObject – Required if you want to copy an object from the source bucket without specifying <code>versionId</code> in the request. • s3:GetObjectVersion – Required if you want to copy a specific version of an object from the source bucket by specifying <code>versionId</code> in the request.
	(Conditionally required) kms:Decrypt	Required if you want to copy an AWS KMS customer managed key encrypted object from the source bucket.

API operations	Policy actions	Description of policy actions
	For destination object:	For destination object:
	(Required) s3:PutObject	Required to put the copied object in the destination bucket.
	(Conditionally required) s3:PutObjectAcl	Required if you want to put the copied object with the object access control list (ACL) to the destination bucket when you make a CopyObject request.
	(Conditionally required) s3:PutObjectTagging	Required if you want to put the copied object with object tagging to the destination bucket when you make a CopyObject request.
	(Conditionally required) kms:GenerateDataKey	Required if you want to encrypt the copied object with an AWS KMS customer managed key and put it to the destination bucket.
	(Conditionally required) s3:PutObjectRetention	Required if you want to set an Object Lock retention configuration for the new object.
	(Conditionally required) s3:PutObjectLegalHold	Required if you want to place an Object Lock legal hold on the new object.
CreateMultipartUpload	(Required) s3:PutObject	Required to create multipart upload.

API operations	Policy actions	Description of policy actions
	(Conditionally required) s3:PutObjectAcl	Required if you want to set the object access control list (ACL) permissions for the uploaded object.
	(Conditionally required) s3:PutObjectTagging	Required if you want to add object tagging(s) to the uploaded object.
	(Conditionally required) kms:GenerateDataKey	Required if you want to use an AWS KMS customer managed key to encrypt an object when you initiate a multipart upload.
	(Conditionally required) s3:PutObjectRetention	Required if you want to set an Object Lock retention configuration for the uploaded object.
	(Conditionally required) s3:PutObjectLegalHold	Required if you want to apply an Object Lock legal hold to the uploaded object.
<u>DeleteObject</u>	(Required) Either s3:DeleteObject or s3:DeleteObjectVersion	<ul style="list-style-type: none"> • s3:DeleteObject – Required if you want to remove an object without specifying <code>versionId</code> in the request. • s3:DeleteObjectVersion – Required if you want to remove a specific version of an object by specifying <code>versionId</code> in the request.

API operations	Policy actions	Description of policy actions
	(Conditionally required) s3:BypassGovernanc eRetention	Required if you want to delete an object that's protected by governance mode for Object Lock retention.
DeleteObjects	(Required) Either s3:DeleteObject or s3:DeleteObjectVersion	<ul style="list-style-type: none"> • s3:DeleteObject – Required if you want to remove an object without specifying <code>versionId</code> in the request. • s3:DeleteObjectVersion – Required if you want to remove a specific version of an object by specifying <code>versionId</code> in the request.
	(Conditionally required) s3:BypassGovernanc eRetention	Required if you want to delete objects that are protected by governance mode for Object Lock retention.

API operations	Policy actions	Description of policy actions
DeleteObjectTagging	(Required) Either s3:DeleteObjectTagging or s3:DeleteObjectVersionTagging	<ul style="list-style-type: none"> s3:DeleteObjectTagging – Required if you want to remove the entire tag set of an object without specifying <code>versionId</code> in the request. s3:DeleteObjectVersionTagging – Required if you want to delete tags of a specific object version by specifying <code>versionId</code> in the request.
GetObject	(Required) Either s3:GetObject or s3:GetObjectVersion	<ul style="list-style-type: none"> s3:GetObject – Required if you want to get an object without specifying <code>versionId</code> in the request. s3:GetObjectVersion – Required if you want to get a specific version of an object by specifying <code>versionId</code> in the request.
	(Conditionally required) kms:Decrypt	Required if you want to get and decrypt an AWS KMS customer managed key encrypted object.

API operations	Policy actions	Description of policy actions
	(Conditionally required) s3:GetObjectTagging	Required if you want to get the tag-set of an object when you make a GetObject request.
	(Conditionally required) s3:GetObjectLegalHold	Required if you want to get an object's current Object Lock legal hold status.
	(Conditionally required) s3:GetObjectRetention	Required if you want to retrieve the Object Lock retention settings for an object.
GetObjectAcl	(Required) Either s3:GetObjectAcl or s3:GetObjectVersionAcl	<ul style="list-style-type: none"> • s3:GetObjectAcl – Required if you want to get the access control list (ACL) of an object without specifying <code>versionId</code> in the request. • s3:GetObjectVersionAcl – Required if you want to get the access control list (ACL) of an object by specifying <code>versionId</code> in the request.

API operations	Policy actions	Description of policy actions
GetObjectAttributes	(Required) Either s3:GetObject or s3:GetObjectVersion	<ul style="list-style-type: none"> • s3:GetObject – Required if you want to retrieve attributes related to an object without specifying <code>versionId</code> in the request. • s3:GetObjectVersion – Required if you want to retrieve attributes related to a specific object version by specifying <code>versionId</code> in the request.
	(Conditionally required) kms:Decrypt	Required if you want to retrieve attributes related to an AWS KMS customer managed key encrypted object.
GetObjectLegalHold	(Required) s3:GetObjectLegalHold	Required to get an object's current Object Lock legal hold status.
GetObjectRetention	(Required) s3:GetObjectRetention	Required to retrieve the Object Lock retention settings for an object.

API operations	Policy actions	Description of policy actions
GetObjectTagging	(Required) Either s3:GetObjectTagging or s3:GetObjectVersionTagging	<ul style="list-style-type: none"> • s3:GetObjectTagging – Required if you want to get the tag set of an object without specifying <code>versionId</code> in the request. • s3:GetObjectVersionTagging – Required if you want to get the tags of a specific object version by specifying <code>versionId</code> in the request.
GetObjectTorrent	(Required) s3:GetObject	Required to return torrent files of an object.
HeadObject	(Required) s3:GetObject	Required to retrieve metadata from an object without returning the object itself.
	(Conditionally required) s3:GetObjectLegalHold	Required if you want to get an object's current Object Lock legal hold status.
	(Conditionally required) s3:GetObjectRetention	Required if you want to retrieve the Object Lock retention settings for an object.
ListMultipartUploads	(Required) s3>ListBucketMultipartUploads	Required to list in-progress multipart uploads in a bucket.
ListParts	(Required) s3>ListMultipartUploadParts	Required to list the parts that have been uploaded for a specific multipart upload.

API operations	Policy actions	Description of policy actions
	(Conditionally required) kms:Decrypt	Required if you want to list parts of an AWS KMS customer managed key encrypted multipart upload.
PutObject	(Required) s3:PutObject	Required to put an object.
	(Conditionally required) s3:PutObjectAcl	Required if you want to put the object access control list (ACL) when you make a PutObject request.
	(Conditionally required) s3:PutObjectTagging	Required if you want to put object tagging when you make a PutObject request.
	(Conditionally required) kms:GenerateDataKey	Required if you want to encrypt an object with an AWS KMS customer managed key.
	(Conditionally required) s3:PutObjectRetention	Required if you want to set an Object Lock retention configuration on an object.
	(Conditionally required) s3:PutObjectLegalHold	Required if you want to apply an Object Lock legal hold configuration to a specified object.

API operations	Policy actions	Description of policy actions
PutObjectAcl	(Required) Either s3:PutObjectAcl or s3:PutObjectVersionAcl	<ul style="list-style-type: none"> • s3:PutObjectAcl – Required if you want to set the access control list (ACL) permissions for a new or existing object without specifying <code>versionId</code> in the request. • s3:PutObjectVersionAcl – Required if you want to set the access control list (ACL) permissions for a new or existing object by specifying <code>versionId</code> in the request.
PutObjectLegalHold	(Required) s3:PutObjectLegalHold	Required to apply an Object Lock legal hold configuration to an object.
PutObjectRetention	(Required) s3:PutObjectRetention	Required to apply an Object Lock retention configuration to an object.
	(Conditionally required) s3:BypassGovernanceRetention	Required if you want to bypass the governance mode of an Object Lock retention configuration.

API operations	Policy actions	Description of policy actions
PutObjectTagging	(Required) Either s3:PutObjectTagging or s3:PutObjectVersionTagging	<ul style="list-style-type: none"> • s3:PutObjectTagging – Required if you want to set the supplied tag set to an object that already exists in a bucket without specifying <code>versionId</code> in the request. • s3:PutObjectVersionTagging – Required if you want to set the supplied tag set to an object that already exists in a bucket by specifying <code>versionId</code> in the request.
RestoreObject	(Required) s3:RestoreObject	Required to restore a copy of an archived object.
SelectObjectContent	(Required) s3:GetObject	Required to filter the contents of an S3 object based on a simple structured query language (SQL) statement.
	(Conditionally required) kms:Decrypt	Required if you want to filter the contents of an S3 object that's encrypted with an AWS KMS customer managed key.
UploadPart	(Required) s3:PutObject	Required to upload a part in a multipart upload.

API operations	Policy actions	Description of policy actions
	(Conditionally required) kms:GenerateDataKey	Required if you want to put an upload part and encrypt it with an AWS KMS customer managed key.
UploadPartCopy	For source object:	For source object:
	(Required) Either s3:GetObject or s3:GetObjectVersion	<ul style="list-style-type: none"> • s3:GetObject – Required if you want to copy an object from the source bucket without specifying <code>versionId</code> in the request. • s3:GetObjectVersion – Required if you want to copy a specific version of an object from the source bucket by specifying <code>versionId</code> in the request.
	(Conditionally required) kms:Decrypt	Required if you want to copy an AWS KMS customer managed key encrypted object from the source bucket.
	For destination part:	For destination part:
	(Required) s3:PutObject	Required to upload a multipart upload part to the destination bucket.

API operations	Policy actions	Description of policy actions
	(Conditionally required) kms : GenerateDataKey	Required if you want to encrypt a part with an AWS KMS customer managed key when you upload the part to the destination bucket.

Access point for general purpose buckets operations and permissions

Access point operations are S3 API operations that operate on the accesspoint resource type. You must specify S3 policy actions for access point operations in IAM identity-based policies, not in bucket policies or access point policies.

In the policies, the Resource element must be the accesspoint ARN. For more information about the Resource element format and example policies, see [Access point for general purpose bucket operations](#).

Note

If you want to use access points to control access to bucket or object operations, note the following:

- For using access points to control access to bucket operations, see [Bucket operations in policies for access points for general purpose buckets](#).
- For using access points to control access to object operations, see [Object operations in access point policies](#).
- For more information about how to configure access point policies, see [Configuring IAM policies for using access points](#).

The following is the mapping of access point operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessPoint	(Required) s3:CreateAccessPoint	Required to create an access point that's associated with an S3 bucket.
DeleteAccessPoint	(Required) s3:DeleteAccessPoint	Required to delete an access point.
DeleteAccessPointPolicy	(Required) s3:DeleteAccessPointPolicy	Required to delete an access point policy.
GetAccessPointPolicy	(Required) s3:GetAccessPointPolicy	Required to retrieve an access point policy.
GetAccessPointPolicyStatus	(Required) s3:GetAccessPointPolicyStatus	Required to retrieve the information on whether the specified access point currently has a policy that allows public access.
PutAccessPointPolicy	(Required) s3:PutAccessPointPolicy	Required to put an access point policy.

Object Lambda Access Point operations and permissions

Object Lambda Access Point operations are S3 API operations that operate on the `objectlambdaaccesspoint` resource type. For more information about how to configure policies for Object Lambda Access Point operations, see [Configuring IAM policies for Object Lambda Access Points](#).

The following is the mapping of Object Lambda Access Point operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessPointForObjectLambda	(Required) s3:CreateAccessPointForObjectLambda	Required to create an Object Lambda Access Point.
DeleteAccessPointForObjectLambda	(Required) s3:DeleteAccessPointForObjectLambda	Required to delete a specified Object Lambda Access Point.
DeleteAccessPointPolicyForObjectLambda	(Required) s3:DeleteAccessPointPolicyForObjectLambda	Required to delete the policy on a specified Object Lambda Access Point.
GetAccessPointConfigurationForObjectLambda	(Required) s3:GetAccessPointConfigurationForObjectLambda	Required to retrieve the configuration of the Object Lambda Access Point.
GetAccessPointForObjectLambda	(Required) s3:GetAccessPointForObjectLambda	Required to retrieve information about the Object Lambda Access Point.
GetAccessPointPolicyForObjectLambda	(Required) s3:GetAccessPointPolicyForObjectLambda	Required to return the access point policy that's associated with the specified Object Lambda Access Point.
GetAccessPointPolicyStatusForObjectLambda	(Required) s3:GetAccessPointPolicyStatusForObjectLambda	Required to return the policy status for a specific Object Lambda Access Point policy.
PutAccessPointConfigurationForObjectLambda	(Required) s3:PutAccessPointConfigurationForObjectLambda	Required to set the configuration of the Object Lambda Access Point.
PutAccessPointPolicyForObjectLambda	(Required) s3:PutAccessPointPolicyForObjectLambda	Required to associate an access policy with a specified Object Lambda Access Point.

Multi-Region Access Point operations and permissions

Multi-Region Access Point operations are S3 API operations that operate on the `multiregionaccesspoint` resource type. For more information about how to configure policies for Multi-Region Access Point operations, see [Multi-Region Access Point policy examples](#).

The following is the mapping of Multi-Region Access Point operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateMultiRegionAccessPoint	(Required) <code>s3:CreateMultiRegionAccessPoint</code>	Required to create a Multi-Region Access Point and associate it with S3 buckets.
DeleteMultiRegionAccessPoint	(Required) <code>s3:DeleteMultiRegionAccessPoint</code>	Required to delete a Multi-Region Access Point.
DescribeMultiRegionAccessPointOperation	(Required) <code>s3:DescribeMultiRegionAccessPointOperation</code>	Required to retrieve the status of an asynchronous request to manage a Multi-Region Access Point.
GetMultiRegionAccessPoint	(Required) <code>s3:GetMultiRegionAccessPoint</code>	Required to return configuration information about the specified Multi-Region Access Point.
GetMultiRegionAccessPointPolicy	(Required) <code>s3:GetMultiRegionAccessPointPolicy</code>	Required to return the access control policy of the specified Multi-Region Access Point.
GetMultiRegionAccessPointPolicyStatus	(Required) <code>s3:GetMultiRegionAccessPointPolicyStatus</code>	Required to return the policy status for a specific Multi-Region Access Point about whether the specified Multi-Region Access Point has an

API operations	Policy actions	Description of policy actions
		access control policy that allows public access.
GetMultiRegionAccessPointRoutes	(Required) s3:GetMultiRegionAccessPointRoutes	Required to return the routing configuration for a Multi-Region Access Point.
PutMultiRegionAccessPointPolicy	(Required) s3:PutMultiRegionAccessPointPolicy	Required to update the access control policy of the specified Multi-Region Access Point.
SubmitMultiRegionAccessPointRoutes	(Required) s3:SubmitMultiRegionAccessPointRoutes	Required to submit an updated route configuration for a Multi-Region Access Point.

Batch job operations and permissions

(Batch Operations) job operations are S3 API operations that operate on the job resource type. You must specify S3 policy actions for job operations in IAM identity-based policies, not in bucket policies.

In the policies, the Resource element must be the job ARN. For more information about the Resource element format and example policies, see [Batch job operations](#).

The following is the mapping of batch job operations and required policy actions.

API operations	Policy actions	Description of policy actions
DeleteJobTagging	(Required) s3:DeleteJobTagging	Required to remove tags from an existing S3 Batch Operations job.
DescribeJob	(Required) s3:DescribeJob	Required to retrieve the configuration parameters and

API operations	Policy actions	Description of policy actions
		status for a Batch Operations job.
GetJobTagging	(Required) s3:GetJobTagging	Required to return the tag set of an existing S3 Batch Operations job.
PutJobTagging	(Required) s3:PutJobTagging	Required to put or replace tags on an existing S3 Batch Operations job.
UpdateJobPriority	(Required) s3:UpdateJobPriority	Required to update the priority of an existing job.
UpdateJobStatus	(Required) s3:UpdateJobStatus	Required to update the status for the specified job.

S3 Storage Lens configuration operations and permissions

S3 Storage Lens configuration operations are S3 API operations that operate on the `storagelensconfiguration` resource type. For more information about how to configure S3 Storage Lens configuration operations, see [Setting Amazon S3 Storage Lens permissions](#).

The following is the mapping of S3 Storage Lens configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
DeleteStorageLensConfiguration	(Required) s3:DeleteStorageLensConfiguration	Required to delete the S3 Storage Lens configuration.
DeleteStorageLensConfigurationTagging	(Required) s3:DeleteStorageLensConfigurationTagging	Required to delete the S3 Storage Lens configuration tags.

API operations	Policy actions	Description of policy actions
GetStorageLensConfiguration	(Required) s3:GetStorageLensConfiguration	Required to get the S3 Storage Lens configuration.
GetStorageLensConfigurationTagging	(Required) s3:GetStorageLensConfigurationTagging	Required to get the tags of S3 Storage Lens configuration.
PutStorageLensConfigurationTagging	(Required) s3:PutStorageLensConfigurationTagging	Required to put or replace tags on an existing S3 Storage Lens configuration.

S3 Storage Lens groups operations and permissions

S3 Storage Lens groups operations are S3 API operations that operate on the `storagelensgroup` resource type. For more information about how to configure S3 Storage Lens groups permissions, see [Storage Lens groups permissions](#).

The following is the mapping of S3 Storage Lens groups operations and required policy actions.

API operations	Policy actions	Description of policy actions
DeleteStorageLensGroup	(Required) s3:DeleteStorageLensGroup	Required to delete an existing S3 Storage Lens group.
GetStorageLensGroup	(Required) s3:GetStorageLensGroup	Required to retrieve the S3 Storage Lens group configuration details.
UpdateStorageLensGroup	(Required) s3:UpdateStorageLensGroup	Required to update the existing S3 Storage Lens group.
CreateStorageLensGroup	(Required) s3>CreateStorageLensGroup	Required to create a new Storage Lens group.

API operations	Policy actions	Description of policy actions
CreateStorageLensGroup , TagResource	(Required) s3:CreateStorageLensGroup , s3:TagResource	Required to create a new Storage Lens group with tags.
ListStorageLensGroups	(Required) s3>ListStorageLensGroups	Required to list all Storage Lens groups in your home Region.
ListTagsForResource	(Required) s3>ListTagsForResource	Required to list the tags that were added to your Storage Lens group.
TagResource	(Required) s3:TagResource	Required to add or update a Storage Lens group tag for an existing Storage Lens group.
UntagResource	(Required) s3:UntagResource	Required to delete a tag from a Storage Lens group.

S3 Access Grants instance operations and permissions

S3 Access Grants instance operations are S3 API operations that operate on the `accessgrantsinstance` resource type. An S3 Access Grants instance is a logical container for your access grants. For more information on working with S3 Access Grants instances, see [Working with S3 Access Grants instances](#).

The following is the mapping of the S3 Access Grants instance configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
AssociateAccessGrantsIdentityCenter	(Required) s3:AssociateAccessGrantsIdentityCenter	Required to associate an AWS IAM Identity Center instance with your S3 Access Grants instance, thus enabling you to create access grants for

API operations	Policy actions	Description of policy actions
		<p>users and groups in your corporate identity directory. You must also have the following permissions:</p> <p><code>sso>CreateApplication</code>, <code>sso:PutApplicationGrant</code>, and <code>sso:PutApplicationAuthenticationMethod</code>.</p>
<u>CreateAccessGrantsInstance</u>	(Required) <code>s3:CreateAccessGrantsInstance</code>	<p>Required to create an S3 Access Grants instance (<code>accessgrantsinstance</code> resource) which is a container for your individual access grants.</p> <p>To associate an AWS IAM Identity Center instance with your S3 Access Grants instance, you must also have the <code>sso:DescribeInstance</code>, <code>sso:CreateApplication</code>, <code>sso:PutApplicationGrant</code>, and <code>sso:PutApplicationAuthenticationMethod</code> permissions.</p>

API operations	Policy actions	Description of policy actions
DeleteAccessGrantsInstance	(Required) s3:DeleteAccessGrantsInstance	Required to delete an S3 Access Grants instance (<code>accessgrantsinstance</code> resource) from an AWS Region in your account.
DeleteAccessGrantsInstanceResourcePolicy	(Required) s3:DeleteAccessGrantsInstanceResourcePolicy	Required to delete a resource policy for your S3 Access Grants instance.
DissociateAccessGrantsIdentityCenter	(Required) s3:DissociateAccessGrantsIdentityCenter	Required to disassociate an AWS IAM Identity Center instance from your S3 Access Grants instance. You must also have the following permissions: <code>sso:DeleteApplication</code>
GetAccessGrantsInstance	(Required) s3:GetAccessGrantsInstance	Required to retrieve the S3 Access Grants instance for an AWS Region in your account.
GetAccessGrantsInstanceForPrefix	(Required) s3:GetAccessGrantsInstanceForPrefix	Required to retrieve the S3 Access Grants instance that contains a particular prefix.
GetAccessGrantsInstanceResourcePolicy	(Required) s3:GetAccessGrantsInstanceResourcePolicy	Required to return the resource policy of your S3 Access Grants instance.
ListAccessGrantsInstances	(Required) s3>ListAccessGrantsInstances	Required to return a list of the S3 Access Grants instances in your account.

API operations	Policy actions	Description of policy actions
PutAccessGrantsInstanceResourcePolicy	(Required) s3:PutAccessGrantsInstanceResourcePolicy	Required to update the resource policy of the S3 Access Grants instance.

S3 Access Grants location operations and permissions

S3 Access Grants location operations are S3 API operations that operate on the `accessgrantslocation` resource type. For more information on working with S3 Access Grants locations, see [Working with S3 Access Grants locations](#).

The following is the mapping of the S3 Access Grants location configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessGrantsLocation	(Required) s3:CreateAccessGrantsLocation	Required to register a location in your S3 Access Grants instance (create an <code>accessgrantslocation</code> resource). You must also have the following permission for the specified IAM role: iam:PassRole
DeleteAccessGrantsLocation	(Required) s3:DeleteAccessGrantsLocation	Required to remove a registered location from your S3 Access Grants instance.
GetAccessGrantsLocation	(Required) s3:GetAccessGrantsLocation	Required to retrieve the details of a particular location registered in your S3 Access Grants instance.
ListAccessGrantsLocations	(Required) s3>ListAccessGrantsLocations	Required to return a list of the locations registere

API operations	Policy actions	Description of policy actions
		Required to update the IAM role of a registered location in your S3 Access Grants instance.
UpdateAccessGrantsLocation	(Required) s3:UpdateAccessGrantsLocation	Required to update the IAM role of a registered location in your S3 Access Grants instance.

S3 Access Grants grant operations and permissions

S3 Access Grants grant operations are S3 API operations that operate on the `accessgrant` resource type. For more information on working with individual grants using S3 Access Grants, see [Working with grants in S3 Access Grants](#).

The following is the mapping of the S3 Access Grants grant configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessGrant	(Required) s3:CreateAccessGrant	<p>Required to create an individual grant (<code>accessgrant</code> resource) for a user or group in your S3 Access Grants instance. You must also have the following permissions:</p> <ul style="list-style-type: none"> For any directory identity — <code>sso:DescribeInstance</code> and <code>sso:DescribeApplication</code> For directory users — <code>identitystore:DescribeUser</code>

API operations	Policy actions	Description of policy actions
DeleteAccessGrant	(Required) s3:DeleteAccessGrant	Required to delete an individual access grant (<code>accessgrant</code> resource) from your S3 Access Grants instance.
GetAccessGrant	(Required) s3:GetAccessGrant	Required to get the details about an individual access grant in your S3 Access Grants instance.
ListAccessGrants	(Required) s3>ListAccessGrants	Required to return a list of individual access grants in your S3 Access Grants instance.
ListCallerAccessGrants	(Required) s3>ListCallerAccessGrants	Required to list the access grants that grant the caller access to Amazon S3 data through S3 Access Grants.

Account operations and permissions

Account operations are S3 API operations that operate on the account level. Account isn't a resource type defined by Amazon S3. You must specify S3 policy actions for account operations in IAM identity-based policies, not in bucket policies.

In the policies, the Resource element must be `"*"`. For more information about example policies, see [Account operations](#).

The following is the mapping of account operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateJob	(Required) s3>CreateJob	Required to create a new S3 Batch Operations job.

API operations	Policy actions	Description of policy actions
CreateStorageLensGroup	(Required) s3:CreateStorageLensGroup	Required to create a new S3 Storage Lens group and associate it with the specified AWS account ID.
	(Conditionally required) s3:TagResource	Required if you want to create an S3 Storage Lens group with AWS resource tags.
DeletePublicAccessBlock (Account-level)	(Required) s3:PutAccountPublicAccessBlock	Required to remove the block public access configuration from an AWS account.
GetAccessPoint	(Required) s3:GetAccessPoint	Required to retrieve configuration information about the specified access point.
GetAccessPointPolicy (Account-level)	(Required) s3:GetAccountPublicAccessBlock	Required to retrieve the block public access configuration for an AWS account.
ListAccessPoints	(Required) s3>ListAccessPoints	Required to list access points of an S3 bucket that are owned by an AWS account.
ListAccessPointsForObjectLambda	(Required) s3>ListAccessPointsForObjectLambda	Required to list the Object Lambda Access Points.
ListBuckets	(Required) s3>ListAllMyBuckets	Required to return a list of all buckets that are owned by the authenticated sender of the request.

API operations	Policy actions	Description of policy actions
ListJobs	(Required) s3>ListJobs	Required to list current jobs and jobs that have ended recently.
ListMultiRegionAccessPoints	(Required) s3>ListMultiRegionAccessPoints	Required to return a list of the Multi-Region Access Points that are currently associated with the specified AWS account.
ListStorageLensConfigurations	(Required) s3>ListStorageLensConfigurations	Required to get a list of S3 Storage Lens configurations for an AWS account.
ListStorageLensGroups	(Required) s3>ListStorageLensGroups	Required to list all the S3 Storage Lens groups in the specified home AWS Region.
PutPublicAccessBlock (Account-level)	(Required) s3>PutAccountPublicAccessBlock	Required to create or modify the block public access configuration for an AWS account.
PutStorageLensConfiguration	(Required) s3>PutStorageLensConfiguration	Required to put an S3 Storage Lens configuration.

Policies and permissions in Amazon S3

This page provides an overview of bucket and user policies in Amazon S3 and describes the basic elements of an AWS Identity and Access Management (IAM) policy. Each listed element links to more details about that element and examples of how to use it.

For a complete list of Amazon S3 actions, resources, and conditions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

In its most basic sense, a policy contains the following elements:

- **Resource** – The Amazon S3 bucket, object, access point, or job that the policy applies to. Use the Amazon Resource Name (ARN) of the bucket, object, access point, or job to identify the resource.

An example for bucket-level operations:

```
"Resource": "arn:aws:s3:::bucket_name"
```

Examples for object-level operations:

- "Resource": "arn:aws:s3:::*bucket_name*/*" for all objects in the bucket.
- "Resource": "arn:aws:s3:::*bucket_name/prefix*/*" for objects under a certain prefix in the bucket.

For more information, see [Policy resources for Amazon S3](#).

- **Actions** – For each resource, Amazon S3 supports a set of operations. You identify resource operations that you will allow (or deny) by using action keywords.

For example, the s3>ListBucket permission allows the user to use the Amazon S3 [ListObjectsV2](#) operation. (The s3>ListBucket permission is a case where the action name doesn't map directly to the operation name.) For more information about using Amazon S3 actions, see [Policy actions for Amazon S3](#). For a complete list of Amazon S3 actions, see [Actions](#) in the *Amazon Simple Storage Service API Reference*.

- **Effect** – What the effect will be when the user requests the specific action—this can be either Allow or Deny.

If you don't explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource. You might do this to make sure that a user can't access the resource, even if a different policy grants access. For more information, see [IAM JSON Policy Elements: Effect](#) in the *IAM User Guide*.

- **Principal** – The account or user who is allowed access to the actions and resources in the statement. In a bucket policy, the principal is the user, account, service, or other entity that is the recipient of this permission. For more information, see [Principals for bucket policies](#).

- **Condition** – Conditions for when a policy is in effect. You can use AWS-wide keys and Amazon S3-specific keys to specify conditions in an Amazon S3 access policy. For more information, see [Bucket policy examples using condition keys](#).

The following example bucket policy shows the Effect, Principal, Action, and Resource elements. This policy allows *Akua*, a user in account **123456789012**, s3:GetObject, s3:GetBucketLocation, and s3>ListBucket Amazon S3 permissions on the **amzn-s3-demo-bucket1** bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "ExamplePolicy01",  
    "Statement": [  
        {  
            "Sid": "ExampleStatement01",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Akua"  
            },  
            "Action": [  
                "s3:GetObject",  
                "s3:GetBucketLocation",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
                "arn:aws:s3:::amzn-s3-demo-bucket1"  
            ]  
        }  
    ]  
}
```

For complete policy language information, see [Policies and permissions in IAM](#) and [IAM JSON policy reference](#) in the *IAM User Guide*.

Permission delegation

If an AWS account owns a resource, it can grant those permissions to another AWS account. That account can then delegate those permissions, or a subset of them, to users in the account. This is referred to as *permission delegation*. But an account that receives permissions from another account can't delegate permission cross-account to another AWS account.

Amazon S3 bucket and object ownership

Buckets and objects are Amazon S3 resources. By default, only the resource owner can access these resources. The resource owner refers to the AWS account that creates the resource. For example:

- The AWS account that you use to create buckets and upload objects owns those resources.
- If you upload an object using AWS Identity and Access Management (IAM) user or role credentials, the AWS account that the user or role belongs to owns the object.
- A bucket owner can grant cross-account permissions to another AWS account (or users in another account) to upload objects. In this case, the AWS account that uploads objects owns those objects. The bucket owner doesn't have permissions on the objects that other accounts own, with the following exceptions:
 - The bucket owner pays the bills. The bucket owner can deny access to any objects, or delete any objects in the bucket, regardless of who owns them.
 - The bucket owner can archive any objects or restore archived objects regardless of who owns them. Archival refers to the storage class used to store the objects. For more information, see [Managing the lifecycle of objects](#).

Ownership and request authentication

All requests to a bucket are either authenticated or unauthenticated. Authenticated requests must include a signature value that authenticates the request sender, and unauthenticated requests do not. For more information about request authentication, see [Making requests](#) in the *Amazon S3 API Reference*.

A bucket owner can allow unauthenticated requests. For example, unauthenticated [PutObject](#) requests are allowed when a bucket has a public bucket policy, or when a bucket ACL grants WRITE or FULL_CONTROL access to the All Users group or the anonymous user specifically. For more information about public bucket policies and public access control lists (ACLs), see [The meaning of "public"](#).

All unauthenticated requests are made by the anonymous user. This user is represented in ACLs by the specific canonical user ID 65a011a29cdf8ec533ec3d1ccaae921c. If an object is uploaded to a bucket through an unauthenticated request, the anonymous user owns the object. The default object ACL grants FULL_CONTROL to the anonymous user as the object's owner. Therefore, Amazon S3 allows unauthenticated requests to retrieve the object or modify its ACL.

To prevent objects from being modified by the anonymous user, we recommend that you do not implement bucket policies that allow anonymous public writes to your bucket or use ACLs that allow the anonymous user write access to your bucket. You can enforce this recommended behavior by using Amazon S3 Block Public Access.

For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#). For more information about ACLs, see [Access control list \(ACL\) overview](#).

Important

We recommend that you don't use the AWS account root user credentials to make authenticated requests. Instead, create an IAM role and grant that role full access. We refer to users with this role as *administrator users*. You can use credentials assigned to the administrator role, instead of AWS account root user credentials, to interact with AWS and perform tasks, such as create a bucket, create users, and grant permissions. For more information, see [AWS security credentials](#) and [Security best practices in IAM](#) in the *IAM User Guide*.

Bucket policies for Amazon S3

A bucket policy is a resource-based policy that you can use to grant access permissions to your Amazon S3 bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. These permissions don't apply to objects that are owned by other AWS accounts.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable access control lists (ACLs). By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. The bucket owner owns all the objects in the bucket and manages access to data exclusively using policies.

Bucket policies use JSON-based AWS Identity and Access Management (IAM) policy language. You can use bucket policies to add or deny permissions for the objects in a bucket. Bucket policies can allow or deny requests based on the elements in the policy. These elements include the requester, S3 actions, resources, and aspects or conditions of the request (such as the IP address that's used to make the request).

For example, you can create a bucket policy that does the following:

- Grants other accounts cross-account permissions to upload objects to your S3 bucket
- Makes sure that you, the bucket owner, has full control of the uploaded objects

For more information, see [Examples of Amazon S3 bucket policies](#).

Important

You can't use a bucket policy to prevent deletions or transitions by an [S3 Lifecycle](#) rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

The topics in this section provide examples and show you how to add a bucket policy in the S3 console. For information about identity-based policies, see [Identity-based policies for Amazon S3](#). For information about bucket policy language, see [Policies and permissions in Amazon S3](#).

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Topics

- [Adding a bucket policy by using the Amazon S3 console](#)
- [Controlling access from VPC endpoints with bucket policies](#)
- [Examples of Amazon S3 bucket policies](#)
- [Bucket policy examples using condition keys](#)

Adding a bucket policy by using the Amazon S3 console

You can use the [AWS Policy Generator](#) and the Amazon S3 console to add a new bucket policy or edit an existing bucket policy. A bucket policy is a resource-based AWS Identity and Access

Management (IAM) policy. You add a bucket policy to a bucket to grant other AWS accounts or IAM users access permissions for the bucket and the objects in it. Object permissions apply only to the objects that the bucket owner creates. For more information about bucket policies, see [Identity and Access Management for Amazon S3](#).

Make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices. To learn more about validating policies by using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

For guidance on troubleshooting errors with a policy, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#).

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the list of buckets, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
4. Choose the **Permissions** tab.
5. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.
6. On the **Edit bucket policy** page, do one of the following:
 - To see examples of bucket policies, choose **Policy examples**. Or see [Examples of Amazon S3 bucket policies](#) in the *Amazon S3 User Guide*.
 - To generate a policy automatically, or edit the JSON in the **Policy** section, choose **Policy generator**.

If you choose **Policy generator**, the AWS Policy Generator opens in a new window.

- a. On the **AWS Policy Generator** page, for **Select Type of Policy**, choose **S3 Bucket Policy**.

- b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat this step for as many statements as you would like to add. For more information about these fields, see the [IAM JSON policy elements reference](#) in the *IAM User Guide*.

 **Note**

For your convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

- c. After you finish adding statements, choose **Generate Policy**.
 - d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.
7. In the **Policy** box, edit the existing policy or paste the bucket policy from the AWS Policy Generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

 **Note**

Bucket policies are limited to 20 KB in size.

8. (Optional) Choose **Preview external access** in the lower-right corner to preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to [create an account analyzer](#) in IAM Access Analyzer. For more information, see [Preview access](#) in the *IAM User Guide*.
9. Choose **Save changes**, which returns you to the **Permissions** tab.

Controlling access from VPC endpoints with bucket policies

You can use Amazon S3 bucket policies to control access to buckets from specific virtual private cloud (VPC) endpoints or specific VPCs. This section contains example bucket policies that you can use to control Amazon S3 bucket access from VPC endpoints. To learn how to set up VPC endpoints, see [VPC Endpoints](#) in the *VPC User Guide*.

A VPC enables you to launch AWS resources into a virtual network that you define. A VPC endpoint enables you to create a private connection between your VPC and another AWS service. This private connection doesn't require access over the internet, through a virtual private network (VPN) connection, through a NAT instance, or through Direct Connect.

A VPC endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. The VPC endpoint routes requests to Amazon S3 and routes responses back to the VPC. VPC endpoints change only how requests are routed. Amazon S3 public endpoints and DNS names will continue to work with VPC endpoints. For important information about using VPC endpoints with Amazon S3, see [Gateway endpoints](#) and [Gateway endpoints for Amazon S3](#) in the *VPC User Guide*.

VPC endpoints for Amazon S3 provide two ways to control access to your Amazon S3 data:

- You can control the requests, users, or groups that are allowed through a specific VPC endpoint. For information about this type of access control, see [Controlling access to VPC endpoints using endpoint policies](#) in the *VPC User Guide*.
- You can control which VPCs or VPC endpoints have access to your buckets by using Amazon S3 bucket policies. For examples of this type of bucket policy access control, see the following topics on restricting access.

Topics

- [Restricting access to a specific VPC endpoint](#)
- [Restricting access to a specific VPC](#)
- [Restricting access to an IPv6 VPC endpoint](#)

Important

When applying the Amazon S3 bucket policies for VPC endpoints described in this section, you might block your access to the bucket unintentionally. Bucket permissions that are intended to specifically limit bucket access to connections originating from your VPC endpoint can block all connections to the bucket. For information about how to fix this issue, see [How do I fix my bucket policy when it has the wrong VPC or VPC endpoint ID?](#) in the *AWS Support Knowledge Center*.

Restricting access to a specific VPC endpoint

The following is an example of an Amazon S3 bucket policy that restricts access to a specific bucket, awsexamplebucket1, only from the VPC endpoint with the ID vpce-1a2b3c4d. If the specified endpoint is not used, the policy denies all access to the bucket. The `aws:SourceVpce` condition specifies the endpoint. The `aws:SourceVpce` condition doesn't require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the VPC endpoint ID. For more information about using conditions in a policy, see [Bucket policy examples using condition keys](#).

Important

- Before using the following example policy, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- This policy disables console access to the specified bucket because console requests don't originate from the specified VPC endpoint.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909152",  
    "Statement": [  
        {  
            "Sid": "Access-to-specific-VPCE-only",  
            "Principal": "*",  
            "Action": "s3:*",  
            "Effect": "Deny",  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",  
                        "arn:aws:s3:::amzn-s3-demo-bucket/*"],  
            "Condition": {  
                "StringNotEquals": {  
                    "aws:SourceVpce": "vpce-0abcdef1234567890"  
                }  
            }  
        }  
    ]  
}
```

Restricting access to a specific VPC

You can create a bucket policy that restricts access to a specific VPC by using the `aws:SourceVpc` condition. This is useful if you have multiple VPC endpoints configured in the same VPC, and you want to manage access to your Amazon S3 buckets for all of your endpoints. The following is an example of a policy that denies access to `awsexamplebucket1` and its objects from anyone outside VPC `vpc-111bbb22`. If the specified VPC isn't used, the policy denies all access to the bucket. This statement doesn't grant access to the bucket. To grant access, you must add a separate `Allow` statement. The `vpc-111bbb22` condition key doesn't require an ARN for the VPC resource, only the VPC ID.

Important

- Before using the following example policy, replace the VPC ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- This policy disables console access to the specified bucket because console requests don't originate from the specified VPC.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909153",  
    "Statement": [  
        {  
            "Sid": "Access-to-specific-VPC-only",  
            "Principal": "*",  
            "Action": "s3:*",  
            "Effect": "Deny",  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",  
                        "arn:aws:s3:::amzn-s3-demo-bucket/*"],  
            "Condition": {  
                "StringNotEquals": {  
                    "aws:SourceVpc": "vpc-1a2b3c4d"  
                }  
            }  
        }  
    ]  
}
```

{

Restricting access to an IPv6 VPC endpoint

The following example policy denies all Amazon S3 (s3:) actions on the *amzn-s3-demo-bucket* bucket and its objects, unless the request originates from the specified VPC endpoint (vpce-0a1b2c3d4e5f6g) and the source IP address matches the provided IPv6 CIDR block.

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909154",  
    "Statement": [  
        {  
            "Sid": "AccessSpecificIPv6VPCEOnly",  
            "Action": "s3:*",  
            "Effect": "Deny",  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",  
                        "arn:aws:s3:::amzn-s3-demo-bucket/*"],  
            "Condition": {  
                "StringNotEquals": {  
                    "aws:SourceVpc": "vpc-0a1b2c3d4e5f6g4h2"  
                },  
                "NotIpAddress": {  
                    "aws:VpcSourceIp": "2001:db8::/32"  
                }  
            }  
        }  
    ]  
}
```

For information on how to restrict access to your bucket based on specific IPs or VPCs, see [How do I allow only specific VPC endpoints or IP addresses to access my Amazon S3 bucket?](#) in the AWS re:Post Knowledge Center.

Examples of Amazon S3 bucket policies

With Amazon S3 bucket policies, you can secure access to objects in your buckets, so that only users with the appropriate permissions can access them. You can even prevent authenticated users without the appropriate permissions from accessing your Amazon S3 resources.

This section presents examples of typical use cases for bucket policies. These sample policies use **amzn-s3-demo-bucket** as the resource value. To test these policies, replace the **user input placeholders** with your own information (such as your bucket name).

To grant or deny permissions to a set of objects, you can use wildcard characters (*) in Amazon Resource Names (ARNs) and other values. For example, you can control access to groups of objects that begin with a common [prefix](#) or end with a specific extension, such as .html.

For more information about AWS Identity and Access Management (IAM) policy language, see [Policies and permissions in Amazon S3](#).

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Note

When testing permissions by using the Amazon S3 console, you must grant additional permissions that the console requires—s3>ListAllMyBuckets, s3:GetBucketLocation, and s3>ListBucket. For an example walkthrough that grants permissions to users and tests those permissions by using the console, see [Controlling access to a bucket with user policies](#).

Additional resources for creating bucket policies include the following:

- For a list of the IAM policy actions, resources, and condition keys that you can use when creating a bucket policy, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.
- For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).
- For guidance on creating your S3 policy, see [Adding a bucket policy by using the Amazon S3 console](#).
- To troubleshoot errors with a policy, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#).

If you're having trouble adding or updating a policy, see [Why do I get the error "Invalid principal in policy" when I try to update my Amazon S3 bucket policy?](#) in the AWS re:Post Knowledge Center.

Granting read-only permission to a public anonymous user

You can use your policy settings to grant access to public anonymous users, which is useful if you're configuring your bucket as a static website. Granting access to public anonymous users requires you to disable the Block Public Access settings for your bucket. For more information about how to do this, and the policy required, see [Setting permissions for website access](#). To learn how to set up more restrictive policies for the same purpose, see [How can I grant public read access to some objects in my Amazon S3 bucket?](#) in the AWS Knowledge Center.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block all public access**, and choose **Save changes**.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#) 

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block all public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through new access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through any access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through new public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through any public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to [edit the Block Public Access settings](#) for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Requiring encryption

You can require server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), as shown in the following examples.

Require SSE-KMS for all objects written to a bucket

The following example policy requires every object that is written to the bucket to be encrypted with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). If the object isn't encrypted with SSE-KMS, the request is denied.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjPolicy",  
    "Statement": [  
        {"Sid": "DenyObjectsThatAreNotSSEKMS",  
         "Principal": "*",  
         "Effect": "Deny",  
         "Action": "s3:PutObject",  
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
         "Condition": {  
             "Null": {  
                 "s3:x-amz-server-side-encryption-aws-kms-key-id": "true"  
             }  
         }  
     ]  
}
```

Require SSE-KMS with a specific AWS KMS key for all objects written to a bucket

The following example policy denies any objects from being written to the bucket if they aren't encrypted with SSE-KMS by using a specific KMS key ID. Even if the objects are encrypted with SSE-KMS by using a per-request header or bucket default encryption, the objects can't be written to the bucket if they haven't been encrypted with the specified KMS key. Make sure to replace the KMS key ARN that's used in this example with your own KMS key ARN.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjPolicy",  
    "Statement": [  
        {  
            "Sid": "DenyObjectsThatAreNotSSEKMSWithSpecificKey",  
            "Principal": "*",  
            "Effect": "Deny",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "ArnNotEqualsIfExists": {  
                    "s3:x-amz-server-side-encryption-aws-kms-key-id": "arn:aws:kms:us-east-1:111122223333:key/01234567-89ab-cdef-0123-456789abcdef"  
                }  
            }  
        }  
    ]  
}
```

Managing buckets using canned ACLs

Granting permissions to multiple accounts to upload objects or set object ACLs for public access

The following example policy grants the s3:PutObject and s3:PutObjectAcl permissions to multiple AWS accounts. Also, the example policy requires that any requests for these operations must include the public-read [canned access control list \(ACL\)](#). For more information, see [Policy actions for Amazon S3](#) and [Policy condition keys for Amazon S3](#).

Warning

The public-read canned ACL allows anyone in the world to view the objects in your bucket. Use caution when granting anonymous access to your Amazon S3 bucket or disabling block public access settings. When you grant anonymous access, anyone in the world can access your bucket. We recommend that you never grant anonymous access to your Amazon S3 bucket unless you specifically need to, such as with [static website hosting](#). If you want to enable block public access settings for static website hosting, see [Tutorial: Configuring a static website on Amazon S3](#).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AddPublicReadCannedAcl",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:root",  
                    "arn:aws:iam::44445556666:root"  
                ]  
            },  
            "Action": [  
                "s3:PutObject",  
                "s3:PutObjectAcl"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": [  
                        "public-read"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control

The following example shows how to allow another AWS account to upload objects to your bucket while ensuring that you have full control of the uploaded objects. This policy grants a specific AWS account ([111122223333](#)) the ability to upload objects only if that account includes the bucket-owner-full-control canned ACL on upload. The `StringEquals` condition in the policy specifies the `s3:x-amz-acl` condition key to express the canned ACL requirement. For more information, see [Policy condition keys for Amazon S3](#).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PolicyForAllowUploadWithACL",  
            "Effect": "Allow",  
            "Principal": {"AWS": "111122223333"},  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringEquals": {"s3:x-amz-acl": "bucket-owner-full-control"}  
            }  
        }  
    ]  
}
```

Managing object access with object tagging

Allow a user to read only objects that have a specific tag key and value

The following permissions policy limits a user to only reading objects that have the environment: production tag key and value. This policy uses the s3:ExistingObjectTag condition key to specify the tag key and value.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:role/JohnDoe"  
            },  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion"  
            ],  
            "Condition": {  
                "StringEquals": {"s3:x-amz-object-tag": "environment:production"}  
            }  
        }  
    ]  
}
```

```
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
        "Condition": {
            "StringEquals": {
                "s3:ExistingObjectTag/environment": "production"
            }
        }
    ]
}
```

Restrict which object tag keys that users can add

The following example policy grants a user permission to perform the s3:PutObjectTagging action, which allows a user to add tags to an existing object. The condition uses the s3:RequestObjectTagKeys condition key to specify the allowed tag keys, such as Owner or CreationDate. For more information, see [Creating a condition that tests multiple key values](#) in the *IAM User Guide*.

The policy ensures that every tag key specified in the request is an authorized tag key. The ForAnyValue qualifier in the condition ensures that at least one of the specified keys must be present in the request.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {"Principal": {"AWS": [
            "arn:aws:iam::111122223333:role/JohnDoe"
        ]},
        "Effect": "Allow",
        "Action": [
            "s3:PutObjectTagging"
        ],
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ],
        "Condition": {"ForAnyValue:StringEquals": {"s3:RequestObjectTagKeys": [
            "Owner",
            "CreationDate"
        ]}}
    ]
}
```

```
        ]
      }
    }
  ]
}
```

Require a specific tag key and value when allowing users to add object tags

The following example policy grants a user permission to perform the s3:PutObjectTagging action, which allows a user to add tags to an existing object. The condition requires the user to include a specific tag key (such as *Project*) with the value set to *X*.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {"Principal": {"AWS": [
      "arn:aws:iam::111122223333:user/JohnDoe"
    ]},
    "Effect": "Allow",
    "Action": [
      "s3:PutObjectTagging"
    ],
    "Resource": [
      "arn:aws:s3:::amzn-s3-demo-bucket/*"
    ],
    "Condition": {"StringEquals": {"s3:RequestObjectTag/Project": "X"}}
  ]
}
```

Allow a user to only add objects with a specific object tag key and value

The following example policy grants a user permission to perform the s3:PutObject action so that they can add objects to a bucket. However, the Condition statement restricts the tag keys

and values that are allowed on the uploaded objects. In this example, the user can only add objects that have the specific tag key (*Department*) with the value set to *Finance* to the bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Principal": {  
            "AWS": [  
                "arn:aws:iam::111122223333:user/JohnDoe"  
            ]  
        },  
        "Effect": "Allow",  
        "Action": [  
            "s3:PutObject"  
        ],  
        "Resource": [  
            "arn:aws:s3:::amzn-s3-demo-bucket/*"  
        ],  
        "Condition": {  
            "StringEquals": {  
                "s3:RequestObjectTag/Department": "Finance"  
            }  
        }  
    }]  
}
```

Managing object access by using global condition keys

[Global condition keys](#) are condition context keys with an aws prefix. AWS services can support global condition keys or service-specific keys that include the service prefix. You can use the Condition element of a JSON policy to compare the keys in a request with the key values that you specify in your policy.

Restrict access to only Amazon S3 server access log deliveries

In the following example bucket policy, the [aws:SourceArn](#) global condition key is used to compare the [Amazon Resource Name \(ARN\)](#) of the resource, making a service-to-service request with the ARN that is specified in the policy. The aws:SourceArn global condition key is used to prevent the

Amazon S3 service from being used as a [confused deputy](#) during transactions between services. Only the Amazon S3 service is allowed to add objects to the Amazon S3 bucket.

This example bucket policy grants s3:PutObject permissions to only the logging service principal (logging.s3.amazonaws.com).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowPutObjectS3ServerAccessLogsPolicy",  
            "Principal": {  
                "Service": "logging.s3.amazonaws.com"  
            },  
            "Effect": "Allow",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket-logs/*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:SourceAccount": "111122223333"  
                },  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-bucket1"  
                }  
            }  
        },  
        {  
            "Sid": "RestrictToS3ServerAccessLogs",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket-logs/*",  
            "Condition": {  
                "ForAllValues:StringNotEquals": {  
                    "aws:PrincipalServiceNamesList": "logging.s3.amazonaws.com"  
                }  
            }  
        }  
    ]  
}
```

Allow access to only your organization

If you want to require all [IAM principals](#) accessing a resource to be from an AWS account in your organization (including the AWS Organizations management account), you can use the `aws:PrincipalOrgID` global condition key.

To grant or restrict this type of access, define the `aws:PrincipalOrgID` condition and set the value to your [organization ID](#) in the bucket policy. The organization ID is used to control access to the bucket. When you use the `aws:PrincipalOrgID` condition, the permissions from the bucket policy are also applied to all new accounts that are added to the organization.

Here's an example of a resource-based bucket policy that you can use to grant specific IAM principals in your organization direct access to your bucket. By adding the `aws:PrincipalOrgID` global condition key to your bucket policy, the principal account is now required to be in your organization to obtain access to the resource. Even if you accidentally specify an incorrect account when granting access, the [aws:PrincipalOrgID global condition key](#) acts as an additional safeguard. When this global key is used in a policy, it prevents all principals from outside of the specified organization from accessing the S3 bucket. Only principals from accounts in the listed organization are able to obtain access to the resource.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Sid": "AllowGetObject",  
        "Principal": {  
            "AWS": "*"  
        },  
        "Effect": "Allow",  
        "Action": "s3:GetObject",  
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
        "Condition": {  
            "StringEquals": {  
                "aws:PrincipalOrgID": ["o-aa111bb222"]  
            }  
        }  
    }]  
}
```

Managing access based on HTTP or HTTPS requests

Restrict access to only HTTPS requests

If you want to prevent potential attackers from manipulating network traffic, you can use HTTPS (TLS) to only allow encrypted connections while restricting HTTP requests from accessing your bucket. To determine whether the request is HTTP or HTTPS, use the [aws:SecureTransport](#) global condition key in your S3 bucket policy. The aws:SecureTransport condition key checks whether a request was sent by using HTTP.

If a request returns true, then the request was sent through HTTPS. If the request returns false, then the request was sent through HTTP. You can then allow or deny access to your bucket based on the desired request scheme.

In the following example, the bucket policy explicitly denies HTTP requests.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Sid": "RestrictToTLSRequestsOnly",  
        "Action": "s3:*",  
        "Effect": "Deny",  
        "Resource": [  
            "arn:aws:s3:::amzn-s3-demo-bucket",  
            "arn:aws:s3:::amzn-s3-demo-bucket/*"  
        ],  
        "Condition": {  
            "Bool": {  
                "aws:SecureTransport": "false"  
            }  
        },  
        "Principal": "*"  
    }]  
}
```

Restrict access to a specific HTTP referer

Suppose that you have a website with the domain name www.example.com or example.com with links to photos and videos stored in your bucket named **amzn-s3-demo-bucket**. By default, all

Amazon S3 resources are private, so only the AWS account that created the resources can access them.

To allow read access to these objects from your website, you can add a bucket policy that allows the s3:GetObject permission with a condition that the GET request must originate from specific webpages. The following policy restricts requests by using the StringLike condition with the aws:Referer condition key.

Make sure that the browsers that you use include the HTTP `referer` header in the request.

Warning

We recommend that you use caution when using the aws:Referer condition key. It is dangerous to include a publicly known HTTP referer header value. Unauthorized parties can use modified or custom browsers to provide any aws:Referer value that they choose. Therefore, do not use aws:Referer to prevent unauthorized parties from making direct AWS requests.

The aws:Referer condition key is offered only to allow customers to protect their digital content, such as content stored in Amazon S3, from being referenced on unauthorized third-party sites. For more information, see [aws:Referer](#) in the *IAM User Guide*.

Managing user access to specific folders

Grant users access to specific folders

Suppose that you're trying to grant users access to a specific folder. If the IAM user and the S3 bucket belong to the same AWS account, then you can use an IAM policy to grant the user access to a specific bucket folder. With this approach, you don't need to update your bucket policy to grant access. You can add the IAM policy to an IAM role that multiple users can switch to.

If the IAM identity and the S3 bucket belong to different AWS accounts, then you must grant cross-account access in both the IAM policy and the bucket policy. For more information about granting cross-account access, see [Bucket owner granting cross-account bucket permissions](#).

The following example bucket policy grants *JohnDoe* full console access to only his folder (`home/JohnDoe/`). By creating a home folder and granting the appropriate permissions to your users, you can have multiple users share a single bucket. This policy consists of three Allow statements:

- **AllowRootAndHomeListingOfCompanyBucket**: Allows the user (*JohnDoe*) to list objects at the root level of the *amzn-s3-demo-bucket* bucket and in the home folder. This statement also allows the user to search on the prefix `home/` by using the console.
- **AllowListingOfUserFolder**: Allows the user (*JohnDoe*) to list all objects in the `home/JohnDoe/` folder and any subfolders.
- **AllowAllS3ActionsInUserFolder**: Allows the user to perform all Amazon S3 actions by granting Read, Write, and Delete permissions. Permissions are limited to the bucket owner's home folder.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowRootAndHomeListingOfCompanyBucket",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/JohnDoe"  
                ]  
            },  
            "Effect": "Allow",  
            "Action": ["s3>ListBucket"],  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket"],  
            "Condition": {  
                "StringEquals": {  
                    "s3:prefix": ["", "home/", "home/JohnDoe"],  
                    "s3:delimiter": ["/"]  
                }  
            }  
        },  
        {  
            "Sid": "AllowListingOfUserFolder",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/JohnDoe"  
                ]  
            },  
            "Action": ["s3>ListBucket"],  
            "Effect": "Allow",  
            "Condition": {  
                "StringEquals": {  
                    "s3:prefix": ["home/JohnDoe/"],  
                    "s3:delimiter": ["/"]  
                }  
            }  
        }  
    ]  
}
```

```
        "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket"],  
        "Condition": {  
            "StringLike": {  
                "s3:prefix": ["home/JohnDoe/*"]  
            }  
        },  
        {  
            "Sid": "AllowAllS3ActionsInUserFolder",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/JohnDoe"  
                ]  
            },  
            "Action": ["s3:*"],  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/home/JohnDoe/*"]  
        }  
    }  
}
```

Managing access for access logs

Grant access to Application Load Balancer for enabling access logs

When you enable access logs for Application Load Balancer, you must specify the name of the S3 bucket where the load balancer will [store the logs](#). The bucket must have an [attached policy](#) that grants ELB permission to write to the bucket.

In the following example, the bucket policy grants ELB (ELB) permission to write the access logs to the bucket:

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:root"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::my-access-logs/*"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Action": "s3:PutObject",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/
AWSLogs/111122223333/*"
    }
]
```

Note

Make sure to replace *elb-account-id* with the AWS account ID for ELB for your AWS Region. For the list of ELB Regions, see [Attach a policy to your Amazon S3 bucket](#) in the *ELB User Guide*.

If your AWS Region does not appear in the supported ELB Regions list, use the following policy, which grants permissions to the specified log delivery service.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Principal": {
                "Service": "logdelivery.elasticloadbalancing.amazonaws.com"
            },
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/AWSLogs/111122223333/*
        }
    ]
}
```

Then, make sure to configure your [ELB access logs](#) by enabling them. You can [verify your bucket permissions](#) by creating a test file.

Managing access to an Amazon CloudFront OAI

Grant permission to an Amazon CloudFront OAI

The following example bucket policy grants a CloudFront origin access identity (OAI) permission to get (read) all objects in your S3 bucket. You can use a CloudFront OAI to allow users to access objects in your bucket through CloudFront but not directly through Amazon S3. For more information, see [Restricting access to Amazon S3 content by using an Origin Access Identity](#) in the *Amazon CloudFront Developer Guide*.

The following policy uses the OAI's ID as the policy's Principal. For more information about using S3 bucket policies to grant access to a CloudFront OAI, see [Migrating from origin access identity \(OAI\) to origin access control \(OAC\)](#) in the *Amazon CloudFront Developer Guide*.

To use this example:

- Replace ***EH1HDMB1FH2TC*** with the OAI's ID. To find the OAI's ID, see the [Origin Access Identity page](#) on the CloudFront console, or use [ListCloudFrontOriginAccessIdentities](#) in the CloudFront API.
- Replace ***amzn-s3-demo-bucket*** with the name of your bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "PolicyForCloudFrontPrivateContent",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access  
Identity EH1HDMB1FH2TC"  
            },  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"  
        }  
    ]  
}
```

Managing access for Amazon S3 Storage Lens

Grant permissions for Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

S3 Storage Lens can export your aggregated storage usage metrics to an Amazon S3 bucket for further analysis. The bucket where S3 Storage Lens places its metrics exports is known as the *destination bucket*. When setting up your S3 Storage Lens metrics export, you must have a bucket policy for the destination bucket. For more information, see [Monitoring your storage activity and usage with Amazon S3 Storage Lens](#).

The following example bucket policy grants Amazon S3 permission to write objects (PUT requests) to a destination bucket. You use a bucket policy like this on the destination bucket when setting up an S3 Storage Lens metrics export.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "S3StorageLensExamplePolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "storage-lens.s3.amazonaws.com"  
            },  
            "Action": "s3:PutObject",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/destination-prefix/  
                StorageLens/111122223333/*"  
            ],  
            "Condition": {  
                "StringLike": {  
                    "aws:SourceArn": "arn:aws:iam::  
                        111122223333:user/StorageLensUser"  
                }  
            }  
        }  
    ]  
}
```

```
        "StringEquals": {
            "s3:x-amz-acl": "bucket-owner-full-control",
            "aws:SourceAccount": "111122223333",
            "aws:SourceArn": "arn:aws:s3:region-
code:111122223333:storage-lens/storage-lens-dashboard-configuration-id"
        }
    }
]
```

When you're setting up an S3 Storage Lens organization-level metrics export, use the following modification to the previous bucket policy's Resource statement.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/destination-prefix/
StorageLens/your-organization-id/*",
```

Managing permissions for S3 Inventory, S3 analytics, and S3 Inventory reports

Grant permissions for S3 Inventory and S3 analytics

S3 Inventory creates lists of the objects in a bucket, and S3 analytics Storage Class Analysis export creates output files of the data used in the analysis. The bucket that the inventory lists the objects for is called the *source bucket*. The bucket where the inventory file or the analytics export file is written to is called a *destination bucket*. When setting up an inventory or an analytics export, you must create a bucket policy for the destination bucket. For more information, see [Cataloging and analyzing your data with S3 Inventory](#) and [Amazon S3 analytics – Storage Class Analysis](#).

The following example bucket policy grants Amazon S3 permission to write objects (PUT requests) from the account for the source bucket to the destination bucket. You use a bucket policy like this on the destination bucket when setting up S3 Inventory and S3 analytics export.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
        "Sid": "InventoryAndAnalyticsExamplePolicy",
        "Effect": "Allow",
        "Principal": [
            "Service": "s3.amazonaws.com"
        ],
        "Action": "s3:PutObject",
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
        ],
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-bucket"
            },
            "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "s3:x-amz-acl": "bucket-owner-full-control"
            }
        }
    }
]
```

Control S3 Inventory report configuration creation

[Cataloging and analyzing your data with S3 Inventory](#) creates lists of the objects in an S3 bucket and the metadata for each object. The `s3:PutInventoryConfiguration` permission allows a user to create an inventory configuration that includes all object metadata fields that are available by default and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory report. For more information about the metadata fields that are available in S3 Inventory, see [Amazon S3 Inventory list](#).

To restrict a user from configuring an S3 Inventory report, remove the `s3:PutInventoryConfiguration` permission from the user.

Some object metadata fields in S3 Inventory report configurations are optional, meaning that they're available by default but they can be restricted when you grant a user the `s3:PutInventoryConfiguration` permission. You can control whether users can include these optional metadata fields in their reports by using the `s3:InventoryAccessibleOptionalFields` condition key. For a list of the optional metadata

fields available in S3 Inventory, see [OptionalFields](#) in the *Amazon Simple Storage Service API Reference*.

To grant a user permission to create an inventory configuration with specific optional metadata fields, use the `s3:InventoryAccessibleOptionalFields` condition key to refine the conditions in your bucket policy.

The following example policy grants a user (*Ana*) permission to create an inventory configuration conditionally. The `ForAllValues:StringEquals` condition in the policy uses the `s3:InventoryAccessibleOptionalFields` condition key to specify the two allowed optional metadata fields, namely `Size` and `StorageClass`. So, when *Ana* is creating an inventory configuration, the only optional metadata fields that she can include are `Size` and `StorageClass`.

JSON

```
{  
    "Id": "InventoryConfigPolicy",  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowInventoryCreationConditionally",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Ana"  
            },  
            "Action":  
                "s3:PutInventoryConfiguration",  
            "Resource":  
                "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET",  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "s3:InventoryAccessibleOptionalFields": [  
                        "Size",  
                        "StorageClass"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

To restrict a user from configuring an S3 Inventory report that includes specific optional metadata fields, add an explicit Deny statement to the bucket policy for the source bucket. The following example bucket policy denies the user *Ana* from creating an inventory configuration in the source bucket *amzn-s3-demo-source-bucket* that includes the optional `ObjectAccessControlList` or `ObjectOwner` metadata fields. The user *Ana* can still create an inventory configuration with other optional metadata fields.

```
{  
    "Id": "InventoryConfigSomeFields",  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowInventoryCreation",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Ana"  
            },  
            "Action": "s3:PutInventoryConfiguration",  
            "Resource":  
                "arn:aws:s3:::amzn-s3-demo-source-bucket",  
        },  
        {  
            "Sid": "DenyCertainInventoryFieldCreation",  
            "Effect": "Deny",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Ana"  
            },  
            "Action": "s3:PutInventoryConfiguration",  
            "Resource":  
                "arn:aws:s3:::amzn-s3-demo-source-bucket",  
            "Condition": {  
                "ForAnyValue:StringEquals": {  
                    "s3:InventoryAccessibleOptionalFields": [  
                        "ObjectOwner",  
                        "ObjectAccessControlList"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

Note

The use of the `s3:InventoryAccessibleOptionalFields` condition key in bucket policies doesn't affect the delivery of inventory reports based on the existing inventory configurations.

Important

We recommend that you use `ForAllValues` with an `Allow` effect or `ForAnyValue` with a `Deny` effect, as shown in the prior examples.

Don't use `ForAllValues` with a `Deny` effect nor `ForAnyValue` with an `Allow` effect, because these combinations can be overly restrictive and block inventory configuration deletion.

To learn more about the `ForAllValues` and `ForAnyValue` condition set operators, see [Multivalued context keys](#) in the *IAM User Guide*.

Requiring MFA

Amazon S3 supports MFA-protected API access, a feature that can enforce multi-factor authentication (MFA) for access to your Amazon S3 resources. Multi-factor authentication provides an extra level of security that you can apply to your AWS environment. MFA is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, see [AWS Multi-Factor Authentication](#). You can require MFA for any requests to access your Amazon S3 resources.

To enforce the MFA requirement, use the `aws:MultiFactorAuthAge` condition key in a bucket policy. IAM users can access Amazon S3 resources by using temporary credentials issued by the AWS Security Token Service (AWS STS). You provide the MFA code at the time of the AWS STS request.

When Amazon S3 receives a request with multi-factor authentication, the `aws:MultiFactorAuthAge` condition key provides a numeric value that indicates how long ago (in seconds) the temporary credential was created. If the temporary credential provided in the request was not created by using an MFA device, this key value is null (absent). In a bucket policy, you can add a condition to check this value, as shown in the following example.

This example policy denies any Amazon S3 operation on the */taxdocuments* folder in the *amzn-s3-demo-bucket* bucket if the request is not authenticated by using MFA. To learn more about MFA, see [Using Multi-Factor Authentication \(MFA\) in AWS](#) in the *IAM User Guide*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "123",  
    "Statement": [  
        {  
            "Sid": "",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:*",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",  
            "Condition": { "Null": { "aws:MultiFactorAuthAge": true } }  
        }  
    ]  
}
```

The Null condition in the Condition block evaluates to true if the aws:MultiFactorAuthAge condition key value is null, indicating that the temporary security credentials in the request were created without an MFA device.

The following bucket policy is an extension of the preceding bucket policy. The following policy includes two policy statements. One statement allows the s3:GetObject permission on a bucket (*amzn-s3-demo-bucket*) to everyone. Another statement further restricts access to the *amzn-s3-demo-bucket/taxdocuments* folder in the bucket by requiring MFA.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "123",  
    "Statement": [  
        {  
            "Sid": "DenyInsecureConnections",  
            "Effect": "Deny",  
            "Principal": "*"  
        }  
    ]  
}
```

```
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
    },
    "Action": "s3:*",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
    "Condition": { "Null": { "aws:MultiFactorAuthAge": true } }
},
{
    "Sid": "AllowGetObject",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
    },
    "Action": ["s3:GetObject"],
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
}
]
```

You can optionally use a numeric condition to limit the duration for which the `aws:MultiFactorAuthAge` key is valid. The duration that you specify with the `aws:MultiFactorAuthAge` key is independent of the lifetime of the temporary security credential that's used in authenticating the request.

For example, the following bucket policy, in addition to requiring MFA authentication, also checks how long ago the temporary session was created. The policy denies any operation if the `aws:MultiFactorAuthAge` key value indicates that the temporary session was created more than an hour ago (3,600 seconds).

JSON

```
{
    "Version": "2012-10-17",
    "Id": "123",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:*",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
            "Condition": { "aws:MultiFactorAuthAge": { "LessThan": 3600 } }
        }
    ]
}
```

```
        "Condition": {"Null": {"aws:MultiFactorAuthAge": true }}
```

```
    },
```

```
    {
```

```
        "Sid": "",
```

```
        "Effect": "Deny",
```

```
        "Principal": "*",
```

```
        "Action": "s3:*",
```

```
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
```

```
        "Condition": {"NumericGreaterThan": {"aws:MultiFactorAuthAge": 3600 }}
```

```
    },
```

```
    {
```

```
        "Sid": "",
```

```
        "Effect": "Allow",
```

```
        "Principal": "*",
```

```
        "Action": ["s3:GetObject"],
```

```
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
```

```
    }
```

```
}
```

```
]
```

```
}
```

Preventing users from deleting objects

By default, users have no permissions. But as you create policies, you might grant users permissions that you didn't intend to grant. To avoid such permission loopholes, you can write a stricter access policy by adding an explicit deny.

To explicitly block users or accounts from deleting objects, you must add the following actions to a bucket policy: s3:DeleteObject, s3:DeleteObjectVersion, and s3:PutLifecycleConfiguration permissions. All three actions are required because you can delete objects either by explicitly calling the DELETE Object API operations or by configuring their lifecycle (see [Managing the lifecycle of objects](#)) so that Amazon S3 can remove the objects when their lifetime expires.

In the following policy example, you explicitly deny DELETE Object permissions to the user *MaryMajor*. An explicit Deny statement always supersedes any other permission granted.

JSON

```
{
```

```
    "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Sid": "statement1",
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/MaryMajor"
        },
        "Action": [
            "s3:GetObjectVersion",
            "s3:GetBucketAcl"
        ],
        "Resource": [
            "arn:aws:s3::::amzn-s3-demo-bucket1",
            "arn:aws:s3::::amzn-s3-demo-bucket1/*"
        ]
    },
    {
        "Sid": "statement2",
        "Effect": "Deny",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/MaryMajor"
        },
        "Action": [
            "s3>DeleteObject",
            "s3>DeleteObjectVersion",
            "s3:PutLifecycleConfiguration"
        ],
        "Resource": [
            "arn:aws:s3::::amzn-s3-demo-bucket1",
            "arn:aws:s3::::amzn-s3-demo-bucket1/*"
        ]
    }
]
```

Bucket policy examples using condition keys

You can use access policy language to specify conditions when you grant permissions. You can use the optional Condition element, or Condition block, to specify conditions for when a policy is in effect.

For policies that use Amazon S3 condition keys for object and bucket operations, see the following examples. For more information about condition keys, see [Policy condition keys for Amazon S3](#). For a complete list of Amazon S3 actions, condition keys, and resources that you can specify in policies, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Examples: Amazon S3 condition keys for object operations

The following examples show how you can use Amazon S3-specific condition keys for object operations. For a complete list of Amazon S3 actions, condition keys, and resources that you can specify in policies, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Several of the example policies show how you can use conditions keys with [PUT Object](#) operations. PUT Object operations allow access control list (ACL)-specific headers that you can use to grant ACL-based permissions. By using these condition keys, you can set a condition to require specific access permissions when the user uploads an object. You can also grant ACL-based permissions with the PutObjectAcl operation. For more information, see [PutObjectAcl](#) in the *Amazon S3 Amazon Simple Storage Service API Reference*. For more information about ACLs, see [Access control list \(ACL\) overview](#).

Topics

- [Example 1: Granting s3:PutObject permission requiring that objects be stored using server-side encryption](#)
- [Example 2: Granting s3:PutObject permission to copy objects with a restriction on the copy source](#)
- [Example 3: Granting access to a specific version of an object](#)
- [Example 4: Granting permissions based on object tags](#)
- [Example 5: Restricting access by the AWS account ID of the bucket owner](#)
- [Example 6: Requiring a minimum TLS version](#)
- [Example 7: Excluding certain principals from a Deny statement](#)
- [Example 8: Enforcing clients to conditionally upload objects based on object key names or ETags](#)

Example 1: Granting s3:PutObject permission requiring that objects be stored using server-side encryption

Suppose that Account A owns a bucket. The account administrator wants to grant Jane, a user in Account A, permission to upload objects with the condition that Jane always request server-side encryption with Amazon S3 managed keys (SSE-S3). The Account A administrator can specify this requirement by using the s3:x-amz-server-side-encryption condition key as shown. The key-value pair in the following Condition block specifies the s3:x-amz-server-side-encryption condition key and SSE-S3 (AES256) as the encryption type:

```
"Condition": {  
    "StringNotEquals": {  
        "s3:x-amz-server-side-encryption": "AES256"  
    }  
}
```

When testing this permission by using the AWS CLI, you must add the required encryption by using the --server-side-encryption parameter, as shown in the following example. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key HappyFace.jpg --body c:\HappyFace.jpg --server-side-encryption "AES256" --profile AccountAdmin
```

Example 2: Granting s3:PutObject permission to copy objects with a restriction on the copy source

In a PUT object request, when you specify a source object, the request is a copy operation (see [CopyObject](#)). Accordingly, the bucket owner can grant a user permission to copy objects with restrictions on the source, for example:

- Allow copying objects only from the specified source bucket (for example, *amzn-s3-demo-source-bucket*).
- Allow copying objects from the specified source bucket and only the objects whose key name prefix starts with a specific prefix, such as *public/* (for example, *amzn-s3-demo-source-bucket/public/**).
- Allow copying only a specific object from the source bucket (for example, *amzn-s3-demo-source-bucket/example.jpg*).

The following bucket policy grants a user (*Dave*) the s3:PutObject permission. This policy allows him to copy objects only with a condition that the request include the s3:x-amz-copy-source header and that the header value specify the /*amzn-s3-demo-source-bucket/public/** key name prefix. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "cross-account permission to user in your own account",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Dave"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
        },  
        {  
            "Sid": "Deny your user permission to upload object if copy source is  
not /bucket/prefix",  
            "Effect": "Deny",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Dave"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-source-bucket/*",  
            "Condition": {  
                "StringNotLike": {  
                    "s3:x-amz-copy-source": "amzn-s3-demo-source-bucket/public/*"  
                }  
            }  
        }  
    ]  
}
```

Test the policy with the AWS CLI

You can test the permission using the AWS CLI copy-object command. You specify the source by adding the --copy-source parameter; the key name prefix must match the prefix allowed in the policy. You need to provide the user *Dave* credentials using the --profile parameter. For more information about setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the [Amazon S3 API Reference](#).

```
aws s3api copy-object --bucket amzn-s3-demo-source-bucket --key HappyFace.jpg
--copy-source amzn-s3-demo-source-bucket/public/PublicHappyFace1.jpg --
profile AccountADave
```

Give permission to copy only a specific object

The preceding policy uses the StringNotLike condition. To grant permission to copy only a specific object, you must change the condition from StringNotLike to StringNotEquals and then specify the exact object key, as shown in the following example. To use this example command, replace the *user input placeholders* with your own information.

```
"Condition": {
    "StringNotEquals": {
        "s3:x-amz-copy-source": "amzn-s3-demo-source-bucket/public/
PublicHappyFace1.jpg"
    }
}
```

Example 3: Granting access to a specific version of an object

Suppose that Account A owns a versioning-enabled bucket. The bucket has several versions of the *HappyFace.jpg* object. The Account A administrator now wants to grant the user *Dave* permission to get only a specific version of the object. The account administrator can accomplish this by granting the user *Dave* the s3:GetObjectVersion permission conditionally, as shown in the following example. The key-value pair in the Condition block specifies the s3:VersionId condition key. In this case, to retrieve the object from the specified versioning-enabled bucket, *Dave* needs to know the exact object version ID. To use this example policy, replace the *user input placeholders* with your own information.

For more information, see [GetObject](#) in the [Amazon Simple Storage Service API Reference](#).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Dave"  
            },  
            "Action": "s3:GetObjectVersion",  
            "Resource": "arn:aws:s3::::amzn-s3-demo-bucket/HappyFace.jpg"  
        },  
        {  
            "Sid": "statement2",  
            "Effect": "Deny",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Dave"  
            },  
            "Action": "s3:GetObjectVersion",  
            "Resource": "arn:aws:s3::::amzn-s3-demo-bucket/HappyFace.jpg",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:VersionId": "AaaHbAQitwil_h47_44lR02DDfL1B05e"  
                }  
            }  
        }  
    ]  
}
```

Test the policy with the AWS CLI

You can test the permissions in this policy by using the AWS CLI get-object command with the --version-id parameter to identify the specific object version to retrieve. The command retrieves the specified version of the object and saves it to the *OutputFile.jpg* file.

```
aws s3api get-object --bucket amzn-s3-demo-bucket --key HappyFace.jpg OutputFile.jpg --  
version-id AaaHbAQitwil_h47_44lR02DDfL1B05e --profile AccountADave
```

Example 4: Granting permissions based on object tags

For examples of how to use object tagging condition keys with Amazon S3 operations, see [Tagging and access control policies](#).

Example 5: Restricting access by the AWS account ID of the bucket owner

You can use either the `aws:ResourceAccount` or `s3:ResourceAccount` condition key to write IAM or virtual private cloud (VPC) endpoint policies that restrict user, role, or application access to the Amazon S3 buckets that are owned by a specific AWS account ID. You can use these condition keys to restrict clients within your VPC from accessing buckets that you don't own.

However, be aware that some AWS services rely on access to AWS managed buckets. Therefore, using the `aws:ResourceAccount` or `s3:ResourceAccount` key in your IAM policy might also affect access to these resources. For more information, see the following resources:

- [Restrict access to buckets in a specified AWS account in the AWS PrivateLink Guide](#)
- [Restrict access to buckets that Amazon ECR uses in the Amazon ECR Guide](#)
- [Provide required access to Systems Manager for AWS managed Amazon S3 buckets in the AWS Systems Manager Guide](#)

For more information about the `aws:ResourceAccount` and `s3:ResourceAccount` condition keys and examples that show how to use them, see [Limit access to Amazon S3 buckets owned by specific AWS accounts](#) in the [AWS Storage Blog](#).

Example 6: Requiring a minimum TLS version

You can use the `s3:TlsVersion` condition key to write IAM, virtual private cloud endpoint (VPCE), or bucket policies that restrict user or application access to Amazon S3 buckets based on the TLS version that's used by the client. You can use this condition key to write policies that require a minimum TLS version.

Note

When AWS services make calls to other AWS services on your behalf (service-to-service calls), certain network-specific authorization context is redacted, including `s3:TlsVersion`, `aws:SecureTransport`, `aws:SourceIp`, and `aws:VpcSourceIp`. If your policy uses these condition keys with Deny statements, AWS service principals might

be unintentionally blocked. To allow AWS services to work properly while maintaining your security requirements, exclude service principals from your Deny statements by adding the `aws:PrincipalIsAWSService` condition key with a value of `false`. For example:

```
{  
    "Effect": "Deny",  
    "Action": "s3:*",  
    "Resource": "*",  
    "Condition": {  
        "Bool": {  
            "aws:SecureTransport": "false",  
            "aws:PrincipalIsAWSService": "false"  
        }  
    }  
}
```

This policy denies access to S3 operations when HTTPS is not used (`aws:SecureTransport` is `false`), but only for non-AWS service principals. This ensures your conditional restrictions apply to all principals except AWS service principals.

Example

The following example bucket policy *denies* `PutObject` requests by clients that have a TLS version earlier than 1.2, for example, 1.1 or 1.0. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:PutObject",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket1",  
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"  
            ],  
            "Condition": {  
                "Bool": {  
                    "aws:SecureTransport": "false",  
                    "aws:PrincipalIsAWSService": "false"  
                }  
            }  
        }  
    ]  
}
```

```
    "Condition": {
        "NumericLessThan": {
            "s3:TlsVersion": 1.2
        }
    }
}
]
```

Example

The following example bucket policy *allows* PutObject requests by clients that have a TLS version later than 1.1, for example, 1.2, 1.3, or later:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1",
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ],
            "Condition": {
                "NumericGreaterThan": {
                    "s3:TlsVersion": 1.1
                }
            }
        }
    ]
}
```

Example 7: Excluding certain principals from a Deny statement

The following bucket policy denies s3:GetObject access to the `amzn-s3-demo-bucket`, except to principals with the account number `123456789012`. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyAccessFromPrincipalNotInSpecificAccount",  
            "Principal": {  
                "AWS": "*"  
            },  
            "Action": "s3:GetObject",  
            "Effect": "Deny",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket/*"  
            ],  
            "Condition": {  
                "StringNotEquals": {  
                    "aws:PrincipalAccount": [  
                        "123456789012"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

Example 8: Enforcing clients to conditionally upload objects based on object key names or ETags

With conditional writes, you can add an additional header to your WRITE requests in order to specify preconditions for your S3 operation. This header specifies a condition that, if not met, will result in the S3 operation failing. For example you can prevent overwrites of existing data by validating there is no object with the same key name already in your bucket during object upload. You can alternatively check an object's entity tag (ETag) in Amazon S3 before writing an object.

For bucket policy examples that use conditions in a bucket policy to enforce conditional writes, see [the section called “Enforce conditional writes”](#).

Examples: Amazon S3 condition keys for bucket operations

The following example policies show how you can use Amazon S3 specific condition keys for bucket operations.

Topics

- [Example 1: Granting s3:GetObject permission with a condition on an IP address](#)
- [Example 2: Getting a list of objects in a bucket with a specific prefix](#)
- [Example 3: Setting the maximum number of keys](#)

Example 1: Granting s3:GetObject permission with a condition on an IP address

You can give authenticated users permission to use the s3:GetObject action if the request originates from a specific range of IP addresses (for example, `192.0.2.*`), unless the IP address is one that you want to exclude (for example, `192.0.2.188`). In the Condition block, IpAddress and NotIpAddress are conditions, and each condition is provided a key-value pair for evaluation. Both of the key-value pairs in this example use the aws:SourceIp AWS wide key. To use this example policy, replace the `user input placeholders` with your own information.

Note

The IPAddress and NotIpAddress key values specified in the Condition block use CIDR notation, as described in RFC 4632. For more information, see <http://www.rfc-editor.org/rfc/rfc4632.txt>.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "S3PolicyId1",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": "user input placeholders",  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::mybucket/*",  
            "Condition": {  
                "IpAddress": "192.0.2.*",  
                "NotIpAddress": "192.0.2.188"  
            }  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Principal": "*",
        "Action": "s3:GetObject",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
        "Condition" : {
            "IpAddress" : {
                "aws:SourceIp": "192.0.2.0/24"
            },
            "NotIpAddress" : {
                "aws:SourceIp": "192.0.2.188/32"
            }
        }
    ]
}
```

You can also use other AWS-wide condition keys in Amazon S3 policies. For example, you can specify the aws:SourceVpc and aws:SourceVpc condition keys in bucket policies for VPC endpoints. For specific examples, see [Controlling access from VPC endpoints with bucket policies](#).

Note

For some AWS global condition keys, only certain resource types are supported. Therefore, check whether Amazon S3 supports the global condition key and resource type that you want to use, or if you'll need to use an Amazon S3 specific condition key instead. For a complete list of supported resource types and condition keys for Amazon S3, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Example 2: Getting a list of objects in a bucket with a specific prefix

You can use the s3:prefix condition key to limit the response of the [ListObjectsV2](#) API operation to key names with a specific prefix. If you are the bucket owner, you can use this condition key to restrict a user to list the contents of a specific prefix in the bucket. The s3:prefix condition key is useful if the objects in the bucket are organized by key name prefixes.

The Amazon S3 console uses key name prefixes to show a folder concept. Only the console supports the concept of folders; the Amazon S3 API supports only buckets and objects. For

example, if you have two objects with the key names `public/object1.jpg` and `public/object2.jpg`, the console shows the objects under the `public` folder. In the Amazon S3 API, these are objects with prefixes, not objects in folders. For more information about using prefixes and delimiters to filter access permissions, see [Controlling access to a bucket with user policies](#).

In the following scenario, the bucket owner and the parent account to which the user belongs are the same. So the bucket owner can use either a bucket policy or a user policy to grant access. For more information about other condition keys that you can use with the `ListObjectsV2` API operation, see [ListObjectsV2](#).

Note

If the bucket is versioning-enabled, to list the objects in the bucket, you must grant the `s3>ListBucketVersions` permission in the following policies, instead of the `s3>ListBucket` permission. The `s3>ListBucketVersions` permission also supports the `s3:prefix` condition key.

User policy

The following user policy grants the `s3>ListBucket` permission (see [ListObjectsV2](#)) with a Condition statement that requires the user to specify a prefix in the request with a value of `projects`. To use this example policy, replace the `user input placeholders` with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Action": "s3>ListBucket",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",  
            "Condition": {  
                "StringEquals": {  
                    "s3:prefix": "projects"  
                }  
            }  
        }  
    ]  
}
```

```
        },
        {
            "Sid": "statement2",
            "Effect": "Deny",
            "Action": "s3>ListBucket",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
            "Condition" : {
                "StringNotEquals" : {
                    "s3:prefix": "projects"
                }
            }
        }
    ]
}
```

The Condition statement restricts the user to listing only object keys that have the *projects* prefix. The added explicit Deny statement denies the user from listing keys with any other prefix, no matter what other permissions the user might have. For example, it's possible that the user could get permission to list object keys without any restriction, either through updates to the preceding user policy or through a bucket policy. Because explicit Deny statements always override Allow statements, if the user tries to list keys other than those that have the *projects* prefix, the request is denied.

Bucket policy

If you add the Principal element to the above user policy, identifying the user, you now have a bucket policy, as shown in the following example. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/bucket-owner"
            },

```

```
        "Action": "s3>ListBucket",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
        "Condition" : {
            "StringEquals" : {
                "s3:prefix": "projects"
            }
        },
    },
{
    "Sid":"statement2",
    "Effect":"Deny",
    "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/bucket-owner"
    },
    "Action": "s3>ListBucket",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
    "Condition" : {
        "StringNotEquals" : {
            "s3:prefix": "projects"
        }
    }
}
]
```

Test the policy with the AWS CLI

You can test the policy using the following `list-object` AWS CLI command. In the command, you provide user credentials using the `--profile` parameter. For more information about setting up and using the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the [Amazon S3 API Reference](#).

```
aws s3api list-objects --bucket amzn-s3-demo-bucket --prefix projects --  
profile AccountA
```

Example 3: Setting the maximum number of keys

You can use the `s3:max-keys` condition key to set the maximum number of keys that a requester can return in a [ListObjectsV2](#) or [ListObjectVersions](#) request. By default, these API operations return up to 1,000 keys. For a list of numeric condition operators that you can use with `s3:max-keys` and accompanying examples, see [Numeric Condition Operators](#) in the [IAM User Guide](#).

Identity-based policies for Amazon S3

By default, users and roles don't have permission to create or modify Amazon S3 resources. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see [Create IAM policies \(console\)](#) in the *IAM User Guide*.

For details about actions and resource types defined by Amazon S3, including the format of the ARNs for each of the resource types, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Topics

- [Policy best practices](#)
- [Controlling access to a bucket with user policies](#)
- [Identity-based policy examples for Amazon S3](#)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon S3 resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](#) or [AWS managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [Validate policies with IAM Access Analyzer](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Secure API access with MFA](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

Controlling access to a bucket with user policies

This walkthrough explains how user permissions work with Amazon S3. In this example, you create a bucket with folders. You then create AWS Identity and Access Management IAM users in your AWS account and grant those users incremental permissions on your Amazon S3 bucket and the folders in it.

Topics

- [Basics of buckets and folders](#)
- [Walkthrough summary](#)
- [Preparing for the walkthrough](#)
- [Step 1: Create a bucket](#)
- [Step 2: Create IAM users and a group](#)
- [Step 3: Verify that IAM users have no permissions](#)
- [Step 4: Grant group-level permissions](#)
- [Step 5: Grant IAM user Alice specific permissions](#)

- [Step 6: Grant IAM user Bob specific permissions](#)
- [Step 7: Secure the private folder](#)
- [Step 8: Clean up](#)
- [Related resources](#)

Basics of buckets and folders

The Amazon S3 data model is a flat structure: You create a bucket, and the bucket stores objects. There is no hierarchy of subbuckets or subfolders, but you can emulate a folder hierarchy. Tools like the Amazon S3 console can present a view of these logical folders and subfolders in your bucket.

The console shows that a bucket named companybucket has three folders, Private, Development, and Finance, and an object, s3-dg.pdf. The console uses the object names (keys) to create a logical hierarchy with folders and subfolders. Consider the following examples:

- When you create the Development folder, the console creates an object with the key Development/. Note the trailing slash (/) delimiter.
- When you upload an object named Projects1.xls in the Development folder, the console uploads the object and gives it the key Development/Projects1.xls.

In the key, Development is the [prefix](#) and / is the delimiter. The Amazon S3 API supports prefixes and delimiters in its operations. For example, you can get a list of all objects from a bucket with a specific prefix and delimiter. On the console, when you open the Development folder, the console lists the objects in that folder. In the following example, the Development folder contains one object.

When the console lists the Development folder in the companybucket bucket, it sends a request to Amazon S3 in which it specifies a prefix of Development and a delimiter of / in the request. The console's response looks just like a folder list in your computer's file system. The preceding example shows that the bucket companybucket has an object with the key Development/Projects1.xls.

The console is using object keys to infer a logical hierarchy. Amazon S3 has no physical hierarchy. Amazon S3 only has buckets that contain objects in a flat file structure. When you create objects using the Amazon S3 API, you can use object keys that imply a logical hierarchy. When you create a logical hierarchy of objects, you can manage access to individual folders, as this walkthrough demonstrates.

Before you start, be sure that you are familiar with the concept of the *root-level* bucket content. Suppose that your companybucket bucket has the following objects:

- Private/privDoc1.txt
- Private/privDoc2.zip
- Development/project1.xls
- Development/project2.xls
- Finance/Tax2011/document1.pdf
- Finance/Tax2011/document2.pdf
- s3-dg.pdf

These object keys create a logical hierarchy with Private, Development, and the Finance as root-level folders and s3-dg.pdf as a root-level object. When you choose the bucket name on the Amazon S3 console, the root-level items appear. The console shows the top-level prefixes (Private/, Development/, and Finance/) as root-level folders. The object key s3-dg.pdf has no prefix, and so it appears as a root-level item.

Walkthrough summary

In this walkthrough, you create a bucket with three folders (Private, Development, and Finance) in it.

You have two users, Alice and Bob. You want Alice to access only the Development folder, and you want Bob to access only the Finance folder. You want to keep the Private folder content private. In the walkthrough, you manage access by creating IAM users (the example uses the usernames Alice and Bob) and granting them the necessary permissions.

IAM also supports creating user groups and granting group-level permissions that apply to all users in the group. This helps you better manage permissions. For this exercise, both Alice and Bob need some common permissions. So you also create a group named Consultants and then add both Alice and Bob to the group. You first grant permissions by attaching a group policy to the group. Then you add user-specific permissions by attaching policies to specific users.

Note

The walkthrough uses companybucket as the bucket name, Alice and Bob as the IAM users, and Consultants as the group name. Because Amazon S3 requires that bucket names be globally unique, you must replace the bucket name with a name that you create.

Preparing for the walkthrough

In this example, you use your AWS account credentials to create IAM users. Initially, these users have no permissions. You incrementally grant these users permissions to perform specific Amazon S3 actions. To test these permissions, you sign in to the console with each user's credentials. As you incrementally grant permissions as an AWS account owner and test permissions as an IAM user, you need to sign in and out, each time using different credentials. You can do this testing with one browser, but the process will go faster if you can use two different browsers. Use one browser to connect to the AWS Management Console with your AWS account credentials and another browser to connect with the IAM user credentials.

To sign in to the AWS Management Console with your AWS account credentials, go to <https://console.aws.amazon.com/>. An IAM user can't sign in using the same link. An IAM user must use an IAM-enabled sign-in page. As the account owner, you can provide this link to your users.

For more information about IAM, see [The AWS Management Console Sign-in Page](#) in the *IAM User Guide*.

To provide a sign-in link for IAM users

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the **Navigation** pane, choose **IAM Dashboard**.
3. Note the URL under **IAM users sign in link**: You will give this link to IAM users to sign in to the console with their IAM user name and password.

Step 1: Create a bucket

In this step, you sign in to the Amazon S3 console with your AWS account credentials, create a bucket, add folders to the bucket, and upload one or two sample documents in each folder.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. Create a bucket.

For step-by-step instructions, see [Creating a general purpose bucket](#).

3. Upload one document to the bucket.

This exercise assumes that you have the s3-dg.pdf document at the root level of this bucket.

If you upload a different document, substitute its file name for s3-dg.pdf.

4. Add three folders named Private, Finance, and Development to the bucket.

For step-by-step instructions to create a folder, see [Organizing objects in the Amazon S3 console by using folders](#) in the *Amazon Simple Storage Service User Guide*.

5. Upload one or two documents to each folder.

For this exercise, assume that you have uploaded a couple of documents in each folder, resulting in the bucket having objects with the following keys:

- Private/privDoc1.txt
- Private/privDoc2.zip
- Development/project1.xls
- Development/project2.xls
- Finance/Tax2011/document1.pdf
- Finance/Tax2011/document2.pdf
- s3-dg.pdf

For step-by-step instructions, see [Uploading objects](#).

Step 2: Create IAM users and a group

Now use the [IAM Console](#) to add two IAM users, Alice and Bob, to your AWS account. For step-by-step instructions, see [Creating an IAM user in your AWS account](#) in the *IAM User Guide*.

Also create an administrative group named Consultants. Then add both users to the group. For step-by-step instructions, see [Creating IAM user groups](#).

Identity-based policies

API Version 2006-03-01 1623

Warning

When you add users and a group, do not attach any policies that grant permissions to these users. At first, these users don't have any permissions. In the following sections, you grant permissions incrementally. First you must ensure that you have assigned passwords to these IAM users. You use these user credentials to test Amazon S3 actions and verify that the permissions work as expected.

For step-by-step instructions for creating a new IAM user, see [Creating an IAM user in your AWS account](#) in the *IAM User Guide*. When you create the users for this walkthrough, select **AWS Management Console access** and clear [programmatic access](#).

For step-by-step instructions for creating an administrative group, see [Creating Your First IAM Admin User and Group](#) in the *IAM User Guide*.

Step 3: Verify that IAM users have no permissions

If you are using two browsers, you can now use the second browser to sign in to the console using one of the IAM user credentials.

1. Using the IAM user sign-in link (see [To provide a sign-in link for IAM users](#)), sign in to the AWS Management Console using either of the IAM user credentials.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

Verify the console message telling you that access is denied.

Now, you can begin granting incremental permissions to the users. First, you attach a group policy that grants permissions that both users must have.

Step 4: Grant group-level permissions

You want the users to be able to do the following:

- List all buckets owned by the parent account. To do so, Bob and Alice must have permission for the s3>ListAllMyBuckets action.
- List root-level items, folders, and objects in the companybucket bucket. To do so, Bob and Alice must have permission for the s3>ListBucket action on the companybucket bucket.

First, you create a policy that grants these permissions, and then you attach it to the Consultants group.

Step 4.1: Grant permission to list all buckets

In this step, you create a managed policy that grants the users minimum permissions to enable them to list all buckets owned by the parent account. Then you attach the policy to the Consultants group. When you attach the managed policy to a user or a group, you grant the user or group permission to obtain a list of buckets owned by the parent AWS account.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.

 **Note**

Because you are granting user permissions, sign in using your AWS account credentials, not as an IAM user.

2. Create the managed policy.
 - a. In the navigation pane on the left, choose **Policies**, and then choose **Create Policy**.
 - b. Choose the **JSON** tab.
 - c. Copy the following access policy and paste it into the policy text field.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowGroupToSeeBucketListInTheConsole",  
            "Action": ["s3>ListAllMyBuckets"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::*"]  
        }  
    ]  
}
```

A policy is a JSON document. In the document, a Statement is an array of objects, each describing a permission using a collection of name-value pairs. The preceding policy describes one specific permission. The Action specifies the type of access. In the policy, the s3>ListAllMyBuckets is a predefined Amazon S3 action. This action covers the Amazon S3 GET Service operation, which returns a list of all buckets owned by the authenticated sender. The Effect element value determines whether specific permission is allowed or denied.

- d. Choose **Review Policy**. On the next page, enter AllowGroupToSeeBucketListInTheConsole in the **Name** field, and then choose **Create policy**.

 **Note**

The **Summary** entry displays a message stating that the policy does not grant any permissions. For this walkthrough, you can safely ignore this message.

3. Attach the AllowGroupToSeeBucketListInTheConsole managed policy that you created to the Consultants group.

For step-by-step instructions for attaching a managed policy, see [Adding and removing IAM identity permissions](#) in the *IAM User Guide*.

You attach policy documents to IAM users and groups in the IAM console. Because you want both users to be able to list the buckets, you attach the policy to the group.

4. Test the permission.
 - a. Using the IAM user sign-in link (see [To provide a sign-in link for IAM users](#)), sign in to the console using any one of IAM user credentials.
 - b. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

The console should now list all the buckets but not the objects in any of the buckets.

Step 4.2: Enable users to list root-level content of a bucket

Next, you allow all users in the Consultants group to list the root-level companybucket bucket items. When a user chooses the company bucket on the Amazon S3 console, the user can see the root-level items in the bucket.

Note

This example uses companybucket for illustration. You must use the name of the bucket that you created.

To understand the request that the console sends to Amazon S3 when you choose a bucket name, the response that Amazon S3 returns, and how the console interprets the response, examine the flow a little more closely.

When you choose a bucket name, the console sends the [GET Bucket \(List Objects\)](#) request to Amazon S3. This request includes the following parameters:

- The prefix parameter with an empty string as its value.
- The delimiter parameter with / as its value.

The following is an example request.

```
GET ?prefix=&delimiter=/ HTTP/1.1
Host: companybucket.s3.amazonaws.com
Date: Wed, 01 Aug 2012 12:00:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:xQE0diMbLRepdf3YB+FIEXAMPLE=
```

Amazon S3 returns a response that includes the following <ListBucketResult> element.

```
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Name>companybucket</Name>
<Prefix></Prefix>
<Delimiter>/</Delimiter>
...
<Contents>
<Key>s3-dg.pdf</Key>
...
```

```
</Contents>
<CommonPrefixes>
  <Prefix>Development/</Prefix>
</CommonPrefixes>
<CommonPrefixes>
  <Prefix>Finance/</Prefix>
</CommonPrefixes>
<CommonPrefixes>
  <Prefix>Private/</Prefix>
</CommonPrefixes>
</ListBucketResult>
```

The key s3-dg.pdf object does not contain the slash (/) delimiter, and Amazon S3 returns the key in the <Contents> element. However, all other keys in the example bucket contain the / delimiter. Amazon S3 groups these keys and returns a <CommonPrefixes> element for each of the distinct prefix values Development/, Finance/, and Private/ that is a substring from the beginning of these keys to the first occurrence of the specified / delimiter.

The console interprets this result and displays the root-level items as three folders and one object key.

If Bob or Alice opens the **Development** folder, the console sends the [GET Bucket \(List Objects\)](#) request to Amazon S3 with the prefix and the delimiter parameters set to the following values:

- The prefix parameter with the value Development/.
- The delimiter parameter with the "/" value.

In response, Amazon S3 returns the object keys that start with the specified prefix.

```
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Name>companybucket</Name>
  <Prefix>Development/<Prefix>
  <Delimiter>/</Delimiter>
  ...
  <Contents>
    <Key>Project1.xls</Key>
    ...
  </Contents>
  <Contents>
    <Key>Project2.xls</Key>
```

```
...
</Contents>
</ListBucketResult>
```

The console shows the object keys.

Now, return to granting users permission to list the root-level bucket items. To list bucket content, users need permission to call the `s3>ListBucket` action, as shown in the following policy statement. To ensure that they see only the root-level content, you add a condition that users must specify an empty prefix in the request—that is, they are not allowed to double-click any of the root-level folders. Finally, you add a condition to require folder-style access by requiring user requests to include the `delimiter` parameter with the value `/`.

```
{
    "Sid": "AllowRootLevelListingOfCompanyBucket",
    "Action": ["s3>ListBucket"],
    "Effect": "Allow",
    "Resource": ["arn:aws:s3:::companybucket"],
    "Condition": {
        "StringEquals": {
            "s3:prefix": [""], "s3:delimiter": ["/"]
        }
    }
}
```

When you choose a bucket on the Amazon S3 console, the console first sends the [GET Bucket location](#) request to find the AWS Region where the bucket is deployed. Then the console uses the Region-specific endpoint for the bucket to send the [GET Bucket \(List Objects\)](#) request. As a result, if users are going to use the console, you must grant permission for the `s3:GetBucketLocation` action as shown in the following policy statement.

```
{
    "Sid": "RequiredByS3Console",
    "Action": ["s3:GetBucketLocation"],
    "Effect": "Allow",
    "Resource": ["arn:aws:s3:::*"]
}
```

To enable users to list root-level bucket content

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.

Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Replace the existing AllowGroupToSeeBucketListInTheConsole managed policy that is attached to the Consultants group with the following policy, which also allows the s3>ListBucket action. Remember to replace **companybucket** in the policy Resource with the name of your bucket.

For step-by-step instructions, see [Editing IAM policies](#) in the *IAM User Guide*. When following the step-by-step instructions, be sure to follow the steps for applying your changes to all principal entities that the policy is attached to.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowGroupToSeeBucketListAndAlsoAllowGetBucketLocationRequiredForListBucket",  
            "Action": [ "s3>ListAllMyBuckets", "s3>GetBucketLocation" ],  
            "Effect": "Allow",  
            "Resource": [ "arn:aws:s3:::*" ]  
        },  
        {  
            "Sid": "AllowRootLevelListingOfCompanyBucket",  
            "Action": [ "s3>ListBucket" ],  
            "Effect": "Allow",  
            "Resource": [ "arn:aws:s3:::companybucket" ],  
            "Condition":{  
                "StringEquals":{  
                    "s3:prefix":[""], "s3:delimiter":["/"]  
                }  
            }  
        }  
    ]  
}
```

3. Test the updated permissions.

- a. Using the IAM user sign-in link (see [To provide a sign-in link for IAM users](#)), sign in to the AWS Management Console.

Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

- b. Choose the bucket that you created, and the console shows the root-level bucket items. If you choose any folders in the bucket, you won't be able to see the folder content because you haven't yet granted those permissions.

This test succeeds when users use the Amazon S3 console. When you choose a bucket on the console, the console implementation sends a request that includes the prefix parameter with an empty string as its value and the delimiter parameter with "/" as its value.

Step 4.3: Summary of the group policy

The net effect of the group policy that you added is to grant the IAM users Alice and Bob the following minimum permissions:

- List all buckets owned by the parent account.
- See root-level items in the companybucket bucket.

However, the users still can't do much. Next, you grant user-specific permissions, as follows:

- Allow Alice to get and put objects in the Development folder.
- Allow Bob to get and put objects in the Finance folder.

For user-specific permissions, you attach a policy to the specific user, not to the group. In the following section, you grant Alice permission to work in the Development folder. You can repeat the steps to grant similar permission to Bob to work in the Finance folder.

Step 5: Grant IAM user Alice specific permissions

Now you grant additional permissions to Alice so that she can see the content of the Development folder and get and put objects in that folder.

Step 5.1: Grant IAM user Alice permission to list the development folder content

For Alice to list the Development folder content, you must apply a policy to the user Alice that grants permission for the s3:ListBucket action on the companybucket bucket, provided the request includes the prefix Development/. You want this policy to be applied only to the user Alice, so you use an inline policy. For more information about inline policies, see [Managed policies and inline policies](#) in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.

Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Create an inline policy to grant the user Alice permission to list the Development folder content.
 - a. In the navigation pane on the left, choose **Users**.
 - b. Choose the username **Alice**.
 - c. On the user details page, choose the **Permissions** tab and then choose **Add inline policy**.
 - d. Choose the **JSON** tab.
 - e. Copy the following policy, and paste it into the policy text field.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowListBucketIfSpecificPrefixIsIncludedInRequest",  
            "Action": ["s3>ListBucket"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::companybucket"],  
            "Condition": { "StringLike": {"s3:prefix": ["Development/*"] } }  
        }  
    ]  
}
```

- f. Choose **Review Policy**. On the next page, enter a name in the **Name** field, and then choose **Create policy**.

3. Test the change to Alice's permissions:

- a. Using the IAM user sign-in link (see [To provide a sign-in link for IAM users](#)), sign in to the AWS Management Console.
- b. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- c. On the Amazon S3 console, verify that Alice can see the list of objects in the Development/ folder in the bucket.

When the user chooses the /Development folder to see the list of objects in it, the Amazon S3 console sends the `ListObjects` request to Amazon S3 with the prefix / Development. Because the user is granted permission to see the object list with the prefix Development and delimiter /, Amazon S3 returns the list of objects with the key prefix Development/, and the console displays the list.

Step 5.2: Grant IAM user Alice permissions to get and put objects in the development folder

For Alice to get and put objects in the Development folder, she needs permission to call the `s3:GetObject` and `s3:PutObject` actions. The following policy statements grant these permissions, provided that the request includes the `prefix` parameter with a value of Development/.

```
{  
    "Sid": "AllowUserReadWriteObjectData",  
    "Action": ["s3:GetObject", "s3:PutObject"],  
    "Effect": "Allow",  
    "Resource": ["arn:aws:s3:::companybucket/Development/*"]  
}
```

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Edit the inline policy that you created in the previous step.
 - a. In the navigation pane on the left, choose **Users**.
 - b. Choose the user name Alice.

- c. On the user details page, choose the **Permissions** tab and expand the **Inline Policies** section.
- d. Next to the name of the policy that you created in the previous step, choose **Edit Policy**.
- e. Copy the following policy and paste it into the policy text field, replacing the existing policy.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowListBucketIfSpecificPrefixIsIncludedInRequest",  
            "Action": ["s3>ListBucket"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::companybucket"],  
            "Condition": {  
                "StringLike": {"s3:prefix": ["Development/*"]} }  
        },  
        {  
            "Sid": "AllowUserToReadWriteObjectDataInDevelopmentFolder",  
            "Action": ["s3>GetObject", "s3>PutObject"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::companybucket/Development/*"]  
        }  
    ]  
}
```

3. Test the updated policy:

- a. Using the IAM user sign-in link (see [To provide a sign-in link for IAM users](#)), sign into the AWS Management Console.
- b. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- c. On the Amazon S3 console, verify that Alice can now add an object and download an object in the Development folder.

Step 5.3: Explicitly deny IAM user Alice permissions to any other folders in the bucket

User Alice can now list the root-level content in the companybucket bucket. She can also get and put objects in the Development folder. If you really want to tighten the access permissions, you could explicitly deny Alice access to any other folders in the bucket. If there is any other policy (bucket policy or ACL) that grants Alice access to any other folders in the bucket, this explicit deny overrides those permissions.

You can add the following statement to the user Alice policy that requires all requests that Alice sends to Amazon S3 to include the prefix parameter, whose value can be either Development/* or an empty string.

```
{  
    "Sid": "ExplicitlyDenyAnyRequestsForAllOtherFoldersExceptDevelopment",  
    "Action": ["s3>ListBucket"],  
    "Effect": "Deny",  
    "Resource": ["arn:aws:s3:::companybucket"],  
    "Condition": { "StringNotLike": {"s3:prefix": ["Development/*", ""] } ,  
                  "Null" : {"s3:prefix": false }  
                }  
}
```

There are two conditional expressions in the Condition block. The result of these conditional expressions is combined by using the logical AND. If both conditions are true, the result of the combined condition is true. Because the Effect in this policy is Deny, when the Condition evaluates to true, users can't perform the specified Action.

- The Null conditional expression ensures that requests from Alice include the prefix parameter.

The prefix parameter requires folder-like access. If you send a request without the prefix parameter, Amazon S3 returns all the object keys.

If the request includes the prefix parameter with a null value, the expression evaluates to true, and so the entire Condition evaluates to true. You must allow an empty string as value of the prefix parameter. From the preceding discussion, recall that allowing the null string allows Alice to retrieve root-level bucket items as the console does in the preceding discussion. For more information, see [Step 4.2: Enable users to list root-level content of a bucket](#).

- The StringNotLike conditional expression ensures that if the value of the prefix parameter is specified and is not Development/*, the request fails.

Follow the steps in the preceding section and again update the inline policy that you created for user Alice.

Copy the following policy and paste it into the policy text field, replacing the existing policy.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowListBucketIfSpecificPrefixIsIncludedInRequest",  
            "Action": ["s3>ListBucket"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::companybucket"],  
            "Condition": {  
                "StringLike": {"s3:prefix": ["Development/*"]}  
            }  
        },  
        {  
            "Sid": "AllowUserToReadWriteObjectDataInDevelopmentFolder",  
            "Action": ["s3>GetObject", "s3>PutObject"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::companybucket/Development/*"]  
        },  
        {  
            "Sid": "ExplicitlyDenyAnyRequestsForAllOtherFoldersExceptDevelopment",  
            "Action": ["s3>ListBucket"],  
            "Effect": "Deny",  
            "Resource": ["arn:aws:s3:::companybucket"],  
            "Condition": {  
                "StringNotLike": {"s3:prefix": ["Development/*", ""]},  
                "Null": {"s3:prefix": false}  
            }  
        }  
    ]  
}
```

Step 6: Grant IAM user Bob specific permissions

Now you want to grant Bob permission to the Finance folder. Follow the steps that you used earlier to grant permissions to Alice, but replace the Development folder with the Finance folder. For step-by-step instructions, see [Step 5: Grant IAM user Alice specific permissions](#).

Step 7: Secure the private folder

In this example, you have only two users. You granted all the minimum required permissions at the group level and granted user-level permissions only when you really need to permissions at the individual user level. This approach helps minimize the effort of managing permissions. As the number of users increases, managing permissions can become cumbersome. For example, you don't want any of the users in this example to access the content of the Private folder. How do you ensure that you don't accidentally grant a user permission to the Private folder? You add a policy that explicitly denies access to the folder. An explicit deny overrides any other permissions.

To ensure that the Private folder remains private, you can add the following two deny statements to the group policy:

- Add the following statement to explicitly deny any action on resources in the Private folder (companybucket/Private/*).

```
{  
    "Sid": "ExplicitDenyAccessToPrivateFolderToEveryoneInTheGroup",  
    "Action": ["s3:*"],  
    "Effect": "Deny",  
    "Resource": ["arn:aws:s3:::companybucket/Private/*"]  
}
```

- You also deny permission for the list objects action when the request specifies the Private/ prefix. On the console, if Bob or Alice opens the Private folder, this policy causes Amazon S3 to return an error response.

```
{  
    "Sid": "DenyListBucketOnPrivateFolder",  
    "Action": ["s3>ListBucket"],  
    "Effect": "Deny",  
    "Resource": ["arn:aws:s3:::*"],  
    "Condition": {  
        "StringLike": {"s3:prefix": ["Private/"]} }  
}
```

{

Replace the Consultants group policy with an updated policy that includes the preceding deny statements. After the updated policy is applied, none of the users in the group can access the Private folder in your bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Replace the existing AllowGroupToSeeBucketListInTheConsole managed policy that is attached to the Consultants group with the following policy. Remember to replace **companybucket** in the policy with the name of your bucket.

For instructions, see [Editing customer managed policies](#) in the *IAM User Guide*. When following the instructions, make sure to follow the directions for applying your changes to all principal entities that the policy is attached to.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowGroupToSeeBucketListAndAlsoAllowGetBucketLocationRequiredForListBucket",  
            "Action": ["s3>ListAllMyBuckets", "s3:GetBucketLocation"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::*"]  
        },  
        {  
            "Sid": "AllowRootLevelListingOfCompanyBucket",  
            "Action": ["s3>ListBucket"],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::companybucket"],  
            "Condition":{  
                "StringEquals": {"s3:prefix": [""]}  
            }  
        },  
        {  
    ]}
```

```
        "Sid": "RequireFolderStyleList",
        "Action": ["s3>ListBucket"],
        "Effect": "Deny",
        "Resource": ["arn:aws:s3:::*"],
        "Condition": {
            "StringNotEquals": {"s3:delimiter": "/"}
        }
    },
    {
        "Sid": "ExplicitDenyAccessToPrivateFolderToEveryoneInTheGroup",
        "Action": ["s3:*"],
        "Effect": "Deny",
        "Resource": ["arn:aws:s3:::companybucket/Private/*"]
    },
    {
        "Sid": "DenyListBucketOnPrivateFolder",
        "Action": ["s3>ListBucket"],
        "Effect": "Deny",
        "Resource": ["arn:aws:s3:::*"],
        "Condition": {
            "StringLike": {"s3:prefix": ["Private/"]}
        }
    }
]
```

Step 8: Clean up

To clean up, open the [IAM Console](#) and remove the users Alice and Bob. For step-by-step instructions, see [Deleting an IAM user](#) in the *IAM User Guide*.

To ensure that you aren't charged further for storage, you should also delete the objects and the bucket that you created for this exercise.

Identity-based policy examples for Amazon S3

This section shows several example AWS Identity and Access Management (IAM) identity-based policies for controlling access to Amazon S3. For example *bucket policies* (resource-based policies), see [Bucket policies for Amazon S3](#). For information about IAM policy language, see [Policies and permissions in Amazon S3](#).

The following example policies will work if you use them programmatically. However, to use them with the Amazon S3 console, you must grant additional permissions that are required by the console. For information about using policies such as these with the Amazon S3 console, see [Controlling access to a bucket with user policies](#).

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Allowing an IAM user access to one of your buckets

In this example, you want to grant an IAM user in your AWS account access to one of your buckets, `amzn-s3-demo-bucket1`, and allow the user to add, update, and delete objects.

In addition to granting the `s3:PutObject`, `s3:GetObject`, and `s3:DeleteObject` permissions to the user, the policy also grants the `s3>ListAllMyBuckets`, `s3:GetBucketLocation`, and `s3>ListBucket` permissions. These are the additional permissions required by the console. Also, the `s3:PutObjectAcl` and the `s3:GetObjectAcl` actions are required to be able to copy, cut,

and paste objects in the console. For an example walkthrough that grants permissions to users and tests them using the console, see [Controlling access to a bucket with user policies](#).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3>ListAllMyBuckets",  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": ["s3>ListBucket", "s3:GetBucketLocation"],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3>PutObject",  
                "s3>PutObjectAcl",  
                "s3>GetObject",  
                "s3>GetObjectAcl",  
                "s3>DeleteObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"  
        }  
    ]  
}
```

Allowing each IAM user access to a folder in a bucket

In this example, you want two IAM users, Mary and Carlos, to have access to your bucket, *amzn-s3-demo-bucket1*, so that they can add, update, and delete objects. However, you want to restrict each user's access to a single prefix (folder) in the bucket. You might create folders with names that match their usernames.

amzn-s3-demo-bucket1

Mary/

Carlos/

To grant each user access only to their folder, you can write a policy for each user and attach it individually. For example, you can attach the following policy to the user Mary to allow her specific Amazon S3 permissions on the *amzn-s3-demo-bucket1/Mary* folder.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject",  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:DeleteObject",  
                "s3:DeleteObjectVersion"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/Mary/*"  
        }  
    ]  
}
```

You can then attach a similar policy to the user Carlos, specifying the folder *Carlos* in the Resource value.

Instead of attaching policies to individual users, you can write a single policy that uses a policy variable and then attach the policy to a group. First, you must create a group and add both Mary and Carlos to the group. The following example policy allows a set of Amazon S3 permissions in the *amzn-s3-demo-bucket1/\${aws:username}* folder. When the policy is evaluated, the policy variable \${aws:username} is replaced by the requester's username. For example, if Mary sends a request to put an object, the operation is allowed only if Mary is uploading the object to the *amzn-s3-demo-bucket1/Mary* folder.

JSON

```
{
```

```
"Version":"2012-10-17",
"Statement": [
    {
        "Effect":"Allow",
        "Action":[
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
        ],
        "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/${aws:username}/*"
    }
]
```

 **Note**

When using policy variables, you must explicitly specify version 2012-10-17 in the policy. The default version of the IAM policy language, 2008-10-17, does not support policy variables.

If you want to test the preceding policy on the Amazon S3 console, the console requires additional permissions, as shown in the following policy. For information about how the console uses these permissions, see [Controlling access to a bucket with user policies](#).

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowGroupToSeeBucketListInTheConsole",
            "Action": [
                "s3>ListAllMyBuckets",
                "s3:GetBucketLocation"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws:s3:::/*"
        }
    ]
}
```

```
},
{
    "Sid": "AllowRootLevelListingOfTheBucket",
    "Action": "s3>ListBucket",
    "Effect": "Allow",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1",
    "Condition": {
        "StringEquals": {
            "s3:prefix": [""], "s3:delimiter": ["/"]
        }
    }
},
{
    "Sid": "AllowListBucketOfASpecificUserPrefix",
    "Action": "s3>ListBucket",
    "Effect": "Allow",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1",
    "Condition": { "StringLike": {"s3:prefix": ["${aws:username}/*"] } }
},
{
    "Sid": "AllowUserSpecificActionsOnlyInTheSpecificUserPrefix",
    "Effect": "Allow",
    "Action": [
        "s3>PutObject",
        "s3>GetObject",
        "s3>GetObjectVersion",
        "s3>DeleteObject",
        "s3>DeleteObjectVersion"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/${aws:username}/*"
}
]
```

Note

In the 2012-10-17 version of the policy, policy variables start with \$. This change in syntax can potentially create a conflict if your object key (object name) includes a \$.

To avoid this conflict, specify the \$ character by using \${\$}. For example, to include the object key my\$file in a policy, specify it as my\${\$}file.

Although IAM user names are friendly, human-readable identifiers, they aren't required to be globally unique. For example, if the user Carlos leaves the organization and another Carlos joins, then the new Carlos could access the old Carlos's information.

Instead of using usernames, you could create folders based on IAM user IDs. Each IAM user ID is unique. In this case, you must modify the preceding policy to use the \${aws:userid} policy variable. For more information about user identifiers, see [IAM Identifiers](#) in the *IAM User Guide*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject",  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:DeleteObject",  
                "s3:DeleteObjectVersion"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/home/${aws:userid}/*"  
        }  
    ]  
}
```

Allowing non-IAM users (mobile app users) access to folders in a bucket

Suppose that you want to develop a mobile app, a game that stores users' data in an S3 bucket. For each app user, you want to create a folder in your bucket. You also want to limit each user's access to their own folder. But you can't create folders before someone downloads your app and starts playing the game, because you don't have their user ID.

In this case, you can require users to sign in to your app by using public identity providers such as Login with Amazon, Facebook, or Google. After users have signed in to your app through one of these providers, they have a user ID that you can use to create user-specific folders at runtime.

You can then use web identity federation in AWS Security Token Service to integrate information from the identity provider with your app and to get temporary security credentials for each user.

You can then create IAM policies that allow the app to access your bucket and perform such operations as creating user-specific folders and uploading data. For more information about web identity federation, see [About web identity Federation](#) in the *IAM User Guide*.

Allowing a group to have a shared folder in Amazon S3

Attaching the following policy to the group grants everybody in the group access to the following folder in Amazon S3: *amzn-s3-demo-bucket1/share/marketing*. Group members are allowed to access only the specific Amazon S3 permissions shown in the policy and only for objects in the specified folder.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject",  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:DeleteObject",  
                "s3:DeleteObjectVersion"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/share/marketing/*"  
        }  
    ]  
}
```

Allowing all your users to read objects in a portion of a bucket

In this example, you create a group named *AllUsers*, which contains all the IAM users that are owned by the AWS account. You then attach a policy that gives the group access to GetObject and GetObjectVersion, but only for objects in the *amzn-s3-demo-bucket1/readonly* folder.

JSON

```
{
```

```
"Version":"2012-10-17",
"Statement": [
    {
        "Effect":"Allow",
        "Action":[
            "s3:GetObject",
            "s3:GetObjectVersion"
        ],
        "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/readonly/*"
    }
]
```

Allowing a partner to drop files into a specific portion of a bucket

In this example, you create a group called *AnyCompany* that represents a partner company. You create an IAM user for the specific person or application at the partner company that needs access, and then you put the user in the group.

You then attach a policy that gives the group PutObject access to the following folder in a bucket:

amzn-s3-demo-bucket1/uploads/anycompany

You want to prevent the *AnyCompany* group from doing anything else with the bucket, so you add a statement that explicitly denies permission to any Amazon S3 actions except PutObject on any Amazon S3 resource in the AWS account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action":"s3:PutObject",
            "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/uploads/anycompany/*"
        },
        {
            "Effect":"Deny",
            "Action":"s3:*",
        }
    ]
}
```

```
        "NotResource": "arn:aws:s3:::amzn-s3-demo-bucket1/uploads/anycompany/*"
    }
]
}
```

Restricting access to Amazon S3 buckets within a specific AWS account

If you want to ensure that your Amazon S3 principals are accessing only the resources that are inside of a trusted AWS account, you can restrict access. For example, this [identity-based IAM policy](#) uses a Deny effect to block access to Amazon S3 actions, unless the Amazon S3 resource that's being accessed is in account **222222222222**. To prevent an IAM principal in an AWS account from accessing Amazon S3 objects outside of the account, attach the following IAM policy:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyS3AccessOutsideMyBoundary",
      "Effect": "Deny",
      "Action": [
        "s3:*"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": [
            "222222222222"
          ]
        }
      }
    ]
  }
}
```

Note

This policy doesn't replace your existing IAM access controls, because it doesn't grant any access. Instead, this policy acts as an additional guardrail for your other IAM permissions, regardless of the permissions granted through other IAM policies.

Make sure to replace account ID **222222222222** in the policy with your own AWS account. To apply a policy to multiple accounts while still maintaining this restriction, replace the account ID with the `aws:PrincipalAccount` condition key. This condition requires that the principal and the resource must be in the same account.

Restricting access to Amazon S3 buckets within your organizational unit

If you have an [organizational unit \(OU\)](#) set up in AWS Organizations, you might want to restrict Amazon S3 bucket access to a specific part of your organization. In this example, we'll use the `aws:ResourceOrgPaths` key to restrict Amazon S3 bucket access to an OU in your organization. For this example, the [OU ID](#) is ***ou-acroot-exampleou***. Make sure to replace this value in your own policy with your own OU IDs.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3AccessOutsideMyBoundary",
            "Effect": "Allow",
            "Action": [
                "s3:*"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "aws:ResourceOrgPaths": [
                        "o-acorg/r-acroot/ou-acroot-exampleou/"
                    ]
                }
            }
        }
    ]
}
```

```
    ]  
}
```

Note

This policy doesn't grant any access. Instead, this policy acts as a backstop for your other IAM permissions, preventing your principals from accessing Amazon S3 objects outside of an OU-defined boundary.

The policy denies access to Amazon S3 actions unless the Amazon S3 object that's being accessed is in the *ou-acroot-exampleou* OU in your organization. The [IAM policy condition](#) requires `aws:ResourceOrgPaths`, a multivalued condition key, to contain any of the listed OU paths. The policy uses the `ForAllValues:StringNotLike` operator to compare the values of `aws:ResourceOrgPaths` to the listed OUs without case-sensitive matching.

Restricting access to Amazon S3 buckets within your organization

To restrict access to Amazon S3 objects within your organization, attach an IAM policy to the root of the organization, applying it to all accounts in your organization. To require your IAM principals to follow this rule, use a [service-control policy \(SCP\)](#). If you choose to use an SCP, make sure to thoroughly [test the SCP](#) before attaching the policy to the root of the organization.

In the following example policy, access is denied to Amazon S3 actions unless the Amazon S3 object that's being accessed is in the same organization as the IAM principal that is accessing it:

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "DenyS3AccessOutsideMyBoundary",  
      "Effect": "Deny",  
      "Action": [  
        "s3:*"  
      ],  
      "Resource": "arn:aws:s3:::/*",  
      "Condition": {
```

```
        "StringNotEquals": {
            "aws:ResourceOrgID": "${aws:PrincipalOrgID}"
        }
    }
}
]
```

Note

This policy doesn't grant any access. Instead, this policy acts as a backstop for your other IAM permissions, preventing your principals from accessing any Amazon S3 objects outside of your organization. This policy also applies to Amazon S3 resources that are created after the policy is put into effect.

The [IAM policy condition](#) in this example requires `aws:ResourceOrgID` and `aws:PrincipalOrgID` to be equal to each other. With this requirement, the principal making the request and the resource being accessed must be in the same organization.

Granting permission to retrieve the PublicAccessBlock configuration for an AWS account

The following example identity-based policy grants the `s3:GetAccountPublicAccessBlock` permission to a user. For these permissions, you set the `Resource` value to `"*"`. For information about resource ARNs, see [Policy resources for Amazon S3](#).

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Action": [
                "s3:GetAccountPublicAccessBlock"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

```
        ]
    }
]
}
```

Restricting bucket creation to one Region

Suppose that an AWS account administrator wants to grant its user (Dave) permission to create a bucket in the South America (São Paulo) Region only. The account administrator can attach the following user policy granting the s3:CreateBucket permission with a condition as shown. The key-value pair in the Condition block specifies the s3:LocationConstraint key and the sa-east-1 Region as its value.

Note

In this example, the bucket owner is granting permission to one of its users, so either a bucket policy or a user policy can be used. This example shows a user policy.

For a list of Amazon S3 Regions, see [Regions and Endpoints](#) in the *AWS General Reference*.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Action": "s3:CreateBucket",
            "Resource": "arn:aws:s3:::*",
            "Condition": {
                "StringLike": {
                    "s3:LocationConstraint": "sa-east-1"
                }
            }
        }
    ]
}
```

Add explicit deny

The preceding policy restricts the user from creating a bucket in any other Region except sa-east-1. However, some other policy might grant this user permission to create buckets in another Region. For example, if the user belongs to a group, the group might have a policy attached to it that allows all users in the group permission to create buckets in another Region. To ensure that the user doesn't get permission to create buckets in any other Region, you can add an explicit deny statement in the above policy.

The Deny statement uses the `StringNotLike` condition. That is, a create bucket request is denied if the location constraint is not `sa-east-1`. The explicit deny doesn't allow the user to create a bucket in any other Region, no matter what other permission the user gets. The following policy includes an explicit deny statement.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Action": "s3:CreateBucket",  
            "Resource": "arn:aws:s3:::*",  
            "Condition": {  
                "StringLike": {  
                    "s3:LocationConstraint": "sa-east-1"  
                }  
            }  
        },  
        {  
            "Sid": "statement2",  
            "Effect": "Deny",  
            "Action": "s3:CreateBucket",  
            "Resource": "arn:aws:s3:::*",  
            "Condition": {  
                "StringNotLike": {  
                    "s3:LocationConstraint": "sa-east-1"  
                }  
            }  
        }  
    ]  
}
```

] }
}

Test the policy with the AWS CLI

You can test the policy using the following `create-bucket` AWS CLI command. This example uses the `bucketconfig.txt` file to specify the location constraint. Note the Windows file path. You need to update the bucket name and path as appropriate. You must provide user credentials using the `--profile` parameter. For more information about setting up and using the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the *Amazon S3 API Reference*.

```
aws s3api create-bucket --bucket examplebucket --profile AccountADave --create-bucket-configuration file://c:/Users/someUser/bucketconfig.txt
```

The `bucketconfig.txt` file specifies the configuration as follows.

```
{"LocationConstraint": "sa-east-1"}
```

Walkthroughs that use policies to manage access to your Amazon S3 resources

This topic provides the following introductory walkthrough examples for granting access to Amazon S3 resources. These examples use the AWS Management Console to create resources (buckets, objects, users) and grant them permissions. The examples then show you how to verify permissions using the command line tools, so you don't have to write any code. We provide commands using both the AWS Command Line Interface (AWS CLI) and the AWS Tools for Windows PowerShell.

- [Example 1: Bucket owner granting its users bucket permissions](#)

The IAM users you create in your account have no permissions by default. In this exercise, you grant a user permission to perform bucket and object operations.

- [Example 2: Bucket owner granting cross-account bucket permissions](#)

In this exercise, a bucket owner, Account A, grants cross-account permissions to another AWS account, Account B. Account B then delegates those permissions to users in its account.

- **Managing object permissions when the object and bucket owners are not the same**

The example scenarios in this case are about a bucket owner granting object permissions to others, but not all objects in the bucket are owned by the bucket owner. What permissions does the bucket owner need, and how can it delegate those permissions?

The AWS account that creates a bucket is called the *bucket owner*. The owner can grant other AWS accounts permission to upload objects, and the AWS accounts that create objects own them. The bucket owner has no permissions on those objects created by other AWS accounts. If the bucket owner writes a bucket policy granting access to objects, the policy doesn't apply to objects that are owned by other accounts.

In this case, the object owner must first grant permissions to the bucket owner using an object ACL. The bucket owner can then delegate those object permissions to others, to users in its own account, or to another AWS account, as illustrated by the following examples.

- [Example 3: Bucket owner granting permissions to objects it does not own](#)

In this exercise, the bucket owner first gets permissions from the object owner. The bucket owner then delegates those permissions to users in its own account.

- [Example 4 - Bucket owner granting cross-account permission to objects it does not own](#)

After receiving permissions from the object owner, the bucket owner can't delegate permission to other AWS accounts because cross-account delegation isn't supported (see [Permission delegation](#)). Instead, the bucket owner can create an IAM role with permissions to perform specific operations (such as get object) and allow another AWS account to assume that role. Anyone who assumes the role can then access objects. This example shows how a bucket owner can use an IAM role to enable this cross-account delegation.

Before you try the example walkthroughs

These examples use the AWS Management Console to create resources and grant permissions. To test permissions, the examples use the command line tools, AWS CLI, and AWS Tools for Windows PowerShell, so you don't need to write any code. To test permissions, you must set up one of these tools. For more information, see [Setting up the tools for the walkthroughs](#).

In addition, when creating resources, these examples don't use root user credentials of an AWS account. Instead, you create an administrator user in these accounts to perform these tasks.

About using an administrator user to create resources and grant permissions

AWS Identity and Access Management (IAM) recommends not using the root user credentials of your AWS account to make requests. Instead, create an IAM user or role, grant them full access, and then use their credentials to make requests. We refer to this as an administrative user or role. For more information, go to [AWS account root user credentials and IAM identities](#) in the *AWS General Reference* and [IAM Best Practices](#) in the *IAM User Guide*.

All example walkthroughs in this section use the administrator user credentials. If you have not created an administrator user for your AWS account, the topics show you how.

To sign in to the AWS Management Console using the user credentials, you must use the IAM user sign-In URL. The [IAM Console](#) provides this URL for your AWS account. The topics show you how to get the URL.

Setting up the tools for the walkthroughs

The introductory examples (see [Walkthroughs that use policies to manage access to your Amazon S3 resources](#)) use the AWS Management Console to create resources and grant permissions. To test permissions, the examples use the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code. To test permissions, you must set up one of these tools.

To set up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the *AWS Command Line Interface User Guide*:

[Install or update to the latest version of the AWS Command Line Interface](#)

[Get started with the AWS Command Line Interface](#)

2. Set the default profile.

You store user credentials in the AWS CLI config file. Create a default profile in the config file using your AWS account credentials. For instructions on finding and editing your AWS CLI config file, see [Configuration and credential file settings](#).

```
[default]
aws_access_key_id = access key ID
aws_secret_access_key = secret access key
region = us-west-2
```

3. Verify the setup by entering the following command at the command prompt. Both these commands don't provide credentials explicitly, so the credentials of the default profile are used.

- Try the help command.

```
aws help
```

- To get a list of buckets on the configured account, use the aws s3 ls command.

```
aws s3 ls
```

As you go through the walkthroughs, you will create users, and you will save user credentials in the config files by creating profiles, as the following example shows. These profiles have the names of AccountAdmin and AccountBadmin.

```
[profile AccountAdmin]
aws_access_key_id = User AccountAdmin access key ID
aws_secret_access_key = User AccountAdmin secret access key
region = us-west-2
```

```
[profile AccountBadmin]
aws_access_key_id = Account B access key ID
aws_secret_access_key = Account B secret access key
region = us-east-1
```

To run a command using these user credentials, you add the `--profile` parameter specifying the profile name. The following AWS CLI command retrieves a listing of objects in *examplebucket* and specifies the AccountBadmin profile.

```
aws s3 ls s3://examplebucket --profile AccountBadmin
```

Alternatively, you can configure one set of user credentials as the default profile by changing the `AWS_DEFAULT_PROFILE` environment variable from the command prompt. After you've done this, whenever you perform AWS CLI commands without the `--profile` parameter, the AWS CLI uses the profile you set in the environment variable as the default profile.

```
$ export AWS_DEFAULT_PROFILE=AccountAadmin
```

To set up AWS Tools for Windows PowerShell

1. Download and configure the AWS Tools for Windows PowerShell. For instructions, go to [Installing the AWS Tools for Windows PowerShell](#) in the *AWS Tools for PowerShell User Guide*.

 **Note**

To load the AWS Tools for Windows PowerShell module, you must enable PowerShell script execution. For more information, see [Enable Script Execution](#) in the *AWS Tools for PowerShell User Guide*.

2. For these walkthroughs, you specify AWS credentials per session using the `Set-AWSCredentials` command. The command saves the credentials to a persistent store (`-StoreAs` parameter).

```
Set-AWSCredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -
storeas string
```

3. Verify the setup.

- To retrieve a list of available commands that you can use for Amazon S3 operations, run the Get-Command command.

```
Get-Command -module awspowershell -noun s3* -StoredCredentials string
```

- To retrieve a list of objects in a bucket, run the Get-S3Object command.

```
Get-S3Object -BucketName bucketname -StoredCredentials string
```

For a list of commands, see [AWS Tools for PowerShell Cmdlet Reference](#).

Now you're ready to try the walkthroughs. Follow the links provided at the beginning of each section.

Example 1: Bucket owner granting its users bucket permissions

⚠ Important

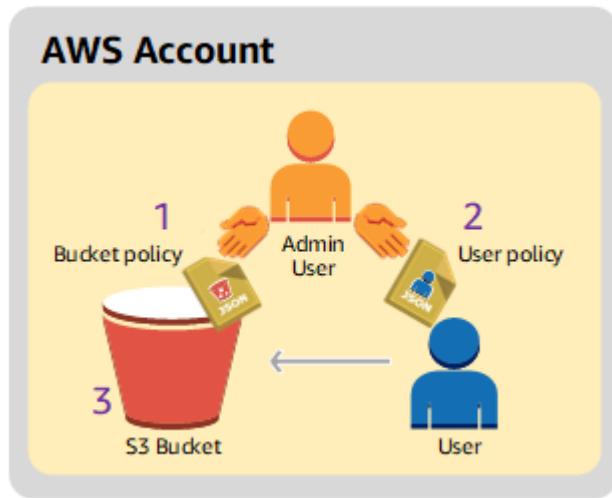

Granting permissions to IAM roles is a better practice than granting permissions to individual users. For more information about how to grant permissions to IAM roles, see [Understanding cross-account permissions and using IAM roles](#).

Topics

- [Preparing for the walkthrough](#)
- [Step 1: Create resources in Account A and grant permissions](#)
- [Step 2: Test permissions](#)

In this walkthrough, an AWS account owns a bucket, and the account includes an IAM user. By default, the user has no permissions. For the user to perform any tasks, the parent account must grant them permissions. The bucket owner and parent account are the same. Therefore, to grant the user permissions on the bucket, the AWS account can use a bucket policy, a user policy, or both. The account owner will grant some permissions using a bucket policy and other permissions using a user policy.

The following steps summarize the walkthrough:

1. Account administrator creates a bucket policy granting a set of permissions to the user.
2. Account administrator attaches a user policy to the user granting additional permissions.
3. User then tries permissions granted via both the bucket policy and the user policy.

For this example, you will need an AWS account. Instead of using the root user credentials of the account, you will create an administrator user (see [About using an administrator user to create resources and grant permissions](#)). We refer to the AWS account and the administrator user as shown in the following table.

Account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAAdmin

 **Note**

The administrator user in this example is **AccountAAdmin**, which refers to Account A, and not **AccountAdmin**.

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Preparing for the walkthrough

1. Make sure you have an AWS account and that it has a user with administrator privileges.
 - a. Sign up for an AWS account, if needed. We refer to this account as Account A.
 - i. Go to <https://aws.amazon.com/s3> and choose **Create an AWS account**.
 - ii. Follow the on-screen instructions.AWS will notify you by email when your account is active and available for you to use.
 - b. In Account A, create an administrator user **AccountAAdmin**. Using Account A credentials, sign in to the [IAM console](#) and do the following:
 - i. Create user **AccountAAdmin** and note the user security credentials.
For instructions, see [Creating an IAM user in your AWS account](#) in the *IAM User Guide*.
 - ii. Grant administrator privileges to **AccountAAdmin** by attaching a user policy giving full access.

For instructions, see [Managing IAM policies](#) in the *IAM User Guide*.

- iii. Note the **IAM user Sign-In URL** for **AccountAdmin**. You will need to use this URL when signing in to the AWS Management Console. For more information about where to find the sign-in URL, see [Sign in to the AWS Management Console as an IAM user](#) in *IAM User Guide*. Note the URL for each of the accounts.
2. Set up either the AWS CLI or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:
- If using the AWS CLI, create a profile, AccountAdmin, in the config file.
 - If using the AWS Tools for Windows PowerShell, make sure you store credentials for the session as AccountAdmin.

For instructions, see [Setting up the tools for the walkthroughs](#).

Step 1: Create resources in Account A and grant permissions

Using the credentials of user AccountAdmin in Account A, and the special IAM user sign-in URL, sign in to the AWS Management Console and do the following:

1. Create resources of a bucket and an IAM user
 - a. In the Amazon S3 console, create a bucket. Note the AWS Region in which you created the bucket. For instructions, see [Creating a general purpose bucket](#).
 - b. In the [IAM Console](#), do the following:
 - i. Create a user named Dave.
For step-by-step instructions, see [Creating IAM users \(console\)](#) in the *IAM User Guide*.
 - ii. Note the UserDave credentials.
 - iii. Note the Amazon Resource Name (ARN) for user Dave. In the [IAM Console](#), select the user, and the **Summary** tab provides the user ARN.
2. Grant permissions.

Because the bucket owner and the parent account to which the user belongs are the same, the AWS account can grant user permissions using a bucket policy, a user policy, or both. In this

example, you do both. If the object is also owned by the same account, the bucket owner can grant object permissions in the bucket policy (or an IAM policy).

- a. In the Amazon S3 console, attach the following bucket policy to [awsexamplebucket1](#).

The policy has two statements.

- The first statement grants Dave the bucket operation permissions `s3:GetBucketLocation` and `s3>ListBucket`.
- The second statement grants the `s3:GetObject` permission. Because Account A also owns the object, the account administrator is able to grant the `s3:GetObject` permission.

In the Principal statement, Dave is identified by his user ARN. For more information about policy elements, see [Policies and permissions in Amazon S3](#).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Dave"  
            },  
            "Action": [  
                "s3:GetBucketLocation",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::awsexamplebucket1"  
            ]  
        },  
        {  
            "Sid": "statement2",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Dave"  
            }  
        }  
    ]  
}
```

```
        },
        "Action": [
            "s3:GetObject"
        ],
        "Resource": [
            "arn:aws:s3:::awsexamplebucket1/*"
        ]
    }
]
```

- b. Create an inline policy for the user Dave by using the following policy. The policy grants Dave the s3:PutObject permission. You need to update the policy by providing your bucket name.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PermissionForObjectOperations",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::awsexamplebucket1/*"
            ]
        }
    ]
}
```

For instructions, see [Managing IAM policies](#) in the *IAM User Guide*. Note you need to sign in to the console using Account A credentials.

Step 2: Test permissions

Using Dave's credentials, verify that the permissions work. You can use either of the following two procedures.

Test permissions using the AWS CLI

1. Update the AWS CLI config file by adding the following UserDaveAccountA profile. For more information, see [Setting up the tools for the walkthroughs](#).

```
[profile UserDaveAccountA]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. Verify that Dave can perform the operations as granted in the user policy. Upload a sample object using the following AWS CLI put-object command.

The --body parameter in the command identifies the source file to upload. For example, if the file is in the root of the C: drive on a Windows machine, you specify c:\HappyFace.jpg. The --key parameter provides the key name for the object.

```
aws s3api put-object --bucket awsexamplebucket1 --key HappyFace.jpg --
body HappyFace.jpg --profile UserDaveAccountA
```

Run the following AWS CLI command to get the object.

```
aws s3api get-object --bucket awsexamplebucket1 --key HappyFace.jpg OutputFile.jpg
--profile UserDaveAccountA
```

Test permissions using the AWS Tools for Windows PowerShell

1. Store Dave's credentials as AccountADave. You then use these credentials to PUT and GET an object.

```
set-awscredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -storeas
AccountADave
```

2. Upload a sample object using the AWS Tools for Windows PowerShell Write-S3Object command using user Dave's stored credentials.

```
Write-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file HappyFace.jpg
-StoredCredentials AccountADave
```

Download the previously uploaded object.

```
Read-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file Output.jpg -  
StoredCredentials AccountADave
```

Example 2: Bucket owner granting cross-account bucket permissions

Important

Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see [Understanding cross-account permissions and using IAM roles](#).

Topics

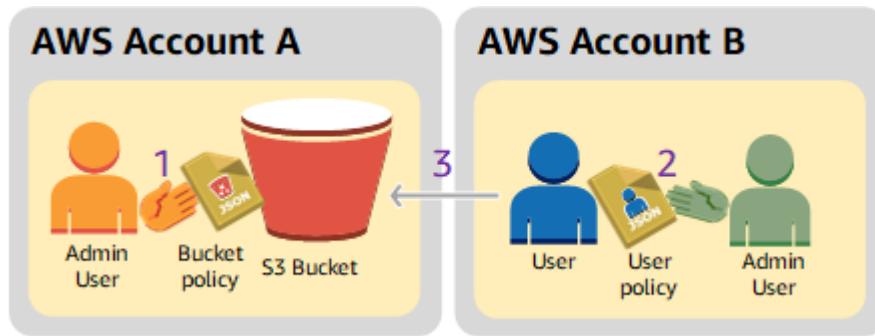

- [Preparing for the walkthrough](#)
- [Step 1: Do the Account A tasks](#)
- [Step 2: Do the Account B tasks](#)
- [Step 3: \(Optional\) Try explicit deny](#)
- [Step 4: Clean up](#)

An AWS account—for example, Account A—can grant another AWS account, Account B, permission to access its resources such as buckets and objects. Account B can then delegate those permissions to users in its account. In this example scenario, a bucket owner grants cross-account permission to another account to perform specific bucket operations.

Note

Account A can also directly grant a user in Account B permissions using a bucket policy. However, the user will still need permission from the parent account, Account B, to which the user belongs, even if Account B doesn't have permissions from Account A. As long as the user has permission from both the resource owner and the parent account, the user will be able to access the resource.

The following is a summary of the walkthrough steps:

1. Account A administrator user attaches a bucket policy granting cross-account permissions to Account B to perform specific bucket operations.

Note that administrator user in Account B will automatically inherit the permissions.

2. Account B administrator user attaches user policy to the user delegating the permissions it received from Account A.
3. User in Account B then verifies permissions by accessing an object in the bucket owned by Account A.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in them. In accordance with the IAM guidelines (see [About using an administrator user to create resources and grant permissions](#)), we don't use the root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Preparing for the walkthrough

1. Make sure you have two AWS accounts and that each account has one administrator user as shown in the table in the preceding section.
 - a. Sign up for an AWS account, if needed.
 - b. Using Account A credentials, sign in to the [IAM console](#) to create the administrator user:
 - i. Create user **AccountAadmin** and note the security credentials. For instructions, see [Creating an IAM user in Your AWS account](#) in the *IAM User Guide*.
 - ii. Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access. For instructions, see [Working with Policies](#) in the *IAM User Guide*.
 - c. While you are in the IAM console, note the **IAM user Sign-In URL** on the **Dashboard**. All users in the account must use this URL when signing in to the AWS Management Console.

For more information, see [How Users Sign in to Your Account](#) in *IAM User Guide*.
 - d. Repeat the preceding step using Account B credentials and create administrator user **AccountBadmin**.
2. Set up either the AWS Command Line Interface (AWS CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:
 - If using the AWS CLI, create two profiles, AccountAadmin and AccountBadmin, in the config file.
 - If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as AccountAadmin and AccountBadmin.

For instructions, see [Setting up the tools for the walkthroughs](#).

3. Save the administrator user credentials, also referred to as profiles. You can use the profile name instead of specifying credentials for each command you enter. For more information, see [Setting up the tools for the walkthroughs](#).
 - a. Add profiles in the AWS CLI credentials file for each of the administrator users, AccountAadmin and AccountBadmin, in the two accounts.

```
[AccountAadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
```

```
region = us-east-1

[AccountBadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
region = us-east-1
```

- b. If you're using the AWS Tools for Windows PowerShell, run the following command.

```
set-awscredentials -AccessKey AcctA-access-key-ID -SecretKey AcctA-secret-access-key -storeas AccountAadmin
set-awscredentials -AccessKey AcctB-access-key-ID -SecretKey AcctB-secret-access-key -storeas AccountBadmin
```

Step 1: Do the Account A tasks

Step 1.1: Sign in to the AWS Management Console

Using the IAM user sign-in URL for Account A, first sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket

1. In the Amazon S3 console, create a bucket. This exercise assumes the bucket is created in the US East (N. Virginia) AWS Region and is named *amzn-s3-demo-bucket*.

For instructions, see [Creating a general purpose bucket](#).

2. Upload a sample object to the bucket.

For instructions, go to [Step 2: Upload an object to your bucket](#).

Step 1.3: Attach a bucket policy to grant cross-account permissions to Account B

The bucket policy grants the s3:GetLifecycleConfiguration and s3>ListBucket permissions to Account B. It's assumed that you're still signed in to the console using **AccountAadmin** user credentials.

1. Attach the following bucket policy to *amzn-s3-demo-bucket*. The policy grants Account B permission for the s3:GetLifecycleConfiguration and s3>ListBucket actions.

For instructions, see [Adding a bucket policy by using the Amazon S3 console](#).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Example permissions",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:root"  
            },  
            "Action": [  
                "s3:GetLifecycleConfiguration",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket"  
            ]  
        }  
    ]  
}
```

- Verify that Account B (and thus its administrator user) can perform the operations.

- Verify using the AWS CLI

```
aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin  
aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --  
profile AccountBadmin
```

- Verify using the AWS Tools for Windows PowerShell

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBadmin  
get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -  
StoredCredentials AccountBadmin
```

Step 2: Do the Account B tasks

Now the Account B administrator creates a user, Dave, and delegates the permissions received from Account A.

Step 2.1: Sign in to the AWS Management Console

Using the IAM user sign-in URL for Account B, first sign in to the AWS Management Console as **AccountBadmin** user.

Step 2.2: Create user Dave in Account B

In the [IAM Console](#), create a user, **Dave**.

For instructions, see [Creating IAM users \(console\)](#) in the *IAM User Guide*.

Step 2.3: Delegate permissions to user Dave

Create an inline policy for the user Dave by using the following policy. You will need to update the policy by providing your bucket name.

It's assumed that you're signed in to the console using **AccountBadmin** user credentials.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Example",  
            "Effect": "Allow",  
            "Action": [  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket"  
            ]  
        }  
    ]  
}
```

For instructions, see [Managing IAM policies](#) in the *IAM User Guide*.

Step 2.4: Test permissions

Now Dave in Account B can list the contents of **amzn-s3-demo-bucket** owned by Account A. You can verify the permissions using either of the following procedures.

Test permissions using the AWS CLI

1. Add the UserDave profile to the AWS CLI config file. For more information about the config file, see [Setting up the tools for the walkthroughs](#).

```
[profile UserDave]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. At the command prompt, enter the following AWS CLI command to verify Dave can now get an object list from the *amzn-s3-demo-bucket* owned by Account A. Note the command specifies the UserDave profile.

```
aws s3 ls s3://amzn-s3-demo-bucket --profile UserDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following get-bucket-lifecycle configuration—Amazon S3 returns permission denied.

```
aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --profile UserDave
```

Test permissions using AWS Tools for Windows PowerShell

1. Store Dave's credentials as AccountBDave.

```
set-awscredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -storeas AccountBDave
```

2. Try the List Bucket command.

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following get-s3bucketlifecycleconfiguration—Amazon S3 returns permission denied.

```
get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -  
StoredCredentials AccountBDave
```

Step 3: (Optional) Try explicit deny

You can have permissions granted by using an access control list (ACL), a bucket policy, or a user policy. But if there is an explicit deny set by either a bucket policy or a user policy, the explicit deny takes precedence over any other permissions. For testing, update the bucket policy and explicitly deny Account B the s3>ListBucket permission. The policy also grants s3>ListBucket permission. However, explicit deny takes precedence, and Account B or users in Account B will not be able to list objects in *amzn-s3-demo-bucket*.

1. Using credentials of user AccountAadmin in Account A, replace the bucket policy by the following.
2. Now if you try to get a bucket list using AccountBadmin credentials, access is denied.

- Using the AWS CLI, run the following command:

```
aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin
```

- Using the AWS Tools for Windows PowerShell, run the following command:

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
```

Step 4: Clean up

1. After you're done testing, you can do the following to clean up:
 - Sign in to the AWS Management Console ([AWS Management Console](#)) using Account A credentials, and do the following:
 - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket*. In the bucket **Properties**, delete the policy in the **Permissions** section.
 - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
 - In the [IAM Console](#), remove the AccountAadmin user.

2. Sign in to the [IAM Console](#) using Account B credentials. Delete user AccountBadmin. For step-by-step instructions, see [Deleting an IAM user](#) in the *IAM User Guide*.

Example 3: Bucket owner granting permissions to objects it does not own

Important

Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see [Understanding cross-account permissions and using IAM roles](#).

Topics

- [Step 0: Preparing for the walkthrough](#)
- [Step 1: Do the Account A tasks](#)
- [Step 2: Do the Account B tasks](#)
- [Step 3: Test permissions](#)
- [Step 4: Clean up](#)

The scenario for this example is that a bucket owner wants to grant permission to access objects, but the bucket owner doesn't own all objects in the bucket. For this example, the bucket owner is trying to grant permission to users in its own account.

A bucket owner can enable other AWS accounts to upload objects. By default, the bucket owner doesn't own objects written to a bucket by another AWS account. Objects are owned by the accounts that write them to an S3 bucket. If the bucket owner doesn't own objects in the bucket, the object owner must first grant permission to the bucket owner using an object access control list (ACL). Then, the bucket owner can grant permissions to an object that they don't own. For more information, see [Amazon S3 bucket and object ownership](#).

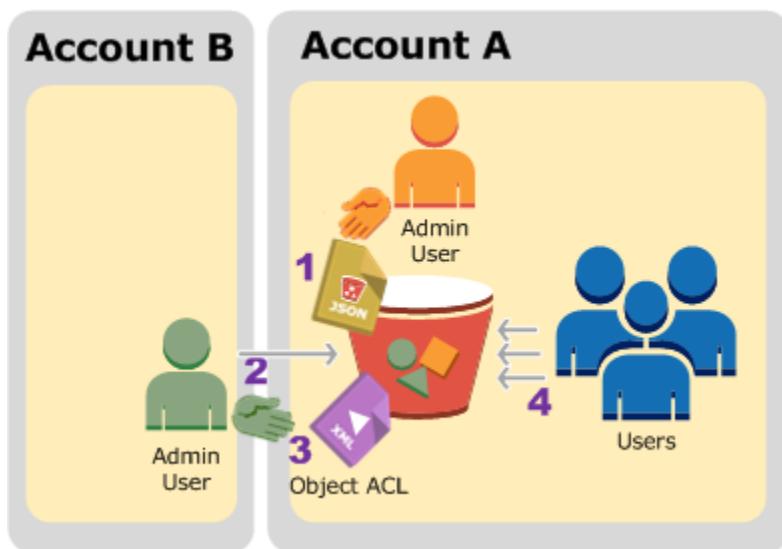

If the bucket owner applies the bucket owner enforced setting for S3 Object Ownership for the bucket, the bucket owner will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts.

Note

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

In this example, we assume the bucket owner has not applied the bucket owner enforced setting for Object Ownership. The bucket owner delegates permission to users in its own account. The following is a summary of the walkthrough steps:

1. Account A administrator user attaches a bucket policy with two statements.
 - Allow cross-account permission to Account B to upload objects.
 - Allow a user in its own account to access objects in the bucket.
2. Account B administrator user uploads objects to the bucket owned by Account A.

3. Account B administrator updates the object ACL adding grant that gives the bucket owner full-control permission on the object.
4. User in Account A verifies by accessing objects in the bucket, regardless of who owns them.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In this walkthrough, you don't use the account root user credentials, according to the recommended IAM guidelines. For more information, see [About using an administrator user to create resources and grant permissions](#). Instead, you create an administrator in each account and use those credentials in creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Step 0: Preparing for the walkthrough

1. Make sure that you have two AWS accounts and each account has one administrator as shown in the table in the preceding section.
 - a. Sign up for an AWS account, if needed.
 - b. Using Account A credentials, sign in to the [IAM Console](#) and do the following to create an administrator user:
 - Create user **AccountAadmin** and note the user's security credentials. For more information about adding users, see [Creating an IAM user in your AWS account](#) in the *IAM User Guide*.
 - Grant administrator permissions to **AccountAadmin** by attaching a user policy that gives full access. For instructions, see [Managing IAM policies](#) in the *IAM User Guide*.

- In the [IAM Console Dashboard](#), note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see [How users sign in to your account](#) in *IAM User Guide*.
- c. Repeat the preceding step using Account B credentials and create administrator user **AccountBadmin**.
2. Set up either the AWS CLI or the Tools for Windows PowerShell. Make sure that you save the administrator credentials as follows:
- If using the AWS CLI, create two profiles, AccountAadmin and AccountBadmin, in the config file.
 - If using the Tools for Windows PowerShell, make sure that you store credentials for the session as AccountAadmin and AccountBadmin.

For instructions, see [Setting up the tools for the walkthroughs](#).

Step 1: Do the Account A tasks

Perform the following steps for Account A:

Step 1.1: Sign in to the console

Using the IAM user sign-in URL for Account A, sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket and user, and add a bucket policy to grant user permissions

1. In the Amazon S3 console, create a bucket. This exercise assumes that the bucket is created in the US East (N. Virginia) AWS Region, and the name is **amzn-s3-demo-bucket1**.

For instructions, see [Creating a general purpose bucket](#).

2. In the [IAM Console](#), create a user **Dave**.

For step-by-step instructions, see [Creating IAM users \(console\)](#) in the *IAM User Guide*.

3. Note the user Dave credentials.

4. In the Amazon S3 console, attach the following bucket policy to **amzn-s3-demo-bucket1** bucket. For instructions, see [Adding a bucket policy by using the Amazon S3 console](#). Follow the steps to add a bucket policy. For information about how to find account IDs, see [Finding your AWS account ID](#).

The policy grants Account B the s3:PutObject and s3>ListBucket permissions. The policy also grants user Dave the s3:GetObject permission.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Statement1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:root"  
            },  
            "Action": [  
                "s3:PutObject",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3::::amzn-s3-demo-bucket1/*",  
                "arn:aws:s3::::amzn-s3-demo-bucket1"  
            ]  
        },  
        {  
            "Sid": "Statement3",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Dave"  
            },  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3::::amzn-s3-demo-bucket1/*"  
            ]  
        }  
    ]  
}
```

Step 2: Do the Account B tasks

Now that Account B has permissions to perform operations on Account A's bucket, the Account B administrator does the following:

- Uploads an object to Account A's bucket
- Adds a grant in the object ACL to allow Account A, the bucket owner, full control

Using the AWS CLI

1. Using the put-object AWS CLI command, upload an object. The --body parameter in the command identifies the source file to upload. For example, if the file is on the C: drive of a Windows machine, specify c:\HappyFace.jpg. The --key parameter provides the key name for the object.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --body HappyFace.jpg --profile AccountBadmin
```

2. Add a grant to the object ACL to allow the bucket owner full control of the object. For information about how to find a canonical user ID, see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.

```
aws s3api put-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --grant-full-control id="AccountA-CanonicalUserID" --profile AccountBadmin
```

Using the Tools for Windows PowerShell

1. Using the Write-S3Object command, upload an object.

```
Write-S3Object -BucketName amzn-s3-demo-bucket1 -key HappyFace.jpg -file HappyFace.jpg -StoredCredentials AccountBadmin
```

2. Add a grant to the object ACL to allow the bucket owner full control of the object.

```
Set-S3ACL -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -CannedACLName "bucket-owner-full-control" -StoredCreden
```

Step 3: Test permissions

Now verify that user Dave in Account A can access the object owned by Account B.

Using the AWS CLI

1. Add user Dave credentials to the AWS CLI config file and create a new profile, UserDaveAccountA. For more information, see [Setting up the tools for the walkthroughs](#).

```
[profile UserDaveAccountA]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. Run the get-object CLI command to download HappyFace.jpg and save it locally. You provide user Dave credentials by adding the --profile parameter.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --key
HappyFace.jpg Outputfile.jpg --profile UserDaveAccountA
```

Using the Tools for Windows PowerShell

1. Store user Dave AWS credentials, as UserDaveAccountA, to persistent store.

```
Set-AWSCredentials -AccessKey UserDave-AccessKey -SecretKey UserDave-
SecretAccessKey -storeas UserDaveAccountA
```

2. Run the Read-S3Object command to download the HappyFace.jpg object and save it locally. You provide user Dave credentials by adding the -StoredCredentials parameter.

```
Read-S3Object -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -file
HappyFace.jpg -StoredCredentials UserDaveAccountA
```

Step 4: Clean up

1. After you're done testing, you can do the following to clean up:

- Sign in to the [AWS Management Console](#) using Account A credentials, and do the following:

- In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.
 - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
 - In the [IAM Console](#), remove the **AccountAadmin** user. For step-by-step instructions, see [Deleting an IAM user](#) in the *IAM User Guide*.
2. Sign in to the [AWS Management Console](#) using Account B credentials. In the [IAM Console](#), delete the user **AccountBadmin**.

Example 4 - Bucket owner granting cross-account permission to objects it does not own

Topics

- [Understanding cross-account permissions and using IAM roles](#)
- [Step 0: Preparing for the walkthrough](#)
- [Step 1: Do the account A tasks](#)
- [Step 2: Do the Account B tasks](#)
- [Step 3: Do the Account C tasks](#)
- [Step 4: Clean up](#)
- [Related resources](#)

In this example scenario, you own a bucket and you have enabled other AWS accounts to upload objects. If you have applied the bucket owner enforced setting for S3 Object Ownership for the bucket, you will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by you, the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts. Suppose the bucket owner enforced setting for S3 Object Ownership is not enabled. That is, your bucket can have objects that other AWS accounts own.

Now, suppose as a bucket owner, you need to grant cross-account permission on objects, regardless of who the owner is, to a user in another account. For example, that user could be a billing application that needs to access object metadata. There are two core issues:

- The bucket owner has no permissions on those objects created by other AWS accounts. For the bucket owner to grant permissions on objects it doesn't own, the object owner must first grant permission to the bucket owner. The object owner is the AWS account that created the objects. The bucket owner can then delegate those permissions.
- The bucket owner account can delegate permissions to users in its own account (see [Example 3: Bucket owner granting permissions to objects it does not own](#)). However, the bucket owner account can't delegate permissions to other AWS accounts because cross-account delegation isn't supported.

In this scenario, the bucket owner can create an AWS Identity and Access Management (IAM) role with permission to access objects. Then, the bucket owner can grant another AWS account permission to assume the role, temporarily enabling it to access objects in the bucket.

 **Note**

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs.

By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Understanding cross-account permissions and using IAM roles

IAM roles enable several scenarios to delegate access to your resources, and cross-account access is one of the key scenarios. In this example, the bucket owner, Account A, uses an IAM role to temporarily delegate object access cross-account to users in another AWS account, Account C. Each IAM role that you create has the following two policies attached to it:

- A trust policy identifying another AWS account that can assume the role.

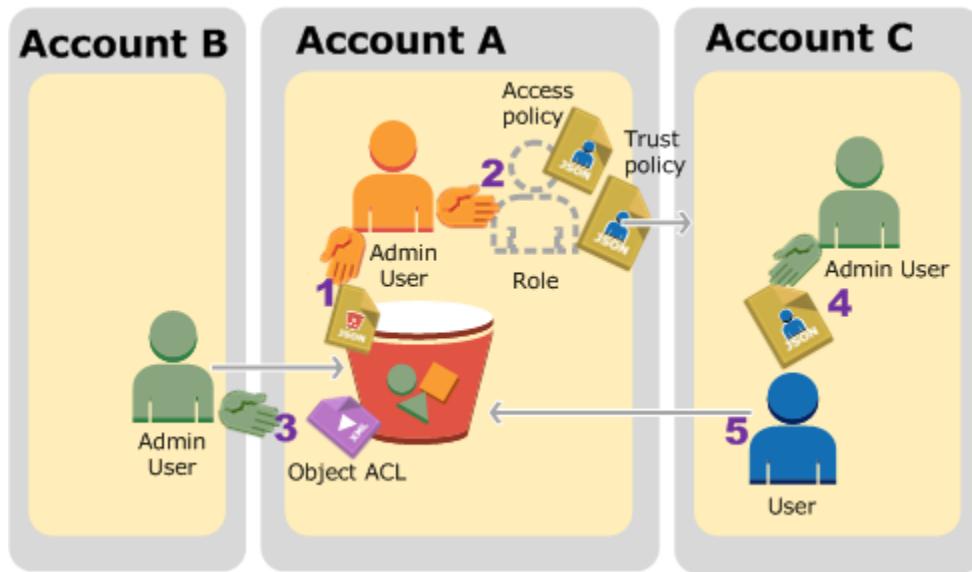

- An access policy defining what permissions—for example, `s3:GetObject`—are allowed when someone assumes the role. For a list of permissions you can specify in a policy, see [Policy actions for Amazon S3](#).

The AWS account identified in the trust policy then grants its user permission to assume the role. The user can then do the following to access objects:

- Assume the role and, in response, get temporary security credentials.
- Using the temporary security credentials, access the objects in the bucket.

For more information about IAM roles, see [IAM Roles](#) in the *IAM User Guide*.

The following is a summary of the walkthrough steps:

- Account A administrator user attaches a bucket policy granting Account B conditional permission to upload objects.
- Account A administrator creates an IAM role, establishing trust with Account C, so users in that account can access Account A. The access policy attached to the role limits what user in Account C can do when the user accesses Account A.
- Account B administrator uploads an object to the bucket owned by Account A, granting full-control permission to the bucket owner.
- Account C administrator creates a user and attaches a user policy that allows the user to assume the role.

5. User in Account C first assumes the role, which returns the user temporary security credentials. Using those temporary credentials, the user then accesses objects in the bucket.

For this example, you need three accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In accordance with the IAM guidelines (see [About using an administrator user to create resources and grant permissions](#)), we don't use the AWS account root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin
3333-3333-3333	Account C	AccountCadmin

Step 0: Preparing for the walkthrough

Note

You might want to open a text editor, and write down some of the information as you go through the steps. In particular, you will need account IDs, canonical user IDs, IAM user Sign-in URLs for each account to connect to the console, and Amazon Resource Names (ARNs) of the IAM users, and roles.

1. Make sure that you have three AWS accounts and each account has one administrator user as shown in the table in the preceding section.
 - a. Sign up for AWS accounts, as needed. We refer to these accounts as Account A, Account B, and Account C.
 - b. Using Account A credentials, sign in to the [IAM console](#) and do the following to create an administrator user:

- Create user **AccountAdmin** and note its security credentials. For more information about adding users, see [Creating an IAM user in your AWS account](#) in the *IAM User Guide*.
 - Grant administrator privileges to **AccountAdmin** by attaching a user policy giving full access. For instructions, see [Managing IAM policies](#) in the *IAM User Guide*.
 - In the IAM Console **Dashboard**, note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see [Sign in to the AWS Management Console as an IAM user](#) in the *IAM User Guide*.
- c. Repeat the preceding step to create administrator users in Account B and Account C.
2. For Account C, note the canonical user ID.
- When you create an IAM role in Account A, the trust policy grants Account C permission to assume the role by specifying the account ID. You can find account information as follows:
- a. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [Amazon S3 console](#).
 - b. Choose the name of an Amazon S3 bucket to view the details about that bucket.
 - c. Choose the **Permissions** tab and then choose **Access Control List**.
 - d. In the **Access for your AWS account** section, in the **Account** column is a long identifier, such as
c1daexampleaaf850ea79cf0430f33d72579fd1611c97f7ded193374c0b163b6. This is your canonical user ID.
3. When creating a bucket policy, you will need the following information. Note these values:

- **Canonical user ID of Account A** – When the Account A administrator grants conditional upload object permission to the Account B administrator, the condition specifies the canonical user ID of the Account A user that must get full-control of the objects.

 **Note**

The canonical user ID is the Amazon S3-only concept. It is a 64-character obfuscated version of the account ID.

- **User ARN for Account B administrator** – You can find the user ARN in the [IAM Console](#). You must select the user and find the user's ARN in the **Summary** tab.

In the bucket policy, you grant AccountBadmin permission to upload objects and you specify the user using the ARN. Here's an example ARN value:

```
arn:aws:iam::AccountB-ID:user/AccountBadmin
```

4. Set up either the AWS Command Line Interface (CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:

- If using the AWS CLI, create profiles, AccountAadmin and AccountBadmin, in the config file.
- If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as AccountAadmin and AccountBadmin.

For instructions, see [Setting up the tools for the walkthroughs](#).

Step 1: Do the account A tasks

In this example, Account A is the bucket owner. So user AccountAadmin in Account A will do the following:

- Create a bucket.
- Attach a bucket policy that grants the Account B administrator permission to upload objects.
- Create an IAM role that grants Account C permission to assume the role so it can access objects in the bucket.

Step 1.1: Sign in to the AWS Management Console

Using the IAM user Sign-in URL for Account A, first sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket and attach a bucket policy

In the Amazon S3 console, do the following:

1. Create a bucket. This exercise assumes the bucket name is **amzn-s3-demo-bucket1**.

For instructions, see [Creating a general purpose bucket](#).

2. Attach the following bucket policy. The policy grants conditional permission to the Account B administrator permission to upload objects.

Update the policy by providing your own values for *amzn-s3-demo-bucket1*, *AccountB-ID*, and the *CanonicalUserId-of-AWSaccountA-BucketOwner*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "111",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"  
        },  
        {  
            "Sid": "112",  
            "Effect": "Deny",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-grant-full-control": "id=CanonicalUserId-of-  
                    AWSaccountA-BucketOwner"  
                }  
            }  
        }  
    ]  
}
```

Step 1.3: Create an IAM role to allow Account C cross-account access in Account A

In the [IAM Console](#), create an IAM role (**examplerole**) that grants Account C permission to assume the role. Make sure that you are still signed in as the Account A administrator because the role must be created in Account A.

1. Before creating the role, prepare the managed policy that defines the permissions that the role requires. You attach this policy to the role in a later step.
 - a. In the navigation pane on the left, choose **Policies** and then choose **Create Policy**.
 - b. Next to **Create Your Own Policy**, choose **Select**.
 - c. Enter **access-accountA-bucket** in the **Policy Name** field.
 - d. Copy the following access policy and paste it into the **Policy Document** field. The access policy grants the role s3:GetObject permission so, when the Account C user assumes the role, it can only perform the s3:GetObject operation.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"  
        }  
    ]  
}
```

- e. Choose **Create Policy**.

The new policy appears in the list of managed policies.

2. In the navigation pane on the left, choose **Roles** and then choose **Create New Role**.
3. Under **Select Role Type**, select **Role for Cross-Account Access**, and then choose the **Select** button next to **Provide access between AWS accounts you own**.
4. Enter the Account C account ID.

For this walkthrough, you don't need to require users to have multi-factor authentication (MFA) to assume the role, so leave that option unselected.

5. Choose **Next Step** to set the permissions that will be associated with the role.
6. Select the checkbox next to the **access-accountA-bucket** policy that you created, and then choose **Next Step**.

The Review page appears so you can confirm the settings for the role before it's created. One very important item to note on this page is the link that you can send to your users who need to use this role. Users who use the link go straight to the **Switch Role** page with the Account ID and Role Name fields already filled in. You can also see this link later on the **Role Summary** page for any cross-account role.

7. Enter **examplerole** for the role name, and then choose **Next Step**.
8. After reviewing the role, choose **Create Role**.

The **examplerole** role is displayed in the list of roles.

9. Choose the role name **examplerole**.
10. Select the **Trust Relationships** tab.
11. Choose **Show policy document** and verify the trust policy shown matches the following policy.

The following trust policy establishes trust with Account C, by allowing it the **sts:AssumeRole** action. For more information, see [AssumeRole](#) in the *AWS Security Token Service API Reference*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:root"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

12. Note the Amazon Resource Name (ARN) of the **examplerole** role that you created.

Later in the following steps, you attach a user policy to allow an IAM user to assume this role, and you identify the role by the ARN value.

Step 2: Do the Account B tasks

The example bucket owned by Account A needs objects owned by other accounts. In this step, the Account B administrator uploads an object using the command line tools.

- Using the put-object AWS CLI command, upload an object to [amzn-s3-demo-bucket1](#).

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --  
body HappyFace.jpg --grant-full-control id="canonicalUserId-ofTheBucketOwner" --  
profile AccountBadmin
```

Note the following:

- The --Profile parameter specifies the AccountBadmin profile, so the object is owned by Account B.
- The parameter grant-full-control grants the bucket owner full-control permission on the object as required by the bucket policy.
- The --body parameter identifies the source file to upload. For example, if the file is on the C: drive of a Windows computer, you specify c:\HappyFace.jpg.

Step 3: Do the Account C tasks

In the preceding steps, Account A has already created a role, `examplerole`, establishing trust with Account C. This role allows users in Account C to access Account A. In this step, the Account C administrator creates a user (Dave) and delegates him the `sts:AssumeRole` permission it received from Account A. This approach allows Dave to assume the `examplerole` and temporarily gain access to Account A. The access policy that Account A attached to the role limits what Dave can do when he accesses Account A—specifically, get objects in [amzn-s3-demo-bucket1](#).

Step 3.1: Create a user in Account C and delegate permission to assume `examplerole`

- Using the IAM user sign-in URL for Account C, first sign in to the AWS Management Console as **AccountCadmin** user.
- In the [IAM Console](#), create a user, Dave.

For step-by-step instructions, see [Creating IAM users \(AWS Management Console\)](#) in the *IAM User Guide*.

3. Note the Dave credentials. Dave will need these credentials to assume the `examplerole` role.
4. Create an inline policy for the Dave IAM user to delegate the `sts:AssumeRole` permission to Dave on the `examplerole` role in Account A.
 - a. In the navigation pane on the left, choose **Users**.
 - b. Choose the user name **Dave**.
 - c. On the user details page, select the **Permissions** tab and then expand the **Inline Policies** section.
 - d. Choose **click here (or Create User Policy)**.
 - e. Choose **Custom Policy**, and then choose **Select**.
 - f. Enter a name for the policy in the **Policy Name** field.
 - g. Copy the following policy into the **Policy Document** field.

You must update the policy by providing the *AccountA-ID*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "sts:AssumeRole"  
            ],  
            "Resource": "arn:aws:iam::111122223333:role/examplerole"  
        }  
    ]  
}
```

h. Choose **Apply Policy**.

5. Save Dave's credentials to the config file of the AWS CLI by adding another profile, `AccountCDave`.

```
[profile AccountCDave]
```

```
aws_access_key_id = UserDaveAccessKeyID
aws_secret_access_key = UserDaveSecretAccessKey
region = us-west-2
```

Step 3.2: Assume role (examplerole) and access objects

Now Dave can access objects in the bucket owned by Account A as follows:

- Dave first assumes the examplerole using his own credentials. This will return temporary credentials.
 - Using the temporary credentials, Dave will then access objects in Account A's bucket.
1. At the command prompt, run the following AWS CLI assume-role command using the AccountCDave profile.

You must update the ARN value in the command by providing the *AccountA-ID* where examplerole is defined.

```
aws sts assume-role --role-arn arn:aws:iam::AccountA-ID:role/examplerole --profile
AccountCDave --role-session-name test
```

In response, AWS Security Token Service (AWS STS) returns temporary security credentials (access key ID, secret access key, and a session token).

2. Save the temporary security credentials in the AWS CLI config file under the TempCred profile.

```
[profile TempCred]
aws_access_key_id = temp-access-key-ID
aws_secret_access_key = temp-secret-access-key
aws_session_token = session-token
region = us-west-2
```

3. At the command prompt, run the following AWS CLI command to access objects using the temporary credentials. For example, the command specifies the head-object API to retrieve object metadata for the HappyFace.jpg object.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --
key HappyFace.jpg SaveFileAs.jpg --profile TempCred
```

Because the access policy attached to `examplerole` allows the actions, Amazon S3 processes the request. You can try any other action on any other object in the bucket.

If you try any other action—for example, `get-object-acl`—you will get permission denied because the role isn't allowed that action.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --profile TempCred
```

We used user Dave to assume the role and access the object using temporary credentials. It could also be an application in Account C that accesses objects in *amzn-s3-demo-bucket1*. The application can obtain temporary security credentials, and Account C can delegate the application permission to assume `examplerole`.

Step 4: Clean up

1. After you're done testing, you can do the following to clean up:
 - Sign in to the [AWS Management Console](#) using Account A credentials, and do the following:
 - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.
 - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
 - In the [IAM Console](#), remove the `examplerole` you created in Account A. For step-by-step instructions, see [Deleting an IAM user](#) in the *IAM User Guide*.
 - In the [IAM Console](#), remove the **AccountAadmin** user.
2. Sign in to the [IAM Console](#) by using Account B credentials. Delete the user **AccountBadmin**.
3. Sign in to the [IAM Console](#) by using Account C credentials. Delete **AccountCadmin** and the user Dave.

For more information that's related to this walkthrough, see the following resources in the *IAM User Guide*:

- [Creating a role to delegate permissions to an IAM user](#)
- [Tutorial: Delegate Access Across AWS accounts Using IAM Roles](#)
- [Managing IAM policies](#)

Using service-linked roles for Amazon S3 Storage Lens

To use Amazon S3 Storage Lens to collect and aggregate metrics across all your accounts in AWS Organizations, you must first ensure that S3 Storage Lens has trusted access enabled by the management account in your organization. S3 Storage Lens creates a service-linked role (SLR) to allow it to get the list of AWS accounts belonging to your organization. This list of accounts is used by S3 Storage Lens to collect metrics for S3 resources in all the member accounts when the S3 Storage Lens dashboard or configurations are created or updated.

Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up S3 Storage Lens easier because you don't have to add the necessary permissions manually. S3 Storage Lens defines the permissions of its service-linked roles, and unless defined otherwise, only S3 Storage Lens can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

You can delete this service-linked role only after first deleting the related resources. This protects your S3 Storage Lens resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon S3 Storage Lens

S3 Storage Lens uses the service-linked role named **AWSServiceRoleForS3StorageLens** – This enables access to AWS services and resources used or managed by S3 Storage Lens. This allows S3 Storage Lens to access AWS Organizations resources on your behalf.

The S3 Storage Lens service-linked role trusts the following service on your organization's storage:

- `storage-lens.s3.amazonaws.com`

The role permissions policy allows S3 Storage Lens to complete the following actions:

- `organizations:DescribeOrganization`
- `organizations>ListAccounts`
- `organizations>ListAWSAccessForOrganization`
- `organizations>ListDelegatedAdministrators`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

Creating a service-linked role for S3 Storage Lens

You don't need to manually create a service-linked role. When you complete one of the following tasks while signed into the AWS Organizations management or the delegate administrator accounts, S3 Storage Lens creates the service-linked role for you:

- Create an S3 Storage Lens dashboard configuration for your organization in the Amazon S3 console.
- PUT an S3 Storage Lens configuration for your organization using the REST API, AWS CLI and SDKs.

 **Note**

S3 Storage Lens will support a maximum of five delegated administrators per organization.

If you delete this service-linked role, the preceding actions will re-create it as needed.

Example policy for S3 Storage Lens service-linked role

Example Permissions policy for the S3 Storage Lens service-linked role

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AwsOrgsAccess",  
            "Effect": "Allow",  
            "Action": [  
                "organizations:DescribeOrganization",  
                "organizations>ListAccounts",  
                "organizations>ListAWSServiceAccessForOrganization",  
                "organizations>ListDelegatedAdministrators"  
            ],  
            "Resource": [  
                "*"  
            ]  
        }  
    ]  
}
```

Editing a service-linked role for Amazon S3 Storage Lens

S3 Storage Lens doesn't allow you to edit the AWSServiceRoleForS3StorageLens service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

Deleting a service-linked role for Amazon S3 Storage Lens

If you no longer need to use the service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

Note

If the Amazon S3 Storage Lens service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the `AWSServiceRoleForS3StorageLens` you must delete all the organization level S3 Storage Lens configurations present in all AWS Regions using the AWS Organizations management or the delegate administrator accounts.

The resources are organization-level S3 Storage Lens configurations. Use S3 Storage Lens to clean up the resources and then use the [IAM Console](#), CLI, REST API, or AWS SDK to delete the role.

In the REST API, AWS CLI, and SDKs, S3 Storage Lens configurations can be discovered using `ListStorageLensConfigurations` in all the Regions where your organization has created S3 Storage Lens configurations. Use the action `DeleteStorageLensConfiguration` to delete these configurations so that you can then delete the role.

Note

To delete the service-linked role, you must delete all the organization-level S3 Storage Lens configurations in all the Regions where they exist.

To delete Amazon S3 Storage Lens resources used by the `AWSServiceRoleForS3StorageLens` SLR

1. To get a list of your organization level configurations, you must use the `ListStorageLensConfigurations` in every Region that you have S3 Storage Lens configurations. This list can also be obtained from the Amazon S3 console.
2. Delete these configurations from the appropriate Regional endpoints by invoking the `DeleteStorageLensConfiguration` API call or by using the Amazon S3 console.

To manually delete the service-linked role using IAM

After you have deleted the configurations, delete the `AWSServiceRoleForS3StorageLens` SLR from the [IAM Console](#) or by invoking the IAM API `DeleteServiceLinkedRole`, or using the AWS CLI or AWS SDK. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

Supported Regions for S3 Storage Lens service-linked roles

S3 Storage Lens supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see [Amazon S3 Regions and Endpoints](#).

Troubleshooting Amazon S3 identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon S3 and IAM.

Topics

- [I received an access denied error](#)
- [I am not authorized to perform an action in Amazon S3](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my Amazon S3 resources](#)
- [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#)

I received an access denied error

Verify that there is not an explicit Deny statement against the requester you are trying to grant permissions to in either the bucket policy or the identity-based policy.

For detailed information about troubleshooting access denied errors, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#).

I am not authorized to perform an action in Amazon S3

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a fictional *my-example-widget* resource but doesn't have the fictional s3:*GetWidget* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:  
s3:GetWidget on resource: my-example-widget
```

In this case, the policy for the mateojackson user must be updated to allow access to the *my-example-widget* resource by using the s3:*GetWidget* action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Amazon S3.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Amazon S3. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:  
    iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my Amazon S3 resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon S3 supports these features, see [How Amazon S3 works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.

- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Troubleshoot access denied (403 Forbidden) errors in Amazon S3

Access denied (HTTP 403 Forbidden) errors appear when AWS explicitly or implicitly denies an authorization request.

- An *explicit denial* occurs when a policy contains a Deny statement for the specific AWS action.
- An *implicit denial* occurs when there is no applicable Deny statement and also no applicable Allow statement.

Because an AWS Identity and Access Management (IAM) policy implicitly denies an IAM principal by default, the policy must explicitly allow the principal to perform an action. Otherwise, the policy implicitly denies access. For more information, see [The difference between explicit and implicit denies](#) in the *IAM User Guide*. For information about the policy evaluation logic that determines whether an access request is allowed or denied, see [Policy evaluation logic](#) in the *IAM User Guide*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

The following topics cover the most common causes of access denied errors in Amazon S3.

Note

For access denied (HTTP 403 Forbidden) errors, Amazon S3 doesn't charge the bucket owner when the request is initiated outside of the bucket owner's individual AWS account or the bucket owner's AWS organization.

Topics

- [Access denied message examples and how to troubleshoot them](#)
- [Access denied due to Requester Pays settings](#)
- [Bucket policies and IAM policies](#)
- [Amazon S3 ACL settings](#)

- [S3 Block Public Access settings](#)

- [S3 Object Lock settings](#)
- [VPC endpoint policies](#)
- [AWS Organizations policies](#)
- [CloudFront distribution access](#)
- [Access point settings](#)
- [Additional resources](#)

 **Note**

If you're trying to troubleshoot a permissions issue, start with the [the section called "Access denied message examples and how to troubleshoot them"](#) section, then go to the [??? section](#). Also be sure to follow the guidance in [the section called "Tips for checking permissions"](#).

Access denied message examples and how to troubleshoot them

Amazon S3 now includes additional context in access denied (HTTP 403 Forbidden) errors for requests made to resources within the same AWS account or same organization in AWS Organizations. This new context includes the type of policy that denied access, the reason for denial, and information about the IAM user or role that requested access to the resource.

This additional context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-account or same-organization requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions.

Most access denied error messages appear in the format User *user-arn* is not authorized to perform *action* on "*resource-arn*" because *context*. In this example, *user-arn* is the [Amazon Resource Name \(ARN\)](#) of the user that doesn't receive access, *action* is the service action that the policy denies, and *resource-arn* is the ARN of the resource on which the policy acts. The *context* field represents additional context about the policy type that explains why the policy denied access.

When a policy explicitly denies access because the policy contains a Deny statement, then the access denied error message includes the phrase with an explicit deny in a *type* policy. When the policy implicitly denies access, then the access denied error message includes the phrase because no *type* policy allows the *action* action.

Important

- Enhanced access denied messages are returned only for same-account requests or for requests within the same organization in AWS Organizations. Cross-account requests outside of the same organization return a generic Access Denied message.

For information about the policy evaluation logic that determines whether a cross-account access request is allowed or denied, see [Cross-account policy evaluation logic](#) in the *IAM User Guide*. For a walkthrough that shows how to grant cross-account access, see [the section called “Granting cross-account permissions”](#).

- For requests within the same organization in AWS Organizations:
 - Enhanced access denied messages aren't returned if a denial occurs because of a virtual private cloud (VPC) endpoint policy.
 - Enhanced access denied messages are provided whenever both the bucket owner and the caller account belong to the same organization in AWS Organizations. Although buckets configured with the S3 Object Ownership **Bucket owner preferred** or **Object writer** settings might contain objects owned by different accounts, object ownership doesn't affect enhanced access denied messages. Enhanced access denied messages are returned for all object requests as long as the bucket owner and caller are in the same organization, regardless of who owns the specific object. For information about Object Ownership settings and configurations, see [the section called “Controlling object ownership”](#).
- Enhanced access denied error messages aren't returned for requests made to directory buckets. Directory bucket requests return a generic Access Denied message.
- If multiple policies of the same policy type deny an authorization request, the access denied error message doesn't specify the number of policies.
- If multiple policy types deny an authorization request, the error message includes only one of those policy types.
- If an access request is denied due to multiple reasons, the error message includes only one of the reasons for denial.

The following examples show the format for different types of access denied error messages and how to troubleshoot each type of message.

Access denied due to Blocked Encryption Type

To limit the server-side encryption types you can use in your general purpose buckets, you can choose to block SSE-C write requests by updating your default encryption configuration for your buckets. This bucket-level configuration blocks requests to upload objects that specify SSE-C. When SSE-C is blocked for a bucket, any PutObject, CopyObject, PostObject, or Multipart Upload or replication requests that specify SSE-C encryption will be rejected with an HTTP 403 AccessDenied error.

This setting is a parameter on the PutBucketEncryption API and can also be updated using the S3 Console, AWS CLI, and AWS SDKs, if you have the s3:PutEncryptionConfiguration permission. Valid values are SSE-C, which blocks SSE-C encryption for the general purpose bucket, and NONE, which allows the use SSE-C for writes to the bucket.

For example, when access is denied for a PutObject request because the BlockedEncryptionTypes setting blocks write requests specifying SSE-C, you receive the following message:

```
An error occurred (AccessDenied) when calling the PutObject operation:  
User: arn:aws:iam::123456789012:user/MaryMajor is not  
authorized to perform: s3:PutObject on resource:  
"arn:aws:s3:::amzn-s3-demo-bucket1/object-name" because this  
bucket has blocked upload requests that specify  
Server Side Encryption with Customer provided keys (SSE-C).  
Please specify a different server-side encryption type
```

For more information about this setting, see [the section called “Blocking or unblocking SSE-C”](#).

Access denied due to a resource control policy – explicit denial

1. Check for a Deny statement for the action in your resource control policies (RCPs). For the following example, the action is s3:GetObject.
2. Update your RCP by removing the Deny statement. For more information, see [Update a resource control policy \(RCP\)](#) in the *AWS Organizations User Guide*.

```
An error occurred (AccessDenied) when calling the GetObject operation:
```

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"
with an explicit deny in a resource control policy

Access denied due to a Service Control Policy – implicit denial

1. Check for a missing Allow statement for the action in your service control policies (SCPs). For the following example, the action is s3:GetObject.
2. Update your SCP by adding the Allow statement. For more information, see [Updating an SCP](#) in the *AWS Organizations User Guide*.

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject because no service control policy allows the s3:GetObject action

Access denied due to a Service Control Policy – explicit denial

1. Check for a Deny statement for the action in your Service Control Policies (SCPs). For the following example, the action is s3:GetObject.
2. Update your SCP by changing the Deny statement to allow the user the necessary access. For an example of how you can do this, see [Prevent IAM users and roles from making specified changes, with an exception for a specified admin role](#) in the *AWS Organizations User Guide*. For more information about updating your SCP, see [Updating an SCP](#) in the *AWS Organizations User Guide*.

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject with an explicit deny in a service control policy

Access denied due to a VPC endpoint policy – implicit denial

1. Check for a missing Allow statement for the action in your virtual private cloud (VPC) endpoint policies. For the following example, the action is s3:GetObject.
2. Update your VPC endpoint policy by adding the Allow statement. For more information, see [Update a VPC endpoint policy](#) in the *AWS PrivateLink Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform:
s3:GetObject because no VPC endpoint policy allows the s3:GetObject action

Access denied due to a VPC endpoint policy – explicit denial

1. Check for an explicit Deny statement for the action in your virtual private cloud (VPC) endpoint policies. For the following example, the action is s3:GetObject.
2. Update your VPC endpoint policy by changing the Deny statement to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition key with the StringNotEquals condition operator to allow the specific principal access, as shown in [the section called “Example 7: Excluding principals from Deny statements”](#). For more information about updating your VPC endpoint policy, see [Update a VPC endpoint policy](#) in the *AWS PrivateLink Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with  
an explicit deny in a VPC endpoint policy
```

Access denied due to a permissions boundary – implicit denial

1. Check for a missing Allow statement for the action in your permissions boundary. For the following example, the action is s3:GetObject.
2. Update your permissions boundary by adding the Allow statement to your IAM policy. For more information, see [Permissions boundaries for IAM entities](#) and [Editing IAM policies](#) in the *IAM User Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"  
because no permissions boundary allows the s3:GetObject action
```

Access denied due to a permissions boundary – explicit denial

1. Check for an explicit Deny statement for the action in your permissions boundary. For the following example, the action is s3:GetObject.
2. Update your permissions boundary by changing the Deny statement in your IAM policy to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition key with the StringNotEquals condition operator to allow the specific principal access, as shown in [aws:PrincipalAccount](#) in the *IAM User Guide*. For

more information, see [Permissions boundaries for IAM entities](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject with an explicit deny in a permissions boundary

Access denied due to session policies – implicit denial

1. Check for a missing Allow statement for the action in your session policies. For the following example, the action is s3:GetObject.
2. Update your session policy by adding the Allow statement. For more information, see [Session policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform:
s3:GetObject because no session policy allows the s3:GetObject action

Access denied due to session policies – explicit denial

1. Check for an explicit Deny statement for the action in your session policies. For the following example, the action is s3:GetObject.
2. Update your session policy by changing the Deny statement to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition key with the StringNotEquals condition operator to allow the specific principal access, as shown in [the section called “Example 7: Excluding principals from Deny statements”](#). For more information about updating your session policy, see [Session policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with
an explicit deny in a session policy

Access denied due to resource-based policies – implicit denial

Note

Resource-based policies means policies such as bucket policies and access point policies.

1. Check for a missing Allow statement for the action in your resource-based policy. Also check whether the IgnorePublicAcls S3 Block Public Access setting is applied on the bucket, access point, or account level. For the following example, the action is s3:GetObject.
2. Update your policy by adding the Allow statement. For more information, see [Resource-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

You might also need to adjust your IgnorePublicAcls block public access setting for the bucket, access point, or account. For more information, see [the section called “Access denied due to Block Public Access settings”](#) and [the section called “Configuring bucket and access point settings”](#).

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject because no resource-based policy allows the s3:GetObject action
```

Access denied due to resource-based policies – explicit denial

Note

Resource-based policies means policies such as bucket policies and access point policies.

1. Check for an explicit Deny statement for the action in your resource-based policy. Also check whether the RestrictPublicBuckets S3 Block Public Access setting is applied on the bucket, access point, or account level. For the following example, the action is s3:GetObject.
2. Update your policy by changing the Deny statement to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition key with the StringNotEquals condition operator to allow the specific principal access, as shown in [the section called “Example 7: Excluding principals from Deny statements”](#). For more information about updating your resource-based policy, see [Resource-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

You might also need to adjust your `RestrictPublicBuckets` block public access setting for the bucket, access point, or account. For more information, see [the section called “Access denied due to Block Public Access settings”](#) and [the section called “Configuring bucket and access point settings”](#).

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with an explicit deny in a resource-based policy

Access denied due to identity-based policies – implicit denial

1. Check for a missing `Allow` statement for the action in identity-based policies attached to the identity. For the following example, the action is `s3:GetObject` attached to the user *MaryMajor*.
2. Update your policy by adding the `Allow` statement. For more information, see [Identity-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject because no identity-based policy allows the `s3:GetObject` action

Access denied due to identity-based policies – explicit denial

1. Check for an explicit `Deny` statement for the action in identity-based policies attached to the identity. For the following example, the action is `s3:GetObject` attached to the user *MaryMajor*.
2. Update your policy by changing the `Deny` statement to allow the user the necessary access. For example, you can update your `Deny` statement to use the `aws:PrincipalAccount` condition key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in [aws:PrincipalAccount](#) in the *IAM User Guide*. For more information, see [Identity-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with an explicit deny in an identity-based policy

Access denied due to Block Public Access settings

The Amazon S3 Block Public Access feature provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. For more information about how Amazon S3 defines "public," see [The meaning of "public"](#).

By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, IAM user policies, object permissions, or access control lists (ACLs) to allow public access. S3 Block Public Access settings override these policies, permissions, and ACLs. Since April 2023, all Block Public Access settings are enabled by default for new buckets.

When Amazon S3 receives a request to access a bucket or an object, it determines whether the bucket or the bucket owner's account has a block public access setting applied. If the request was made through an access point, Amazon S3 also checks for block public access settings for the access point. If there is an existing block public access setting that prohibits the requested access, Amazon S3 rejects the request.

Amazon S3 Block Public Access provides four settings. These settings are independent and can be used in any combination. Each setting can be applied to an access point, a bucket, or an entire AWS account. If the block public access settings for the access point, bucket, or account differ, then Amazon S3 applies the most restrictive combination of the access point, bucket, and account settings.

When Amazon S3 evaluates whether an operation is prohibited by a block public access setting, it rejects any request that violates an access point, bucket, or account setting.

The four settings provided by Amazon S3 Block Public Access are as follows:

- **BlockPublicAcls** – This setting applies to PutBucketAcl, PutObjectAcl, PutObject, CreateBucket, CopyObject, and POST Object requests. The BlockPublicAcls setting causes the following behavior:
 - PutBucketAcl and PutObjectAcl calls fail if the specified access control list (ACL) is public.
 - PutObject calls fail if the request includes a public ACL.
 - If this setting is applied to an account, then CreateBucket calls fail with an HTTP 400 (Bad Request) response if the request includes a public ACL.

For example, when access is denied for a CopyObject request because of the BlockPublicAcls setting, you receive the following message:

An error occurred (AccessDenied) when calling the CopyObject operation:
User: arn:aws:sts::123456789012:user/*MaryMajor* is not authorized to
perform: s3:CopyObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"
because public ACLs are prevented by the BlockPublicAcls setting in S3 Block Public
Access.

- **IgnorePublicAcls** – The IgnorePublicAcls setting causes Amazon S3 to ignore all public ACLs on a bucket and any objects that it contains. If your request's permission is granted only by a public ACL, then the IgnorePublicAcls setting rejects the request.

Any denial resulting from the IgnorePublicAcls setting is implicit. For example, if IgnorePublicAcls denies a GetObject request because of a public ACL, you receive the following message:

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform:
s3:GetObject because no resource-based policy allows the s3:GetObject action

- **BlockPublicPolicy** – This setting applies to PutBucketPolicy and PutAccessPointPolicy requests.

Setting BlockPublicPolicy for a bucket causes Amazon S3 to reject calls to PutBucketPolicy if the specified bucket policy allows public access. This setting also causes Amazon S3 to reject calls to PutAccessPointPolicy for all of the bucket's same-account access points if the specified policy allows public access.

Setting BlockPublicPolicy for an access point causes Amazon S3 to reject calls to PutAccessPointPolicy and PutBucketPolicy that are made through the access point if the specified policy (for either the access point or the underlying bucket) allows public access.

For example, when access is denied on a PutBucketPolicy request because of the BlockPublicPolicy setting, you receive the following message:

An error occurred (AccessDenied) when calling the PutBucketPolicy operation:
User: arn:aws:sts::123456789012:user/*MaryMajor* is not authorized to
perform: s3:PutBucketPolicy on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-
name"
because public policies are prevented by the BlockPublicPolicy setting in S3 Block
Public Access.

- **RestrictPublicBuckets** – The **RestrictPublicBuckets** setting restricts access to an access point or bucket with a public policy to only AWS service principals and authorized users within the bucket owner's account and the access point owner's account. This setting blocks all cross-account access to the access point or bucket (except by AWS service principals), while still allowing users within the account to manage the access point or bucket. This setting also rejects all anonymous (or unsigned) calls.

Any denial resulting from the **RestrictPublicBuckets** setting is explicit. For example, if **RestrictPublicBuckets** denies a **GetObject** request because of a public bucket or access point policy, you receive the following message:

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with  
an explicit deny in a resource-based policy
```

For more information about these settings, see [the section called “Block public access settings”](#). To review and update these settings, see [the section called “Configuring block public access”](#).

Access denied due to Requester Pays settings

If the Amazon S3 bucket you are trying to access has the Requester Pays feature enabled, you need to make sure you are passing the correct request parameters when making requests to that bucket. The Requester Pays feature in Amazon S3 allows the requester, instead of the bucket owner, to pay the data transfer and request costs for accessing objects in the bucket. When Requester Pays is enabled for a bucket, the bucket owner is not charged for requests made by other AWS accounts.

If you make a request to a Requester Pays-enabled bucket without passing the necessary parameters, you will receive an Access Denied (403 Forbidden) error. To access objects in a Requester Pays-enabled bucket, you must do the following:

1. When making requests using the AWS CLI, you must include the `--request-payer requester` parameter. For example, to copy an object with the key `object.txt` located in the `s3://amzn-s3-demo-bucket/` S3 bucket to a location on your local machine, you must also pass the parameter `--request-payer requester` if this bucket has Requester Pays enabled.

```
aws s3 cp s3://amzn-s3-demo-bucket/object.txt /local/path \  
--request-payer requester
```

2. When making programmatic requests using an AWS SDK, set the `x-amz-request-payer` header to the value `requester`. For an example, see [Downloading objects from Requester Pays buckets](#).
3. Make sure that the IAM user or role making the request has the necessary permissions to access the Requester Pays bucket, such as the `s3:GetObject` and `s3>ListBucket` permissions.

By including the `--request-payer requester` parameter or setting the `x-amz-request-payer` header, you are informing Amazon S3 that you, the requester, will pay the costs associated with accessing the objects in the Requester Pays-enabled bucket. This will prevent the Access Denied (403 Forbidden) error.

Bucket policies and IAM policies

Bucket-level operations

If there is no bucket policy in place, then the bucket implicitly allows requests from any AWS Identity and Access Management (IAM) identity in the bucket-owner's account. The bucket also implicitly denies requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they're the AWS account root user) is implicitly denied from making any requests. For more information about this evaluation logic, see [Determining whether a request is denied or allowed within an account](#) in the *IAM User Guide*.

Object-level operations

If the object is owned by the bucket-owning account, the bucket policy and IAM user policy will function in the same way for object-level operations as they do for bucket-level operations. For example, if there is no bucket policy in place, then the bucket implicitly allows object requests from any IAM identity in the bucket-owner's account. The bucket also implicitly denies object requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they're the AWS account root user) is implicitly denied from making any object requests.

If the object is owned by an external account, then access to the object can be granted only through object access control lists (ACLs). The bucket policy and IAM user policy can still be used to deny object requests.

Therefore, to ensure that your bucket policy or IAM user policy isn't causing an Access Denied (403 Forbidden) error, make sure that the following requirements are met:

- For same-account access, there must not be an explicit Deny statement against the requester you are trying to grant permissions to, in either the bucket policy or the IAM user policy. If you want to grant permissions by using only the bucket policy and the IAM user policy, there must be at least one explicit Allow statement in one of these policies.
- For cross-account access, there must not be an explicit Deny statement against the requester that you're trying to grant permissions to, in either the bucket policy or the IAM user policy. To grant cross-account permissions by using only the bucket policy and IAM user policy, make sure that both the bucket policy and the IAM user policy of the requester include an explicit Allow statement.

 **Note**

Allow statements in a bucket policy apply only to objects that are [owned by the same bucket-owning account](#). However, Deny statements in a bucket policy apply to all objects regardless of object ownership.

To review or edit your bucket policy

 **Note**

To view or edit a bucket policy, you must have the `s3:GetBucketPolicy` permission.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that you want to view or edit a bucket policy for.
4. Choose the **Permissions** tab.
5. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.

To review or edit your bucket policy by using the AWS Command Line Interface (AWS CLI), use the [get-bucket-policy](#) command.

Note

If you get locked out of a bucket because of an incorrect bucket policy, [sign in to the AWS Management Console by using your AWS account root user credentials](#). To regain access to your bucket, make sure to delete the incorrect bucket policy by using your AWS account root user credentials.

Tips for checking permissions

To check whether the requester has proper permissions to perform an Amazon S3 operation, try the following:

- Identify the requester. If it's an unsigned request, then it's an anonymous request without an IAM user policy. If it's a request that uses a presigned URL, then the user policy is the same as the one for the IAM user or role that signed the request.
- Verify that you're using the correct IAM user or role. You can verify your IAM user or role by checking the upper-right corner of the AWS Management Console or by using the [aws sts get-caller-identity](#) command.
- Check the IAM policies that are related to the IAM user or role. You can use one of the following methods:
 - [Test IAM policies with the IAM policy simulator](#).
 - Review the different [IAM policy types](#).
 - If needed, [edit your IAM user policy](#).
- Review the following examples of policies that explicitly deny or allow access:
 - Explicit allow IAM user policy: [IAM: Allows and denies access to multiple services programmatically and in the console](#)
 - Explicit allow bucket policy: [Granting permissions to multiple accounts to upload objects or set object ACLs for public access](#)
 - Explicit deny IAM user policy: [AWS: Denies access to AWS based on the requested AWS Region](#)
 - Explicit deny bucket policy: [Require SSE-KMS for all objects written to a bucket](#)

Amazon S3 ACL settings

When checking your ACL settings, first [review your Object Ownership setting](#) to check whether ACLs are enabled on the bucket. Be aware that ACL permissions can be used only to grant

permissions and can't be used to reject requests. ACLs also can't be used to grant access to requesters that are rejected by explicit denials in bucket policies or IAM user policies.

The Object Ownership setting is set to Bucket owner enforced

If the **Bucket owner enforced** setting is enabled, then ACL settings are unlikely to cause an Access Denied (403 Forbidden) error because this setting disables all ACLs that apply to bucket and objects. **Bucket owner enforced** is the default (and recommended) setting for Amazon S3 buckets.

The Object Ownership setting is set to Bucket owner preferred or Object writer

ACL permissions are still valid with the **Bucket owner preferred** setting or the **Object writer** setting. There are two kinds of ACLs: bucket ACLs and object ACLs. For the differences between these two types of ACLs, see [Mapping of ACL permissions and access policy permissions](#).

Depending on the action of the rejected request, [check the ACL permissions for your bucket or the object](#):

- If Amazon S3 rejected a LIST, PUT object, GetBucketAcl, or PutBucketAcl request, then [review the ACL permissions for your bucket](#).

 **Note**

You can't grant GET object permissions with bucket ACL settings.

- If Amazon S3 rejected a GET request on an S3 object, or a [PutObjectAcl](#) request, then [review the ACL permissions for the object](#).

 **Important**

If the account that owns the object is different from the account that owns the bucket, then access to the object isn't controlled by the bucket policy.

Troubleshooting an Access Denied (403 Forbidden) error from a GET object request during cross-account object ownership

Review the bucket's [Object Ownership settings](#) to determine the object owner. If you have access to the [object ACLs](#), then you can also check the object owner's account. (To view the object owner's account, review the object ACL setting in the Amazon S3 console.) Alternatively, you can also

make a `GetObjectAcl` request to find the object owner's [canonical ID](#) to verify the object owner account. By default, ACLs grant explicit allow permissions for GET requests to the object owner's account.

After you've confirmed that the object owner is different from the bucket owner, then depending on your use case and access level, choose one of the following methods to help address the Access Denied (403 Forbidden) error:

- **Disable ACLs (recommended)** – This method will apply to all objects and can be performed by the bucket owner. This method automatically gives the bucket owner ownership and full control over every object in the bucket. Before you implement this method, check the [prerequisites for disabling ACLs](#). For information about how to set your bucket to **Bucket owner enforced** (recommended) mode, see [Setting Object Ownership on an existing bucket](#).

 **Important**

To prevent an Access Denied (403 Forbidden) error, be sure to migrate the ACL permissions to a bucket policy before you disable ACLs. For more information, see [Bucket policy examples for migrating from ACL permissions](#).

- **Change the object owner to the bucket owner** – This method can be applied to individual objects, but only the object owner (or a user with the appropriate permissions) can change an object's ownership. Additional PUT costs might apply. (For more information, see [Amazon S3 pricing](#).) This method grants the bucket owner full ownership of the object, allowing the bucket owner to control access to the object through a bucket policy.

To change the object's ownership, do one of the following:

- You (the bucket owner) can [copy the object](#) back to the bucket.
- You can change the Object Ownership setting of the bucket to **Bucket owner preferred**. If versioning is disabled, the objects in the bucket are overwritten. If versioning is enabled, duplicate versions of the same object will appear in the bucket, which the bucket owner can [set a lifecycle rule to expire](#). For instructions on how to change your Object Ownership setting, see [Setting Object Ownership on an existing bucket](#).

Note

When you update your Object Ownership setting to **Bucket owner preferred**, the setting is applied only to new objects that are uploaded to the bucket.

- You can have the object owner upload the object again with the `bucket-owner-full-control` canned object ACL.

Note

For cross-account uploads, you can also require the `bucket-owner-full-control` canned object ACL in your bucket policy. For an example bucket policy, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).

- **Keep the object writer as the object owner** – This method doesn't change the object owner, but it does allow you to grant access to objects individually. To grant access to an object, you must have the `PutObjectAcl` permission for the object. Then, to fix the Access Denied (403 Forbidden) error, add the requester as a [grantee](#) to access the object in the object's ACLs. For more information, see [Configuring ACLs](#).

S3 Block Public Access settings

If the failed request involves public access or public policies, then check the S3 Block Public Access settings on your account, bucket, or access point. For more information about troubleshooting access denied errors related to S3 Block Public Access settings, see [the section called “Access denied due to Block Public Access settings”](#).

Amazon S3 encryption settings

Amazon S3 supports server-side encryption on your bucket. Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it.

By default, Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Amazon S3 also allows you to specify the server-side encryption method when uploading objects.

To review your bucket's server-side encryption status and encryption settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the bucket that you want to check the encryption settings for.
4. Choose the **Properties** tab.
5. Scroll down to the **Default encryption** section and view the **Encryption type** settings.

To check your encryption settings by using the AWS CLI, use the [get-bucket-encryption](#) command.

To check the encryption status of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that contains the object.
4. From the **Objects** list, choose the name of the object that you want to add or change encryption for.

The object's details page appears.

5. Scroll down to the **Server-side encryption settings** section to view the object's server-side encryption settings.

To check your object encryption status by using the AWS CLI, use the [head-object](#) command.

Encryption and permissions requirements

Amazon S3 supports three types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

Based on your encryption settings, make sure that the following permissions requirements are met:

- **SSE-S3** – No extra permissions are required.
- **SSE-KMS (with a customer managed key)** – To upload objects, the `kms:GenerateDataKey` permission on the AWS KMS key is required. To download objects and perform multipart uploads of objects, the `kms:Decrypt` permission on the KMS key is required.
- **SSE-KMS (with an AWS managed key)** – The requester must be from the same account that owns the `aws/s3` KMS key. The requester must also have the correct Amazon S3 permissions to access the object.
- **SSE-C (with a customer provided key)** – No additional permissions are required. You can configure the bucket policy to [require and restrict server-side encryption with customer-provided encryption keys](#) for objects in your bucket.

If the object is encrypted with a customer managed key, make sure that the KMS key policy allows you to perform the `kms:GenerateDataKey` or `kms:Decrypt` actions. For instructions on checking your KMS key policy, see [Viewing a key policy](#) in the *AWS Key Management Service Developer Guide*.

S3 Object Lock settings

If your bucket has [S3 Object Lock](#) enabled and the object is protected by a [retention period](#) or [legal hold](#) and you try to delete an object, Amazon S3 returns one of the following responses, depending on how you tried to delete the object:

- **Permanent DELETE request** – If you issued a permanent DELETE request (a request that specifies a version ID), Amazon S3 returns an Access Denied (403 Forbidden) error when you try to delete the object.
- **Simple DELETE request** – If you issued a simple DELETE request (a request that doesn't specify a version ID), Amazon S3 returns a 200 OK response and inserts a [delete marker](#) in the bucket, and that marker becomes the current version of the object with a new ID.

To check whether the bucket has Object Lock enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that you want to review.
4. Choose the **Properties** tab.

5. Scroll down to the **Object Lock** section. Verify whether the **Object Lock** setting is **Enabled** or **Disabled**.

To determine whether the object is protected by a retention period or legal hold, [view the lock information](#) for your object.

If the object is protected by a retention period or legal hold, check the following:

- If the object version is protected by the compliance retention mode, there is no way to permanently delete it. A permanent DELETE request from any requester, including the AWS account root user, will result in an Access Denied (403 Forbidden) error. Also, be aware that when you submit a DELETE request for an object that's protected by the compliance retention mode, Amazon S3 creates a [delete marker](#) for the object.
- If the object version is protected with governance retention mode and you have the `s3:BypassGovernanceRetention` permission, you can bypass the protection and permanently delete the version. For more information, see [Bypassing governance mode](#).
- If the object version is protected by a legal hold, then a permanent DELETE request can result in an Access Denied (403 Forbidden) error. To permanently delete the object version, you must remove the legal hold on the object version. To remove a legal hold, you must have the `s3:PutObjectLegalHold` permission. For more information about removing a legal hold, see [Configuring S3 Object Lock](#).

VPC endpoint policies

If you're accessing Amazon S3 by using a virtual private cloud (VPC) endpoint, make sure that the VPC endpoint policy isn't blocking you from accessing your Amazon S3 resources. By default, the VPC endpoint policy allows all requests to Amazon S3. You can also configure the VPC endpoint policy to restrict certain requests. For information about how to check your VPC endpoint policy, see the following resources:

- [the section called "Access denied due to a VPC endpoint policy – implicit denial"](#)
- [the section called "Access denied due to a VPC endpoint policy – explicit denial"](#)
- [Control access to VPC endpoints by using endpoint policies](#) in the *AWS PrivateLink Guide*

AWS Organizations policies

If your AWS account belongs to an organization, AWS Organizations policies can block you from accessing Amazon S3 resources. By default, AWS Organizations policies don't block any requests to Amazon S3. However, make sure that your AWS Organizations policies haven't been configured to block access to S3 buckets. For instructions on how to check your AWS Organizations policies, see the following resources:

- [the section called "Access denied due to a Service Control Policy – implicit denial"](#)
- [the section called "Access denied due to a Service Control Policy – explicit denial"](#)
- [the section called "Access denied due to a resource control policy – explicit denial"](#)
- [Listing all policies](#) in the *AWS Organizations User Guide*

Additionally, if you incorrectly configured your bucket policy for a member account to deny all users access to your S3 bucket, you can unlock the bucket by launching a privileged session for the member account in IAM. After you launch a privileged session, you can delete the misconfigured bucket policy to regain access to the bucket. For more information, see [Perform a privileged task on an AWS Organizations member account](#) in the *AWS Identity and Access Management User Guide*.

CloudFront distribution access

If you receive a Access Denied (403 Forbidden) error when trying to access your S3 static website through CloudFront, check these common issues:

- **Do you have the correct origin domain name format?**
 - Make sure you're using the S3 website endpoint format (bucket-name.s3-website-region.amazonaws.com) rather than the REST API endpoint
 - Verify that static website hosting is enabled on your bucket
- **Does your bucket policy allow CloudFront access?**
 - Ensure your bucket policy includes permissions for your CloudFront distribution's Origin Access Identity (OAI) or Origin Access Control (OAC)
 - Verify the policy includes the required s3:GetObject permissions

For additional troubleshooting steps and configurations, including error page setups and protocol settings, see [Why do I get a "403 access denied" error when I use an Amazon S3 website endpoint as the origin of my CloudFront distribution?](#) in the AWS re:Post Knowledge Center.

Note

This error is different from 403 errors you might receive when accessing S3 directly. For CloudFront-specific issues, make sure to check both your CloudFront distribution settings and S3 configurations.

Access point settings

If you receive an Access Denied (403 Forbidden) error while making requests through Amazon S3 access points, you might need to check the following:

- The configurations for your access points
- The IAM user policy that's used for your access points
- The bucket policy that's used to manage or configure your cross-account access points

Access point configurations and policies

- When you create an access point, you can choose to designate **Internet** or **VPC** as the network origin. If the network origin is set to VPC only, Amazon S3 will reject any requests made to the access point that don't originate from the specified VPC. To check the network origin of your access point, see [Creating access points restricted to a virtual private cloud](#).
- With access points, you can also configure custom Block Public Access settings, which work similarly to the Block Public Access settings at the bucket or account level. To check your custom Block Public Access settings, see [Managing public access to access points for general purpose buckets](#).
- To make successful requests to Amazon S3 by using access points, make sure that the requester has the necessary IAM permissions. For more information, see [Configuring IAM policies for using access points](#).
- If the request involves cross-account access points, make sure that the bucket owner has updated the bucket policy to authorize requests from the access point. For more information, see [Granting permissions for cross-account access points](#).

If the Access Denied (403 Forbidden) error still persists after checking all the items in this topic, [retrieve your Amazon S3 request ID](#) and contact Support for additional guidance.

Additional resources

For more guidance on Access Denied (403 Forbidden) errors you can check the following resources:

- [How do I troubleshoot 403 Access Denied errors from Amazon S3?](#) in the AWS re:Post Knowledge Center.
- [Why do I get a 403 Forbidden error when I try to access an Amazon S3 bucket or object?](#) in the AWS re:Post Knowledge Center.
- [Why do I get an Access Denied error when I try to access an Amazon S3 resource in the same AWS account?](#) in the AWS re:Post Knowledge Center.
- [Why do I get an Access Denied error when I try to access an Amazon S3 bucket with public read access?](#) in the AWS re:Post Knowledge Center.
- [Why do I get a "signature mismatch" error when I try to use a presigned URL to upload an object to Amazon S3?](#) in the AWS re:Post Knowledge Center.
- [Why do I get an Access Denied error for ListObjectsV2 when I run the sync command on my Amazon S3 bucket?](#) in the AWS re:Post Knowledge Center.
- [Why do I get a "403 access denied" error when I use an Amazon S3 website endpoint as the origin of my CloudFront distribution?](#) in the AWS re:Post Knowledge Center.

AWS managed policies for Amazon S3

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see [AWS managed policies](#) in the *IAM User Guide*.

AWS managed policy: AmazonS3FullAccess

You can attach the AmazonS3FullAccess policy to your IAM identities. This policy grants permissions that allow full access to Amazon S3.

To view the permissions for this policy, see [AmazonS3FullAccess](#) in the AWS Management Console.

AWS managed policy: AmazonS3ReadOnlyAccess

You can attach the AmazonS3ReadOnlyAccess policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon S3.

To view the permissions for this policy, see [AmazonS3ReadOnlyAccess](#) in the AWS Management Console.

AWS managed policy: AmazonS3ObjectLambdaExecutionRolePolicy

Provides AWS Lambda functions the required permissions to send data to S3 Object Lambda when requests are made to an S3 Object Lambda access point. Also grants Lambda permissions to write to Amazon CloudWatch logs.

To view the permissions for this policy, see [AmazonS3ObjectLambdaExecutionRolePolicy](#) in the AWS Management Console.

AWS managed policy: S3UnlockBucketPolicy

If you incorrectly configured your bucket policy for a member account to deny all users access to your S3 bucket, you can use this AWS managed policy (S3UnlockBucketPolicy) to unlock the bucket. For more information on how to remove a misconfigured bucket policy that denies all principals from accessing an Amazon S3 bucket, see [Perform a privileged task on an AWS Organizations member account](#) in the *AWS Identity and Access Management User Guide*.

Amazon S3 updates to AWS managed policies

View details about updates to AWS managed policies for Amazon S3 since this service began tracking these changes.

Change	Description	Date
Amazon S3 added S3UnlockBucketPolicy	Amazon S3 added a new AWS-managed policy called	November 1, 2024

Change	Description	Date
	S3UnlockBucketPolicy to unlock a bucket and remove a misconfigured bucket policy that denies all principals from accessing an Amazon S3 bucket.	
Amazon S3 added Describe permissions to AmazonS3ReadonlyAccess	Amazon S3 added s3:Describe* permissions to AmazonS3ReadonlyAccess .	August 11, 2023
Amazon S3 added S3 Object Lambda permissions to AmazonS3FullAccess and AmazonS3ReadonlyAccess	Amazon S3 updated the AmazonS3FullAccess and AmazonS3ReadonlyAccess policies to include permissions for S3 Object Lambda.	September 27, 2021
Amazon S3 added AmazonS3ObjectLambdaExecutionRolePolicy	Amazon S3 added a new AWS-managed policy called AmazonS3ObjectLambdaExecutionRolePolicy that provides Lambda functions permissions to interact with S3 Object Lambda and write to CloudWatch logs.	August 18, 2021
Amazon S3 started tracking changes	Amazon S3 started tracking changes for its AWS managed policies.	August 18, 2021

Managing access to shared datasets with access points

Amazon S3 access points simplify data access for any AWS service or customer application that stores data in S3. Access points are named network endpoints that are attached to a data source such as a bucket, Amazon FSx for NetApp ONTAP volume, or Amazon FSx for OpenZFS volume. For information about working with buckets, see [General purpose buckets overview](#). For information about working with FSx for NetApp ONTAP, see [What is Amazon FSx for NetApp ONTAP](#) in the *FSx for ONTAP User Guide*. For information about working with FSx for OpenZFS, see [What is Amazon FSx for OpenZFS](#) in the *FSx for OpenZFS User Guide*.

You can use access points to perform S3 object operations, such as `GetObject` and `PutObject`. Each access point has distinct permissions and network controls that S3 applies for any request that is made through that access point. Each endpoint enforces a customized access point policy that allow you to control use by resource, user, or other conditions. If your access point is attached to a bucket the access point policy works in conjunction with the underlying bucket policy. You can configure any access point to accept requests only from a virtual private cloud (VPC) to restrict Amazon S3 data access to a private network. You can also configure custom block public access settings for each access point.

Note

You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as deleting buckets or creating S3 Replication configurations. For a complete list of S3 operations that support access points, see [Access point compatibility](#).

The topics in this section explain how to work with Amazon S3 access points. For topics on using access points with directory buckets see, [Managing access to shared datasets in directory buckets with access points](#).

Topics

- [Access points naming rules, restrictions, and limitations](#)
- [Referencing access points with ARNs, access point aliases, or virtual-hosted-style URLs](#)
- [Access point compatibility](#)
- [Configuring IAM policies for using access points](#)

- [Monitoring and logging access points](#)
- [Creating an access point](#)
- [Managing your Amazon S3 access points for general purpose buckets](#)
- [Using Amazon S3 access points for general purpose buckets](#)
- [Using tags with S3 Access Points for general purpose buckets](#)

Access points naming rules, restrictions, and limitations

Access points are named network endpoints attached to a bucket or a volume on an Amazon FSx file system that simplify managing data. When you create an access point you choose a name and the AWS Region to create it in. The following topics provide information about access point naming rules, restrictions and limitations.

Topics

- [Naming rules for access points](#)
- [Restrictions and limitations for access points](#)
- [Restrictions and limitations for access points attached to a volume on an Amazon FSx file system](#)

Naming rules for access points

When you create an access point, you choose its name and the AWS Region to create it in. Unlike general purpose buckets access point names do not need to be unique across AWS accounts or AWS Regions. The same AWS account may create access points with the same name in different AWS Regions or two different AWS accounts may use the same access point name. However, within a single AWS Region an AWS account may not have two identically named access points.

Note

If you choose to publicize your access point name, avoid including sensitive information in the access point name. Access point names are published in a publicly accessible database known as the Domain Name System (DNS).

Access point names must be DNS-compliant and must meet the following conditions:

- Must be unique within a single AWS account and AWS Region

- Must begin with a number or lowercase letter
- Must be between 3 and 50 characters long
- Can't begin or end with a hyphen (-)
- Can't contain underscores (_), uppercase letters, spaces, or periods (.)
- Can't end with the suffix -s3alias or -ext-s3alias. These suffixes are reserved for access point alias names. For more information, see [Access point aliases](#).

Restrictions and limitations for access points

Amazon S3 access points have the following restrictions and limitations:

- Each access point is associated with exactly one bucket or FSx for OpenZFS volume. You must specify this when you create the access point. After you create an access point, you can't associate it with a different bucket or FSx for OpenZFS volume. However, you can delete an access point, and then create another one with the same name.
- After you create an access point, you can't change its virtual private cloud (VPC) configuration.
- Access point policies are limited to 20 KB in size.
- You can create a maximum of 10,000 access points per AWS account per AWS Region. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see [AWS service quotas](#) in the *AWS General Reference*.
- You can't use an access point as a destination for S3 Replication. For more information about replication, see [Replicating objects within and across Regions](#).
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.
- You can address access points only by using virtual-host-style URLs. For more information about virtual-host-style addressing, see [Accessing an Amazon S3 general purpose bucket](#).
- API operations that control access point functionality (for example, PutAccessPoint and GetAccessPointPolicy) don't support cross-account calls.
- You must use AWS Signature Version 4 when making requests to an access point by using the REST APIs. For more information about authenticating requests, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.
- Access points only support requests over HTTPS. Amazon S3 will automatically respond with an HTTP redirect for any requests made via HTTP, to upgrade the request to HTTPS.

- Access points don't support anonymous access.
- After you create an access point, you can't change its block public access settings.
- Cross-account access points don't grant you access to data until you are granted permissions from the bucket owner. The bucket owner always retains ultimate control over access to the data and must update the bucket policy to authorize requests from the cross-account access point. To view a bucket policy example, see [Configuring IAM policies for using access points](#).
- In AWS Regions where you have more than 1,000 access points, you can't search for an access point by name in the Amazon S3 console.
- When you're viewing a cross-account access point in the Amazon S3 console, the **Access** column displays **Unknown**. The Amazon S3 console can't determine if public access is granted for the associated bucket and objects. Unless you require a public configuration for a specific use case, we recommend that you and the bucket owner block all public access to the access point and the bucket. For more information, see [Blocking public access to your Amazon S3 storage](#).

Restrictions and limitations for access points attached to a volume on an Amazon FSx file system

The following are specific limitations when using access points attached to a volume on an Amazon FSx file system:

- When creating an access points you can only attach the access point to a volume on a Amazon FSx file systems that you own. You cannot attach to a volume owned by another AWS account.
- You cannot use the `CreateAccessPoint` API when creating and attaching an access point to a volume on a Amazon FSx file system. You must use the [CreateAndAttachS3AccessPoint](#) API.
- You can not turn off any block public access settings when creating or using an access point attached to a volume on an Amazon FSx file system.
- You can't list objects or use **Copy** or **Move** operations in the S3 console with access points attached to a volume on an Amazon FSx file system.
- `CopyObject` is supported for access points attached to an FSx for NetApp ONTAP or FSx for OpenZFS volume only if the source and destination are the same access point. For more information, about access point compatibility, see [Access point compatibility](#).
- Multipart uploads are limited to 5GB.
- FSx for OpenZFS deployment type and storage class support varies by AWS Region. For more information, see [Availability by AWS Region](#) in the *OpenZFS User Guide*.

Referencing access points with ARNs, access point aliases, or virtual-hosted-style URIs

After you create an access point you can use these endpoints to perform a number of operations. When referring to an access point you can use the Amazon Resource Names (ARNs), access point alias, or virtual-hosted-style URI.

Topics

- [Access point ARNs](#)
- [Access point aliases](#)
- [Virtual-hosted-style URI](#)

Access point ARNs

Access points have Amazon Resource Names (ARNs). Access point ARNs are similar to bucket ARNs, but they are explicitly typed and encode the access point's AWS Region and the AWS account ID of the access point's owner. For more information about ARNs, see [Identify AWS resources with Amazon Resource Names \(ARNs\)](#) in the *IAM User Guide*.

Access point ARNs use the following format:

```
arn:aws:s3:region:account-id:accesspoint/resource
```

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test` represents the access point named `test`, owned by account `123456789012` in the Region `us-west-2`.
- `arn:aws:s3:us-west-2:123456789012:accesspoint/*` represents all access points under account `123456789012` in the Region `us-west-2`.

ARNs for objects accessed through an access point use the following format:

```
arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource
```

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01` represents the object `unit-01`, accessed through the access point named `test`, owned by account `123456789012` in the Region `us-west-2`.

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/*` represents all objects for the access point named `test`, in account `123456789012` in the Region `us-west-2`.
- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01/finance/*` represents all objects under prefix `unit-01/finance/` for the access point named `test`, in account `123456789012` in the Region `us-west-2`.

Access point aliases

When you create an access point, Amazon S3 automatically generates an alias that you can use instead of an Amazon S3 bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for access point data plane operations. For a list of these operations, see [Access point compatibility](#).

An access point alias name is created within the same namespace as an Amazon S3 bucket. This alias name is automatically generated and cannot be changed. An access point alias name meets all the requirements of a valid Amazon S3 bucket name and consists of the following parts:

`ACCESS POINT NAME`-METADATA-s3alias (for access points attached to an Amazon S3 bucket)

`ACCESS POINT NAME`-METADATA-ext-s3alias (for access points attached to a non-S3 bucket data source)

 **Note**

The `-s3alias` and `-ext-s3alias` suffixes are reserved for access point alias names and can't be used for bucket or access point names. For more information about Amazon S3 bucket-naming rules, see [General purpose bucket naming rules](#).

Access points aliases use cases and limitations

When adopting access points, you can use access point alias names without requiring extensive code changes.

When you create an access point, Amazon S3 automatically generates an access point alias name, as shown in the following example. To run this command, replace the `user input placeholders` with your own information.

```
aws s3control create-access-point --bucket amzn-s3-demo-bucket1 --name my-access-point
--account-id 111122223333
{
    "AccessPointArn": "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
    "Alias": "my-access-point-aqfqprnstaefdfbarligizwgyfouse1a-s3alias"
}
```

You can use this access point alias name instead of an Amazon S3 bucket name in any data plane operation. For a list of these operations, see [Access point compatibility](#).

The following AWS CLI example for the get-object command uses the bucket's access point alias to return information about the specified object. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket my-access-point-aqfqprnstaefdfbarligizwgyfouse1a-s3alias --key dir/my_data.rtf my_data.rtf

{
    "AcceptRanges": "bytes",
    "LastModified": "2020-01-08T22:16:28+00:00",
    "ContentLength": 910,
    "ETag": "\\"00751974dc146b76404bb7290f8f51bb\\\"",
    "VersionId": "null",
    "ContentType": "text/rtf",
    "Metadata": {}
}
```

Access point alias limitations

- Aliases cannot be configured by customers.
- Aliases cannot be deleted or modified or disabled on an access point.
- You can use this access point alias name instead of an Amazon S3 bucket name in some data plane operations. For a list of these operations, see [Access points compatibility with S3 operations](#).
- You can't use an access point alias name for Amazon S3 control plane operations. For a list of Amazon S3 control plane operations, see [Amazon S3 Control](#) in the *Amazon Simple Storage Service API Reference*.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.

- Aliases cannot be used in AWS Identity and Access Management (IAM) policies.
- Aliases cannot be used as a logging destination for S3 server access logs.
- Aliases cannot be used as a logging destination for AWS CloudTrail logs.
- Amazon SageMaker AI GroundTruth does not support access point aliases.

Virtual-hosted-style URI

Access points only support virtual-host-style addressing. In a virtual-hosted-style URI, the access point name, AWS account, and AWS Region is part of the domain name in the URL. For more information about virtual hosting, see [Virtual hosting of general purpose buckets](#).

Virtual-hosted-style URI for access points use the following format:

```
https://access-point-name-account-id.s3-accesspoint.region.amazonaws.com
```

Note

- If your access point name includes dash (-) characters, include the dashes in the URL and insert another dash before the account ID. For example, to use an access point named *finance-docs* owned by account *123456789012* in the Region *us-west-2*, the appropriate URL would be `https://finance-docs-123456789012.s3-accesspoint.us-west-2.amazonaws.com`.
- S3 access points don't support access through HTTP. Access points support only secure access through HTTPS.

Access point compatibility

You can use access points to access objects using the following subset of Amazon S3 APIs. All the operations listed below can accept either access point ARNs or access point aliases.

For examples of using access points to perform operations on objects, see [Using Amazon S3 access points for general purpose buckets](#).

Access points compatibility with S3 operations

The following table is a partial list of Amazon S3 operations and if they are compatible with access points. All operations below are supported by access points using an S3 bucket as its data source, while only some operations are supported by access points using an FSx for ONTAP or FSx for OpenZFS volume as a data source.

For more information see, access point compatibility in the [FSx for ONTAP User Guide](#) or the [FSx for OpenZFS User Guide](#).

S3 operation	Access point attached to an S3 bucket	Access point attached to an FSx for OpenZFS volume
AbortMultipartUpload	Supported	Supported
CompleteMultipartUpload	Supported	Supported
CopyObject (same-Region copies only)	Supported	Supported, if source and destination are the same access point

Configuring IAM policies for using access points

Amazon S3 access points support AWS Identity and Access Management (IAM) resource policies that allow you to control the use of the access point by resource, user, or other conditions. For an application or user to be able to access objects through an access point, both the access point and the underlying bucket or Amazon FSx file system must permit the request.

Important

Restrictions that you include in an access point policy apply only to requests made through that access point. Attaching an access point to a bucket does not change underlying resource's behavior. All existing operations against the bucket not made through your access point will continue to work as before.

When you're using IAM resource policies, make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide recommendations to help you author policies that are functional and conform to security best practices.

To learn more about validating policies by using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

Policy examples for access points

The following examples demonstrate how to create IAM policies to control requests made through an access point.

Note

Permissions granted in an access point policy are effective only if the underlying bucket also allows the same access. You can accomplish this in two ways:

1. **(Recommended)** Delegate access control from the bucket to the access point, as described in [Delegating access control to access points](#).
2. Add the same permissions contained in the access point policy to the underlying bucket's policy. The Example 1 access point policy example demonstrates how to modify the underlying bucket policy to allow the necessary access.

Example 1 – Access point policy grant

The following access point policy grants IAM user *Jane* in account *123456789012* permissions to GET and PUT objects with the prefix *Jane/* through the access point *my-access-point* in account *123456789012*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Jane"  
            },  
            "Action": ["s3:GetObject", "s3:PutObject"],  
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-  
point/object/Jane/*"  
        }]  
}
```

Note

For the access point policy to effectively grant access to *Jane*, the underlying bucket must also allow the same access to *Jane*. You can delegate access control from the bucket to the access point as described in [Delegating access control to access points](#). Or, you can add the following policy to the underlying bucket to grant the necessary permissions to Jane. Note that the Resource entry differs between the access point and bucket policies.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Jane"  
            },  
            "Action": ["s3:GetObject", "s3:PutObject"],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/Jane/*"  
        }]  
}
```

Example 2 – Access point policy with tag condition

The following access point policy grants IAM user *Mateo* in account *123456789012* permissions to GET objects through the access point *my-access-point* in the account *123456789012* that have the tag key *data* set with a value of *finance*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Mateo"  
            },  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::123456789012-my-access-point/*"  
        }]  
}
```

```
    },
    "Action": "s3:GetObject",
    "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point/object/*",
    "Condition": {
        "StringEquals": {
            "s3:ExistingObjectTag/datafinance"
        }
    }
}
```

Example 3 – Access point policy that allows bucket listing

The following access point policy allows IAM user Arnav in the account **123456789012** permission to view the objects contained in the bucket underlying the access point **my-access-point** in the account **123456789012**.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Arnav"
            },
            "Action": "s3>ListBucket",
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point"
        }
    ]
}
```

Example 4 – Service control policy

The following service control policy requires all new access points to be created with a virtual private cloud (VPC) network origin. With this policy in place, users in your organization can't create new access points that are accessible from the internet.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Action": "s3>CreateAccessPoint",  
            "Resource": "*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:AccessPointNetworkOrigin": "VPC"  
                }  
            }  
        }  
    ]  
}
```

Example 5 – Bucket policy to limit S3 operations to VPC network origins

The following bucket policy limits access to all S3 object operations for the bucket `amzn-s3-demo-bucket` to access points with a VPC network origin.

Important

Before using a statement like the one shown in this example, make sure that you don't need to use features that aren't supported by access points, such as Cross-Region Replication.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": [  
                "s3:AbortMultipartUpload",
```

```
        "s3:BypassGovernanceRetention",
        "s3>DeleteObject",
        "s3>DeleteObjectTagging",
        "s3>DeleteObjectVersion",
        "s3>DeleteObjectVersionTagging",
        "s3:GetObject",
        "s3:GetObjectAcl",
        "s3:GetObjectLegalHold",
        "s3:GetObjectRetention",
        "s3:GetObjectTagging",
        "s3:GetObjectVersion",
        "s3:GetObjectVersionAcl",
        "s3:GetObjectVersionTagging",
        "s3>ListMultipartUploadParts",
        "s3:PutObject",
        "s3:PutObjectAcl",
        "s3:PutObjectLegalHold",
        "s3:PutObjectRetention",
        "s3:PutObjectTagging",
        "s3:PutObjectVersionAcl",
        "s3:PutObjectVersionTagging",
        "s3:RestoreObject"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
    "Condition": {
        "StringNotEquals": {
            "s3:AccessPointNetworkOrigin": "VPC"
        }
    }
}
]
```

Condition keys

S3 access points have condition keys that you can use in IAM policies to control access to your resources. The following condition keys represent only part of an IAM policy. For full policy examples, see [Policy examples for access points](#), [the section called “Delegating access control to access points”](#), and [the section called “Granting permissions for cross-account access points”](#).

s3:DataAccessPointArn

This example shows a string that you can use to match on an access point ARN. The following example matches all access points for AWS account [123456789012](#) in Region [us-west-2](#):

```
"Condition" : {  
    "StringLike": {  
        "s3:DataAccessPointArn": "arn:aws:s3:us-west-2:123456789012:accesspoint/*"  
    }  
}
```

s3:DataAccessPointAccount

This example shows a string operator that you can use to match on the account ID of the owner of an access point. The following example matches all access points that are owned by the AWS account [123456789012](#).

```
"Condition" : {  
    "StringEquals": {  
        "s3:DataAccessPointAccount": "123456789012"  
    }  
}
```

s3:AccessPointNetworkOrigin

This example shows a string operator that you can use to match on the network origin, either Internet or VPC. The following example matches only access points with a VPC origin.

```
"Condition" : {  
    "StringEquals": {  
        "s3:AccessPointNetworkOrigin": "VPC"  
    }  
}
```

For more information about using condition keys with Amazon S3, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Delegating access control to access points

You can delegate access control for a bucket to the bucket's access points. The following example bucket policy allows full access to all access points that are owned by the bucket owner's account. Thus, all access to this bucket is controlled by the policies attached to its access points. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket.

Example 6 – Bucket policy that delegates access control to access points

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Effect": "Allow",  
            "Principal" : { "AWS": "*" },  
            "Action" : "*",  
            "Resource" : [ "arn:aws:s3:::amzn-s3-demo-bucket", "arn:aws:s3:::amzn-s3-  
demo-bucket/*"],  
            "Condition": {  
                "StringEquals" : { "s3:DataAccessPointAccount" : "111122223333" }  
            }  
        }  
    ]  
}
```

Granting permissions for cross-account access points

To create an access point to a bucket that's owned by another account, you must first create the access point by specifying the bucket name and account owner ID. Then, the bucket owner must update the bucket policy to authorize requests from the access point. Creating an access point is similar to creating a DNS CNAME in that the access point doesn't provide access to the bucket contents. All bucket access is controlled by the bucket policy. The following example bucket policy allows GET and LIST requests on the bucket from an access point that's owned by a trusted AWS account.

Replace *Bucket ARN* with the ARN of the bucket.

Example 7 – Bucket policy delegating permissions to another AWS account

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Effect": "Allow",  
            "Principal" : { "AWS": "*" },  
            "Action" : ["s3:GetObject","s3>ListBucket"],  
            "Resource" : ["arn:aws:s3:::amzn-s3-demo-bucket", "arn:aws:s3:::amzn-s3-  
demo-bucket/*"],  
            "Condition": {  
                "StringEquals" : { "s3:DataAccessPointAccount" : "Access point  
owner's account ID" }  
            }  
        }]  
    }  
}
```

Note

Cross-account access points are only available for access points attached to S3 buckets. You cannot attach an access point to a volume on an Amazon FSx file system owned by another AWS account.

Monitoring and logging access points

Amazon S3 logs requests made through access points and requests made to the API operations that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`. To monitor and manage usage patterns, you can also configure Amazon CloudWatch Logs request metrics for access points.

Topics

- [CloudWatch request metrics](#)
- [AWS CloudTrail logs for requests made through access points](#)

CloudWatch request metrics

To understand and improve the performance of applications that are using access points, you can use CloudWatch for Amazon S3 request metrics. Request metrics help you monitor Amazon S3 requests to quickly identify and act on operational issues.

By default, request metrics are available at the bucket level. However, you can define a filter for request metrics using a shared prefix, object tags, or an access point. When you create an access point filter, the request metrics configuration includes requests to the access point that you specify. You can receive metrics, set alarms, and access dashboards to view real-time operations performed through this access point.

You must opt in to request metrics by configuring them in the console or by using the Amazon S3 API. Request metrics are available at 1-minute intervals after some latency for processing. Request metrics are billed at the same rate as CloudWatch custom metrics. For more information, see [Amazon CloudWatch pricing](#).

To create a request metrics configuration that filters by access point, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

AWS CloudTrail logs for requests made through access points

You can log requests made through access points and requests made to the APIs that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`, by using server access logging and AWS CloudTrail.

CloudTrail log entries for requests made through access points include the access point ARN in the resources section of the log.

For example, suppose you have the following configuration:

- A bucket named *amzn-s3-demo-bucket1* in Region *us-west-2* that contains an object named *my-image.jpg*
- An access point named *my-bucket-ap* that is associated with *amzn-s3-demo-bucket1*
- An AWS account ID of *123456789012*

The following example shows the resources section of a CloudTrail log entry for the preceding configuration:

```
"resources": [
    {"type": "AWS::S3::Object",
     "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1/my-image.jpg"
    },
    {"accountId": "123456789012",
     "type": "AWS::S3::Bucket",
     "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1"
    },
    {"accountId": "123456789012",
     "type": "AWS::S3::AccessPoint",
     "ARN": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-bucket-ap"
    }
]
```

If you are using an access point attached to a volume on an Amazon FSx file system, the `resources` section of a CloudTrail log entry will look different. For example:

```
"resources": [
    {
        "accountId": "123456789012",
        "type": "AWS::FSx::Volume",
        "ARN": "arn:aws:fsx:us-east-1:123456789012:volume/fs-0123456789abcdef9/
fsvol-01234567891112223"
    }
]
```

For more information about S3 Server Access Logs, see [Logging requests with server access logging](#). For more information about AWS CloudTrail, see [What is AWS CloudTrail?](#) in the [AWS CloudTrail User Guide](#).

Creating an access point

You can create S3 access points by using the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. Access points are named network endpoints that are attached to a data source such as a bucket, Amazon FSx for ONTAP volume, or Amazon FSx for OpenZFS volume.

By default, you can create up to 10,000 access points per Region for each of your AWS accounts. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see [AWS Service Quotas](#) in the [AWS General Reference](#).

Topics

- [Creating access points with S3 buckets](#)
- [Creating access points with Amazon FSx](#)
- [Creating access points restricted to a virtual private cloud](#)
- [Managing public access to access points for general purpose buckets](#)

Creating access points with S3 buckets

An access point is associated with exactly one Amazon S3 general purpose bucket. If you want to use a bucket in your AWS account, you must first create a bucket. For more information about creating buckets, see [Creating, configuring, and working with Amazon S3 general purpose buckets](#).

You can also create a cross-account access point that's associated with a bucket in another AWS account, as long as you know the bucket name and the bucket owner's account ID. However, creating cross-account access points doesn't grant you access to data in the bucket until you are granted permissions from the bucket owner. The bucket owner must grant the access point owner's account (your account) access to the bucket through the bucket policy. For more information, see [Granting permissions for cross-account access points](#).

Using the S3 console

To create an access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create an access point. The access point must be created in the same Region as the associated bucket.
3. In the left navigation pane, choose **Access Points**.
4. On the **Access Points** page, choose **Create access point**.
5. In the **Access point name** field, enter the name for the access point. For more information about naming access points, see [Naming rules for access points](#).
6. For **Data source**, specify the S3 bucket that you want to use with the access point.

To use a bucket in your account, choose **Choose a bucket in this account**, and enter or browse for the bucket name.

To use a bucket in a different AWS account, choose **Specify a bucket in another account**, and enter the AWS account ID and name of the bucket. If you're using a bucket in a different AWS account, the bucket owner must update the bucket policy to authorize requests from the access point. For an example bucket policy, see [Granting permissions for cross-account access points](#).

 **Note**

For information about using an FSx for OpenZFS volume as a data source, see [Creating access points with Amazon FSx](#).

7. Choose a **Network origin**, either **Internet** or **virtual private cloud (VPC)**. If you choose **virtual private cloud (VPC)**, enter the **VPC ID** that you want to use with the access point.

For more information about network origins for access points, see [Creating access points restricted to a virtual private cloud](#).

8. Under **Block Public Access settings for this Access Point**, select the block public access settings that you want to apply to the access point. All block public access settings are enabled by default for new access points. We recommend that you keep all settings enabled unless you know that you have a specific need to disable any of them.

 **Note**

After you create an access point, you can't change its block public access settings.

For more information about using Amazon S3 Block Public Access with access points, see [Managing public access to access points for general purpose buckets](#).

9. (Optional) Under **Access Point policy - optional**, specify the access point policy. Before you save your policy, make sure to resolve any security warnings, errors, general warnings, and suggestions. For more information about specifying an access point policy, see [Policy examples for access points](#).
10. Choose **Create access point**.

Using the AWS CLI

The following example command creates an access point named *example-ap* for the bucket *amzn-s3-demo-bucket* in the account *111122223333*. To create the access point, you send a request to Amazon S3 that specifies the following:

- The access point name. For information about naming rules, see [the section called “Naming rules for access points”](#).
- The name of the bucket that you want to associate the access point with.
- The account ID for the AWS account that owns the access point.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --bucket amzn-s3-demo-bucket
```

When you're creating an access point by using a bucket in a different AWS account, include the --bucket-account-id parameter. The following example command creates an access point in the AWS account *111122223333*, using the bucket *amzn-s3-demo-bucket2*, which is in the AWS account *444455556666*.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --bucket amzn-s3-demo-bucket --bucket-account-id 444455556666
```

Using the REST API

You can use the REST API to create an access point. For more information, see [CreateAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Creating access points with Amazon FSx

You can create and attach an access point to an FSx for OpenZFS volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data. Your data continues to reside on the Amazon FSx file system and continues to be directly accessible for your existing workloads. You continue to manage your storage using all the FSx for OpenZFS storage management capabilities, including backups, snapshots, user and group quotas, and compression.

For instructions on creating an access point and attaching it to an FSx for OpenZFS volume see, [Creating an access point](#) in the *FSx for OpenZFS User Guide*.

Creating access points restricted to a virtual private cloud

When you create an access point you can choose to make the access point accessible from the internet, or you can specify that all requests made through that access point must originate from a specific virtual private cloud (VPC). An access point that's accessible from the internet is said to have a network origin of Internet. It can be used from anywhere on the internet, subject to any other access restrictions in place for the access point, underlying data source, and related resources, such as the requested objects. An access point that's only accessible from a specified VPC has a network origin of VPC, and Amazon S3 rejects any request made to the access point that doesn't originate from that VPC.

Important

You can only specify an access point's network origin when you create the access point. After you create the access point, you can't change its network origin.

To restrict an access point to VPC-only access, you include the `VpcConfiguration` parameter with the request to create the access point. In the `VpcConfiguration` parameter, you specify the VPC ID that you want to be able to use the access point. If a request is made through the access point, the request must originate from the VPC or Amazon S3 will reject it.

You can retrieve an access point's network origin using the AWS CLI, AWS SDKs, or REST APIs. If an access point has a VPC configuration specified, its network origin is VPC. Otherwise, the access point's network origin is Internet.

Example: Create and restrict an access point to a VPC ID

The following example creates an access point named `example-vpc-ap` for bucket `amzn-s3-demo-bucket` in account 123456789012 that allows access only from the `vpc-1a2b3c` VPC. The example then verifies that the new access point has a network origin of VPC.

AWS CLI

```
aws s3control create-access-point --name example-vpc-ap --account-id 123456789012 --bucket amzn-s3-demo-bucket --vpc-configuration VpcId=vpc-1a2b3c
```

```
aws s3control get-access-point --name example-vpc-ap --account-id 123456789012
```

```
{  
    "Name": "example-vpc-ap",  
    "Bucket": "amzn-s3-demo-bucket",  
    "NetworkOrigin": "VPC",  
    "VpcConfiguration": {  
        "VpcId": "vpc-1a2b3c"  
    },  
    "PublicAccessBlockConfiguration": {  
        "BlockPublicAccls": true,  
        "IgnorePublicAccls": true,  
        "BlockPublicPolicy": true,  
        "RestrictPublicBuckets": true  
    },  
    "CreationDate": "2019-11-27T00:00:00Z"  
}
```

To use an access point with a VPC, you must modify the access policy for your VPC endpoint. VPC endpoints allow traffic to flow from your VPC to Amazon S3. They have access control policies that control how resources within the VPC are allowed to interact with Amazon S3. Requests from your VPC to Amazon S3 only succeed through an access point if the VPC endpoint policy grants access to both the access point and the underlying bucket.

 **Note**

To make resources accessible only within a VPC, make sure to create a [private hosted zone](#) for your VPC endpoint. To use a private hosted zone, [modify your VPC settings](#) so that the [VPC network attributes](#) enableDnsHostnames and enableDnsSupport are set to true.

The following example policy statement configures a VPC endpoint to allow calls to GetObject for a bucket named awsexamplebucket1 and an access point named example-vpc-ap.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject",  
                "s3:ListBucket"  
            ]  
        }  
    ]  
}
```

```
        "s3:GetObject"
    ],
    "Effect": "Allow",
    "Resource": [
        "arn:aws:s3:::awsexamplebucket1/*",
        "arn:aws:s3:us-west-2:123456789012:accesspoint/example-vpc-ap/object/*
    ]
}
}
```

Note

The "Resource" declaration in this example uses an Amazon Resource Name (ARN) to specify the access point. For more information about access point ARNs, see [Referencing access points with ARNs, access point aliases, or virtual-hosted-style URIs](#).

For more information about VPC endpoint policies, see [Using endpoint policies for Amazon S3](#) in the *VPC User Guide*.

For a tutorial on creating access points with VPC endpoints, see [Managing Amazon S3 access with VPC endpoints and access points](#).

Example: Create and restrict an access point attached to an FSx for OpenZFS volume to a VPC ID

You can create an access point that is attached it to an FSx for OpenZFS volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data from a specified VPC.

For instructions on creating and restricting an access point attached to an FSx for OpenZFS volume see, the [Creating access points restricted to a virtual private cloud \(VPC\)](#) in the *FSx for OpenZFS User Guide*.

Example: Create and restrict an access point attached to an FSX for ONTAP volume to a VPC ID

You can create an access point that is attached it to an FSx for ONTAP volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data from a specified VPC.

For instructions on creating and restricting an access point attached to an FSx for ONTAP volume see, the [FSx for ONTAP User Guide](#).

Managing public access to access points for general purpose buckets

Amazon S3 access points support independent *block public access* settings for each access point. When you create an access point, you can specify block public access settings that apply to that access point. For any request made through an access point, Amazon S3 evaluates the block public access settings for that access point, the underlying bucket, and the bucket owner's account. If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request.

For more information about the S3 Block Public Access feature, see [Blocking public access to your Amazon S3 storage](#).

Important

- All block public access settings are enabled by default for access points. You must explicitly disable any settings that you don't want during access point creation.
- You can not turn off any block public access settings when creating or using an access point attached to an Amazon FSx file system.
- After you create an access point, you can't change its block public access settings.

Example

Example: Create an access point with Custom Block Public Access Settings

This example creates an access point named example-ap for bucket `amzn-s3-demo-bucket` in account 123456789012 with non-default Block Public Access settings. The example then retrieves the new access point's configuration to verify its Block Public Access settings.

AWS CLI

```
aws s3control create-access-point --name example-ap --account-id  
123456789012 --bucket amzn-s3-demo-bucket--public-access-block-configuration  
BlockPublicAcls=false,IgnorePublicAcls=false,BlockPublicPolicy=true,RestrictPublicBuckets=t
```

```
aws s3control get-access-point --name example-ap --account-id 123456789012
```

```
{  
    "Name": "example-ap",  
    "Bucket": "amzn-s3-demo-bucket",  
    "NetworkOrigin": "Internet",  
    "PublicAccessBlockConfiguration": {  
        "BlockPublicAcls": false,  
        "IgnorePublicAcls": false,  
        "BlockPublicPolicy": true,  
        "RestrictPublicBuckets": true  
    },  
    "CreationDate": "2019-11-27T00:00:00Z"  
}
```

Managing your Amazon S3 access points for general purpose buckets

This section explains how to manage your Amazon S3 access points for general purpose buckets using the AWS Management Console, AWS Command Line Interface, or REST API. For information on managing access points attached to an FSx for OpenZFS volume, see [Managing your Amazon S3 access points](#) in the *FSx for OpenZFS User Guide*.

Note

You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as deleting buckets or creating S3 Replication configurations. For a complete list of S3 operations that support access points, see [Access point compatibility](#).

Topics

- [List your access points for general purpose buckets](#)
- [View details for your access point for general purpose buckets](#)
- [Delete your access point for a general purpose bucket](#)

List your access points for general purpose buckets

This section explains how to list your access points for general purpose buckets using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To list access points in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.

Using the AWS CLI

The following `list-access-points` example command shows how you can use the AWS CLI to list your access points.

The following command lists access points for AWS account `111122223333`.

```
aws s3control list-access-points --account-id 111122223333
```

The following command lists access points for AWS account `111122223333` that are attached to bucket `amzn-s3-demo-bucket`.

```
aws s3control list-access-points --account-id 111122223333 --bucket amzn-s3-demo-bucket
```

For more information and examples, see [list-access-points](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to list your access points. For more information, see [ListAccessPoints](#) in the *Amazon Simple Storage Service API Reference*.

View details for your access point for general purpose buckets

This section explains how to view details for your access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To view details for your access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Select the **Properties** tab to view the access point data source, account ID, AWS Region, creation date, network origin, S3 URI, ARN, and access point alias for the selected access point.
7. Select the **Permissions** tab to view the block public access settings and access point policy for the selected access point.

 **Note**

You can't change any block public access settings for an access point after the access point is created.

Using the AWS CLI

The following get-access-point example command shows how you can use the AWS CLI to view details for your access point.

The following command lists details for the access point *my-access-point* for AWS account *111122223333* attached to S3 bucket *amzn-s3-demo-bucket*.

```
aws s3control get-access-point --name my-access-point --account-id 111122223333
```

Example output:

```
{  
  "Name": "my-access-point",
```

```
"Bucket": "amzn-s3-demo-bucket",
"NetworkOrigin": "Internet",
"PublicAccessBlockConfiguration": {
    "BlockPublicAcls": true,
    "IgnorePublicAcls": true,
    "BlockPublicPolicy": true,
    "RestrictPublicBuckets": true
},
"CreationDate": "2016-08-29T22:57:52Z",
"Alias": "my-access-point-u1ny6bhm7moymqx8cuon8o1g4mwikuse2a-s3alias",
"AccessPointArn": "arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point",
"Endpoints": {
    "ipv4": "s3-accesspoint.AWS Region.amazonaws.com",
    "fips": "s3-accesspoint-fips.AWS Region.amazonaws.com",
    "fips_dualstack": "s3-accesspoint-fips.dualstack.AWS Region.amazonaws.com",
    "dualstack": "s3-accesspoint.dualstack.AWS Region.amazonaws.com"
},
"BucketAccountId": "111122223333"
}
```

The following command lists details for the access point *example-fsx-ap* for AWS account **444455556666**. This access point is attached to an Amazon FSx file system.

```
aws s3control get-access-point --name example-fsx-ap --account-id 444455556666
```

Example output:

```
{
    "Name": "example-fsx-ap",
    "Bucket": "",
    "NetworkOrigin": "Internet",
    "PublicAccessBlockConfiguration": {
        "BlockPublicAcls": true,
        "IgnorePublicAcls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2025-01-19T14:16:12Z",
    "Alias": "example-fsx-ap-qrqbyebjtsxorhhaa5exx6r3q7-ext-s3alias",
    "AccessPointArn": "arn:aws:s3:AWS Region:444455556666:accesspoint/example-fsx-ap",
    "Endpoints": {
        "ipv4": "s3-accesspoint.AWS Region.amazonaws.com",
        "fips": "s3-accesspoint-fips.AWS Region.amazonaws.com",
        "fips_dualstack": "s3-accesspoint-fips.dualstack.AWS Region.amazonaws.com",
        "dualstack": "s3-accesspoint.dualstack.AWS Region.amazonaws.com"
    }
}
```

```
        "fips_dualstack": "s3-accesspoint-fips.dualstack.AWS Region.amazonaws.com",
        "dualstack": "s3-accesspoint.dualstack.AWS Region.amazonaws.com"
    },
    "DataSourceId": "arn:aws::fsx:AWS Region:44445556666:file-system/
fs-5432106789abcdef0/volume/vol-0123456789abcdef0",
    "DataSourceType": "FSX_OPENZFS"
}
```

For more information and examples, see [get-access-point](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to view details for your access point. For more information, see [GetAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Delete your access point for a general purpose bucket

This section explains how to delete your access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To delete for your access points in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. From the **Access Point** page, select **Delete** to delete the access point you've selected.
7. To confirm deletion, type the name of the access point and choose **Delete**.

Using the AWS CLI

The following `delete-access-point` example command shows how you can use the AWS CLI to delete your access point.

The following command deletes the access point *my-access-point* for AWS account **111122223333**.

```
aws s3control delete-access-point --name my-access-point --account-id 111122223333
```

For more information and examples, see [delete-access-point](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to view details for your access point. For more information, see [DeleteAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Using Amazon S3 access points for general purpose buckets

The following examples demonstrate how to use access points for general purpose buckets with compatible operations in Amazon S3.

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

You can only use access points for general purpose buckets to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see [Access point compatibility](#).

Topics

- [List objects through an access point for a general purpose bucket](#)
- [Download an object through an access point for a general purpose bucket](#)
- [Configure access control lists \(ACLs\) through an access point for a general purpose bucket](#)
- [Upload an object through an access point for a general purpose bucket](#)
- [Add a tag-set through an access point for a general purpose bucket](#)
- [Delete an object through an access point for a general purpose bucket](#)

List objects through an access point for a general purpose bucket

This section explains how to list your objects through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To list your objects through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, you can view the name of objects that you want to access through the access point. While you're using the access point, you can only perform the object operations that are allowed by the access point permissions.

Note

- The console view always shows all objects in the bucket. Using an access point as described in this procedure restricts the operations you can perform on those objects, but not whether you can see that they exist in the bucket.
- The AWS Management Console doesn't support using virtual private cloud (VPC) access points to access bucket resources. To access bucket resources from a VPC access point, use the AWS CLI, AWS SDKs, or Amazon S3 REST APIs.

Using the AWS CLI

The following `list-objects-v2` example command shows how you can use the AWS CLI to list your object through an access point.

The following command lists objects for AWS account **111122223333** using access point **my-access-point**.

```
aws s3api list-objects-v2 --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point
```

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [list-access-points](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to list your access points. For more information, see [ListObjectsV2](#) in the *Amazon Simple Storage Service API Reference*.

Download an object through an access point for a general purpose bucket

This section explains how to download an object through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To download an object through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.

6. Under the **Objects** tab, select the name of object that you want to download.
7. Choose **Download**.

Using the AWS CLI

The following get-object example command shows how you can use the AWS CLI to download an object through an access point.

The following command downloads the object puppy.jpg for AWS account **111122223333** using access point *my-access-point*. You must include an outfile, which is a file name for the downloaded object, such as *my_downloaded_image.jpg*.

```
aws s3api get-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg my_downloaded_image.jpg
```

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [get-object](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to download an object through an access point. For more information, see [GetObject](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

You can use the AWS SDK for Python to download an object through an access point.

Python

In the following example, the file named *hello.txt* is downloaded for AWS account **111122223333** using the access point named *my-access-point*.

```
import boto3
```

```
s3 = boto3.client('s3')
s3.download_file('arn:aws:s3:::us-east-1:111122223333:accesspoint/my-access-point',
    'hello.txt', '/tmp/hello.txt')
```

Configure access control lists (ACLs) through an access point for a general purpose bucket

This section explains how to configure ACLs through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API. For more information about ACLs, see [Access control list \(ACL\) overview](#).

Using the S3 console

To configure ACLs through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object you wish to configure an ACL for.
7. Under the **Permissions** tab, select **Edit** to configure the object ACL.

Note

Amazon S3 currently doesn't support changing an access point's block public access settings after the access point has been created.

Using the AWS CLI

The following `put-object-acl` example command shows how you can use the AWS CLI to configure access permissions through an access point using an ACL.

The following command applies an ACL to an existing object puppy.jpg through an access point owned by AWS account **111122223333**.

```
aws s3api put-object-acl --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg --acl private
```

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [put-object-acl](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to configure access permissions through an access point using an ACL. For more information, see [PutObjectAcl](#) in the *Amazon Simple Storage Service API Reference*.

Upload an object through an access point for a general purpose bucket

This section explains how to upload an object through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To upload an object through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.

6. Under the **Objects** tab, select **Upload**.
7. Drag and drop files and folders you want to upload here, or choose **Add files** or **Add folder**.

 **Note**

The maximum size of a file that you can upload by using the Amazon S3 console is 160 GB. To upload a file larger than 160 GB, use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

8. To change access control list permissions, choose **Permissions**.
9. Under **Access control list (ACL)**, edit the permissions.

For information about object access permissions, see [Using the S3 console to set ACL permissions for an object](#). You can grant read access to your objects to the public (everyone in the world) for all of the files that you're uploading. However, we recommend not changing the default setting for public read access. Granting public read access is applicable to a small subset of use cases, such as when buckets are used for websites. You can always change the object permissions after you upload the object.

10. To configure other additional properties, choose **Properties**.
11. Under **Storage class**, choose the storage class for the files that you're uploading.

For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

12. To update the encryption settings for your objects, under **Server-side encryption settings**, do the following.
 - a. Choose **Specify an encryption key**.
 - b. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
 - c. If you chose **Override bucket settings for default encryption**, you must configure the following encryption settings.
 - To encrypt the uploaded files by using keys that are managed by Amazon S3, choose **Amazon S3 managed key (SSE-S3)**.

For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

- To encrypt the uploaded files by using keys stored in AWS Key Management Service (AWS KMS), choose **AWS Key Management Service key (SSE-KMS)**. Then choose one of the following options for **AWS KMS key**:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

13. To use additional checksums, choose **On**. Then for **Checksum function**, choose the function that you would like to use. Amazon S3 calculates and stores the checksum value after it receives the entire object. You can use the **Precalculated value** box to supply a precalculated value. If you do, Amazon S3 compares the value that you provided to the value that it calculates. If the two values do not match, Amazon S3 generates an error.

Additional checksums enable you to specify the checksum algorithm that you would like to use to verify your data. For more information about additional checksums, see [Checking object integrity in Amazon S3](#).

14. To add tags to all of the objects that you are uploading, choose **Add tag**. Enter a tag name in the **Key** field. Enter a value for the tag.

Object tagging gives you a way to categorize storage. Each tag is a key-value pair. Key and tag values are case sensitive. You can have up to 10 tags per object. A tag key can be up to 128 Unicode characters in length, and tag values can be up to 255 Unicode characters in length. For more information about object tags, see [Categorizing your objects using tags](#).

15. To add metadata, choose **Add metadata**.

- a. Under **Type**, choose **System defined** or **User defined**.

For system-defined metadata, you can select common HTTP headers, such as **Content-Type** and **Content-Disposition**. For a list of system-defined metadata and information about whether you can add the value, see [System-defined object metadata](#). Any metadata starting with the prefix `x-amz-meta-` is treated as user-defined metadata. User-defined metadata is stored with the object and is returned when you download the object. Both the keys and their values must conform to US-ASCII standards. User-defined metadata can be as large as 2 KB. For more information about system-defined and user-defined metadata, see [Working with object metadata](#).

- b. For **Key**, choose a key.
 - c. Type a value for the key.

16. To upload your objects, choose **Upload**.

Amazon S3 uploads your object. When the upload completes, you can see a success message on the **Upload: status** page.

Using the AWS CLI

The following put-object example command shows how you can use the AWS CLI to upload an object through an access point.

The following command uploads the object `puppy.jpg` for AWS account `111122223333` using access point `my-access-point`.

```
aws s3api put-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg --body puppy.jpg
```

Note

S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [put-object](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to upload an object through an access point. For more information, see [PutObject](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

You can use the AWS SDK for Python to upload an object through an access point.

Python

In the following example, the file named *hello.txt* is uploaded for AWS account *111122223333* using the access point named *my-access-point*.

```
import boto3
s3 = boto3.client('s3')
s3.upload_file('/tmp/hello.txt', 'arn:aws:s3:us-east-1:111122223333:accesspoint/my-access-point', 'hello.txt')
```

Add a tag-set through an access point for a general purpose bucket

This section explains how to add a tag-set through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API. For more information, see [Categorizing your objects using tags](#).

Using the S3 console

To add a tag-set through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object you wish to add a tag-set to.
7. Under the **Properties** tab, find the **Tags** sub-header and choose **Edit**.
8. Review the objects listed, and choose **Add tag**.
9. Each object tag is a key-value pair. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**.

You can enter up to 10 tags for an object.

10. Choose **Save changes**.

Using the AWS CLI

The following put-object-tagging example command shows how you can use the AWS CLI to add a tag-set through an access point.

The following command adds a tag-set for existing object puppy.jpg using access point *my-access-point*.

```
aws s3api put-object-tagging --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg --tagging TagSet=[{Key="animal",Value="true"}]
```

Note

S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [put-object-tagging](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to add a tag-set to an object through an access point. For more information, see [PutObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.

Delete an object through an access point for a general purpose bucket

This section explains how to delete an object through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To delete an object or objects through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object or objects you wish to delete.
7. Review the objects listed for deletion, and type *delete* in the confirmation box.
8. Choose **Delete objects**.

Using the AWS CLI

The following delete-object example command shows how you can use the AWS CLI to delete an object through an access point.

The following command deletes the existing object `puppy.jpg` using access point *my-access-point*.

```
aws s3api delete-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg
```

Note

S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [delete-object](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to delete an object through an access point. For more information, see [DeleteObject](#) in the *Amazon Simple Storage Service API Reference*.

Using tags with S3 Access Points for general purpose buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 Access Points. You can tag access points when you create them or manage tags on existing access points. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

Note

There is no additional charge for using tags on access points beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with access points

Attribute-based access control (ABAC) allows you to scale access permissions and grant access to access points based on their tags. For more information about ABAC in Amazon S3, see [Using tags for ABAC](#).

ABAC for S3 Access Points

Amazon S3 Access Points support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and Access Points policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to access points based on the access point's tags by using the following [global condition keys](#):

- aws:ResourceTag/key-name

 **Important**

The aws:ResourceTag condition key can only be used for S3 actions performed via an access point ARN for general purpose buckets and covers the underlying access point tags only.

- Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key Dept with the value Marketing. For more information, see [Controlling access to AWS resources](#).
- aws:RequestTag/key-name
 - Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key Dept and that it has the value Accounting. For more information, see [Controlling access during AWS requests](#). You can use this condition key to restrict which tag key-value pairs can be passed during the TagResource and CreateAccessPoint API operations.
- aws:TagKeys
 - Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the aws:TagKeys condition key to define what tag keys are allowed. For example policies and more information,

see [Controlling access based on tag keys](#). You can create an access point with tags. To allow tagging during the CreateAccessPoint API operation, you must create a policy that includes both the s3:TagResource and s3:CreateAccessPoint actions. You can then use the aws:TagKeys condition key to enforce using specific tags in the CreateAccessPoint request.

- s3:AccessPointTag/tag-key
 - Use this condition key to grant permissions to specific data via access points using tags. When using aws:ResourceTag/tag-key in an IAM policy, both the access point as well as the bucket to which the access point points to are required to have the same tag as they are both considered during authorization. If you want to control access to your data specifically via the access-point tag only, you can use s3:AccessPointTag/tag-key condition key.

Example ABAC policies for access points

See the following example ABAC policies for Amazon S3 Access Points.

1.1 - IAM policy to create or modify buckets with specific tags

In this IAM policy, users or roles with this policy can only create access points if they tag the access points with the tag key project and tag value Trinity in the access points creation request. They can also add or modify tags on existing access points as long as the TagResource request includes the tag key-value pair project:Trinity.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "CreateAccessPointWithTags",  
            "Effect": "Allow",  
            "Action": [  
                "s3:CreateAccessPoint",  
                "s3:TagResource"  
            ],  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:RequestTag/project": [  
                        "Trinity"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

```
    }
}
]
}
```

1.2 - Access Point policy to restrict operations on the access point using tags

In this Access Point policy, IAM principals (users and roles) can perform operations using the `GetObject` action on the access point only if the value of the access point's project tag matches the value of the principal's project tag.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowObjectOperations",
      "Effect": "Allow",
      "Principal": {
        "AWS": "111122223333"
      },
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        }
      }
    }
  ]
}
```

1.3 - IAM policy to modify tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on an access point only if the value of the access point's project tag matches the value of the principal's project tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these access points. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your access points.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Sid": "EnforceTaggingRulesOnModification",
        "Effect": "Allow",
        "Action": [
            "s3:TagResource"
        ],
        "Resource": "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
        "Condition": {
            "StringEquals": {
                "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
            },
            "ForAllValues:StringEquals": {
                "aws:TagKeys": [
                    "project",
                    "environment",
                    "owner",
                    "cost-center"
                ]
            }
        }
    }
]
```

1.4 - Using the s3:AccessPointTag condition key

In this IAM policy, the condition statement allows access to the bucket's data if the access point has the tag key Environment and tag value Production.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAccessToSpecificAccessPoint",
            "Effect": "Allow",
            "Action": "*",
            "Resource": "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
            "Condition": {
                "StringEquals": {
                    "s3:AccessPointTag/Environment": "Production"
                }
            }
        }
]
```

```
        }
    }
]
}
```

1.5 - Using a bucket delegate policy

In Amazon S3, you can delegate access to or control of your S3 bucket policy to another AWS account or to a specific AWS Identity and Access Management (IAM) user or role in the other account. The delegate bucket policy grants this other account, user, or role permission to your bucket and its objects. For more information, see [Permission delegation](#).

If using a delegate bucket policy, such as the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {"AWS": "*"},
      "Effect": "Allow",
      "Action": ["s3:*"],
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/*", "arn:aws:s3:::amzn-s3-demo-bucket"],
      "Condition": {
        "StringEquals" : {
          "s3:DataAccessPointAccount" : "111122223333"
        }
      }
    }
  ]
}
```

In the following IAM policy, the condition statement allows access to the bucket's data if the access point has the tag key Environment and tag value Production.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToSpecificAccessPoint",
      "Effect": "Allow",
      "Action": "*",
      "Resource": "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
      "Condition": {
```

```
        "StringEquals": {
            "s3:AccessPointTag/Environment": "Production"
        }
    }
}
]
```

Working with tags for access points for general purpose buckets

You can add or manage tags for access points using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see:

Topics

- [Creating access points with tags](#)
- [Adding a tag to an access point](#)
- [Viewing access point tags](#)
- [Deleting a tag from an access point](#)

Creating access points with tags

You can tag access points when you create them. There is no additional charge for using tags on access points beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging access points, see [Using tags with S3 Access Points for general purpose buckets](#).

Permissions

To create an access point with tags, you must have the following permissions:

- s3:CreateBucket
- s3:TagResource

Troubleshooting errors

If you encounter an error when attempting to create an access point with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the access point and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your access points only with specific tag keys and values. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

Steps

You can create an access point with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create an access point with tags using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose **create access point** to create a new access point.
4. On the **Create access point** page, **Tags** is an option when creating a new access point.
5. Enter a name for the access point. For more information, see [Access points naming rules, restrictions, and limitations](#).
6. Choose **Add new Tag** to open the **Tags** editor and enter a tag key-value pair. The tag key is required, but the value is optional.
7. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
8. After you complete specifying the options for your new access point, choose **Create access point**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to create an access point with tags by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
CreateAccessPointRequest createAccessPointRequest =  
    CreateAccessPointRequest.builder()  
        .accountId(111122223333)
```

```
.name(my-access-point)
.bucket(amzn-s3-demo-bucket)

.tags(Collections.singletonList(Tag.builder().key("key1").value("value1").build()))
    .build();
awsS3Control.createAccessPoint(createAccessPointRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for creating an access point with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- [CreateAccessPoint](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create an access point with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control create-access-point --name my-access-point \
--bucket amzn-s3-demo-bucket \
--account-id 111122223333 \
--profile personal \
--tags [{Key=key1,Value=value1},{Key=key2,Value=value2}] \
--region region
```

Adding a tag to an access point

You can add tags to Amazon S3 Access Points and modify these tags. There is no additional charge for using tags on access points beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging access points, see [Using tags with S3 Access Points for general purpose buckets](#).

Permissions

To add a tag to an access point, you must have the following permission:

- `s3:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to an access point, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to an access point.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.

Steps

You can add tags to access points by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To add tags to an access point using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to add tags to an access point by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
TagResourceRequest tagResourceRequest =
    TagResourceRequest.builder().resourceArn(arn:aws::s3:region:111122223333:accesspoint/my-access-point/*)
    .accountId(111122223333)
    .tags(List.of(Tag.builder().key("key1").value("value1").build(),
        Tag.builder().key("key2").value("value2").build()))
    .build();
awss3Control.tagResource(tagResourceRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for adding tags to an access point, see the following section in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to an access point by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control tag-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:region:111122223333:accesspoint/my-access-point/* \
--tags "Key=key1,Value=value1"
```

Response:

```
{  
    "ResponseMetadata": {  
        "RequestId": "EXAMPLE123456789",  
        "HTTPStatusCode": 200,  
        "HTTPHeaders": {  
            "date": "Wed, 19 Jun 2025 10:30:00 GMT",  
            "content-length": "0"  
        },  
    },  
}
```

```
        "RetryAttempts": 0
    }
}
```

Viewing access point tags

You can view or list tags applied to access points. For more information about tags, see [Using tags with S3 Access Points for general purpose buckets](#).

Permissions

To view tags applied to an access point, you must have the following permission:

- `s3>ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of an access point, you can do the following:

- Verify that you have the required [Permissions](#) to view or list the tags of the access point.

Steps

You can view tags applied to access points by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to an access point using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the access point.
6. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your access point by AWS services.

Using the AWS SDKs

This section provides an example of how to view tags applied to an access point by using the AWS SDKs.

SDK for Java 2.x

This example shows you how to view tags applied to an access point by using the AWS SDK for Java 2.x.

```
ListTagsForResourceRequest listTagsForResourceRequest = ListTagsForResourceRequest
.builder().resourceArn(arn:aws::s3:region:111122223333:accesspoint/my-access-point/
*)
    .accountId(111122223333).build();
awss3Control.listTagsForResource(listTagsForResourceRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to an access point, see the following section in the *Amazon Simple Storage Service API Reference*:

- [ListTagsforResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to an access point. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:region:444455556666:bucket/prefix--use1-az4--x-s3 \
```

Response - tags present:

```
{
```

```
"Tags": [  
    {  
        "Key": "MyKey1",  
        "Value": "MyValue1"  
    },  
    {  
        "Key": "MyKey2",  
        "Value": "MyValue2"  
    },  
    {  
        "Key": "MyKey3",  
        "Value": "MyValue3"  
    }  
]
```

Response - no tags present:

```
{  
    "Tags": []  
}
```

Deleting a tag from an access point

You can remove tags from Amazon S3 Access Points. An AWS tag is a key-value pair that holds metadata about resources, in this case Access Points. For more information about tags, see [Using tags with S3 Access Points for general purpose buckets](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the access point.

Permissions

To delete a tag from an access point, you must have the following permission:

- s3:UntagResource

Troubleshooting errors

If you encounter an error when attempting to delete a tag from an access point, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from an access point.

Steps

You can delete tags from access points by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from an access point using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to delete tags from an access point by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
UntagResourceRequest tagResourceRequest = UntagResourceRequest.builder()
    .resourceArn(arn:aws:s3:::region:111122223333:accesspoint/my-access-point/*)
```

```
.accountId(111122223333)
.tagKeys(List.of("key1", "key2")).build();
awss3Control.untagResource(tagResourceRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from an access point, see the following section in the *Amazon Simple Storage Service API Reference*:

- [UntagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from an access point by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control untag-resource \
--account-id 111122223333 \
--resource-arn arn:aws:s3:region:444455556666:access-point/my-access-point \
--tag-keys "tagkey1" "tagkey2"

aws s3control untag-resource \
--account-id 111122223333 \
--resource-arn arn:aws:s3:region:444455556666:accesspointmy-access-point/* \
--tag-keys "key1" "key2"
```

Response:

```
{
  "ResponseMetadata": {
    "RequestId": "EXAMPLE123456789",
    "HTTPStatusCode": 204,
    "HTTPHeaders": {
      "date": "Wed, 19 Jun 2025 10:30:00 GMT",
      "content-length": "0"
    }
  },
}
```

```
        "RetryAttempts": 0
    }
}
```

Managing access with S3 Access Grants

To adhere to the principle of least privilege, you define granular access to your Amazon S3 data based on applications, personas, groups, or organizational units. You can use various approaches to achieve granular access to your data in Amazon S3, depending on the scale and complexity of the access patterns.

The simplest approach for managing access to small-to-medium numbers of datasets in Amazon S3 by AWS Identity and Access Management (IAM) principals is to define [IAM permission policies](#) and [S3 bucket policies](#). This strategy works, so long as the necessary policies fit within the policy size limits of S3 bucket policies (20 KB) and IAM policies (5 KB), and within the [number of IAM principals allowed per account](#).

As your number of datasets and use cases scales, you might require more policy space. An approach that offers significantly more space for policy statements is to use [S3 Access Points](#) as additional endpoints for S3 buckets, because each access point can have its own policy. You can define quite granular access control patterns, because you can have thousands of access points per AWS Region per account, with a policy up to 20 KB in size for each access point. Although S3 Access Points increases the amount of policy space available, it requires a mechanism for clients to discover the right access point for the right dataset.

A third approach is to implement an [IAM session broker](#) pattern, in which you implement access-decision logic and dynamically generate short-term IAM session credentials for each access session. While the IAM session broker approach supports arbitrarily dynamic permissions patterns and scales effectively, you must build the access-pattern logic.

Instead of using these approaches, you can use S3 Access Grants to manage access to your Amazon S3 data. S3 Access Grants provides a simplified model for defining access permissions to data in Amazon S3 by prefix, bucket, or object. In addition, you can use S3 Access Grants to grant access to both IAM principals and directly to users or groups from your corporate directory.

You commonly define permissions to data in Amazon S3 by mapping users and groups to datasets. You can use S3 Access Grants to define direct access mappings of S3 prefixes to users and roles within Amazon S3 buckets and objects. With the simplified access scheme in S3 Access Grants, you

can grant read-only, write-only, or read-write access on a per-S3-prefix basis to both IAM principals and directly to users or groups from a corporate directory. With these S3 Access Grants capabilities, applications can request data from Amazon S3 on behalf of the application's current authenticated user.

When you integrate S3 Access Grants with the [trusted identity propagation](#) feature of AWS IAM Identity Center, your applications can make requests to AWS services (including S3 Access Grants) directly on behalf of an authenticated corporate directory user. Your applications no longer need to first map the user to an IAM principal. Furthermore, because end-user identities are propagated all the way to Amazon S3, auditing which user accessed which S3 object is simplified. You no longer need to reconstruct the relationship between different users and IAM sessions. When you're using S3 Access Grants with IAM Identity Center trusted identity propagation, each [AWS CloudTrail](#) data event for Amazon S3 contains a direct reference to the end user on whose behalf the data was accessed.

[Trusted identity propagation](#) is an AWS IAM Identity Center feature that administrators of connected AWS services can use to grant and audit access to service data. Access to this data is based on user attributes such as group associations. Setting up trusted identity propagation requires collaboration between the administrators of connected AWS services and the IAM Identity Center administrators. For more information, see [Prerequisites and considerations](#).

For more information about S3 Access Grants, see the following topics.

S3 Access Grants concepts

S3 Access Grants workflow

The S3 Access Grants workflow is:

1. Create an S3 Access Grants instance. See [Working with S3 Access Grants instances](#).
2. Within your S3 Access Grants instance, register locations in your Amazon S3 data, and map these locations to AWS Identity and Access Management (IAM) roles. See [Register a location](#).
3. Create grants for grantees, which give grantees access to your S3 resources. See [Working with grants in S3 Access Grants](#).
4. The grantee requests temporary credentials from S3 Access Grants. See [Request access to Amazon S3 data through S3 Access Grants](#).
5. The grantee accesses the S3 data using those temporary credentials. See [Accessing S3 data using credentials vended by S3 Access Grants](#).

For more information, see [Getting started with S3 Access Grants](#).

S3 Access Grants instances

An *S3 Access Grants instance* is a logical container for individual *grants*. When you create an S3 Access Grants instance, you must specify an AWS Region. Each AWS Region in your AWS account can have one S3 Access Grants instance. For more information, see [Working with S3 Access Grants instances](#).

If you want to use S3 Access Grants to grant access to user and group identities from your corporate directory, you must also associate your S3 Access Grants instance with an AWS IAM Identity Center instance. For more information, see [S3 Access Grants and corporate directory identities](#).

A newly created S3 Access Grants instance is empty. You must register a location in the instance, which can be the S3 default path (`s3://`), a bucket, or a prefix within a bucket. After you register at least one location, you can create access grants that give access to data in this registered location.

Locations

An S3 Access Grants *location* maps buckets or prefixes to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials

to the grantee that's accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in the AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the *amzn-s3-demo-bucket* is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

- The default S3 location (`s3://`)
- A bucket (for example, *amzn-s3-demo-bucket*) or multiple buckets
- A bucket and a prefix (for example, *amzn-s3-demo-bucket/prefix**) or multiple prefixes

For the maximum number of locations that you can register in your S3 Access Grants instance, see [S3 Access Grants limitations](#). For more information about registering an S3 Access Grants location, see [Register a location](#).

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. So, no access has been granted yet to any of your S3 data. You can now create access grants to give access. For more information about creating grants, see [Working with grants in S3 Access Grants](#).

Grants

An individual *grant* in an S3 Access Grants instance allows a specific identity—an IAM principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance.

When you create a grant, you don't have to grant access to the entire registered location. You can narrow the grant's scope of access within a location. If the registered location is the default S3 path (`s3://`), you are required to narrow the scope of the grant to a bucket, a prefix within a bucket, or a specific object. If the registered location of the grant is a bucket or a prefix, then you can give access to the entire bucket or prefix, or you can optionally narrow the scope of the grant to a prefix, subprefix, or an object.

In the grant, you also set the access level of the grant to READ, WRITE, or READWRITE. Suppose you have a grant that gives the corporate directory group `01234567-89ab-cdef-0123-456789abcdef` READ access to the bucket `s3://amzn-s3-demo-bucket/projects/items/*`. Users in this group can have READ access to every object that has an object key name which starts with the prefix `projects/items/` in the bucket named `amzn-s3-demo-bucket`.

For the maximum number of grants that you can create in your S3 Access Grants instance, see [S3 Access Grants limitations](#). For more information about creating grants, see [Create grants](#).

S3 Access Grants temporary credentials

After you create a grant, an authorized application that utilizes the identity specified in the grant can request *just-in-time access credentials*. To do this, the application calls the [GetDataAdapter](#) S3 API operation. Grantees can use this API operation to request access to the S3 data you have shared with them.

The S3 Access Grants instance evaluates the `GetDataAdapter` request against the grants that it has. If there is a matching grant for the requestor, S3 Access Grants assumes the IAM role that's associated with the registered location of the matching grant. S3 Access Grants scopes the permissions of the temporary credentials to access only the S3 bucket, prefix, or object that's specified by the grant's scope.

The expiration time of the temporary access credentials defaults to 1 hour, but you can set it to any value from 15 minutes to 12 hours. See the maximum duration session in the [AssumeRole](#) API reference.

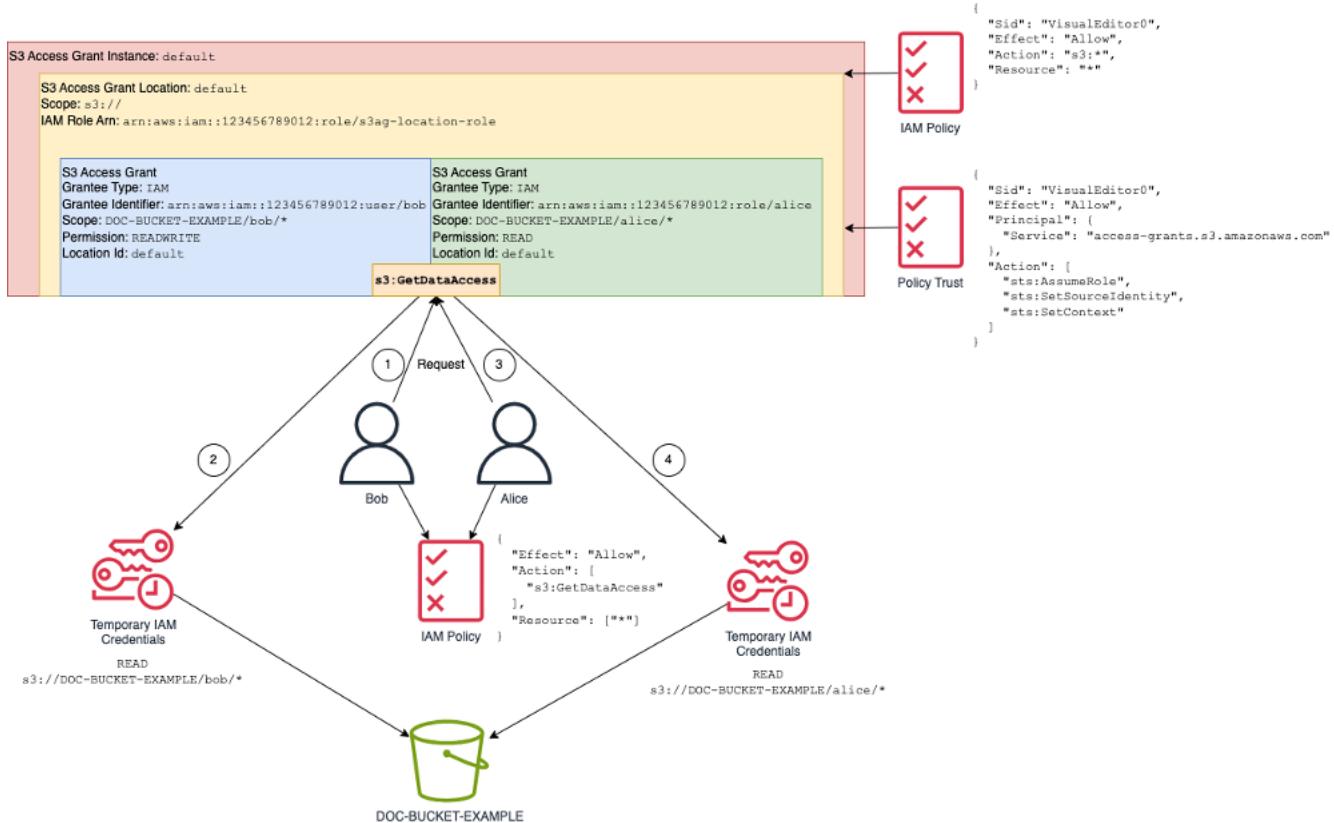

How it works

In the following diagram, a default Amazon S3 location with the scope `s3://` is registered with the IAM role `s3ag-location-role`. This IAM role has permissions to perform Amazon S3 actions within the account when its credentials are obtained through S3 Access Grants.

Within this location, two individual access grants are created for two IAM users. The IAM user Bob is granted both READ and WRITE access on the `bob/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. Another IAM role, Alice, is granted only READ access on the `alice/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in blue, is defined for Bob to access the prefix `bob/` in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in green, is defined for Alice to access the prefix `alice/` in the `DOC-BUCKET-EXAMPLE` bucket.

When it's time for Bob to READ data, the IAM role that's associated with the location that his grant is in calls the S3 Access Grants [GetDataAdapter](#) API operation. If Bob tries to READ any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, the `GetDataAdapter` request returns a set of temporary IAM session credentials with permission to `s3://DOC-BUCKET-EXAMPLE/bob/*`. Similarly, Bob can WRITE to any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, because the grant also allows that.

Similarly, Alice can READ anything that starts with `s3://DOC-BUCKET-EXAMPLE/alice/`. However, if she tries to WRITE anything to any bucket, prefix, or object in `s3://`, she will get an Access Denied (403 Forbidden) error, because there is no grant that gives her WRITE access to any data. In addition, if Alice requests any level of access (READ or WRITE) to data outside of `s3://DOC-BUCKET-EXAMPLE/alice/`, she will again receive an Access Denied error.

This pattern scales to a high number of users and buckets and simplifies management of those permissions. Rather than editing potentially large S3 bucket policies every time you want to add or remove an individual user-prefix access relationship, you can add and remove individual, discrete grants.

S3 Access Grants and corporate directory identities

You can use Amazon S3 Access Grants to grant access to AWS Identity and Access Management (IAM) principals (users or roles), both in the same AWS account and in others. However, in many cases, the entity accessing the data is an end user from your corporate directory. Instead of granting access to IAM principals, you can use S3 Access Grants to grant access directly to your corporate users and groups. With S3 Access Grants, you no longer need to map your corporate identities to intermediate IAM principals in order to access your S3 data through your corporate applications.

This new functionality—support for using end-user identities access to data—is provided by associating your S3 Access Grants instance with an AWS IAM Identity Center instance. IAM Identity Center supports standards-based identity providers and is the hub in AWS for any services or features, including S3 Access Grants, that support end-user identities. IAM Identity Center provides

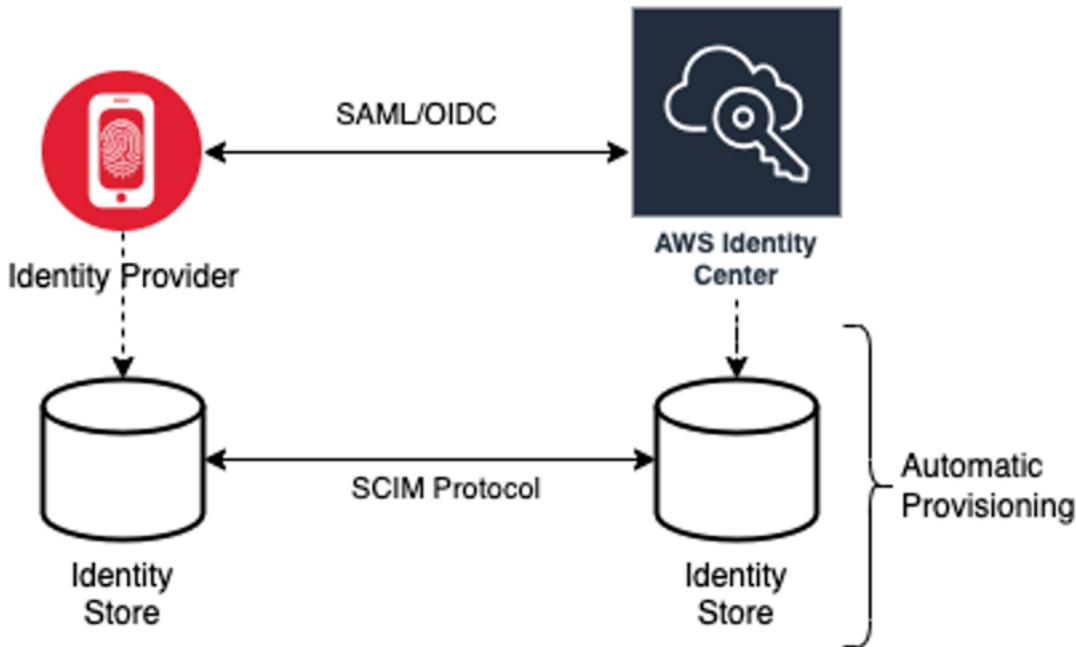

authentication support for corporate identities through its trusted identity propagation feature. For more information, see [Trusted identity propagation across applications](#).

To get started with workforce identity support in S3 Access Grants, as a prerequisite, you start in IAM Identity Center by configuring identity provisioning between your corporate identity provider and IAM Identity Center. IAM Identity Center supports corporate identity providers such as Okta, Microsoft Entra ID (formerly Azure Active Directory), or any other external identity provider (IdP) that supports the System for Cross-domain Identity Management (SCIM) protocol. When you connect IAM Identity Center to your IdP and enable automatic provisioning, the users and groups from your IdP are synchronized into the identity store in IAM Identity Center. After this step, IAM Identity Center has its own view of your users and groups, so that you can refer to them by using other AWS services and features, such as S3 Access Grants. For more information about configuring IAM Identity Center automatic provisioning, see [Automatic provisioning in the AWS IAM Identity Center User Guide](#).

IAM Identity Center is integrated with AWS Organizations so that you can centrally manage permissions across multiple AWS accounts without configuring each of your accounts manually. In a typical organization, your identity administrator configures one IAM Identity Center instance for the entire organization, as a single point of identity synchronization. This IAM Identity Center instance typically runs in a dedicated AWS account in your organization. In this common configuration, you can refer to user and group identities in S3 Access Grants from any AWS account in the organization.

However, if your AWS Organizations administrator hasn't yet configured a central IAM Identity Center instance, you can create a local one in the same account as your S3 Access Grants instance. Such a configuration is more common for proof-of-concept or local development use cases. In all cases, the IAM Identity Center instance must be in the same AWS Region as the S3 Access Grants instance to which it will be associated.

In the following diagram of an IAM Identity Center configuration with an external IdP, the IdP is configured with SCIM to synchronize the identity store from the IdP to the identity store in IAM Identity Center.

To use your corporate directory identities with S3 Access Grants, do the following:

- Set up [Automatic provisioning](#) in IAM Identity Center to synchronize user and group information from your IdP into IAM Identity Center.
- Configure your external identity source within IAM Identity Center as a trusted token issuer. For more information, see [Trusted identity propagation across applications](#) in the *AWS IAM Identity Center User Guide*.
- Associate your S3 Access Grants instance with your IAM Identity Center instance. You can do this when you [create your S3 Access Grants instance](#). If you've already created your S3 Access Grants instance, see [Associate or disassociate your IAM Identity Center instance](#).

How directory identities can access S3 data

Suppose that you have corporate directory users who need to access your S3 data through a corporate application, for example, a document-viewer application, that is integrated with your external IdP (for example, Okta) to authenticate users. Authentication of the user in these applications is typically done through redirects in the user's web browser. Because users in the directory are not IAM principals, your application needs IAM credentials with which it can call the S3 Access Grants `GetDataAccess` API operation to [get access credentials to S3 data](#) on the users' behalf. Unlike IAM users and roles who get credentials themselves, your application needs a way to represent a directory user, who isn't mapped to an IAM role, so that the user can get data access through S3 Access Grants.

This transition, from authenticated directory user to an IAM caller that can make requests to S3 Access Grants on behalf of the directory user, is done by the application through the trusted token issuer feature of IAM Identity Center. The application, after authenticating the directory user, has an identity token from the IdP (for example, Okta) that represents the directory user according to Okta. The trusted token issuer configuration in IAM Identity Center enables the application to exchange this Okta token (the Okta tenant is configured as the "trusted issuer") for a different identity token from IAM Identity Center that will securely represent the directory user within AWS services. The data application will then assume an IAM role, providing the directory user's token from IAM Identity Center as additional context. The application can use the resulting IAM session to call S3 Access Grants. The token represents both the identity of the application (the IAM principal itself) as well as the directory user's identity.

The main step of this transition is the token exchange. The application performs this token exchange by calling the `CreateTokenWithIAM` API operation in IAM Identity Center. Of course, that too is an AWS API call and requires an IAM principal to sign it. The IAM principal that makes this request is typically an IAM role that's associated with the application. For example, if the application runs on Amazon EC2, the `CreateTokenWithIAM` request is typically performed by the IAM role that's associated with the EC2 instance on which the application runs. The result of a successful `CreateTokenWithIAM` call is a new identity token, which will be recognized within AWS services.

The next step, before the application can call `GetDataAccess` on the directory user's behalf, is for the application to obtain an IAM session that includes the directory user's identity. The application does this with an AWS Security Token Service (AWS STS) `AssumeRole` request that also includes the IAM Identity Center token for the directory user as additional identity context. This additional context is what enables IAM Identity Center to propagate the directory user's identity to the next step. The IAM role that the application assumes is the role that will need IAM permissions to call the `GetDataAccess` operation.

Having assumed the identity bearer IAM role with the IAM Identity Center token for the directory user as additional context, the application now has everything it needs to make a signed request to `GetDataAccess` on behalf of the authenticated directory user.

Token propagation is based on the following steps:

Create an IAM Identity Center application

First, create a new application in IAM Identity Center. This application will use a template that allows IAM Identity Center to identify which type of application settings that you can use. The

command to create the application requires you to provide the IAM Identity Center instance Amazon Resource Name (ARN), an application name, and the application provider ARN. The application provider is the SAML or OAuth application provider that the application will use to make calls to IAM Identity Center.

To use the following example command, replace the *user input placeholders* with your own information:

```
aws sso-admin create-application \
--instance-arn "arn:aws:sso::::instance/ssoins-ssoins-1234567890abcdef" \
--application-provider-arn "arn:aws:sso::::aws:applicationProvider/custom" \
--name MyDataApplication
```

Response:

```
{  
    "ApplicationArn": "arn:aws:sso:::123456789012:application/ssoins-  
    ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"  
}
```

Create a trusted token issuer

Now that you have your IAM Identity Center application, the next step is to configure a trusted token issuer that will be used to exchange your IdToken values from your IdP with IAM Identity Center tokens. In this step you need to provide the following items:

- The identity provider issuer URL
- The trusted token issuer name
- The claim attribute path
- The identity store attribute path
- The JSON Web Key Set (JWKS) retrieval option

The claim attribute path is the identity provider attribute that will be used to map to the identity store attribute. Normally, the claim attribute path is the email address of the user, but you can use other attributes to perform the mapping.

Create a file called `oidc-configuration.json` with the following information. To use this file, replace the *user input placeholders* with your own information.

```
{  
    "OidcJwtConfiguration":  
    {  
        "IssuerUrl": "https://login.microsoftonline.com/a1b2c3d4-abcd-1234-b7d5-  
b154440ac123/v2.0",  
        "ClaimAttributePath": "preferred_username",  
        "IdentityStoreAttributePath": "userName",  
        "JwksRetrievalOption": "OPEN_ID_DISCOVERY"  
    }  
}
```

To create the trusted token issuer, run the following command. To use this example command, replace the *user input placeholders* with your own information.

```
aws sso-admin create-trusted-token-issuer \  
--instance-arn "arn:aws:sso::::instance/ssoins-1234567890abcdef" \  
--name MyEntraIDTrustedIssuer \  
--trusted-token-issuer-type OIDC_JWT \  
--trusted-token-issuer-configuration file://./oidc-configuration.json
```

Response

```
{  
    "TrustedTokenIssuerArn": "arn:aws:sso:::123456789012:trustedTokenIssuer/  
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-a1b2c3d41234"  
}
```

Connect the IAM Identity Center application with the trusted token issuer

The trusted token issuer requires a few more configuration settings to work. Set the audience that the trusted token issuer will trust. The audience is the value inside the IdToken that's identified by the key and can be found in the identity provider settings. For example:

```
1234973b-abcd-1234-abcd-345c5a9c1234
```

Create a file named grant.json that contains the following content. To use this file, change the audience to match your identity provider settings and provide the trusted token issuer ARN that was returned by the previous command.

```
{
```

```
"JwtBearer":  
{  
    "AuthorizedTokenIssuers":  
    [  
        {  
            "TrustedTokenIssuerArn": "arn:aws:sso::123456789012:trustedTokenIssuer/  
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-a1b2c3d41234",  
            "AuthorizedAudiences":  
            [  
                "1234973b-abcd-1234-abcd-345c5a9c1234"  
            ]  
        }  
    ]  
}
```

Run the following example command. To use this command, replace the *user input placeholders* with your own information.

```
aws sso-admin put-application-grant \  
--application-arn "arn:aws:sso::123456789012:application/ssoins-  
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \  
--grant-type "urn:ietf:params:oauth:grant-type:jwt-bearer" \  
--grant file://./grant.json \  

```

This command sets the trusted token issuer with configuration settings to trust the audience in the grant.json file and link this audience with the application created in the first step for exchanging tokens of the type jwt-bearer. The string `urn:ietf:params:oauth:grant-type:jwt-bearer` is not an arbitrary string. It is a registered namespace in OAuth JSON Web Token (JWT) assertion profiles. You can find more information about this namespace in [RFC 7523](#).

Next, use the following command to set up which scopes the trusted token issuer will include when exchanging IdToken values from your identity provider. For S3 Access Grants, the value for the --scope parameter is `s3:access_grants:read_write`.

```
aws sso-admin put-application-access-scope \  
--application-arn "arn:aws:sso::111122223333:application/ssoins-  
ssoins-111122223333abcdef/apl-abcd1234a1b2c3d" \  
--scope "s3:access_grants:read_write" \  

```

The last step is to attach a resource policy to the IAM Identity Center application. This policy will allow your application IAM role to make requests to the API operation `sso-oauth:CreateTokenWithIAM` and receive the `IdToken` values from IAM Identity Center.

Create a file named `authentication-method.json` that contains the following content. Replace `123456789012` with your account ID.

```
{  
  "Iam":  
    {  
      "ActorPolicy":  
        {  
          "Version": "2012-10-17" , TCX5-2025-waiver;,  
          "Statement":  
            [  
              {  
                "Effect": "Allow",  
                "Principal":  
                  {  
                    "AWS": "arn:aws:iam::123456789012:role/webapp"  
                  },  
                "Action": "sso-oauth:CreateTokenWithIAM",  
                "Resource": "*"  
              }  
            ]  
        }  
    }  
}
```

To attach the policy to the IAM Identity Center application, run the following command:

```
aws sso-admin put-application-authentication-method \  
  --application-arn "arn:aws:sso::123456789012:application/ssoins-  
  ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \  
  --authentication-method-type IAM \  
  --authentication-method file://./authentication-method.json
```

This completes the configuration settings for using S3 Access Grants with directory users through a web application. You can test this setup directly in the application or you can call the `CreateTokenWithIAM` API operation by using the following command from an allowed IAM role in the IAM Identity Center application policy:

```
aws sso-oidc create-token-with-iam \
--client-id "arn:aws:sso::123456789012:application/ssoins-ssoins-1234567890abcdef/" \
apl-abcd1234a1b2c3d" \
--grant-type urn:ietf:params:oauth:grant-type:jwt-bearer \
--assertion IdToken
```

The response will be similar to this:

```
{  
    "accessToken": "<suppressed long string to reduce space>",  
    "tokenType": "Bearer",  
    "expiresIn": 3600,  
    "refreshToken": "<suppressed long string to reduce space>",  
    "idToken": "<suppressed long string to reduce space>",  
    "issuedTokenType": "urn:ietf:params:oauth:token-type:refresh_token",  
    "scope": [  
        "sts:identity_context",  
        "s3:access_grants:read_write",  
        "openid",  
        "aws"  
    ]  
}
```

If you decode the IdToken value that is encoded with base64, you can see the key-value pairs in JSON format. The key `sts:identity_context` contains the value that your application needs to send in the `sts:AssumeRole` request to include the identity information of the directory user. Here is an example of the IdToken decoded:

```
{  
    "aws:identity_store_id": "d-996773e796",  
    "sts:identity_context": "AQoJb3JpZ2luX2VjE0Tt1;<SUPPRESSED>",  
    "sub": "83d43802-00b1-7054-db02-f1d683aacba5",  
    "aws:instance_account": "123456789012",  
    "iss": "https://identitycenter.amazonaws.com/ssoins-1234567890abcdef",  
    "sts:audit_context": "AQoJb3JpZ2luX2VjE0T<SUPPRESSED>==",  
    "aws:identity_store_arn": "arn:aws:identitystore::232642235904:identitystore/  
d-996773e796",  
    "aud": "abcd12344U0gi7n4Yyp0-WV1LWNlbnRyYWwtMQ",  
    "aws:instance_arn": "arn:aws:sso:::instance/ssoins-6987d7fb04cf7a51",  
    "aws:credential_id": "EXAMPLEHI5glPh40y9TpApJn8...",  
    "act": {
```

```
    "sub": "arn:aws:sso::232642235904:trustedTokenIssuer/  
ssoins-6987d7fb04cf7a51/43b4a822-1020-7053-3631-cb2d3e28d10e"  
,  
    "auth_time": "2023-11-01T20:24:28Z",  
    "exp": 1698873868,  
    "iat": 1698870268  
}
```

You can get the value from `sts:identity_context` and pass this information in an `sts:AssumeRole` call. The following is a CLI example of the syntax. The role to be assumed is a temporary role with permissions to invoke `s3:GetDataAccess`.

```
aws sts assume-role \  
--role-arn "arn:aws:iam::123456789012:role/temp-role" \  
--role-session-name "TempDirectoryUserRole" \  
--provided-contexts ProviderArn="arn:aws:iam::aws:contextProvider/  
IdentityCenter",ContextAssertion="value from sts:identity_context"
```

You can now use the credentials received from this call to invoke the `s3:GetDataAccess` API operation and receive the final credentials with access to your S3 resources.

Getting started with S3 Access Grants

Amazon S3 Access Grants is an Amazon S3 feature that provides a scalable access control solution for your S3 data. S3 Access Grants is an S3 credential vendor, meaning that you register with S3 Access Grants your list of grants and at what level. Thereafter, when users or clients need access to your S3 data, they first ask S3 Access Grants for credentials. If there is a corresponding grant that authorizes access, S3 Access Grants vends temporary, least-privilege access credentials. The users or clients can then use S3 Access Grants vended credentials to access your S3 data. With that in mind, if your S3 data requirements mandate a complex or large permission configuration, you can use S3 Access Grants to scale S3 data permissions for users, groups, roles, and applications.

For most use cases, you can manage access control for your S3 data by using AWS Identity and Access Management (IAM) with bucket policies or IAM identity-based policies.

However, if you have complex S3 access control requirements, such as the following, you could benefit greatly from using S3 Access Grants:

- You are running into the bucket policy size limit of 20 KB.

- You grant human identities, for example, Microsoft Entra ID (formerly Azure Active Directory), Okta, or Ping users and groups, access to S3 data for analytics and big data.
- You must provide cross-account access without making frequent updates to IAM policies.
- Your data is unstructured and object-level rather than structured, in row and column format.

The S3 Access Grants workflow is as follows:

Steps	Description
1	<p>Create an S3 Access Grants instance</p> <p>To get started, initiate an S3 Access Grants instance that will contain your individual access grants.</p>
2	<p>Register a location</p> <p>Second, register an S3 data location (such as the default, s3://) and then specify a default IAM role that S3 Access Grants assumes when providing access to the S3 data location. You can also add custom locations to specific buckets or prefixes and map those to custom IAM roles.</p>
3	<p>Create grants</p> <p>Create individual permission grants. Specify in these permission grants the registered S3 location, the scope of data access within the location, the identity of the grantee, and their access level (READ, WRITE, or READWRITE).</p>
4	<p>Request access to S3 data</p> <p>When users, applications, and AWS services want to access S3 data, they first make an access request. S3 Access Grants determines if the request should be authorized. If there is a corresponding grant that authorizes access, S3 Access Grants uses the registered location's IAM role that's associated with that grant to vend temporary credentials back to the requester.</p>

Steps	Description
5	<p>Access S3 data</p> <p>Applications use the temporary credentials vended by S3 Access Grants to access S3 data.</p>

Working with S3 Access Grants instances

To get started with using AmazonS3 Access Grants, you first create an S3 Access Grants instance. You can create only one S3 Access Grants instance per AWS Region per account. The S3 Access Grants instance serves as the container for your S3 Access Grants resources, which include registered locations and grants.

With S3 Access Grants, you can create permission grants to your S3 data for AWS Identity and Access Management (IAM) users and roles. If you've [added your corporate identity directory](#) to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance. After you've done so, you can create access grants for your corporate users and groups. If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

Topics

- [Create an S3 Access Grants instance](#)
- [Get the details of an S3 Access Grants instance](#)
- [List your S3 Access Grants instances](#)
- [Associate or disassociate your IAM Identity Center instance](#)
- [Delete an S3 Access Grants instance](#)

Create an S3 Access Grants instance

To get started with using AmazonS3 Access Grants, you first create an S3 Access Grants instance. You can create only one S3 Access Grants instance per AWS Region per account. The S3 Access Grants instance serves as the container for your S3 Access Grants resources, which include registered locations and grants.

With S3 Access Grants, you can create permission grants to your S3 data for AWS Identity and Access Management (IAM) users and roles. If you've [added your corporate identity directory](#) to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance. After you've done so, you can create access grants for your corporate users and groups. If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

You can create an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must first create an S3 Access Grants instance in the same AWS Region as your S3 data.

Prerequisites

If you want to grant access to your S3 data by using identities from your corporate directory, [add your corporate identity directory](#) to AWS IAM Identity Center. If you're not yet ready to do so, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

To create an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Access Grants**.
4. On the **S3 Access Grants** page, choose **Create S3 Access Grants instance**.
 - a. In **Step 1 of the Set up Access Grants instance wizard**, verify that you want to create the instance in the current AWS Region. Make sure that this is the same AWS Region where your S3 data is located. You can create one S3 Access Grants instance per AWS Region per account.
 - b. (Optional) If you've [added your corporate identity directory](#) to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance.

To do so, select **Add IAM Identity Center instance in *region***. Then enter the IAM Identity Center instance Amazon Resource Name (ARN).

If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

- c. To create the S3 Access Grants instance, choose **Next**. To register a location, see [Step 2 - register a location](#).
5. If **Next or Create S3 Access Grants instance** is disabled:

Cannot create instance

- You might already have an S3 Access Grants instance in the same AWS Region. In the left navigation pane, choose **Access Grants**. On the **S3 Access Grants** page, scroll down to the **S3 Access Grants instance in your account** section to determine if an instance already exists.
- You might not have the `s3:CreateAccessGrantsInstance` permission which is required to create an S3 Access Grants instance. Contact your account administrator. For additional permissions that are required if you are associating an IAM Identity Center instance, with your S3 Access Grants instance, see [CreateAccessGrantsInstance](#) .

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example Create an S3 Access Grants instance

```
aws s3control create-access-grants-instance \
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{  
  "CreatedAt": "2023-05-31T17:54:07.893000+00:00",  
  "AccessGrantsInstanceId": "default",  
  "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
  default"
```

{

Using the REST API

You can use the Amazon S3 REST API to create an S3 Access Grants instance. For information on the REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [AssociateAccessGrantsIdentityCenter](#)
- [CreateAccessGrantsInstance](#)
- [DeleteAccessGrantsInstance](#)
- [DissociateAccessGrantsIdentityCenter](#)
- [GetAccessGrantsInstance](#)
- [GetAccessGrantsInstanceForPrefix](#)
- [GetAccessGrantsInstanceResourcePolicy](#)
- [ListAccessGrantsInstances](#)
- [PutAccessGrantsInstanceResourcePolicy](#)

Using the AWS SDKs

This section provides an example of how to create an S3 Access Grants instance by using the AWS SDKs.

Java

This example creates the S3 Access Grants instance, which serves as a container for your individual access grants. You can have one S3 Access Grants instance per AWS Region in your account. The response includes the instance ID default and an Amazon Resource Name (ARN) that's generated for your S3 Access Grants instance.

Example Create an S3 Access Grants instance request

```
public void createAccessGrantsInstance() {  
    CreateAccessGrantsInstanceRequest createRequest =  
        CreateAccessGrantsInstanceRequest.builder().accountId("11122223333").build();  
    CreateAccessGrantsInstanceResponse createResponse =  
        s3Control.createAccessGrantsInstance(createRequest);  
    LOGGER.info("CreateAccessGrantsInstance  
" + createResponse);  
}
```

```
}
```

Response:

```
CreateAccessGrantsInstanceResponse(  
    CreatedAt=2023-06-07T01:46:20.507Z,  
    AccessGrantsInstanceId=default,  
    AccessGrantsInstanceArn=arn:aws:s3:us-east-2:111122223333:access-grants/default)
```

Get the details of an S3 Access Grants instance

You can get the details of your Amazon S3 Access Grants instance in a particular AWS Region. You can get the details of your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To get the details of an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. The **S3 Access Grants** page lists your S3 Access Grants instances and any cross-account instances that have been shared with your account. To view the details of an instance, choose **View details**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Get the details of an S3 Access Grants instance

```
aws s3control get-access-grants-instance \  
--account-id 111122223333 \  
\\
```

```
--region us-east-2
```

Response:

```
{  
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/  
    default",  
    "AccessGrantsInstanceId": "default",  
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"  
}
```

Using the REST API

For information about the Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GetAccessGrantsInstance](#)
- [GetAccessGrantsInstanceForPrefix](#)

Using the AWS SDKs

This section provides examples of how to get the details of an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – Get an S3 Access Grants instance

```
public void getAccessGrantsInstance() {  
    GetAccessGrantsInstanceRequest getRequest = GetAccessGrantsInstanceRequest.builder()  
        .accountId("111122223333")  
        .build();  
    GetAccessGrantsInstanceResponse getResponse =  
        s3Control.getAccessGrantsInstance(getRequest);  
    LOGGER.info("GetAccessGrantsInstanceResponse: " + getResponse);  
}
```

Response:

```
GetAccessGrantsInstanceResponse(  
AccessGrantsInstanceArn=arn:aws:s3:us-east-2: 111122223333:access-grants/default,  
CreatedAt=2023-06-07T01:46:20.507Z)
```

List your S3 Access Grants instances

You can list your S3 Access Grants instances, including the instances that have been shared with you through AWS Resource Access Manager (AWS RAM).

You can list your S3 Access Grants instances by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To list your S3 Access Grants instances

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. The **S3 Access Grants** page lists your S3 Access Grants instances and any cross-account instances that have been shared with your account. To view the details of an instance, choose **View details**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – List all S3 Access Grants instances for an account

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per AWS Region. This action also lists other cross-account S3 Access Grants instances that your account has access to.

```
aws s3control list-access-grants-instances \
```

```
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/default",
    "AccessGrantsInstanceId": "default",
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"
}
```

Using the REST API

For information about the Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [ListAccessGrantsInstances](#)

Using the AWS SDKs

This section provides examples of how to get the details of an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – List all S3 Access Grants instances for an account

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per Region. This action can also list other cross-account S3 Access Grants instances that your account has access to.

```
public void listAccessGrantsInstances() {
    ListAccessGrantsInstancesRequest listRequest =
        ListAccessGrantsInstancesRequest.builder()
            .accountId("111122223333")
            .build();
    ListAccessGrantsInstancesResponse listResponse =
        s3Control.listAccessGrantsInstances(listRequest);
```

```
LOGGER.info("ListAccessGrantsInstancesResponse: " + listResponse);  
}
```

Response:

```
ListAccessGrantsInstancesResponse(  
AccessGrantsInstancesList=[  
ListAccessGrantsInstanceEntry(  
AccessGrantsInstanceId=default,  
AccessGrantsInstanceArn=arn:aws:s3:us-east-2:1112222333:access-grants/default,  
CreatedAt=2023-06-07T04:28:11.728Z  
)  
]  
)
```

Associate or disassociate your IAM Identity Center instance

In Amazon S3 Access Grants, you can associate the AWS IAM Identity Center instance of your corporate identity directory with an S3 Access Grants instance. After you do so, you can create access grants for your corporate directory users and groups, in addition to AWS Identity and Access Management (IAM) users and roles.

If you no longer want to create access grants for your corporate directory users and groups, you can disassociate your IAM Identity Center instance from your S3 Access Grants instance.

You can associate or disassociate an IAM Identity Center instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

Before you associate your IAM Identity Center instance with your S3 Access Grants instance, you must add your corporate identity directory to IAM Identity Center. For more information, see [the section called “S3 Access Grants and corporate directory identities”](#).

To associate an IAM Identity Center instance with an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.

3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, in the **IAM Identity Center** section, choose to either **Add** an IAM Identity Center instance or **Deregister** an already associated IAM Identity Center instance.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Associate an IAM Identity Center instance with an S3 Access Grants instance

```
aws s3control associate-access-grants-identity-center \
--account-id 111122223333 \
--identity-center-arn arn:aws:sso::::instance/ssoins-1234a567bb89012c \
--profile access-grants-profile \
--region eu-central-1

// No response body
```

Example – Disassociate an IAM Identity Center instance from an S3 Access Grants instance

```
aws s3control dissociate-access-grants-identity-center \
--account-id 111122223333 \
--profile access-grants-profile \
--region eu-central-1

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for managing the association between an IAM Identity Center instance and an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [AssociateAccessGrantsIdentityCenter](#)
- [DissociateAccessGrantsIdentityCenter](#)

Delete an S3 Access Grants instance

You can delete an Amazon S3 Access Grants instance from an AWS Region in your account.

However, before you can delete an S3 Access Grants instance, you must first do the following:

- Delete all resources within the S3 Access Grants instance, including all grants and locations. For more information, see [Delete a grant](#) and [Delete a location](#).
- If you've associated an AWS IAM Identity Center instance with your S3 Access Grants instance, you must disassociate the IAM Identity Center instance. For more information, see [Associate or disassociate your IAM Identity Center instance](#).

Important

If you delete an S3 Access Grants instance, the deletion is permanent and can't be undone.

All grantees that were given access through the grants in this S3 Access Grants instance will lose access to your S3 data.

You can delete an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the instance details page, choose **Delete instance** in the upper-right corner.
6. In the dialog box that appears, choose **Delete**. This action can't be undone.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Note

Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

Example – Delete an S3 Access Grants instance

```
aws s3control delete-access-grants-instance \
--account-id 111122223333 \
--profile access-grants-profile \
--region us-east-2 \
--endpoint-url https://s3-control.us-east-2.amazonaws.com \

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for deleting an S3 Access Grants instance, see [DeleteAccessGrantsInstance](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to delete an S3 Access Grants instance by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Note

Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an

IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

Example – Delete an S3 Access Grants instance

```
public void deleteAccessGrantsInstance() {  
    DeleteAccessGrantsInstanceRequest deleteRequest =  
        DeleteAccessGrantsInstanceRequest.builder()  
            .accountId("111122223333")  
            .build();  
    DeleteAccessGrantsInstanceResponse deleteResponse =  
        s3Control.deleteAccessGrantsInstance(deleteRequest);  
    LOGGER.info("DeleteAccessGrantsInstanceResponse: " + deleteResponse);  
}
```

Working with S3 Access Grants locations

After you [create an Amazon S3 Access Grants instance](#) in an AWS Region in your account, you register an S3 location in that instance. An S3 Access Grants location maps the default S3 location (`s3://`), a bucket, or a prefix to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that is accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

You can register a location, view a location's details, edit a location, and delete a location.

Note

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. To create an access grant, see [Create grants](#).

Topics

- [Register a location](#)
- [View the details of a registered location](#)

- [Update a registered location](#)
- [Delete a registered location](#)

Register a location

After you [create an Amazon S3 Access Grants instance](#) in an AWS Region in your account, you register an S3 location in that instance. An S3 Access Grants location maps the default S3 location (`s3://`), a bucket, or a prefix to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that is accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

Recommended use case

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in that AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

Complex access-management use cases

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the `amzn-s3-demo-bucket` is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

When you register a location, you must also specify the IAM role that S3 Access Grants assumes to vend temporary credentials and to scope the permissions for a specific grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

S3 URI	IAM role	Description
s3://	<i>Default-IAM-role</i>	The default location, s3://, includes all buckets in the AWS Region.
s3:// <i>amzn-s3-demo-bucket1</i> /	<i>IAM-role-For-bucket</i>	This location includes all objects in the specified bucket.
s3:// <i>amzn-s3-demo-bucket1</i> / <i>prefix-name</i>	<i>IAM-role-For-prefix</i>	This location includes all objects in the bucket with an object key name that starts with this prefix.

Before you can register a specific bucket or prefix, make sure that you do the following:

- Create one or more buckets that contain the data that you want to grant access to. These buckets must be located in the same AWS Region as your S3 Access Grants instance. For more information, see [Creating a bucket](#).

Adding a prefix is an optional step. Prefixes are strings at the beginning of an object key name. You can use them to organize objects in your bucket as well as for access management. To add a prefix to a bucket, see [Creating object key names](#).

- Create an IAM role that has permission to access your S3 data in the AWS Region. For more information, see [Creating IAM roles](#) in the *AWS IAM Identity Center user guide*.
- In the IAM role trust policy, give the S3 Access Grants service (`access-grants.s3.amazonaws.com`) principal access to the IAM role that you created. To do so, you can create a JSON file that contains the following statements. To add the trust policy to your account, see [Create a role using custom trust policies](#).

TestRolePolicy.json

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{  
    "Sid": "TestRolePolicy",  
    "Effect": "Allow",  
    "Principal": {  
        "Service": "access-grants.s3.amazonaws.com"  
    },  
    "Action": [  
        "sts:AssumeRole",  
        "sts:SetSourceIdentity"  
    ],  
    "Condition": {  
        "StringEquals": {  
            "aws:SourceAccount": "111122223333",  
            "aws:SourceArn": "arn:aws:s3:::111122223333:access-grants/default"  
        }  
    }  
}  
]  
}
```

Alternatively, for an IAM Identity Center use case, use the following policy which includes a second statement:

- Create an IAM policy to attach Amazon S3 permissions to the IAM role that you created. See the following example `iam-policy.json` file and replace the *user input placeholders* with your own information.

 **Note**

- If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example includes the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.
- You can restrict the IAM role to access S3 data only if the credentials are vended by S3 Access Grants. This example shows you how to add a Condition statement for a specific S3 Access Grants instance. To use this Condition, replace the S3 Access Grants instance ARN in the Condition statement with your S3 Access Grants instance ARN, which has the format: `arn:aws:s3:region:accountId:access-grants/default`

iam-policy.json

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ObjectLevelReadPermissions",  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:GetObjectAcl",  
                "s3:GetObjectVersionAcl",  
                "s3>ListMultipartUploadParts"  
            ],  
            "Resource": [  
                "arn:aws:s3:::*"  
            ],  
            "Condition": {  
                "StringEquals": { "aws:ResourceAccount": "accountId" },  
                "ArnEquals": {  
                    "s3:AccessGrantsInstanceArn": ["arn:aws:s3:region:accountId:access-  
grants/default"]  
                }  
            }  
        },  
        {  
            "Sid": "ObjectLevelWritePermissions",  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject",  
                "s3:PutObjectAcl",  
                "s3:PutObjectVersionAcl",  
                "s3>DeleteObject",  
                "s3>DeleteObjectVersion",  
                "s3:AbortMultipartUpload"  
            ],  
            "Resource": [  
                "arn:aws:s3:::*"  
            ],  
            "Condition": {
```

```
        "StringEquals": { "aws:ResourceAccount": "accountId" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS Region:accountId:access-grants/default"]
        }
    },
    {
        "Sid": "BucketLevelReadPermissions",
        "Effect": "Allow",
        "Action": [
            "s3>ListBucket"
        ],
        "Resource": [
            "arn:aws:s3:::*"
        ],
        "Condition": {
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS Region:accountId:access-grants/default"]
            }
        }
    },
    // Optionally add the following section if you use SSE-KMS encryption
    {
        "Sid": "KMSPermissions",
        "Effect": "Allow",
        "Action": [
            "kms:Decrypt",
            "kms:GenerateDataKey"
        ],
        "Resource": [
            "*"
        ]
    }
]
```

You can register a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

Note

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. To create an access grant, see [Create grants](#).

Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must have at least one registered location.

To register a location in your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

If you're using S3 Access Grants instance for the first time, make sure that you have completed [Step 1 - create an S3 Access Grants instance](#) and navigated to [Step 2 of the Set up Access Grants instance](#) wizard. If you already have an S3 Access Grants instance, choose **View details**, and then from the **Locations** tab, choose **Register location**.

- a. For the **Location scope**, choose **Browse S3** or enter the S3 URI path to the location that you want to register. For S3 URI formats, see the [location formats](#) table. After you enter a URI, you can choose **View** to browse the location.
- b. For the **IAM role**, choose one of the following:

- **Choose from existing IAM roles**

Choose an IAM role from the dropdown list. After you choose a role, choose **View** to make sure that this role has the necessary permissions to manage the location that you're registering. Specifically, make sure that this role grants S3 Access Grants the permissions `sts:AssumeRole` and `sts:SetSourceIdentity`.

- **Enter IAM role ARN**

Navigate to the [IAM Console](#). Copy the Amazon Resource Name (ARN) of the IAM role and paste it in this box.

- c. To finish, choose **Next or Register location**.
4. Troubleshooting:

Cannot register location

- The location might already be registered.

You might not have the `s3:CreateAccessGrantsLocation` permission to register locations. Contact your account administrator.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

You can register the default location, `s3://`, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *user input placeholders* with your own information.

Example Create a resource policy

Create a policy that allows S3 Access Grants to assume the IAM role. To do so, you can create a JSON file that contains the following statements. To add the resource policy to your account, see [Create and attach your first customer managed policy](#).

TestRolePolicy.json

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Stmt1234567891011",  
            "Action": ["sts:AssumeRole", "sts:SetSourceIdentity"],  
            "Effect": "Allow",  
            "Principal": "s3-access-grants",  
            "Resource": "arn:aws:iam::1234567891011:role/test-role"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Principal": {"Service": "access-grants.s3.amazonaws.com"}
    }
]
}
```

Example Create the role

Run the following IAM command to create the role.

```
aws iam create-role --role-name accessGrantsTestRole \
--region us-east-2 \
--assume-role-policy-document file://TestRolePolicy.json
```

Running the `create-role` command returns the policy:

```
{
    "Role": {
        "Path": "/",
        "RoleName": "accessGrantsTestRole",
        "RoleId": "AROASRDGX4WM4GH55GIDA",
        "Arn": "arn:aws:iam::111122223333:role/accessGrantsTestRole",
        "CreateDate": "2023-05-31T18:11:06+00:00",
        "AssumeRolePolicyDocument": {
            "Version": "2012-10-17",
            "Statement": [
                {
                    "Sid": "Stmt1685556427189",
                    "Action": [
                        "sts:AssumeRole",
                        "sts:SetSourceIdentity"
                    ],
                    "Effect": "Allow",
                    "Principal": {
                        "Service": "access-grants.s3.amazonaws.com"
                    }
                }
            ]
        }
    }
}
```

Example

Create an IAM policy to attach Amazon S3 permissions to the IAM role. See the following example `iam-policy.json` file and replace the *user input placeholders* with your own information.

Note

If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example adds the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.

To make sure that the IAM role can only be used to access data in S3 if the credentials are vended out by S3 Access Grants, this example shows you how to add a Condition statement that specifies the S3 Access Grants instance (`s3:AccessGrantsInstance: InstanceArn`) in your IAM policy. When using following example policy, replace the *user input placeholders* with your own information.

`iam-policy.json`

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ObjectLevelReadPermissions",  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:GetObjectAcl",  
                "s3:GetObjectVersionAcl",  
                "s3>ListMultipartUploadParts"  
            ],  
            "Resource": [  
                "arn:aws:s3:::*"  
            ],  
            "Condition": {  
                "StringEquals": {"  
                    "s3:AccessGrantsInstance": "  
                }  
            }  
        }  
    ]  
}
```

```
        "StringEquals": { "aws:ResourceAccount": "111122223333" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:us-east-1::access-
grants/default"]
        }
    },
{
    "Sid": "ObjectLevelWritePermissions",
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl",
        "s3:PutObjectVersionAcl",
        "s3:DeleteObject",
        "s3:DeleteObjectVersion",
        "s3:AbortMultipartUpload"
    ],
    "Resource": [
        "arn:aws:s3:::/*"
    ],
    "Condition": {
        "StringEquals": { "aws:ResourceAccount": "111122223333" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:us-east-1::access-
grants/default"]
        }
    }
},
{
    "Sid": "BucketLevelReadPermissions",
    "Effect": "Allow",
    "Action": [
        "s3>ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::/*"
    ],
    "Condition": {
        "StringEquals": { "aws:ResourceAccount": "111122223333" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:us-east-1::access-
grants/default"]
        }
    }
}
```

```
        }
    },
{
    "Sid": "KMSPermissions",
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "kms:ViaService": "s3.us-east-1.amazonaws.com"
        }
    }
}
]
```

Example

Run the following command:

```
aws iam put-role-policy \
--role-name accessGrantsTestRole \
--policy-name accessGrantsTestRole \
--policy-document file://iam-policy.json
```

Example Register the default location

```
aws s3control create-access-grants-location \
--account-id 111122223333 \
--location-scope s3:// \
--iam-role-arn arn:aws:iam::111122223333:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
```

```
"AccessGrantsLocationId": "default",
"AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/default",
"LocationScope": "s3://"
"IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

Example Register a custom location

```
aws s3control create-access-grants-location \
--account-id 111122223333 \
--location-scope s3://DOC-BUCKET-EXAMPLE/ \
--iam-role-arn arn:aws:iam::123456789012:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
"AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",
"AccessGrantsLocationArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
default/location/635f1139-1af2-4e43-8131-a4de006eb888",
"LocationScope": "s3://DOC-BUCKET-EXAMPLE/",
"IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

Using the REST API

For information about Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [CreateAccessGrantsLocation](#)
- [DeleteAccessGrantsLocation](#)
- [GetAccessGrantsLocation](#)
- [ListAccessGrantsLocations](#)
- [UpdateAccessGrantsLocation](#)

Using the AWS SDKs

This section provides examples of how to register locations by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

You can register the default location, s3://, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *user input placeholders* with your own information.

Example Register a default location

Request:

```
public void createAccessGrantsLocation() {  
    CreateAccessGrantsLocationRequest createRequest =  
        CreateAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .locationScope("s3://")  
            .iamRoleArn("arn:aws:iam::123456789012:role/accessGrantsTestRole")  
            .build();  
    CreateAccessGrantsLocationResponse createResponse =  
        s3Control.createAccessGrantsLocation(createRequest);  
    LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);  
}
```

Response:

```
CreateAccessGrantsLocationResponse(  
    CreatedAt=2023-06-07T04:35:11.027Z,  
    AccessGrantsLocationId=default,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
        location/default,  
    LocationScope=s3://,  
    IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
)
```

Example Register a custom location

Request:

```
public void createAccessGrantsLocation() {  
    CreateAccessGrantsLocationRequest createRequest =  
        CreateAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .locationScope("s3://DOC-BUCKET-EXAMPLE/")  
            .iamRoleArn("arn:aws:iam::111122223333:role/accessGrantsTestRole")  
            .build();  
    CreateAccessGrantsLocationResponse createResponse =  
        s3Control.createAccessGrantsLocation(createRequest);  
    LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);  
}
```

Response:

```
CreateAccessGrantsLocationResponse(  
    CreatedAt=2023-06-07T04:35:10.027Z,  
    AccessGrantsLocationId=18cfe6fb-eb5a-4ac5-aba9-8d79f04c2012,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
    location/18cfe6fb-eb5a-4ac5-aba9-8d79f04c2666,  
    LocationScope= s3://test-bucket-access-grants-user123/,  
    IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
)
```

View the details of a registered location

You can get the details of a location that's registered in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To view the locations registered in your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.

5. On the details page for the instance, choose the **Locations** tab.
6. Find the registered location that you want to view. To filter the list of registered locations, use the search box.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Get the details of a registered location

```
aws s3control get-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id default
```

Response:

```
{  
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",  
    "AccessGrantsLocationId": "default",  
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
default/location/default",  
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"  
}
```

Example – List all of the locations that are registered in an S3 Access Grants instance

To restrict the results to an S3 prefix or bucket, you can optionally use the --location-scope `s3://bucket-and-or-prefix` parameter.

```
aws s3control list-access-grants-locations \
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{"AccessGrantsLocationsList": [
```

```
{  
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",  
    "AccessGrantsLocationId": "default",  
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
default/location/default",  
    "LocationScope": "s3://"  
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"  
},  
{  
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",  
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",  
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
default/location/635f1139-1af2-4e43-8131-a4de006eb888",  
    "LocationScope": "s3://amzn-s3-demo-bucket/prefixA*",  
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"  
}  
]  
}
```

Using the REST API

For information about the Amazon S3 REST API support for getting the details of a registered location or listing all of the locations that are registered with an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GetAccessGrantsLocation](#)
- [ListAccessGrantsLocations](#)

Using the AWS SDKs

This section provides examples of how to get the details of a registered location or list all of the registered locations in an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – Get the details of a registered location

```
public void getAccessGrantsLocation() {
```

```
GetAccessGrantsLocationRequest getAccessGrantsLocationRequest =
    GetAccessGrantsLocationRequest.builder()
    .accountId("111122223333")
    .accessGrantsLocationId("default")
    .build();
GetAccessGrantsLocationResponse getAccessGrantsLocationResponse =
    s3Control.getAccessGrantsLocation(getAccessGrantsLocationRequest);
LOGGER.info("GetAccessGrantsLocationResponse: " + getAccessGrantsLocationResponse);
}
```

Response:

```
GetAccessGrantsLocationResponse(
    CreatedAt=2023-06-07T04:35:10.027Z,
    AccessGrantsLocationId=default,
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
        location/default,
    LocationScope= s3://,
    IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
```

Example – List all registered locations in an S3 Access Grants instance

To restrict the results to an S3 prefix or bucket, you can optionally pass an S3 URI, such as `s3://bucket-and-or-prefix`, in the LocationScope parameter.

```
public void listAccessGrantsLocations() {

    ListAccessGrantsLocationsRequest listRequest =
        ListAccessGrantsLocationsRequest.builder()
        .accountId("111122223333")
        .build();

    ListAccessGrantsLocationsResponse listResponse =
        s3Control.listAccessGrantsLocations(listRequest);
    LOGGER.info("ListAccessGrantsLocationsResponse: " + listResponse);
}
```

Response:

```
ListAccessGrantsLocationsResponse(
    AccessGrantsLocationsList=[
```

```
ListAccessGrantsLocationsEntry(  
    CreatedAt=2023-06-07T04:35:11.027Z,  
    AccessGrantsLocationId=default,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
        location/default,  
    LocationScope=s3://,  
    IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
,  
    ListAccessGrantsLocationsEntry(  
        CreatedAt=2023-06-07T04:35:10.027Z,  
        AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb456,  
        AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
            location/635f1139-1af2-4e43-8131-a4de006eb888,  
        LocationScope=s3://amzn-s3-demo-bucket/prefixA*,  
        IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
)  
)  
]
```

Update a registered location

You can update the AWS Identity and Access Management (IAM) role of a location that's registered in your Amazon S3 Access Grants instance. For each new IAM role that you use to register a location in S3 Access Grants, be sure to give the S3 Access Grants service principal (`access-grants.s3.amazonaws.com`) access to this role. To do this, add an entry for the new IAM role in the same trust policy JSON file that you used when you first [registered the location](#).

You can update a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To update the IAM role of a location registered with your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.

5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the options button next to the registered location that you want to update.
8. Update the IAM role, and then choose **Save changes**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Update the IAM role of a registered location

```
aws s3control update-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id 635f1139-1af2-4e43-8131-a4de006eb999 \
--iam-role-arn arn:aws:iam::777788889999:role/accessGrantsTestRole
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb999",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:777788889999:access-grants/
default/location/635f1139-1af2-4e43-8131-a4de006eb888",
    "LocationScope": "s3://amzn-s3-demo-bucket/prefixB*",
    "IAMRoleArn": "arn:aws:iam::777788889999:role/accessGrantsTestRole"
}
```

Using the REST API

For information on the Amazon S3 REST API support for updating a location in an S3 Access Grants instance, see [UpdateAccessGrantsLocation](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to update the IAM role of a registered location by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Example – Update the IAM role of a registered location

```
public void updateAccessGrantsLocation() {  
    UpdateAccessGrantsLocationRequest updateRequest =  
        UpdateAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .accessGrantsLocationId("635f1139-1af2-4e43-8131-a4de006eb999")  
            .iamRoleArn("arn:aws:iam::777788889999:role/accessGrantsTestRole")  
        .build();  
    UpdateAccessGrantsLocationResponse updateResponse =  
        s3Control.updateAccessGrantsLocation(updateRequest);  
    LOGGER.info("UpdateAccessGrantsLocationResponse: " + updateResponse);  
}
```

Response:

```
UpdateAccessGrantsLocationResponse(  
    CreatedAt=2023-06-07T04:35:10.027Z,  
    AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb999,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:777788889999:access-grants/default/  
    location/635f1139-1af2-4e43-8131-a4de006eb888,  
    LocationScope=s3://amzn-s3-demo-bucket/prefixB*,  
    IAMRoleArn=arn:aws:iam::777788889999:role/accessGrantsTestRole  
)
```

Delete a registered location

You can delete a location registration from an Amazon S3 Access Grants instance. Deleting the location deregisters it from the S3 Access Grants instance.

Before you can remove a location registration from an S3 Access Grants instance, you must delete all of the grants that are associated with this location. For information about how to delete grants, see [Delete a grant](#).

You can delete a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete a location registration from your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the option button next to the registered location that you want to delete.
8. Choose **Deregister**.
9. A dialog box appears that warns you that this action can't be undone. To delete the location, choose **Deregister**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Delete a location registration

```
aws s3control delete-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id a1b2c3d4-5678-90ab-cdef-EXAMPLE1111
// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for deleting a location from an S3 Access Grants instance, see [DeleteAccessGrantsLocation](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how to delete a location by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Example – Delete a location registration

```
public void deleteAccessGrantsLocation() {  
    DeleteAccessGrantsLocationRequest deleteRequest =  
        DeleteAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLE1111")  
            .build();  
    DeleteAccessGrantsLocationResponse deleteResponse =  
        s3Control.deleteAccessGrantsLocation(deleteRequest);  
    LOGGER.info("DeleteAccessGrantsLocationResponse: " + deleteResponse);  
}
```

Response:

```
DeleteAccessGrantsLocationResponse()
```

Working with grants in S3 Access Grants

An individual access *grant* in an S3 Access Grants instance allows a specific identity—an AWS Identity and Access Management (IAM) principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance. A location maps buckets or prefixes to an IAM role. S3 Access Grants assumes this IAM role to vend temporary credentials to grantees.

After you [register at least one location](#) in your S3 Access Grants instance, you can create an access grant.

The grantee can be an IAM user or role or a directory user or group. A directory user is a user from your corporate directory or external identity source that you [associated with your S3 Access Grants instance](#). For more information, see [S3 Access Grants and corporate directory](#)

identities. To create a grant for a specific directory user or group from IAM Identity Center, find the GUID that IAM Identity Center uses to identify that user in IAM Identity Center, for example, a1b2c3d4-5678-90ab-cdef-EXAMPLE11111. For more information about how to use IAM Identity Center to view user information, see [View user and group assignments](#) in the *AWS IAM Identity Center user guide*.

You can grant access to a bucket, a prefix, or an object. A prefix in Amazon S3 is a string of characters in the beginning of an object key name that is used to organize objects within a bucket. This can be any string of allowed characters, for example, object key names in your bucket that start with the engineering/ prefix.

Topics

- [Create grants](#)
- [View a grant](#)
- [Delete a grant](#)

Create grants

An individual access *grant* in an S3 Access Grants instance allows a specific identity—an AWS Identity and Access Management (IAM) principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance. A location maps buckets or prefixes to an IAM role. S3 Access Grants assumes this IAM role to vend temporary credentials to grantees.

After you [register at least one location](#) in your S3 Access Grants instance, you can create an access grant.

The grantee can be an IAM user or role or a directory user or group. A directory user is a user from your corporate directory or external identity source that you [associated with your S3 Access Grants instance](#). For more information, see [S3 Access Grants and corporate directory identities](#). To create a grant for a specific directory user or group from IAM Identity Center, find the GUID that IAM Identity Center uses to identify that user in IAM Identity Center, for example, a1b2c3d4-5678-90ab-cdef-EXAMPLE11111. For more information about how to use IAM Identity Center to view user information, see [View user and group assignments](#) in the *AWS IAM Identity Center user guide*.

You can grant access to a bucket, a prefix, or an object. A prefix in Amazon S3 is a string of characters in the beginning of an object key name that is used to organize objects within a bucket.

This can be any string of allowed characters, for example, object key names in your bucket that start with the engineering/ prefix.

Subprefix

When granting access to a registered location, you can use the Subprefix field to narrow the scope of access to a subset of the location scope. If the registered location that you choose for the grant is the default S3 path (`s3://`), you must narrow the grant scope. You cannot create an access grant for the default location (`s3://`), which would give the grantee access to every bucket in an AWS Region. Instead, you must narrow the grant scope to one of the following:

- A bucket: `s3://bucket/*`
- A prefix within a bucket: `s3://bucket/prefix*`
- A prefix within a prefix: `s3://bucket/prefixA/prefixB*`
- An object: `s3://bucket/object-key-name`

If you are creating an access grant where the registered location is a bucket, you can pass one of the following in the Subprefix field to narrow the grant scope:

- A prefix within the bucket: `prefix*`
- A prefix within a prefix: `prefixA/prefixB*`
- An object: `/object-key-name`

After you create the grant, the grant scope that's displayed in the Amazon S3 console or the GrantScope that is returned in the API or AWS Command Line Interface (AWS CLI) response is the result of concatenating the location path with the Subprefix. Make sure that this concatenated path maps correctly to the S3 bucket, prefix, or object to which you want to grant access.

Note

- If you need to create an access grant that grants access to only one object, you must specify that the grant type is for an object. To do this in an API call or a CLI command, pass the `s3PrefixType` parameter with the value `Object`. In the Amazon S3 console, when you create the grant, after you select a location, under **Grant Scope**, select the **Grant scope is an object** checkbox.

- You cannot create a grant to a bucket if the bucket does not yet exist. However, you can create a grant to a prefix that does not yet exist.
- For the maximum number of grants that you can create in your S3 Access Grants instance, see [S3 Access Grants limitations](#).

You can create an access grant by using the Amazon S3 console, AWS CLI, the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

If you're using the S3 Access Grants instance for the first time, make sure that you have completed [Step 2 - register a location](#) and navigated to [Step 3 of the Set up Access Grants instance](#) wizard. If you already have an S3 Access Grants instance, choose **View details**, and then from the **Grants** tab, choose **Create grant**.

- a. In the **Grant scope** section, select or enter a registered location.

If you selected the default `s3://` location, use the **Subprefix** box to narrow the scope of the access grant. For more information, see [Subprefix](#). If you're granting access only to an object, select **Grant scope is an object**.

- b. Under **Permissions and access**, select the **Permission** level, either **Read**, **Write**, or both.

Then choose the **Grantee type**. If you have added your corporate directory to IAM Identity Center and associated this IAM Identity Center instance with your S3 Access Grants instance, you can choose **Directory identity from IAM Identity Center**. If you choose this option, get the ID of the user or group from IAM Identity Center and enter it in this section.

If the **Grantee type** is an IAM user or role, choose **IAM principal**. Under **IAM principal type**, choose **User or Role**. Then, under **IAM principal user**, either choose from the list or enter the identity's ID.

- c. To create the S3 Access Grants grant, choose **Next** or **Create grant**.
4. If **Next** or **Create grant** is disabled:

Cannot create grant

- You might need to [register a location](#) first in your S3 Access Grants instance.
- You might not have the s3:CreateAccessGrant permission to create an access grant. Contact your account administrator.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following examples show how to create an access grant request for an IAM principal and how to create an access grant request for a corporate directory user or group.

To use the following example commands, replace the *user input placeholders* with your own information.

Note

If you're creating an access grant that grants access to only one object, include the required parameter --s3-prefix-type Object.

Example Create an access grant request for an IAM principal

```
aws s3control create-access-grant \
--account-id 111122223333 \
--access-grants-location-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222 \
--access-grants-location-configuration S3SubPrefix=prefixB* \
--permission READ \
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::123456789012:user/data-consumer-3
```

Example Create an access grant response

```
{"CreatedAt": "2023-05-31T18:41:34.663000+00:00",
 "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
 "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
 "Grantee": {
     "GranteeType": "IAM",
     "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
 },
 "AccessGrantsLocationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
 "AccessGrantsLocationConfiguration": {
     "S3SubPrefix": "prefixB*"
 },
 "GrantScope": "s3://amzn-s3-demo-bucket/prefix*",
 "Permission": "READ"
}
```

Create an access grant request for a directory user or group

To create an access grant request for a directory user or group, you must first get the GUID for the directory user or group by running one of the following commands.

Example Get a GUID for a directory user or group

You can find the GUID of an IAM Identity Center user through the IAM Identity Center console or by using the AWS CLI or AWS SDKs. The following command lists the users in the specified IAM Identity Center instance, with their names and identifiers.

```
aws identitystore list-users --identity-store-id d-1a2b3c4d1234
```

This command lists the groups in the specified IAM Identity Center instance.

```
aws identitystore list-groups --identity-store-id d-1a2b3c4d1234
```

Example Create an access grant for a directory user or group

This command is similar to creating a grant for IAM users or roles, except the grantee type is DIRECTORY_USER or DIRECTORY_GROUP, and the grantee identifier is the GUID for the directory user or group.

```
aws s3control create-access-grant \
--account-id 123456789012 \
--access-grants-location-id default \
--access-grants-location-configuration S3SubPrefix="amzn-s3-demo-bucket/rafael/*" \
--permission READWRITE \
--grantee GranteeType= DIRECTORY_USER,GranteeIdentifier=83d43802-00b1-7054-db02-
f1d683aacba5 \
```

Using the REST API

For information about the Amazon S3 REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [CreateAccessGrant](#)
- [DeleteAccessGrant](#)
- [GetAccessGrant](#)
- [ListAccessGrants](#)

Using the AWS SDKs

This section provides examples of how to create an access grant by using the AWS SDKs.

Java

To use the following example, replace the *user input placeholders* with your own information:

 **Note**

If you are creating an access grant that grants access to only one object, include the required parameter `.s3PrefixType(S3PrefixType.Object)`.

Example Create an access grant request

```
public void createAccessGrant() {
    CreateAccessGrantRequest createRequest = CreateAccessGrantRequest.builder()
        .accountId("111122223333")
        .accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaa")
```

```
.permission("READ")
.accessGrantsLocationConfiguration(AccessGrantsLocationConfiguration.builder().s3SubPrefix("data-consumer-3")
.grantee(Grantee.builder().granteeType("IAM").granteeIdentifier("arn:aws:iam::111122223333:user/data-consumer-3").build())
.build();
CreateAccessGrantResponse createResponse =
s3Control.createAccessGrant(createRequest);
LOGGER.info("CreateAccessGrantResponse: " + createResponse);
}
```

Example Create an access grant response

```
CreateAccessGrantResponse(
CreatedAt=2023-06-07T05:20:26.330Z,
AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,
AccessGrantArn=arn:aws:s3:us-east-2:4444555666:access-grants/default/grant/a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,
Grantee=Grantee(
GranteeType=IAM,
GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3
),
AccessGrantsLocationId=a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaa,
AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(
S3SubPrefix=prefixB*
),
GrantScope=s3://amzn-s3-demo-bucket/prefixB,
Permission=READ
)
```

View a grant

You can view the details of an access grant in your Amazon S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To view the details of an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.
6. In the **Grants** section, find the access grant that you want to view. To filter the list of grants, use the search box.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *user input placeholders* with your own information.

Example – Get the details of an access grant

```
aws s3control get-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:41:34.663000+00:00",
    "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant-a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "Grantee": {
        "GranteeType": "IAM",
        "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
    },
    "Permission": "READ",
    "AccessGrantsLocationId": "12a6710f-5af8-41f5-b035-0bc795bf1a2b",
    "AccessGrantsLocationConfiguration": {
        "S3SubPrefix": "prefixB*"
    },
    "GrantScope": "s3://amzn-s3-demo-bucket/"
}
```

Example – List all of the access grants in an S3 Access Grants instance

You can optionally use the following parameters to restrict the results to an S3 prefix or AWS Identity and Access Management (IAM) identity:

- **Subprefix** ---grant-scope s3://*bucket-name/prefix**
- **IAM identity** ---grantee-type IAM and --grantee-identifier arn:aws:iam::*123456789000*:role/*accessGrantsConsumerRole*

```
aws s3control list-access-grants \
--account-id 111122223333
```

Response:

```
{
    "AccessGrantsList": [{"CreatedAt": "2023-06-14T17:54:46.542000+00:00",  

        "AccessGrantId": "dd8dd089-b224-4d82-95f6-975b4185bbaa",  

        "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/  

grant/dd8dd089-b224-4d82-95f6-975b4185bbaa",  

        "Grantee": {  

            "GranteeType": "IAM",  

            "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"  

        },  

        "Permission": "READ",  

        "AccessGrantsLocationId": "23514a34-ea2e-4ddf-b425-d0d4bfccard1",  

        "GrantScope": "s3://amzn-s3-demo-bucket/prefixA*"  

    },  

    {"CreatedAt": "2023-06-24T17:54:46.542000+00:00",  

        "AccessGrantId": "ee8ee089-b224-4d72-85f6-975b4185a1b2",  

        "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/  

grant/ee8ee089-b224-4d72-85f6-975b4185a1b2",  

        "Grantee": {  

            "GranteeType": "IAM",  

            "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-9"  

        },  

        "Permission": "READ",  

        "AccessGrantsLocationId": "12414a34-ea2e-4ddf-b425-d0d4bfccacao0",  

        "GrantScope": "s3://amzn-s3-demo-bucket/prefixB*"  

    },  

]
```

{}

Using the REST API

You can use Amazon S3 API operations to view the details of an access grant and list all access grants in an S3 Access Grants instance. For information about the REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GetAccessGrant](#)
- [ListAccessGrants](#)

Using the AWS SDKs

This section provides examples of how to get the details of an access grant by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – Get the details of an access grant

```
public void getAccessGrant() {  
    GetAccessGrantRequest getRequest = GetAccessGrantRequest.builder()  
        .accountId("111122223333")  
        .accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE2222")  
        .build();  
    GetAccessGrantResponse getResponse = s3Control.getAccessGrant(getRequest);  
    LOGGER.info("GetAccessGrantResponse: " + getResponse);  
}
```

Response:

```
GetAccessGrantResponse(  
    CreatedAt=2023-06-07T05:20:26.330Z,  
    AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE2222,  
    AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
    grant-fd3a5086-42f7-4b34-9fad-472e2942c70e,  
    Grantee=Grantee)
```

```
GranteeType=IAM,  
GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3  
,  
Permission=READ,  
AccessGrantsLocationId=12a6710f-5af8-41f5-b035-0bc795bf1a2b,  
AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(  
S3SubPrefix=prefixB*  
,  
GrantScope=s3://amzn-s3-demo-bucket/  
)
```

Example – List all of the access grants in an S3 Access Grants instance

You can optionally use these parameters to restrict the results to an S3 prefix or IAM identity:

- **Scope** – GrantScope=s3://*bucket-name/prefix**
- **Grantee** – GranteeType=IAM and GranteeIdentifier=
arn:aws:iam::111122223333:role/accessGrantsConsumerRole

```
public void listAccessGrants() {  
    ListAccessGrantsRequest listRequest = ListAccessGrantsRequest.builder()  
        .accountId("111122223333")  
        .build();  
    ListAccessGrantsResponse listResponse = s3Control.listAccessGrants(listRequest);  
    LOGGER.info("ListAccessGrantsResponse: " + listResponse);  
}
```

Response:

```
ListAccessGrantsResponse(  
    AccessGrantsList=[  
        ListAccessGrantEntry(  
            CreatedAt=2023-06-14T17:54:46.540z,  
            AccessGrantId=dd8dd089-b224-4d82-95f6-975b4185bbbaa,  
            AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
            grant/dd8dd089-b224-4d82-95f6-975b4185bbbaa,  
            Grantee=Grantee(  
                GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-3  
,
```

```
Permission=READ,
AccessGrantsLocationId=23514a34-ea2e-4ddf-b425-d0d4bfcarda1,
GrantScope=s3://amzn-s3-demo-bucket/prefixA
),
ListAccessGrantEntry(
CreatedAt=2023-06-24T17:54:46.540Z,
AccessGrantId=ee8ee089-b224-4d72-85f6-975b4185a1b2,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/ee8ee089-b224-4d72-85f6-975b4185a1b2,
Grantee=Grantee(
GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-9
),
Permission=READ,
AccessGrantsLocationId=12414a34-ea2e-4ddf-b425-d0d4bfccacao0,
GrantScope=s3://amzn-s3-demo-bucket/prefixB*
)
]
)
```

Delete a grant

You can delete access grants from your Amazon S3 Access Grants instance. You can't undo an access grant deletion. After you delete an access grant, the grantee will no longer have access to your Amazon S3 data.

You can delete an access grant by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.

6. Search for the grant that you want to delete. When you locate the grant, choose the radio button next to it.
7. Choose **Delete**. A dialog box appears with a warning that your action can't be undone. Choose **Delete** again to delete the grant.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Delete an access grant

```
aws s3control delete-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE1111

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for managing access grants, see [DeleteAccessGrant](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to delete an access grant by using the AWS SDKs. To use the following example, replace the *user input placeholders* with your own information.

Java

Example – Delete an access grant

```
public void deleteAccessGrant() {
    DeleteAccessGrantRequest deleteRequest = DeleteAccessGrantRequest.builder()
        .accountId("111122223333")
        .accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE1111")
        .build();
    DeleteAccessGrantResponse deleteResponse =
        s3Control.deleteAccessGrant(deleteRequest);
```

```
LOGGER.info("DeleteAccessGrantResponse: " + deleteResponse);  
}
```

Response:

```
DeleteAccessGrantResponse()
```

Getting S3 data using access grants

Grantees who have been given access to S3 data through S3 Access Grants must request temporary credentials from S3 Access Grants, which they use to access the S3 data. For more information, see [Request access to Amazon S3 data through S3 Access Grants](#). Grantees then use the temporary credentials to perform allowable S3 actions on the S3 data. For more information, see [Accessing S3 data using credentials vended by S3 Access Grants](#). Grantees can optionally request a list of their access grants for an AWS account before requesting these credentials. For more information, see [List the caller's access grants](#).

Topics

- [Request access to Amazon S3 data through S3 Access Grants](#)
- [Accessing S3 data using credentials vended by S3 Access Grants](#)
- [List the caller's access grants](#)

Request access to Amazon S3 data through S3 Access Grants

After you [create an access grant](#) using S3 Access Grants, grantees can request credentials to access the S3 data that they were granted access to. Grantees can be AWS Identity and Access Management (IAM) principals, your corporate directory identities, or authorized applications.

An application or AWS service can use the S3 Access Grants GetDataAccess API operation to ask S3 Access Grants for access to your S3 data on behalf of a grantee. GetDataAccess first verifies that you have granted this identity access to the data. Then, S3 Access Grants uses the [AssumeRole](#) API operation to obtain a temporary credential token and vends it to the requester. This temporary credential token is an AWS Security Token Service (AWS STS) token.

The GetDataAccess request must include the target parameter, which specifies the scope of the S3 data that the temporary credentials apply to. This target scope can be the same as the scope of the grant or a subset of that scope, but the target scope must be within the scope of the

grant that was given to the grantee. The request must also specify the permission parameter to indicate the permission level for the temporary credentials, whether READ, WRITE, or READWRITE.

Privilege

The requester can specify the privilege level of the temporary token in their credential request. Using the privilege parameter, the requester can reduce or increase the temporary credentials' scope of access, within the boundaries of the grant scope. The default value of the privilege parameter is Default, which means that the target scope of the credential returned is the original grant scope. The other possible value for privilege is Minimal. If the target scope is reduced from the original grant scope, then the temporary credential is de-scoped to match the target scope, as long as the target scope is within the grant scope.

The following table details the effect of the privilege parameter on two grants. One grant has the scope S3://*amzn-s3-demo-bucket1*/bob/*, which includes the entire bob/ prefix in the *amzn-s3-demo-bucket1* bucket. The other grant has the scope S3://*amzn-s3-demo-bucket1*/bob/reports/*, which includes only the bob/reports/ prefix in the *amzn-s3-demo-bucket1* bucket.

Grant scope	Requested scope	Privilege	Returned scope	Effect
S3:// <i>amzn-s3-demo-bucket1</i> /t1/bob/*	<i>amzn-s3-demo-bucket1</i> /t1/bob/*	Default	<i>amzn-s3-demo-bucket1</i> /bob/*	The requester has access to all objects that have key names that start with the prefix <i>bob/</i> in the <i>amzn-s3-demo-bucket1</i> bucket.
S3:// <i>amzn-s3-demo-bucket1</i> /t1/bob/*	<i>amzn-s3-demo-bucket1</i> /t1/bob/*	Minimal	<i>amzn-s3-demo-bucket1</i> /bob/	Without a wild card * character after the prefix name <i>bob/</i> , the requester has access to only the object named <i>bob/</i> in the <i>amzn-s3-demo-bucket1</i> bucket. It's not common to have such an object.

Grant scope	Requested scope	Privilege	Returned scope	Effect
				The requester doesn't have access to any other objects, including those that have key names that start with the <i>bob/</i> prefix.
S3:// <i>amzn-s3-demo-bucket1</i> / <i>t1/bob/images/*</i>	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/images/*</i>	Minimal	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/images/*</i>	The requester has access to all objects that have key names that start with the prefix <i>bob/images/*</i> in the <i>amzn-s3-demo-bucket1</i> bucket.
S3:// <i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/*</i>	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/*</i>	Default	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/*</i>	The requester has access to all objects that have key names that start with the <i>bob/reports</i> prefix in the <i>amzn-s3-demo-bucket1</i> bucket, which is the scope of the matching grant.
S3:// <i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/file.txt</i>	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/file.txt</i>	Minimal	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/file.txt</i>	The requester has access only to the object with the key name <i>bob/reports/file.txt</i> in the <i>amzn-s3-demo-bucket1</i> bucket. The requester has no access to any other object.

Directory identities

GetDataAccess considers all of the identities involved in a request when matching suitable grants. For corporate directory identities, GetDataAccess also returns the grants of the IAM identity that is used for the identity-aware session. For more information on identity-aware sessions, see [Granting permissions to use identity-aware console sessions](#) in the *AWS Identity and Access Management User Guide*. GetDataAccess generates credentials restricting scope to the most restrictive grant, as shown in the following table:

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
S3://amzn-s3-demo-bucket1/t1/bob/*	S3://amzn-s3-demo-bucket1/t1/bob/images/*	S3://amzn-s3-demo-bucket1/t1/bob/	S3://amzn-s3-demo-bucket1/bob/images/*	Default	The requestor has access to all of the objects that have key names that start with the prefix <i>bob/</i> as a part of the grant for the IAM role but is restricted to the prefixes <i>bob/images/</i> as a part of the grant for the directory identity. Both the IAM role and directory identity provide access to the requested scope, which is <i>bob/images/image1.jpeg</i> , but the directory identity has a more restrictive grant. So, the returned scope is restricted to the more

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
					restrictive grant for the directory identity.
S3:// <i>amzi</i> s3-d <i>emo-bucket1</i> / <i>bob/*</i>	amzn-s3-d <i>emo-bucket</i>	S3:// <i>amzi</i> s3-d <i>emo-bucket</i>	S3:// <i>amzn-s3-demo-bucket1</i> / <i>bob/images/image1.jpeg</i>	Minimal	Because the Privilege is set to Minimal, even though the identity has access to a bigger scope, only the requested scope is returned <i>bob/images/image1.jpeg</i> .

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
S3://amzn-s3-demo-bucket1/t1/bob/images/*	S3://amzn-s3-demo-bucket1/t1/bob/*	S3://amzn-s3-demo-bucket1/t1/bob/	S3://amzn-s3-demo-bucket1/bob/images/*	Default	The requestor has access to all of the objects that have key names that start with the prefix <i>bob/</i> as a part of the grant for the directory identity but is restricted to the prefixes <i>bob/images/</i> as a part of the grant for the IAM role. Both the IAM role and directory identity provide access to the requested scope, which is <i>bob/images/image1.jpeg</i> , but the IAM role has a more restrictive grant. So, the returned scope is restricted to the more restrictive grant for the IAM role.

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
S3://amzn-s3-demo-bucket1 / bob/images/*	amzn-s3-demo-bucket1 / bob/*	S3://amzn-s3-demo-bucket1 / bob/*	S3://amzn-s3-demo-bucket1 / bob/images/ image1.jpeg	Minimal	Because the Privilege is set to Minimal, even though the identity has access to a bigger scope, only the requested scope is returned bob/images/image1.jpeg .

Duration

The `durationSeconds` parameter sets the temporary credential's duration, in seconds. The default value is 3600 seconds (1 hour), but the requester (the grantee) can specify a range from 900 seconds (15 minutes) up to 43200 seconds (12 hours). If the grantee requests a value higher than this maximum, the request fails.

Note

In your request for a temporary token, if the location is an object, set the value of the `targetType` parameter in your request to `Object`. This parameter is required only if the location is an object and the privilege level is `Minimal`. If the location is a bucket or a prefix, you don't need to specify this parameter.

Examples

You can request temporary credentials by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs. See these examples.

For additional information, see [GetDataAccess](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example Request temporary credentials

Request:

```
aws s3control get-data-access \
--account-id 111122223333 \
--target s3://amzn-s3-demo-bucket/prefixA* \
--permission READ \
--privilege Default \
--region us-east-2
```

Response:

```
{
  "Credentials": {
    "AccessKeyId": "Example-key-id",
    "SecretAccessKey": "Example-access-key",
    "SessionToken": "Example-session-token",
    "Expiration": "2023-06-14T18:56:45+00:00"},
    "MatchedGrantTarget": "s3://amzn-s3-demo-bucket/prefixA**",
    "Grantee": {
      "GranteeType": "IAM",
      "GranteeIdentifier": "arn:aws:iam::111122223333:role/role-name"
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for requesting temporary credentials from S3 Access Grants, see [GetDataAccess](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how grantees request temporary credentials from S3 Access Grants by using the AWS SDKs.

Java

The following code example returns the temporary credentials that the grantee uses to access your S3 data. To use this code example, replace the *user input placeholders* with your own information.

Example Get temporary credentials

Request:

```
public void getDataAccess() {  
    GetDataAccessRequest getDataAccessRequest = GetDataAccessRequest.builder()  
        .accountId("111122223333")  
        .permission(Permission.READ)  
        .privilege(Privilege.MINIMAL)  
        .target("s3://amzn-s3-demo-bucket/prefixA*")  
        .build();  
    GetDataAccessResponse getDataAccessResponse =  
        s3Control.getDataAccess(getDataAccessRequest);  
    LOGGER.info("GetDataAccessResponse: " + getDataAccessResponse);  
}
```

Response:

```
GetDataAccessResponse(  
    Credentials=Credentials(  
        AccessKeyId="Example-access-key-id",  
        SecretAccessKey="Example-secret-access-key",  
        SessionToken="Example-session-token",  
        Expiration=2023-06-07T06:55:24Z  
    ))
```

Accessing S3 data using credentials vended by S3 Access Grants

After a grantee [obtains temporary credentials](#) through their access grant, they can use these temporary credentials to call Amazon S3 API operations to access your data.

Grantees can access S3 data by using the AWS Command Line Interface (AWS CLI), the AWS SDKs, and the Amazon S3 REST API. Additionally, you can use the AWS [Python](#) and [Java](#) plugins to call S3 Access Grants

Using the AWS CLI

After the grantee obtains their temporary credentials from S3 Access Grants, they can set up a profile with these credentials to retrieve the data.

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *user input placeholders* with your own information.

Example – Set up a profile

```
aws configure set aws_access_key_id "$accessKey" --profile access-grants-consumer-access-profile
aws configure set aws_secret_access_key "$secretKey" --profile access-grants-consumer-access-profile
aws configure set aws_session_token "$sessionToken" --profile access-grants-consumer-access-profile
```

To use the following example command, replace the *user input placeholders* with your own information.

Example – Get the S3 data

The grantee can use the [get-object](#) AWS CLI command to access the data. The grantee can also use [put-object](#), [ls](#), and other S3 AWS CLI commands.

```
aws s3api get-object \
--bucket amzn-s3-demo-bucket1 \
--key myprefix \
--region us-east-2 \
--profile access-grants-consumer-access-profile
```

Using the AWS SDKs

This section provides examples of how grantees can access your S3 data by using the AWS SDKs.

Java

The following Java code example gets an object from an S3 bucket. For instructions on creating and testing a working sample, see [Getting Started](#) in the *AWS SDK for Java Developer Guide*.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.GetObjectRequest;
import com.amazonaws.services.s3.model.ResponseHeaderOverrides;
import com.amazonaws.services.s3.model.S3Object;

import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;

public class GetObject2 {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String key = "*** Object key ***";

        S3Object fullObject = null, objectPortion = null, headerOverrideObject =
null;
        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withRegion(clientRegion)
                .withCredentials(new ProfileCredentialsProvider())
                .build();

            // Get an object and print its contents.
            System.out.println("Downloading an object");
            fullObject = s3Client.getObject(new GetObjectRequest(bucketName, key));
            System.out.println("Content-Type: " +
fullObject.getObjectMetadata().getContentType());
            System.out.println("Content: ");
            displayTextInputStream(fullObject.getObjectContent());

            // Get a range of bytes from an object and print the bytes.
            GetObjectRequest rangeObjectRequest = new GetObjectRequest(bucketName,
key)
                .withRange(0, 9);
            objectPortion = s3Client.getObject(rangeObjectRequest);
            System.out.println("Printing bytes retrieved.");
        }
    }

    private void displayTextInputStream(InputStream in) {
        BufferedReader reader = new BufferedReader(new InputStreamReader(in));
        String line;
        try {
            while ((line = reader.readLine()) != null) {
                System.out.println(line);
            }
        } catch (IOException e) {
            e.printStackTrace();
        }
    }
}
```

```
        displayTextInputStream(objectPortion.getObjectContent());

        // Get an entire object, overriding the specified response headers, and
print
        // the object's content.
        ResponseHeaderOverrides headerOverrides = new ResponseHeaderOverrides()
            .withCacheControl("No-cache")
            .withContentDisposition("attachment; filename=example.txt");
        GetObjectRequest getObjectRequestHeaderOverride = new
GetObjectRequest(bucketName, key)
            .withResponseHeaders(headerOverrides);
        headerOverrideObject =
s3Client.getObject(getObjectRequestHeaderOverride);
        displayTextInputStream(headerOverrideObject.getObjectContent());
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    } finally {
        // To ensure that the network connection doesn't remain open, close any
open
        // input streams.
        if (fullObject != null) {
            fullObject.close();
        }
        if (objectPortion != null) {
            objectPortion.close();
        }
        if (headerOverrideObject != null) {
            headerOverrideObject.close();
        }
    }
}

private static void displayTextInputStream(InputStream input) throws IOException
{
    // Read the text input stream one line at a time and display each line.
    BufferedReader reader = new BufferedReader(new InputStreamReader(input));
    String line = null;
    while ((line = reader.readLine()) != null) {
```

```
        System.out.println(line);
    }
    System.out.println();
}
}
```

Supported S3 actions in S3 Access Grants

A grantee can use the temporary credential vended by S3 Access Grants to perform S3 actions on the S3 data they have access to. The following is a list of allowable S3 actions that a grantee can perform. Which actions are allowable depends on the level of permission granted in the access grant, either READ, WRITE, or READWRITE.

Note

In addition to the Amazon S3 permissions listed below, Amazon S3 can call the AWS Key Management Service (AWS KMS) [Decrypt](#) (kms:decrypt) READ permission or the AWS KMS [GenerateDataKey](#) (kms:generateDataKey) WRITE permission. These permissions don't allow direct access to the AWS KMS key.

S3 IAM action	API action & doc	S3 Access Grants Permission	S3 resource			
s3:GetObject	GetObject	READ	Object			
s3:GetObjectVersion	GetObject	READ	Object			
s3:GetObjectAcl	GetObjectAcl	READ	Object			

S3 IAM action	API action & doc	S3 Access Grants Permission	S3 resource			
s3:GetObjectVersionAcl	GetObjectAcl	READ	Object			
s3>ListMultipartUploads	ListParts	READ	Object			
s3:PutObject	PutObject , CreateMultipartUpload , UploadPart , UploadPartCopy , CompleteMultipartUpload	WRITE	Object			
s3:PutObjectVersionAcl	PutObjectAcl	WRITE	Object			
s3:PutObjectVersionAcl	PutObjectAcl	WRITE	Object			
s3>DeleteObject	DeleteObject	WRITE	Object			
s3>DeleteObjectVersion	DeleteObject	WRITE	Object			
s3:AbortMultipartUpload	AbortMultipartUpload	WRITE	Object			

S3 IAM action	API action & doc	S3 Access Grants Permission	S3 resource			
s3:ListBucket	HeadBucket , ListObjectsV2 , ListObjects	READ	Bucket			
s3:ListBucketVersions	ListObjectVersions	READ	Bucket			
s3:ListBucketMultipartUploads	ListMultipartUploads	READ	Bucket			

List the caller's access grants

S3 data owners can use S3 Access Grants to create access grants for AWS Identity and Access Management (IAM) identities or for AWS IAM Identity Center corporate directory identities. IAM identities and IAM Identity Center directory identities can in turn use the [ListCallerAccessGrants](#) API to list all of the Amazon S3 buckets, prefixes, and objects they can access, as defined by their S3 Access Grants. Use this API to discover all of the S3 data an IAM or directory identity can access through S3 Access Grants.

You can use this feature to build applications that show the data that is accessible to specific end-users. For example, the AWS Storage Browser for S3, an open source UI component that customers use to access S3 buckets, uses this feature to present end-users with the data that they have access to in Amazon S3, based on their S3 Access Grants. Another example is when building an application for browsing, uploading, or downloading data in Amazon S3, you can use this feature to build a tree structure in your application that an end-user could then browse.

Note

For corporate directory identities, when listing the caller's access grants, S3 Access Grants returns the grants of the IAM identity that is used for the identity-aware session. For more

information on identity-aware sessions, see [Granting permissions to use identity-aware console sessions](#) in the *AWS Identity and Access Management User Guide*.

The grantee whether an IAM identity, or a corporate directory identity can get a list of their access grants by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example List a caller's access grants

Request:

```
aws s3control list-caller-access-grants \
--account-id 111122223333 \
--region us-east-2
--max-results 5
```

Response:

```
{
  "NextToken": "6J9S...",
  "CallerAccessGrantsList": [
    {
      "Permission": "READWRITE",
      "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix1/*",
      "ApplicationArn": "NA"
    },
    {
      "Permission": "READWRITE",
      "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix2/*",
      "ApplicationArn": "ALL"
    },
    {
      "Permission": "READWRITE",
```

```
"GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix3/*",
"ApplicationArn": "arn:aws:sso::111122223333:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"
}
]
}
```

Example List a caller's access grants for a bucket

You can narrow the scope of the results using the grantscope parameter.

Request:

```
aws s3control list-caller-access-grants \
--account-id 111122223333 \
--region us-east-2
--grant-scope "s3://amzn-s3-demo-bucket"
--max-results 1000
```

Response:

```
{
"NextToken": "6J9S...",
"CallerAccessGrantsList": [
{
"Permission": "READ",
"GrantScope": "s3://amzn-s3-demo-bucket*",
"ApplicationArn": "ALL"
},
{
"Permission": "READ",
"GrantScope": "s3://amzn-s3-demo-bucket/prefix1/*",
"ApplicationArn": "arn:aws:sso::111122223333:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"
}
]
```

Using the REST API

For information about the Amazon S3 REST API support for getting a list of the API caller's access grants, see [ListCallerAccessGrants](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how grantees request temporary credentials from S3 Access Grants by using the AWS SDKs.

Java

The following code example returns the API caller's access grants to the S3 data of a particular AWS account. To use this code example, replace the *user input placeholders* with your own information.

Example List a caller's access grants

Request:

```
Public void ListCallerAccessGrants() {  
    ListCallerAccessGrantsRequest listRequest = ListCallerAccessGrantsRequest.builder()  
        .withMaxResults(1000)  
        .withGrantScope("s3://")  
        .accountId("1112222333");  
    ListCallerAccessGrantsResponse listResponse =  
        s3control.listCallerAccessGrants(listRequest);  
    LOGGER.info("ListCallerAccessGrantsResponse: " + listResponse);  
}
```

Response:

```
ListCallerAccessGrantsResponse(  
    CallerAccessGrantsList=[  
        ListCallerAccessGrantsEntry(  
            S3Prefix=s3://amzn-s3-demo-bucket/prefix1/  
            Permission=READ,  
            ApplicationArn=ALL  
        )  
    ])
```

S3 Access Grants cross-account access

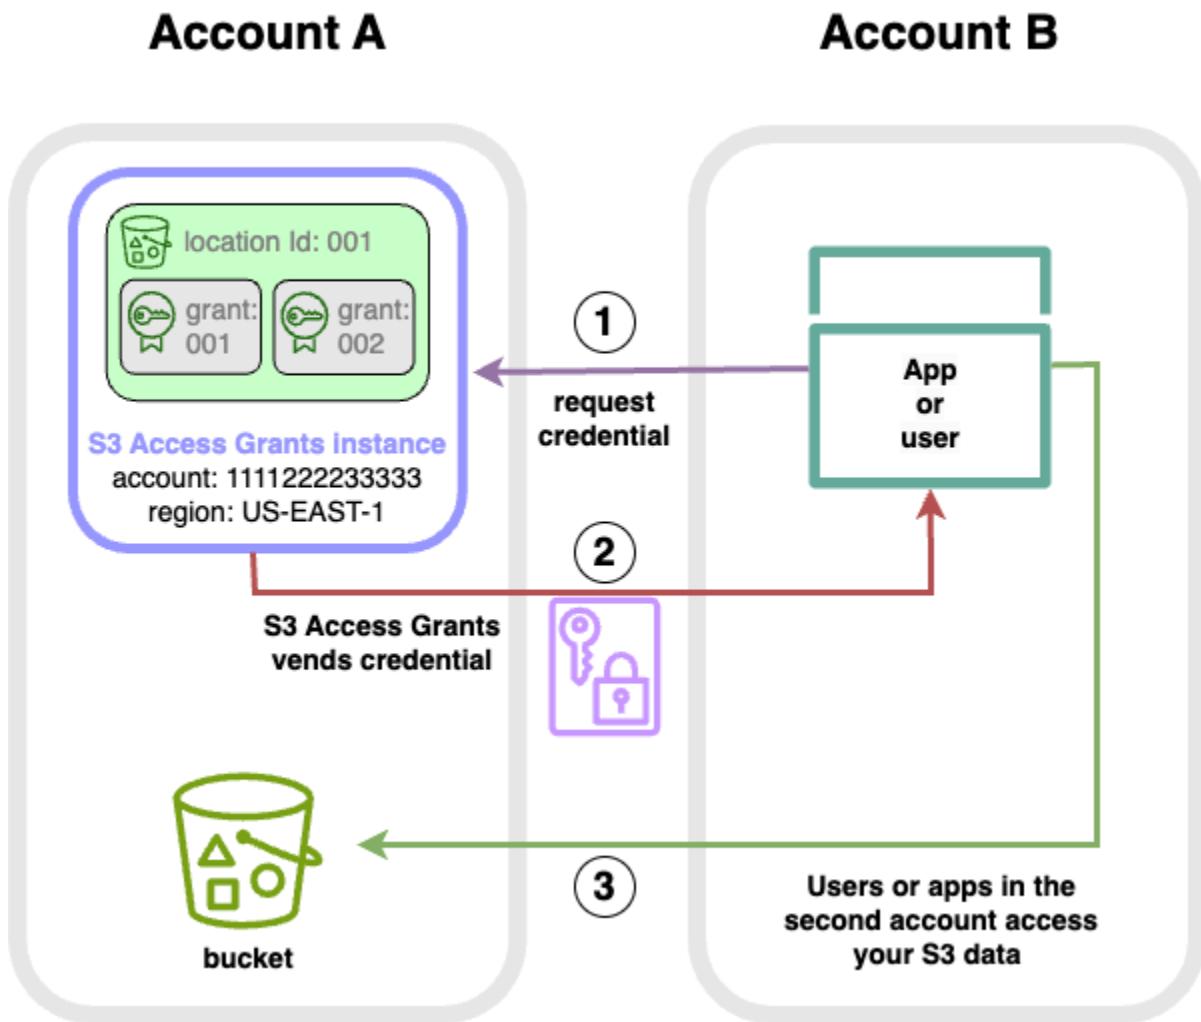

With S3 Access Grants, you can grant Amazon S3 data access to the following:

- AWS Identity and Access Management (IAM) identities within your account

- IAM identities in other AWS accounts
- Directory users or groups in your AWS IAM Identity Center instance

First, configure cross-account access for the other account. This includes granting access to your S3 Access Grants instance by using a resource policy. Then, grant access to your S3 data (buckets, prefixes, or objects) by using grants.

After you configure cross-account access, the other account can request temporary access credentials to your Amazon S3 data from S3 Access Grants. The following image shows the user flow for cross-account S3 access through S3 Access Grants:

1. Users or applications in a second account (B) request credentials from the S3 Access Grants instance in your account (A), where the Amazon S3 data is stored. For more information, see [Request access to Amazon S3 data through S3 Access Grants](#).

2. The S3 Access Grants instance in your account (A) returns temporary credentials if there is a grant that gives the second account access to your Amazon S3 data. For more information on access grants, see [Working with grants in S3 Access Grants](#).
3. Users or applications in the second account (B) use the S3 Access Grants-vended credentials to access the S3 data in your account (A).

Configuring S3 Access Grants cross-account access

To grant cross-account S3 access through S3 Access Grants, follow these steps:

- **Step 1:** Configure an S3 Access Grants instance in your account, for example, account ID 111122223333, where the S3 data is stored.
- **Step 2:** Configure the resource policy for the S3 Access Grants instance in your account 111122223333 to give access to the second account, for example, account ID 444455556666.
- **Step 3:** Configure the IAM permissions for the IAM Principal in the second account 444455556666 to request credentials from the S3 Access Grants instance in your account 111122223333.
- **Step 4:** Create a grant in your account 111122223333 that gives the IAM Principal in the second account 444455556666 access to some of the S3 data in your account 111122223333.

Step 1: Configure an S3 Access Grants instance in your account

First, you must have an S3 Access Grants instance in your account 111122223333 to manage access to your Amazon S3 data. You must create an S3 Access Grants instance in each AWS Region where the S3 data that you want to share is stored. If you are sharing data in more than one AWS Region, then repeat each of these configuration steps for each AWS Region. If you already have an S3 Access Grants instance in the AWS Region where your S3 data is stored, proceed to the next step. If you haven't configured an S3 Access Grants instance, see [Working with S3 Access Grants instances](#) to complete this step.

Step 2: Configure the resource policy for your S3 Access Grants instance to grant cross-account access

After you create an S3 Access Grants instance in your account 111122223333 for cross-account access, configure the resource-based policy for the S3 Access Grants instance in your account 111122223333 to grant cross-account access. The S3 Access Grants instance itself supports

resource-based policies. With the correct resource-based policy in place, you can grant access for AWS Identity and Access Management (IAM) users or roles from other AWS accounts to your S3 Access Grants instance. Cross-account access only grants these permissions (actions):

- `s3:GetAccessGrantsInstanceForPrefix` — the user, role, or app can retrieve the S3 Access Grants instance that contains a particular prefix.
- `s3>ListAccessGrants`
- `s3>ListAccessLocations`
- `s3>ListCallerAccessGrants`
- `s3:GetDataAccess` — the user, role, or app can request temporary credentials based on the access you were granted through S3 Access Grants. Use these credentials to access the S3 data to which you have been granted access.

You can choose which of these permissions to include in the resource policy. This resource policy on the S3 Access Grants instance is a normal resource-based policy and supports everything that the [IAM policy language](#) supports. In the same policy, you can grant access to specific IAM identities in your account 111122223333, for example, by using the `aws:PrincipalArn` condition, but you don't have to do that with S3 Access Grants. Instead, within your S3 Access Grants instance, you can create grants for individual IAM identities from your account, as well as for the other account. By managing each access grant through S3 Access Grants, you can scale your permissions.

If you already use [AWS Resource Access Manager](#) (AWS RAM), you can use it to share your `s3:AccessGrants` resources with other accounts or within your organization. See [Working with shared AWS resources](#) for more information. If you don't use AWS RAM, you can also add the resource policy by using the S3 Access Grants API operations or the AWS Command Line Interface (AWS CLI).

Using the S3 console

We recommend that you use the AWS Resource Access Manager (AWS RAM) Console to share your `s3:AccessGrants` resources with other accounts or within your organization. To share S3 Access Grants cross-account, do the following:

To configure the S3 Access Grants instance resource policy:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. Select the AWS Region from the AWS Region selector.
3. From the left navigation pane, select **Access Grants**.
4. On the Access Grants instance page, in the **Instance in this account** section, select **Share instance**. This will redirect you to the AWS RAM Console.
5. Select **Create resource share**.
6. Follow the AWS RAM steps to create the resource share. For more information, see [Creating a resource share in AWS RAM](#).

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

You can add the resource policy by using the `put-access-grants-instance-resource-policy` CLI command.

If you want to grant cross-account access for the S3 Access Grants instance in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- `s3>ListAccessGrants`
- `s3>ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the **Resource**, and the second account 444455556666 as the **Principal**. To use the following example, replace the **user input placeholders** with your own information.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Principal": {  
        "AWS": "444455556666"  
      }  
    }  
  ]  
}
```

```
},
  "Action": [
    "s3>ListAccessGrants",
    "s3>ListAccessGrantsLocations",
    "s3>GetDataAccess",
    "s3>GetAccessGrantsInstanceForPrefix"
  ],
  "Resource": "arn:aws:s3:us-east-2:1112222333:access-grants/default"
} ]
}
```

To add or update the S3 Access Grants instance resource policy, use the following command. When you use the following example command, replace the *user input placeholders* with your own information.

Example Add or update the S3 Access Grants instance resource policy

```
aws s3control put-access-grants-instance-resource-policy \
--account-id 1112222333 \
--policy file://resourcePolicy.json \
--region us-east-2
{
  "Policy": "{\n    \"Version\": \"2012-10-17\", \n    \"Statement\": [{\n        \"Effect\": \"Allow\", \n        \"Principal\": {\"AWS\": \"44445556666\"},\n        \"Action\": [\n            \"s3>ListAccessGrants\", \n            \"s3>ListAccessGrantsLocations\", \n            \"s3>GetDataAccess\", \n            \"s3>GetAccessGrantsInstanceForPrefix\", \n            \"s3>ListCallerAccessGrants\"\n        ],\n        \"Resource\": \"arn:aws:s3:us-east-2:1112222333:access-grants/default\"\n    }],\n    \"CreatedAt\": \"2023-06-16T00:07:47.473000+00:00\"\n  }"
}
```

Example Get an S3 Access Grants resource policy

You can also use the CLI to get or delete a resource policy for an S3 Access Grants instance.

To get an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-access-grants-instance-resource-policy \
--account-id 111122223333 \
--region us-east-2

{
  "Policy": "{\"Version\": \"2012-10-17\", \"Statement\":[{\"Effect\": \"Allow\",
  \"Principal\": {\"AWS\": \"arn:aws:iam::111122223333:root\"}, \"Action\":
  [\"s3>ListAccessGrants\", \"s3>ListAccessGrantsLocations\", \"s3:GetDataAccess\",
  \"s3:GetAccessGrantsInstanceForPrefix\", \"s3>ListCallerAccessGrants\"], \"Resource\":
  \"arn:aws:
  s3:us-east-2:111122223333:access-grants/default\"]}]",
  "CreatedAt": "2023-06-16T00:07:47.473000+00:00"
}
```

Example Delete an S3 Access Grants resource policy

To delete an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-access-grants-instance-resource-policy \
--account-id 111122223333 \
--region us-east-2

// No response body
```

Using the REST API

You can add the resource policy by using the [PutAccessGrantsInstanceResourcePolicy API](#).

If you want to grant cross-account access for the S3 Access Grants instance in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- s3>ListAccessGrants

- `s3>ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the Resource, and the second account 444455556666 as the Principal. To use the following example, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "444455556666"  
            },  
            "Action": [  
                "s3>ListAccessGrants",  
                "s3>ListAccessGrantsLocations",  
                "s3:GetDataAccess",  
                "s3:GetAccessGrantsInstanceForPrefix"  
            ],  
            "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"  
        } ]  
    } }
```

You can then use the [PutAccessGrantsInstanceResourcePolicy API](#) to configure the policy.

For information on the REST API support to update, get, or delete a resource policy for an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [PutAccessGrantsInstanceResourcePolicy](#)
- [GetAccessGrantsInstanceResourcePolicy](#)
- [DeleteAccessGrantsInstanceResourcePolicy](#)

Using the AWS SDKs

This section provides you with the AWS SDK examples of how to configure your S3 Access Grants resource policy to grant a second AWS account access to some of your S3 data.

Java

Add, update, get, or delete a resource policy to manage cross-account access to your S3 Access Grants instance.

Example Add or update an S3 Access Grants instance resource policy

If you want to grant cross-account access for the S3 Access Grants instance in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- s3>ListAccessGrants
- s3>ListAccessGrantsLocations
- s3>GetDataAccess
- s3>GetAccessGrantsInstanceForPrefix

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the Resource, and the second account 444455556666 as the Principal. To use the following example, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "444455556666"  
            },  
            "Action": [  
                "s3>ListAccessGrants",  
                "s3>ListAccessGrantsLocations",  
                "s3>GetDataAccess",  
                "s3>GetAccessGrantsInstanceForPrefix"  
            ],  
        }  
    ]  
}
```

```
"Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"  
} ]  
}
```

To add or update an S3 Access Grants instance resource policy, use the following code example:

```
public void putAccessGrantsInstanceResourcePolicy() {  
    PutAccessGrantsInstanceResourcePolicyRequest putRequest =  
        PutAccessGrantsInstanceResourcePolicyRequest.builder()  
            .accountId(111122223333)  
            .policy(RESOURCE_POLICY)  
            .build();  
    PutAccessGrantsInstanceResourcePolicyResponse putResponse =  
        s3Control.putAccessGrantsInstanceResourcePolicy(putRequest);  
    LOGGER.info("PutAccessGrantsInstanceResourcePolicyResponse: " + putResponse);  
}
```

Response:

```
PutAccessGrantsInstanceResourcePolicyResponse  
Policy={  
"Version": "2012-10-17",  
"Statement": [{  
"Effect": "Allow",  
"Principal": {  
"AWS": "444455556666"  
},  
"Action": [  
"s3>ListAccessGrants",  
"s3>ListAccessGrantsLocations",  
"s3>GetDataAccess",  
"s3>GetAccessGrantsInstanceForPrefix",  
"s3>ListCallerAccessGrants"  
],  
"Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"  
}]  
}
```

Example Get an S3 Access Grants resource policy

To get an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *user input placeholders* with your own information.

```
public void getAccessGrantsInstanceResourcePolicy() {  
    GetAccessGrantsInstanceResourcePolicyRequest getRequest =  
        GetAccessGrantsInstanceResourcePolicyRequest.builder()  
            .accountId(111122223333)  
            .build();  
    GetAccessGrantsInstanceResourcePolicyResponse getResponse =  
        s3Control.getAccessGrantsInstanceResourcePolicy(getRequest);  
    LOGGER.info("GetAccessGrantsInstanceResourcePolicyResponse: " + getResponse);  
}
```

Response:

```
GetAccessGrantsInstanceResourcePolicyResponse(  
    Policy={"Version": "2012-10-17", "Statement":  
        [{"Effect": "Allow", "Principal": {"AWS": "arn:aws:iam::444455556666:root"}, "Action":  
            ["s3>ListAccessGrants", "s3>ListAccessGrantsLocations", "s3:GetDataAccess", "s3:GetAccessGrants"],  
            "Condition": {"StringEquals": {"s3:Region": "east-2:111122223333:access-grants/default"}},  
        "Created": "2023-06-15T22:54:44.319Z"  
    })
```

Example Delete an S3 Access Grants resource policy

To delete an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *user input placeholders* with your own information.

```
public void deleteAccessGrantsInstanceResourcePolicy() {  
    DeleteAccessGrantsInstanceResourcePolicyRequest deleteRequest =  
        DeleteAccessGrantsInstanceResourcePolicyRequest.builder()  
            .accountId(111122223333)  
            .build();  
    DeleteAccessGrantsInstanceResourcePolicyResponse deleteResponse =  
        s3Control.putAccessGrantsInstanceResourcePolicy(deleteRequest);  
    LOGGER.info("DeleteAccessGrantsInstanceResourcePolicyResponse: " + deleteResponse);  
}
```

Response:

```
DeleteAccessGrantsInstanceResourcePolicyResponse()
```

Step 3: Grant IAM identities in a second account permission to call the S3 Access Grants instance in your account

After the owner of the Amazon S3 data has configured the cross-account policy for the S3 Access Grants instance in account 111122223333, the owner of the second account 444455556666 must create an identity-based policy for its IAM users or roles, and the owner must give them access to the S3 Access Grants instance. In the identity-based policy, include one or more of the following actions, depending on what's granted in the S3 Access Grants instance resource policy and the permissions you want to grant:

- s3>ListAccessGrants
- s3>ListAccessGrantsLocations
- s3:GetDataAccess
- s3:GetAccessGrantsInstanceForPrefix
- s3>ListCallerAccessGrants

Following the [AWS cross-account access pattern](#), the IAM users or roles in the second account 444455556666 must explicitly have one or more of these permissions. For example, grant the s3:GetDataAccess permission so that the IAM user or role can call the S3 Access Grants instance in account 111122223333 to request credentials.

To use this example command, replace the *user input placeholders* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetDataAccess"
      ],
      "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
    }
  ]
}
```

```
 }  
 ]  
 }
```

For information on editing IAM identity-based policy, see [Editing IAM policies](#) in the *AWS Identity and Access Management guide*.

Step 4: Create a grant in the S3 Access Grants instance of your account that gives the IAM identity in the second account access to some of your S3 data

For the final configuration step, you can create a grant in the S3 Access Grants instance in your account 111122223333 that gives access to the IAM identity in the second account 444455556666 to some of the S3 data in your account. You can do this by using the Amazon S3 Console, CLI, API, and SDKs. For more information, see [Create grants](#).

In the grant, specify the AWS ARN of the IAM identity from the second account, and specify which location in your S3 data (a bucket, prefix, or object) that you are granting access to. This location must already be registered with your S3 Access Grants instance. For more information, see [Register a location](#). You can optionally specify a subprefix. For example, if the location you are granting access to is a bucket, and you want to limit the access further to a specific object in that bucket, then pass the object key name in the S3SubPrefix field. Or if you want to limit access to the objects in the bucket with key names that start with a specific prefix, such as 2024-03-research-results/, then pass S3SubPrefix=2024-03-research-results/.

The following is an example CLI command for creating an access grant for an identity in the second account. See [Create grants](#) for more information. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-access-grant \  
--account-id 111122223333 \  
--access-grants-location-id default \  
--access-grants-location-configuration S3SubPrefix=prefixA* \  
--permission READ \  
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::444455556666:role/data-consumer-1
```

After configuring cross-account access, the user or role in the second account can do the following:

- Calls `ListAccessGrantsInstances` to list the S3 Access Grants instances shared with it through AWS RAM. For more information, see [Get the details of an S3 Access Grants instance](#).

- Requests temporary credentials from S3 Access Grants. For more information on how to make these requests, see [Request access to Amazon S3 data through S3 Access Grants](#).

Managing tags for S3 Access Grants

Tags in Amazon S3 Access Grants have similar characteristics to [object tags](#) in Amazon S3. Each tag is a key-value pair. The resources in S3 Access Grants that you can tag are S3 Access Grants [instances](#), [locations](#), and [grants](#).

 **Note**

Tagging in S3 Access Grants uses different API operations than object tagging. S3 Access Grants uses the [TagResource](#), [UntagResource](#), and [ListTagsForResource](#) API operations, where a resource can be either an S3 Access Grants instance, a registered location, or an access grant.

Similar to [object tags](#), the following limitations apply:

- You can add tags to new S3 Access Grants resources when you create them, or you can add tags to existing resources.
- You can associate up to 10 tags with a resource. If multiple tags are associated with the same resource, they must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Tags are internally represented in UTF-16. In UTF-16, characters consume either 1 or 2 character positions.
- The keys and values are case sensitive.

For more information about tag restrictions, see [User-defined tag restrictions](#) in the *AWS Billing User Guide*.

You can tag resources in S3 Access Grants by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

You can tag an S3 Access Grants resource when you create it or after you have created it. The following examples show how you tag or untag an S3 Access Grants instance. You can perform similar operations for registered locations and access grants.

To use the following example commands, replace the *user input placeholders* with your own information.

Example – Create an S3 Access Grants instance with tags

```
aws s3control create-access-grants-instance \
--account-id 111122223333 \
--profile access-grants-profile \
--region us-east-2 \
--tags Key=tagKey1,Value=tagValue1
```

Response:

```
{
  "CreatedAt": "2023-10-25T01:09:46.719000+00:00",
  "AccessGrantsInstanceId": "default",
  "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default"
}
```

Example – Tag an already created S3 Access Grants instance

```
aws s3control tag-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2 \
--tags Key=tagKey2,Value=tagValue2
```

Example – List tags for the S3 Access Grants instance

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2
```

Response:

```
{  
    "Tags": [  
        {  
            "Key": "tagKey1",  
            "Value": "tagValue1"  
        },  
        {  
            "Key": "tagKey2",  
            "Value": "tagValue2"  
        }  
    ]  
}
```

Example – Untag the S3 Access Grants instance

```
aws s3control untag-resource \  
--account-id 111122223333 \  
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \  
--profile access-grants-profile \  
--region us-east-2 \  
--tag-keys "tagKey2"
```

Using the REST API

You can use the Amazon S3 API to tag, untag, or list tags for an S3 Access Grants instance, registered location, or access grant. For information about the REST API support for managing S3 Access Grants tags, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)
- [UntagResource](#)
- [ListTagsForResource](#)

S3 Access Grants limitations

[S3 Access Grants](#) has the following limitations:

Note

If your use case exceeds these limitations, [contact AWS support](#) to request higher limits.

S3 Access Grants instance

You can create **1 S3 Access Grants instance** per AWS Region per account. See [Create an S3 Access Grants instance](#).

S3 Access Grants location

You can register **1,000 S3 Access Grants locations** per S3 Access Grants instance. See [Register an S3 Access Grants location](#).

Grant

You can create **100,000 grants** per S3 Access Grants instance. See [Create a grant](#).

S3 Access Grants AWS Regions

S3 Access Grants is currently available in the following AWS Regions:

AWS Region code	AWS Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-1	US West (N. California)
us-west-2	US West (Oregon)
af-south-1	Africa (Cape Town)
ap-east-1	Asia Pacific (Hong Kong)
ap-northeast-1	Asia Pacific (Tokyo)
ap-northeast-2	Asia Pacific (Seoul)
ap-northeast-3	Asia Pacific (Osaka)

AWS Region code	AWS Region name
ap-south-1	Asia Pacific (Mumbai)
ap-south-2	Asia Pacific (Hyderabad)
ap-southeast-1	Asia Pacific (Singapore)
ap-southeast-2	Asia Pacific (Sydney)
ap-southeast-3	Asia Pacific (Jakarta)
ap-southeast-4	Asia Pacific (Melbourne)
ap-southeast-7	Asia Pacific (Thailand)
ca-central-1	Canada (Central)
ca-west-1	Canada West (Calgary)
eu-central-1	Europe (Frankfurt)
eu-central-2	Europe (Zurich)
eu-north-1	Europe (Stockholm)
eu-south-1	Europe (Milan)
eu-south-2	Europe (Spain)
eu-west-1	Europe (Ireland)
eu-west-2	Europe (London)
eu-west-3	Europe (Paris)
il-central-1	Israel (Tel Aviv)
me-central-1	Middle East (UAE)
me-south-1	Middle East (Bahrain)

AWS Region code	AWS Region name
mx-central-1	Mexico (Central)
sa-east-1	South America (São Paulo)
us-gov-east-1	AWS GovCloud (US-East)
us-gov-west-1	AWS GovCloud (US-West)

S3 Access Grants integrations

S3 Access Grants can be used with the following AWS services and features. This page will be updated as new integrations become available.

 **Tip**

This [AWS workshop for S3 Access Grants](#) walks you through using S3 Access Grants with AWS Identity and Access Management (IAM) users, IAM Identity Center users, Amazon EMR, and AWS Transfer Family.

Amazon Athena

[Using IAM Identity Center enabled Athena workgroups](#)

Amazon EMR

[Launch an Amazon EMR cluster with S3 Access Grants](#)

Amazon EMR on EKS

[Launch an Amazon EMR on EKS cluster with S3 Access Grants](#)

Amazon EMR Serverless application

[Launch an Amazon EMR Serverless application with S3 Access Grants](#)

Amazon Redshift

[Amazon Redshift integration with Amazon S3 Access Grants](#)

Amazon SageMaker AI Studio

[Adding Amazon S3 data to Amazon SageMaker AI Unified Studio](#)

Using S3 Access Grants in Amazon SageMaker AI Unified Studio, you can share your Amazon S3 data in multiple projects. To enable granting access to data using S3 Access Grants, an S3 Access Grants instance is required. Amazon SageMaker AI Unified Studio will use an S3 Access Grants instance if one is already available or can create an instance. First, you add your Amazon S3 data and then publish the data to the catalog or share it directly with consumers.

[Using Amazon S3 Access Grants with Amazon SageMaker AI Studio and the SDK for Python \(Boto3\) plugin](#)

Using S3 Access Grants in Amazon SageMaker AI Studio notebooks is now easier when using the SDK for Python (Boto3) plugin. Set up access grants for IAM principals and AWS IAM Identity Center directory users, beforehand. Although Amazon SageMaker AI Studio does not natively support identity provider directory users, you can write custom Python code, using the plugin that allows these identities to access S3 data via S3 Access Grants. The data access is taking place with the help of the plugin and not through Amazon SageMaker AI.

AWS Glue

[Amazon S3 Access Grants with AWS Glue](#)

AWS IAM Identity Center

[Trusted identity propagation across applications](#)

AWS Transfer Family

[Configure Amazon S3 Access Grants for AWS Transfer Family](#)

Storage Browser for S3

[Managing data access at scale](#) using Storage Browser for S3

Open source Python frameworks

[Amazon S3 Access Grants now integrates with open source Python frameworks](#)

Managing access with ACLs

Access control lists (ACLs) are one of the resource-based options that you can use to manage access to your buckets and objects. You can use ACLs to grant basic read/write permissions to other AWS accounts. There are limits to managing permissions using ACLs.

For example, you can grant permissions only to other AWS accounts; you cannot grant permissions to users in your account. You cannot grant conditional permissions, nor can you explicitly deny permissions. ACLs are suitable for specific scenarios. For example, if a bucket owner allows other AWS accounts to upload objects, permissions to these objects can only be managed using object ACL by the AWS account that owns the object.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

For more information about ACLs, see the following topics.

Topics

- [Access control list \(ACL\) overview](#)
- [Configuring ACLs](#)

- [Policy examples for ACLs](#)

Access control list (ACL) overview

Amazon S3 access control lists (ACLs) enable you to manage access to buckets and objects. Each bucket and object has an ACL attached to it as a subresource. It defines which AWS accounts or groups are granted access and the type of access. When a request is received against a resource, Amazon S3 checks the corresponding ACL to verify that the requester has the necessary access permissions.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported.

When you create a bucket or an object, Amazon S3 creates a default ACL that grants the resource owner full control over the resource. This is shown in the following sample bucket ACL (the default object ACL has the same structure):

Example

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>*** Owner-Canonical-User-ID ***</ID>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:type="Canonical User">
        <ID>*** Owner-Canonical-User-ID ***</ID>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
</AccessControlPolicy>
```

The sample ACL includes an `Owner` element that identifies the owner by the AWS account's canonical user ID. For instructions on finding your canonical user ID, see [Finding an AWS account canonical user ID](#). The `Grant` element identifies the grantee (either an AWS account or a predefined group) and the permission granted. This default ACL has one `Grant` element for the owner. You grant permissions by adding `Grant` elements, with each grant identifying the grantee and the permission.

 **Note**

An ACL can have up to 100 grants.

Topics

- [Who is a grantee?](#)
- [What permissions can I grant?](#)
- [aclRequired values for common Amazon S3 requests](#)
- [Sample ACL](#)
- [Canned ACL](#)

Who is a grantee?

When you grant access rights, you specify each grantee as a `type="value"` pair, where `type` is one of the following:

- **id** – If the value specified is the canonical user ID of an AWS account
- **uri** – If you are granting permissions to a predefined group

Warning

When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see [Creating a Role to Delegate Permissions to an IAM User](#) in the *IAM User Guide*.

Finding an AWS account canonical user ID

The canonical user ID is associated with your AWS account. This ID is a long string of characters, such as:

79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be

For information about how to find the canonical user ID for your account, see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.

You can also look up the canonical user ID of an AWS account by reading the ACL of a bucket or an object to which the AWS account has access permissions. When an individual AWS account is granted permissions by a grant request, a grant entry is added to the ACL with the account's canonical user ID.

Note

If you make your bucket public (not recommended), any unauthenticated user can upload objects to the bucket. These anonymous users don't have an AWS account. When an anonymous user uploads an object to your bucket, Amazon S3 adds a special canonical user ID (65a011a29cdf8ec533ec3d1ccaae921c) as the object owner in the ACL. For more information, see [Amazon S3 bucket and object ownership](#).

Amazon S3 predefined groups

Amazon S3 has a set of predefined groups. When granting account access to a group, you specify one of the Amazon S3 URIs instead of a canonical user ID. Amazon S3 provides the following predefined groups:

- **Authenticated Users group** – Represented by `http://acs.amazonaws.com/groups/global/AuthenticatedUsers`.

This group represents all AWS accounts. **Access permission to this group allows any AWS account to access the resource.** However, all requests must be signed (authenticated).

Warning

When you grant access to the **Authenticated Users group**, any AWS authenticated user in the world can access your resource.

- **All Users group** – Represented by `http://acs.amazonaws.com/groups/global/AllUsers`.

Access permission to this group allows anyone in the world access to the resource. The requests can be signed (authenticated) or unsigned (anonymous). Unsigned requests omit the Authentication header in the request.

Warning

We highly recommend that you never grant the **All Users group** WRITE, WRITE_ACP, or FULL_CONTROL permissions. For example, although WRITE permissions deny non-owners the ability to overwrite or delete existing objects, WRITE permissions still allow anyone to store objects in your bucket, for which you are billed. For more details about these permissions, see the following section [What permissions can I grant?](#).

- **Log Delivery group** – Represented by `http://acs.amazonaws.com/groups/s3/LogDelivery`.

WRITE permission on a bucket enables this group to write server access logs (see [Logging requests with server access logging](#)) to the bucket.

Note

When using ACLs, a grantee can be an AWS account or one of the predefined Amazon S3 groups. However, the grantee cannot be an IAM user. For more information about AWS users and permissions within IAM, see [Using AWS Identity and Access Management](#).

What permissions can I grant?

The following table lists the set of permissions that Amazon S3 supports in an ACL. The set of ACL permissions is the same for an object ACL and a bucket ACL. However, depending on the context (bucket ACL or object ACL), these ACL permissions grant permissions for specific buckets or object operations. The table lists the permissions and describes what they mean in the context of objects and buckets.

For more information about ACL permissions in the Amazon S3 console, see [Configuring ACLs](#).

Permission	When granted on a bucket	When granted on an object
READ	Allows grantee to list the objects in the bucket	Allows grantee to read the object data and its metadata
WRITE	Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects	Not applicable
READ_ACP	Allows grantee to read the bucket ACL	Allows grantee to read the object ACL
WRITE_ACP	Allows grantee to write the ACL for the applicable bucket	Allows grantee to write the ACL for the applicable object
FULL_CONTROL	Allows grantee the READ, WRITE, READ_ACP, and WRITE_ACP permissions on the bucket	Allows grantee the READ, READ_ACP, and WRITE_ACP permissions on the object

Warning

Use caution when granting access permissions to your S3 buckets and objects. For example, granting WRITE access to a bucket allows the grantee to create objects in the bucket. We highly recommend that you read through the entire [Access control list \(ACL\) overview](#) section before granting permissions.

Mapping of ACL permissions and access policy permissions

As shown in the preceding table, an ACL allows only a finite set of permissions, compared to the number of permissions that you can set in an access policy (see [Policy actions for Amazon S3](#)). Each of these permissions allows one or more Amazon S3 operations.

The following table shows how each ACL permission maps to the corresponding access policy permissions. As you can see, access policy allows more permissions than an ACL does. You use ACLs primarily to grant basic read/write permissions, similar to file system permissions. For more information about when to use an ACL, see [Identity and Access Management for Amazon S3](#).

For more information about ACL permissions in the Amazon S3 console, see [Configuring ACLs](#).

ACL permission	Corresponding access policy permissions when the ACL permission is granted on a bucket	Corresponding access policy permissions when the ACL permission is granted on an object
READ	s3>ListBucket , s3>ListBucketVersions , and s3>ListBucketMultipartUploads	s3:GetObject and s3:GetObjectVersion
WRITE	<p>s3:PutObject</p> <p>Bucket owner can create, overwrite, and delete any object in the bucket, and object owner has FULL_CONTROL over their object.</p> <p>In addition, when the grantee is the bucket owner, granting WRITE permission in a bucket ACL allows</p>	Not applicable

ACL permission	Corresponding access policy permissions when the ACL permission is granted on a bucket	Corresponding access policy permissions when the ACL permission is granted on an object
	the s3:DeleteObjectVersion action to be performed on any version in that bucket.	
READ_ACP	s3:GetBucketAcl	s3:GetObjectAcl and s3:GetObjectVersionAcl
WRITE_ACP	s3:PutBucketAcl	s3:PutObjectAcl and s3:PutObjectVersionAcl
FULL_CONTROL	Equivalent to granting READ, WRITE, READ_ACP, and WRITE_ACP ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions.	Equivalent to granting READ, READ_ACP, and WRITE_ACP ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions.

Condition keys

When you grant access policy permissions, you can use condition keys to constrain the value for the ACL on an object using a bucket policy. The following context keys correspond to ACLs. You can use these context keys to mandate the use of a specific ACL in a request:

- s3:x-amz-grant-read - Require read access.
- s3:x-amz-grant-write - Require write access.
- s3:x-amz-grant-read-acp - Require read access to the bucket ACL.
- s3:x-amz-grant-write-acp - Require write access to the bucket ACL.
- s3:x-amz-grant-full-control - Require full control.
- s3:x-amz-acl - Require a [Canned ACL](#).

For example policies that involve ACL-specific headers, see [Granting s3:PutObject permission with a condition requiring the bucket owner to get full control](#). For a complete list of Amazon S3

specific condition keys, see [Actions, resources, and condition keys for Amazon S3 in the Service Authorization Reference](#).

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

aclRequired values for common Amazon S3 requests

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. The `aclRequired` value that appears in CloudTrail or Amazon S3 server access logs depends on which operations were called and certain information about the requester, object owner, and bucket owner. If no ACLs were required, or if you are setting the `bucket-owner-full-control` canned ACL, or if the requests are allowed by your bucket policy, the `aclRequired` value string is `"-"` in Amazon S3 server access logs and is absent in CloudTrail.

The following tables list the expected `aclRequired` values in CloudTrail or Amazon S3 server access logs for the various Amazon S3 API operations. You can use this information to understand which Amazon S3 operations depend on ACLs for authorization. In the following tables, A, B, and C represent the different accounts associated with the requester, object owner, and bucket owner. Entries with an asterisk (*) indicate any of accounts A, B, or C.

 **Note**

PutObject operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a `bucket-owner-full-control` ACL. A null value for `aclRequired` indicates that `aclRequired` is absent in AWS CloudTrail logs.

The following table shows the `aclRequired` values for CloudTrail.

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
GetObject	A	A	A	Yes or No	null	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
GetObject	A	B	A	Yes or No	null	Same-account access with bucket owner enforced
GetObject	A	A	B	Yes	null	Cross-account access granted by bucket policy
GetObject	A	A	B	No	Yes	Cross-account access relies on ACL
GetObject	A	A	B	Yes	null	Cross-account access granted by bucket policy
GetObject	A	B	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
GetObject	A	B	C	Yes	null	Cross-account access granted by bucket policy
GetObject	A	B	C	No	Yes	Cross-account access relies on ACL
PutObject	A	Not applicable	A	Yes or No	null	Same-account access
PutObject	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
PutObject	A	Not applicable	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
PutObject with an ACL (except for bucket-owner-full-control)	*	Not applicable	*	Yes or No	Yes	Request grants ACL
ListObjects	A	Not applicable	A	Yes or No	null	Same-account access
ListObjects	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
ListObjects	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
DeleteObject	A	Not applicable	A	Yes or No	null	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
DeleteObject	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
DeleteObject	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
PutObjectAcl	*	*	*	Yes or No	Yes	Request grants ACL
PutBucketAcl	*	Not applicable	*	Yes or No	Yes	Request grants ACL

 **Note**

REST.PUT.OBJECT operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a bucket-owner-full-control ACL. An aclRequired value string of "-" indicates a null value in Amazon S3 server access logs.

The following table shows the aclRequired values for Amazon S3 server access logs.

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.GET. OBJECT	A	A	A	Yes or No	-	Same-account access
REST.GET. OBJECT	A	B	A	Yes or No	-	Same-account access with bucket owner enforced
REST.GET. OBJECT	A	A	B	Yes	-	Cross-account access granted by bucket policy
REST.GET. OBJECT	A	A	B	No	Yes	Cross-account access relies on ACL
REST.GET. OBJECT	A	B	B	Yes	-	Cross-account access granted by bucket policy
REST.GET. OBJECT	A	B	B	No	Yes	Cross-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
						relies on ACL
REST.GET.OBJECT	A	B	C	Yes	-	Cross-account access granted by bucket policy
REST.GET.OBJECT	A	B	C	No	Yes	Cross-account access relies on ACL
REST.PUT.OBJECT	A	Not applicable	A	Yes or No	-	Same-account access
REST.PUT.OBJECT	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.PUT.OBJECT	A	Not applicable	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.PUT.OBJECT with an ACL (except for bucket-owner-full-control)	*	Not applicable	*	Yes or No	Yes	Request grants ACL
REST.GET.BUCKET	A	Not applicable	A	Yes or No	-	Same-account access
REST.GET.BUCKET	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.GET.BUCKET	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
REST.DELETE.OBJECT	A	Not applicable	A	Yes or No	-	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.DELETE.OBJECT	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.DELETE.OBJECT	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
REST.PUT.ACL	*	*	*	Yes or No	Yes	Request grants ACL

Sample ACL

The following sample ACL on a bucket identifies the resource owner and a set of grants. The format is the XML representation of an ACL in the Amazon S3 REST API. The bucket owner has FULL_CONTROL of the resource. In addition, the ACL shows how permissions are granted on a resource to two AWS accounts, identified by canonical user ID, and two of the predefined Amazon S3 groups discussed in the preceding section.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>Owner-canonical-user-ID</ID>
  </Owner>
  <AccessControlList>
    <Grant>
```

```
<Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
    <ID>Owner-canonical-user-ID</ID>
</Grantee>
<Permission>FULL_CONTROL</Permission>
</Grant>

<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
        <ID>user1-canonical-user-ID</ID>
    </Grantee>
    <Permission>WRITE</Permission>
</Grant>

<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
        <ID>user2-canonical-user-ID</ID>
    </Grantee>
    <Permission>READ</Permission>
</Grant>

<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
    </Grantee>
    <Permission>READ</Permission>
</Grant>
<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
    </Grantee>
    <Permission>WRITE</Permission>
</Grant>

</AccessControlList>
</AccessControlPolicy>
```

Canned ACL

Amazon S3 supports a set of predefined grants, known as *canned ACLs*. Each canned ACL has a predefined set of grantees and permissions. The following table lists the set of canned ACLs and the associated predefined grants.

Canned ACL	Applies to	Permissions added to ACL
private	Bucket and object	Owner gets FULL_CONTROL . No one else has access rights (default).
public-read	Bucket and object	Owner gets FULL_CONTROL . The AllUsers group (see Who is a grantee?) gets READ access.
public-read-write	Bucket and object	Owner gets FULL_CONTROL . The AllUsers group gets READ and WRITE access. Granting this on a bucket is generally not recommended.
aws-exec-read	Bucket and object	Owner gets FULL_CONTROL . Amazon EC2 gets READ access to GET an Amazon Machine Image (AMI) bundle from Amazon S3.
authenticated-read	Bucket and object	Owner gets FULL_CONTROL . The AuthenticatedUsers group gets READ access.
bucket-owner-read	Object	Object owner gets FULL_CONTROL . Bucket owner gets READ access. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it.
bucket-owner-full-control	Object	Both the object owner and the bucket owner get FULL_CONTROL over the object. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it.

Canned ACL	Applies to	Permissions added to ACL
log-delivery-write	Bucket	The LogDelivery group gets WRITE and READ_ACP permissions on the bucket. For more information about logs, see (Logging requests with server access logging).

Note

You can specify only one of these canned ACLs in your request.

You specify a canned ACL in your request by using the `x-amz-acl` request header. When Amazon S3 receives a request with a canned ACL in the request, it adds the predefined grants to the ACL of the resource.

Configuring ACLs

This section explains how to manage access permissions for S3 buckets and objects using access control lists (ACLs). You can add grants to your resource ACL using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs.

Bucket and object permissions are independent of each other. An object does not inherit the permissions from its bucket. For example, if you create a bucket and grant write access to a user, you can't access that user's objects unless the user explicitly grants you access.

You can grant permissions to other AWS account users or to predefined groups. The user or group that you are granting permissions to is called the *grantee*. By default, the owner, which is the AWS account that created the bucket, has full permissions.

Each permission you grant for a user or group adds an entry in the ACL that is associated with the bucket. The ACL lists grants, which identify the grantee and the permission granted.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled.

When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Warning

We highly recommend that you avoid granting write access to the **Everyone (public access)** or **Authenticated Users group (all AWS authenticated users)** groups. For more information about the effects of granting write access to these groups, see [Amazon S3 predefined groups](#).

Using the S3 console to set ACL permissions for a bucket

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs.

The following table shows the ACL permissions that you can configure for buckets in the Amazon S3 console.

Amazon S3 console ACL permissions for buckets

Console permission	ACL permission	Access
Objects - List	READ	Allows grantee to list the objects in the bucket.
Objects - Write	WRITE	Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects.
Bucket ACL - Read	READ_ACP	Allows grantee to read the bucket ACL.
Bucket ACL - Write	WRITE_ACP	Allows grantee to write the ACL for the applicable bucket.
Everyone (public access): Objects - List	READ	Grants public read access for the objects in the bucket. When you grant list access to Everyone (public access) , anyone in the world can access the objects in the bucket.
Everyone (public access): Bucket ACL - Read	READ_ACP	Grants public read access for the bucket ACL. When you grant read access to Everyone (public access) , anyone in the world can access the bucket ACL.

For more information about ACL permissions, see [Access control list \(ACL\) overview](#).

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To set ACL permissions for a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to set permissions for.
4. Choose **Permissions**.
5. Under **Access control list**, choose **Edit**.

You can edit the following ACL permissions for the bucket:

Objects

- **List** – Allows a grantee to list the objects in the bucket.
- **Write** – Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects.

In the S3 console, you can only grant write access to the S3 log delivery group and the bucket owner (your AWS account). We highly recommend that you do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.

Bucket ACL

- **Read** – Allows grantee to read the bucket ACL.
 - **Write** – Allows grantee to write the ACL for the applicable bucket.
6. To change the bucket owner's permissions, beside **Bucket owner (your AWS account)**, clear or select from the following ACL permissions:
 - **Objects – List or Write**
 - **Bucket ACL – Read or Write**

The *owner* refers to the AWS account root user, not an AWS Identity and Access Management IAM user. For more information about the root user, see [The AWS account root user](#) in the *IAM User Guide*.

7. To grant or undo permissions for the general public (everyone on the internet), beside **Everyone (public access)**, clear or select from the following ACL permissions:

- **Objects – List**
- **Bucket ACL – Read**

 **Warning**

Use caution when granting the **Everyone** group public access to your S3 bucket. When you grant access to this group, anyone in the world can access your bucket. We highly recommend that you never grant any kind of public write access to your S3 bucket.

8. To grant or undo permissions for anyone with an AWS account, beside **Authenticated Users group (anyone with an AWS account)**, clear or select from the following ACL permissions:

- **Objects – List**
- **Bucket ACL – Read**

9. To grant or undo permissions for Amazon S3 to write server access logs to the bucket, under **S3 log delivery group**, clear or select from the following ACL permissions:

- **Objects – List or Write**
- **Bucket ACL – Read or Write**

If a bucket is set up as the target bucket to receive access logs, the bucket permissions must allow the **Log Delivery** group write access to the bucket. When you enable server access logging on a bucket, the Amazon S3 console grants write access to the **Log Delivery** group for the target bucket that you choose to receive the logs. For more information about server access logging, see [Enabling Amazon S3 server access logging](#).

10. To grant access to another AWS account, do the following:

- a. Choose **Add grantee**.
- b. In the **Grantee** box, enter the canonical ID of the other AWS account.
- c. Select from the following ACL permissions:
 - **Objects – List or Write**
 - **Bucket ACL – Read or Write**

⚠️ Warning

When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see [Creating a Role to Delegate Permissions to an IAM User](#) in the *IAM User Guide*.

11. To remove access to another AWS account, under **Access for other AWS accounts**, choose **Remove**.
12. To save your changes, choose **Save changes**.

Using the S3 console to set ACL permissions for an object

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs. The following table shows the ACL permissions that you can configure for objects in the Amazon S3 console.

Amazon S3 console ACL permissions for objects

Console permission	ACL permission	Access
Object - Read	READ	Allows grantee to read the object data and its metadata.
Object ACL - Read	READ_ACP	Allows grantee to read the object ACL.
Object ACL - Write	WRITE_ACP	Allows grantee to write the ACL for the applicable object

For more information about ACL permissions, see [Access control list \(ACL\) overview](#).

⚠️ Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control

lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To set ACL permissions for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object for which you want to set permissions.
4. Choose **Permissions**.
5. Under Access control list (ACL), choose **Edit**.

You can edit the following ACL permissions for the object:

Object

- **Read** – Allows grantee to read the object data and its metadata.

Object ACL

- **Read** – Allows grantee to read the object ACL.
- **Write** – Allows grantee to write the ACL for the applicable object. In the S3 console, you can only grant write access to the bucket owner (your AWS account). We highly recommend that you do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.

6. You can manage object access permissions for the following:
 - a. **Access for object owner**

The *owner* refers to the AWS account root user, and not an AWS Identity and Access Management IAM user. For more information about the root user, see [The AWS account root user](#) in the *IAM User Guide*.

To change the owner's object access permissions, under **Access for object owner**, choose **Your AWS Account (owner)**.

Select the check boxes for the permissions that you want to change, and then choose **Save**.

b. **Access for other AWS accounts**

To grant permissions to an AWS user from a different AWS account, under **Access for other AWS accounts**, choose **Add account**. In the **Enter an ID** field, enter the canonical ID of the AWS user that you want to grant object permissions to. For information about finding a canonical ID, see [Your AWS account identifiers](#) in the *Amazon Web Services General Reference*. You can add as many as 99 users.

Select the check boxes for the permissions that you want to grant to the user, and then choose **Save**. To display information about the permissions, choose the Help icons.

c. **Public access**

To grant access to your object to the general public (everyone in the world), under **Public access**, choose **Everyone**. Granting public access permissions means that anyone in the world can access the object.

Select the check boxes for the permissions that you want to grant, and then choose **Save**.

 **Warning**

- Use caution when granting the **Everyone** group anonymous access to your Amazon S3 objects. When you grant access to this group, anyone in the world can access your object. If you need to grant access to everyone, we highly recommend that you only grant permissions to **Read objects**.
- We highly recommend that you *do not* grant the **Everyone** group write object permissions. Doing so allows anyone to overwrite the ACL permissions for the object.

Using the AWS SDKs

This section provides examples of how to configure access control list (ACL) grants on buckets and objects.

⚠ Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Java

This section provides examples of how to configure access control list (ACL) grants on buckets and objects. The first example creates a bucket with a canned ACL (see [Canned ACL](#)), creates a list of custom permission grants, and then replaces the canned ACL with an ACL containing the custom grants. The second example shows how to modify an ACL using the `AccessControlList.grantPermission()` method.

Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group

This example creates a bucket. In the request, the example specifies a canned ACL that grants the Log Delivery group permission to write logs to the bucket.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.IOException;
import java.util.ArrayList;

public class CreateBucketWithACL {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String userEmailForReadPermission = "*** user@example.com ***";
```

```
try {
    AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
        .withRegion(clientRegion)
        .build();

    // Create a bucket with a canned ACL. This ACL will be replaced by the
    // setBucketAcl()
    // calls below. It is included here for demonstration purposes.
    CreateBucketRequest createBucketRequest = new
CreateBucketRequest(bucketName, clientRegion.getName())
    .withCannedAcl(CannedAccessControlList.LogDeliveryWrite);
    s3Client.createBucket(createBucketRequest);

    // Create a collection of grants to add to the bucket.
    ArrayList<Grant> grantCollection = new ArrayList<Grant>();

    // Grant the account owner full control.
    Grant grant1 = new Grant(new
CanonicalGrantee(s3Client.getS3AccountOwner().getId()),
        Permission.FullControl);
    grantCollection.add(grant1);

    // Grant the LogDelivery group permission to write to the bucket.
    Grant grant2 = new Grant(GroupGrantee.LogDelivery, Permission.Write);
    grantCollection.add(grant2);

    // Save grants by replacing all current ACL grants with the two we just
created.
    AccessControlList bucketAcl = new AccessControlList();
    bucketAcl.grantAllPermissions(grantCollection.toArray(new Grant[0]));
    s3Client.setBucketAcl(bucketName, bucketAcl);

    // Retrieve the bucket's ACL, add another grant, and then save the new
ACL.
    AccessControlList newBucketAcl = s3Client.getBucketAcl(bucketName);
    Grant grant3 = new Grant(new
EmailAddressGrantee(userEmailForReadPermission), Permission.Read);
    newBucketAcl.grantAllPermissions(grant3);
    s3Client.setBucketAcl(bucketName, newBucketAcl);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
```

```
// Amazon S3 couldn't be contacted for a response, or the client  
// couldn't parse the response from Amazon S3.  
e.printStackTrace();  
}  
}  
}
```

Example Update ACL on an existing object

This example updates the ACL on an object. The example performs the following tasks:

- Retrieves an object's ACL
- Clears the ACL by removing all existing permissions
- Adds two permissions: full access to the owner, and WRITE_ACP (see [What permissions can I grant?](#)) to a user identified by an email address
- Saves the ACL to the object

```
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import com.amazonaws.auth.profile.ProfileCredentialsProvider;  
import com.amazonaws.regions.Regions;  
import com.amazonaws.services.s3.AmazonS3;  
import com.amazonaws.services.s3.AmazonS3ClientBuilder;  
import com.amazonaws.services.s3.model.AccessControlList;  
import com.amazonaws.services.s3.model.CanonicalGrantee;  
import com.amazonaws.services.s3.model.EmailAddressGrantee;  
import com.amazonaws.services.s3.model.Permission;  
  
import java.io.IOException;  
  
public class ModifyACLExistingObject {  
  
    public static void main(String[] args) throws IOException {  
        Regions clientRegion = Regions.DEFAULT_REGION;  
        String bucketName = "**** Bucket name ****";  
        String keyName = "**** Key name ****";  
        String emailGrantee = "**** user@example.com ****";  
  
        try {
```

```
AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(clientRegion)
    .build();

    // Get the existing object ACL that we want to modify.
    AccessControlList acl = s3Client.getObjectAcl(bucketName, keyName);

    // Clear the existing list of grants.
    acl.getGrantsAsList().clear();

    // Grant a sample set of permissions, using the existing ACL owner for
Full
    // Control permissions.
    acl.grantPermission(new CanonicalGrantee(acl.getOwner().getId()),
Permission.FullControl);
    acl.grantPermission(new EmailAddressGrantee(emailGrantee),
Permission.WriteAcp);

    // Save the modified ACL back to the object.
    s3Client.setObjectAcl(bucketName, keyName, acl);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

.NET

Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group

This C# example creates a bucket. In the request, the code also specifies a canned ACL that grants the Log Delivery group permissions to write the logs to the bucket.

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingBucketACLTest
    {
        private const string newBucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            CreateBucketUseCannedACLAsync().Wait();
        }

        private static async Task CreateBucketUseCannedACLAsync()
        {
            try
            {
                // Add bucket (specify canned ACL).
                PutBucketRequest putBucketRequest = new PutBucketRequest()
                {
                    BucketName = newBucketName,
                    BucketRegion = S3Region.EUW1, // S3Region.US,
                                            // Add canned ACL.
                    CannedACL = S3CannedACL.LogDeliveryWrite
                };
                PutBucketResponse putBucketResponse = await
client.PutBucketAsync(putBucketRequest);

                // Retrieve bucket ACL.
                GetACLResponse getACLResponse = await client.GetACLAsync(new
GetACLRequest
                {
                    BucketName = newBucketName
                });
            }
        }
    }
}
```

```
        }
        catch (AmazonS3Exception amazonS3Exception)
        {
            Console.WriteLine("S3 error occurred. Exception: " +
amazonS3Exception.ToString());
        }
        catch (Exception e)
        {
            Console.WriteLine("Exception: " + e.ToString());
        }
    }
}
```

Example Update ACL on an existing object

This C# example updates the ACL on an existing object. The example performs the following tasks:

- Retrieves an object's ACL.
- Clears the ACL by removing all existing permissions.
- Adds two permissions: full access to the owner, and WRITE_ACP to a user identified by email address.
- Saves the ACL by sending a PutAcl request.

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingObjectACLTTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** object key name ***";
```

```
private const string emailAddress = "*** email address ***";
// Specify your bucket region (an example region is shown).
private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
private static IAmazonS3 client;
public static void Main()
{
    client = new AmazonS3Client(bucketRegion);
    TestObjectACLTestAsync().Wait();
}
private static async Task TestObjectACLTestAsync()
{
    try
    {
        // Retrieve the ACL for the object.
        GetACLResponse aclResponse = await client.GetACLAsync(new
GetACLRequest
{
    BucketName = bucketName,
    Key = keyName
});

        S3AccessControlList acl = aclResponse.AccessControlList;

        // Retrieve the owner (we use this to re-add permissions after
we clear the ACL).
        Owner owner = acl.Owner;

        // Clear existing grants.
        acl.Grants.Clear();

        // Add a grant to reset the owner's full permission (the
previous clear statement removed all permissions).
        S3Grant fullControlGrant = new S3Grant
{
    Grantee = new S3Grantee { CanonicalUser = owner.Id },
    Permission = S3Permission.FULL_CONTROL
};

        // Describe the grant for the permission using an email address.
        S3Grant grantUsingEmail = new S3Grant
{
    Grantee = new S3Grantee { EmailAddress = emailAddress },
}
```

```
        Permission = S3Permission.WRITE_ACP
    };
    acl.Grants.AddRange(new List<S3Grant> { fullControlGrant,
grantUsingEmail });

        // Set a new ACL.
PutACLResponse response = await client.PutACLAsync(new
PutACLRequest
{
    BucketName = bucketName,
    Key = keyName,
    AccessControlList = acl
});
}
catch (AmazonS3Exception amazonS3Exception)
{
    Console.WriteLine("An AmazonS3Exception was thrown. Exception: " +
amazonS3Exception.ToString());
}
catch (Exception e)
{
    Console.WriteLine("Exception: " + e.ToString());
}
}
}
}
```

Using the REST API

Amazon S3 APIs enable you to set an ACL when you create a bucket or an object. Amazon S3 also provides API to set an ACL on an existing bucket or an object. These APIs provide the following methods to set an ACL:

- **Set ACL using request headers**— When you send a request to create a resource (bucket or object), you set an ACL using the request headers. Using these headers, you can either specify a canned ACL or specify grants explicitly (identifying grantee and permissions explicitly).
- **Set ACL using request body**— When you send a request to set an ACL on an existing resource, you can set the ACL either in the request header or in the body.

For information on the REST API support for managing ACLs, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GetBucketAcl](#)
- [PutBucketAcl](#)
- [GetObjectAcl](#)
- [PutObjectAcl](#)
- [PutObject](#)
- [CreateBucket](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)

 **Important**

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported.

Access Control List (ACL)-Specific Request Headers

You can use headers to grant access control list (ACL)-based permissions. By default, all objects are private. Only the owner has full access control. When adding a new object, you can grant permissions to individual AWS accounts or to predefined groups defined by Amazon S3. These permissions are then added to the Access Control List (ACL) on the object. For more information, see [Access control list \(ACL\) overview](#).

With this operation, you can grant access permissions using one of these two methods:

- **Canned ACL (`x-amz-acl`)** — Amazon S3 supports a set of predefined ACLs, known as canned ACLs. Each canned ACL has a predefined set of grantees and permissions. For more information, see [Canned ACL](#).
- **Access Permissions** — To explicitly grant access permissions to specific AWS accounts or groups, use the following headers. Each header maps to specific permissions that Amazon S3 supports in

an ACL. For more information, see [Access control list \(ACL\) overview](#). In the header, you specify a list of grantees who get the specific permission.

- x-amz-grant-read
- x-amz-grant-write
- x-amz-grant-read-acp
- x-amz-grant-write-acp
- x-amz-grant-full-control

Using the AWS CLI

For more information about managing ACLs using the AWS CLI, see [put-bucket-acl](#) in the *AWS CLI Command Reference*.

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported.

Policy examples for ACLs

You can use condition keys in bucket policies to control access to Amazon S3.

Topics

- [Granting s3:PutObject permission with a condition requiring the bucket owner to get full control](#)
- [Granting s3:PutObject permission with a condition on the x-amz-acl header](#)

Granting s3:PutObject permission with a condition requiring the bucket owner to get full control

The [PUT Object](#) operation allows access control list (ACL)-specific headers that you can use to grant ACL-based permissions. Using these keys, the bucket owner can set a condition to require specific access permissions when the user uploads an object.

Suppose that Account A owns a bucket, and the account administrator wants to grant Dave, a user in Account B, permissions to upload objects. By default, objects that Dave uploads are owned by Account B, and Account A has no permissions on these objects. Because the bucket owner is paying the bills, it wants full permissions on the objects that Dave uploads. The Account A administrator can do this by granting the `s3:PutObject` permission to Dave, with a condition that the request include ACL-specific headers that either grant full permission explicitly or use a canned ACL. For more information, see [PUT Object](#).

Require the `x-amz-full-control` header

You can require the `x-amz-full-control` header in the request with full control permission to the bucket owner. The following bucket policy grants the `s3:PutObject` permission to user Dave with a condition using the `s3:x-amz-grant-full-control` condition key, which requires the request to include the `x-amz-full-control` header.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/Dave"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3::::awsexamplebucket1/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"  
                }  
            }  
        }  
    ]  
}
```

Note

This example is about cross-account permission. However, if Dave (who is getting the permission) belongs to the AWS account that owns the bucket, this conditional permission is not necessary. This is because the parent account to which Dave belongs owns objects that the user uploads.

Add explicit deny

The preceding bucket policy grants conditional permission to user Dave in Account B. While this policy is in effect, it is possible for Dave to get the same permission without any condition via some other policy. For example, Dave can belong to a group, and you grant the group s3:PutObject permission without any condition. To avoid such permission loopholes, you can write a stricter access policy by adding explicit deny. In this example, you explicitly deny the user Dave upload permission if he does not include the necessary headers in the request granting full permissions to the bucket owner. Explicit deny always supersedes any other permission granted. The following is the revised access policy example with explicit deny added.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"  
                }  
            }  
        },  
        {  
            "Sid": "statement2",  
            "Effect": "Deny",  
            "Principal": "arn:aws:iam::111122223333:user/AccountBadmin",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"  
                }  
            }  
        }  
    ]  
}
```

```
        "Effect": "Deny",
        "Principal": {
            "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"
        },
        "Action": "s3:PutObject",
        "Resource": "arn:aws:s3:::awsexamplebucket1/*",
        "Condition": {
            "StringNotEquals": {
                "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
            }
        }
    }
}
```

Test the policy with the AWS CLI

If you have two AWS accounts, you can test the policy using the AWS Command Line Interface (AWS CLI). You attach the policy and use Dave's credentials to test the permission using the following AWS CLI put-object command. You provide Dave's credentials by adding the --profile parameter. You grant full control permission to the bucket owner by adding the --grant-full-control parameter. For more information about setting up and using the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the *Amazon S3 API Reference*.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg
--grant-full-control id="AccountA-CanonicalUserID" --profile AccountBUserProfile
```

Require the x-amz-acl header

You can require the x-amz-acl header with a canned ACL granting full control permission to the bucket owner. To require the x-amz-acl header in the request, you can replace the key-value pair in the Condition block and specify the s3:x-amz-acl condition key, as shown in the following example.

```
"Condition": {
    "StringEquals": {
        "s3:x-amz-acl": "bucket-owner-full-control"
    }
}
```

To test the permission using the AWS CLI, you specify the `--acl` parameter. The AWS CLI then adds the `x-amz-acl` header when it sends the request.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg  
--acl "bucket-owner-full-control" --profile AccountBadmin
```

Granting s3:PutObject permission with a condition on the x-amz-acl header

The following bucket policy grants the `s3:PutObject` permission for two AWS accounts if the request includes the `x-amz-acl` header making the object publicly readable. The Condition block uses the `StringEquals` condition, and it is provided a key-value pair, "`s3:x-amz-acl`": `["public-read"]`, for evaluation. In the key-value pair, the `s3:x-amz-acl` is an Amazon S3-specific key, as indicated by the prefix `s3:`.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AddCannedAcl",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:root",  
                    "arn:aws:iam::111122223333:root"  
                ]  
            },  
            "Action": "s3:PutObject",  
            "Resource": [  
                "arn:aws:s3:::awsexamplebucket1/*"  
            ],  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": [  
                        "public-read"  
                    ]  
                }  
            }  
        }  
    ]
```

{

Important

Not all conditions make sense for all actions. For example, it makes sense to include an `s3:LocationConstraint` condition on a policy that grants the `s3:CreateBucket` Amazon S3 permission. However, it does not make sense to include this condition on a policy that grants the `s3:GetObject` permission. Amazon S3 can test for semantic errors of this type that involve Amazon S3-specific conditions. However, if you are creating a policy for an IAM user or role and you include a semantically invalid Amazon S3 condition, no error is reported because IAM cannot validate Amazon S3 conditions.

Blocking public access to your Amazon S3 storage

The Amazon S3 Block Public Access feature provides settings for access points, buckets, accounts, and AWS Organizations to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, or object permissions to allow public access. S3 Block Public Access settings override these policies and permissions so that you can limit public access to these resources.

With S3 Block Public Access, organization administrators, account administrators, and bucket owners can easily set up centralized controls to limit public access to their Amazon S3 resources that are enforced regardless of how the resources are created.

You can manage Block Public Access settings at multiple levels: organization level (using AWS Organizations), account level, and bucket and access point level. For instructions on configuring public block access, see [Configuring block public access](#).

When Amazon S3 receives a request to access a bucket or an object, it determines whether the bucket or the bucket owner's account has a block public access setting applied. If the account is part of an AWS Organizations with Block Public Access policies, Amazon S3 also checks for organization-level settings. If the request was made through an access point, Amazon S3 also checks for block public access settings for the access point. If there is an existing block public access setting that prohibits the requested access, Amazon S3 rejects the request.

Amazon S3 Block Public Access provides four settings. These settings are independent and can be used in any combination. Each setting can be applied to an access point, a bucket, or an entire AWS account. At the organization level, all four settings are applied together as a unified policy - you cannot select individual settings granularly. If the block public access settings for the access point, bucket, or account differ, then Amazon S3 applies the most restrictive combination of the access point, bucket, and account settings. Account-level settings automatically inherit organization-level policies when present, and S3 takes the most restrictive policy between bucket-level and effective account-level settings. For example, if your organization has a Block Public Access policy enabled, but a specific bucket has Block Public Access disabled at the bucket level, the bucket will still be protected because S3 applies the more restrictive organization/account-level settings. Conversely, if your organization policy is disabled but a bucket has Block Public Access enabled, that bucket remains protected by its bucket-level settings.

When Amazon S3 evaluates whether an operation is prohibited by a block public access setting, it rejects any request that violates an organization policy (which enforces the account BPA setting) or an access point, bucket, or account setting.

Important

Public access is granted to buckets and objects through access control lists (ACLs), access point policies, bucket policies, or all. To help ensure that all of your Amazon S3 access points, buckets, and objects have their public access blocked, we recommend that you turn on all four settings for block public access for your account. For organizations managing multiple accounts, consider using organization-level Block Public Access policies for centralized control. Additionally, we recommend that you also turn on all four settings for each bucket to comply with AWS Security Hub Foundational Security Best Practices control S3.8. These settings block public access for all current and future buckets and access points. Before applying these settings, verify that your applications will work correctly without public access. If you require some level of public access to your buckets or objects, for example to host a static website as described at [Hosting a static website using Amazon S3](#), you can customize the individual settings to suit your storage use cases.

Enabling Block Public Access helps protect your resources by preventing public access from being granted through the resource policies or access control lists (ACLs) that are directly attached to S3 resources. In addition to enabling Block Public Access, carefully inspect the following policies to confirm that they don't grant public access:

- Identity-based policies attached to associated AWS principals (for example, IAM roles)

- Resource-based policies attached to associated AWS resources (for example, AWS Key Management Service (KMS) keys)

Note

- You can enable block public access settings only for organizations, access points, buckets, and AWS accounts. Amazon S3 doesn't support block public access settings on a per-object basis.
- When you apply block public access settings to an account, the settings apply to all AWS Regions globally. The settings might not take effect in all Regions immediately or simultaneously, but they eventually propagate to all Regions.
- When you apply organization-level block public access policies, they automatically propagate to selected member accounts and override account-level settings.

- [Configuring block public access settings for your S3 buckets](#)

Block public access settings

S3 Block Public Access provides four settings. You can apply these settings in any combination to individual access points, buckets, or entire AWS accounts. At the organization level, you can only enable or disable all four settings together using an "all" or "none" approach - granular control over individual settings is not available. If you apply a setting to an account, it applies to all buckets and

access points that are owned by that account. Account-level settings automatically inherit from organization policies when present. Similarly, if you apply a setting to a bucket, it applies to all access points associated with that bucket.

The policy inheritance and enforcement works as follows:

- Organization-level policies automatically apply to member accounts, enforcing any existing account-level settings
- Account-level setting inherit from organization policies when present, or use locally configured settings when no organization policy exists
- Bucket-level settings operate independently but are subject to enforcement restrictions. S3 applies the most restrictive combination across all applicable levels - organization/account-level and bucket-level settings. This means a bucket inherits the baseline protection from its account (which may be organization-managed), but S3 will enforce whichever configuration is more restrictive between the bucket's settings and the account's effective settings.

The following table contains the available settings.

Name	Description
BlockPublicAcls	<p>Setting this option to TRUE causes the following behavior:</p> <ul style="list-style-type: none">• PutBucketAcl and PutObjectAcl calls fail if the specified access control list (ACL) is public.• PutObject calls fail if the request includes a public ACL.• If this setting is applied to an account, then PUT Bucket calls fail if the request includes a public ACL. <p>When this setting is set to TRUE, the specified operations fail (whether made through the REST API, AWS CLI, or AWS SDKs). However, existing policies and ACLs for buckets and objects aren't modified. This setting enables you to protect against public access while allowing you to audit, refine, or otherwise alter the existing policies and ACLs for your buckets and objects.</p>

Name	Description
	<p>Note</p> <p>Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled.</p>
IgnorePublicAccls	<p>Setting this option to TRUE causes Amazon S3 to ignore all public ACLs on a bucket and any objects that it contains. This setting enables you to safely block public access granted by ACLs while still allowing PutObject calls that include a public ACL (as opposed to BlockPublicAccls, which rejects PutObject calls that include a public ACL). Enabling this setting doesn't affect the persistence of any existing ACLs and doesn't prevent new public ACLs from being set.</p> <p>Note</p> <p>Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled.</p>

Name	Description
BlockPublicPolicy	<p>Setting this option to TRUE for a bucket causes Amazon S3 to reject calls to <code>PutBucketPolicy</code> if the specified bucket policy allows public access. Setting this option to TRUE for a bucket also causes Amazon S3 to reject calls to <code>PutAccessPointPolicy</code> for all of the bucket's same-account access points if the specified policy allows public access.</p> <p>Setting this option to TRUE for an access point causes Amazon S3 to reject calls to <code>PutAccessPointPolicy</code> and <code>PutBucketPolicy</code> that are made through the access point if the specified policy (for either the access point or the underlying bucket) allows public access.</p> <p>You can use this setting to allow users to manage access point and bucket policies without allowing them to publicly share the bucket or the object it contains. Enabling this setting doesn't affect existing access point or bucket policies.</p>

 **Important**

To use this setting effectively, we recommend that you apply it at the *account* level. A bucket policy can allow users to alter a bucket's block public access settings. Therefore, users who have permission to change a bucket policy could insert a policy that allows them to disable the block public access settings for the bucket. If this setting is enabled for the entire account, rather than for a specific bucket, Amazon S3 blocks public policies even if a user alters the bucket policy to disable this setting.

Name	Description
RestrictPublicBuckets	<p>Setting this option to TRUE restricts access to an access point or bucket with a public policy to only AWS service principals and authorized users within the bucket owner's account and access point owner's account. This setting blocks all cross-account access to the access point or bucket (except by AWS service principals), while still allowing users within the account to manage the access point or bucket.</p> <p>Enabling this setting doesn't affect existing access point or bucket policies, except that Amazon S3 blocks public and cross-account access derived from any public access point or bucket policy, including non-public delegation to specific accounts.</p>

Important

- Calls to `GetBucketAcl` and `GetObjectAcl` always return the effective permissions in place for the specified bucket or object. For example, suppose that a bucket has an ACL that grants public access, but the bucket also has the `IgnorePublicAccls` setting enabled. In this case, `GetBucketAcl` returns an ACL that reflects the access permissions that Amazon S3 is enforcing, rather than the actual ACL that is associated with the bucket.
- Block public access settings don't alter existing policies or ACLs. Therefore, removing a block public access setting causes a bucket or object with a public policy or ACL to again be publicly accessible.

Managing block public access at organization level

Organization-level block public access uses AWS Organizations policies to centrally manage S3 public access controls across your entire organization. When enabled, these policies automatically apply to selected accounts and override individual account-level settings.

For additional information on block public access at an organization level, see [S3 policy](#) in the *AWS Organizations user guide*.

Performing block public access operations on an access point

To perform block public access operations on an access point, use the AWS CLI service `s3control`.

Important

You can't change an access point's block public access settings after creating the access point. You can specify block public access settings for an access point only when creating the access point.

The meaning of "public"

ACLs

Amazon S3 considers a bucket or object ACL public if it grants any permissions to members of the predefined `AllUsers` or `AuthenticatedUsers` groups. For more information about predefined groups, see [Amazon S3 predefined groups](#).

Bucket policies

When evaluating a bucket policy, Amazon S3 begins by assuming that the policy is public. It then evaluates the policy to determine whether it qualifies as non-public. To be considered non-public, a bucket policy must grant access only to fixed values (values that don't contain a wildcard or [an AWS Identity and Access Management Policy Variable](#)) for one or more of the following:

- An AWS principal, user, role, or service principal (e.g. `aws:PrincipalOrgID`)
- A set of Classless Inter-Domain Routings (CIDR) blocks, using `aws:SourceIp`. For more information about CIDR, see [RFC 4632](#) on the RFC Editor website.

Note

Bucket policies that grant access conditioned on the `aws:SourceIp` condition key with very broad IP ranges (for example, `0.0.0.0/1`) are evaluated as "public." This includes values broader than `/8` for IPv4 and `/32` for IPv6 (excluding RFC1918 private ranges). Block public access will reject these "public" policies and prevent cross-account access to buckets that are already using these "public" policies.

- aws:SourceArn
- aws:SourceVpc
- aws:SourceVpce
- aws:SourceOwner
- aws:SourceAccount
- aws:userid, outside the pattern "AROLEID: *"
- s3:DataAccessPointArn

 **Note**

When used in a bucket policy, this value can contain a wildcard for the access point name without rendering the policy public, as long as the account ID is fixed. For example, allowing access to `arn:aws:s3:us-west-2:123456789012:accesspoint/*` would permit access to any access point associated with account 123456789012 in Region us-west-2, without rendering the bucket policy public. This behavior is different for access point policies. For more information, see [Access points](#).

- s3:DataAccessPointAccount

For more information about bucket policies, see [Bucket policies for Amazon S3](#).

 **Note**

When using [multivalued context keys](#), you must use the `ForAllValues` or `ForAnyValue` set operators.

Example : Public bucket policies

Under these rules, the following example policies are considered public.

```
{  
    "Principal": "*",  
    "Resource": "*",  
    "Action": "s3:PutObject",  
    "Effect": "Allow"  
}
```

```
{  
    "Principal": "*",
    "Resource": "*",
    "Action": "s3:PutObject",
    "Effect": "Allow",
    "Condition": { "StringLike": {"aws:SourceVpc": "vpc-*"} }
}
```

You can make these policies non-public by including any of the condition keys listed previously, using a fixed value. For example, you can make the last policy preceding non-public by setting `aws:SourceVpc` to a fixed value, like the following.

```
{  
    "Principal": "*",
    "Resource": "*",
    "Action": "s3:PutObject",
    "Effect": "Allow",
    "Condition": {"StringEquals": {"aws:SourceVpc": "vpc-91237329"}}
}
```

How Amazon S3 evaluates a bucket policy that contains both public and non-public access grants

This example shows how Amazon S3 evaluates a bucket policy that contains both public and non-public access grants.

Suppose that a bucket has a policy that grants access to a set of fixed principals. Under the previously described rules, this policy isn't public. Thus, if you enable the `RestrictPublicBuckets` setting, the policy remains in effect as written, because `RestrictPublicBuckets` only applies to buckets that have public policies. However, if you add a public statement to the policy, `RestrictPublicBuckets` takes effect on the bucket. It allows only AWS service principals and authorized users of the bucket owner's account to access the bucket.

As an example, suppose that a bucket owned by "Account-1" has a policy that contains the following:

1. A statement that grants access to AWS CloudTrail (which is an AWS service principal)
2. A statement that grants access to account "Account-2"

3. A statement that grants access to the public, for example by specifying "Principal": "*" with no limiting Condition

This policy qualifies as public because of the third statement. With this policy in place and `RestrictPublicBuckets` enabled, Amazon S3 allows access only by CloudTrail. Even though statement 2 isn't public, Amazon S3 disables access by "Account-2." This is because statement 3 renders the entire policy public, so `RestrictPublicBuckets` applies. As a result, Amazon S3 disables cross-account access, even though the policy delegates access to a specific account, "Account-2." But if you remove statement 3 from the policy, then the policy doesn't qualify as public, and `RestrictPublicBuckets` no longer applies. Thus, "Account-2" regains access to the bucket, even if you leave `RestrictPublicBuckets` enabled.

Access points

Amazon S3 evaluates block public access settings slightly differently for access points compared to buckets. The rules that Amazon S3 applies to determine when an access point policy is public are generally the same for access points as for buckets, except in the following situations:

- An access point that has a VPC network origin is always considered non-public, regardless of the contents of its access point policy.
- An access point policy that grants access to a set of access points using `s3:DataAccessPointArn` is considered public. Note that this behavior is different than for bucket policies. For example, a bucket policy that grants access to values of `s3:DataAccessPointArn` that match `arn:aws:s3:us-west-2:123456789012:accesspoint/*` is not considered public. However, the same statement in an access point policy would render the access point public.

Using IAM Access Analyzer for S3 to review public buckets

You can use IAM Access Analyzer for S3 to review buckets with bucket ACLs, bucket policies, or access point policies that grant public access. IAM Access Analyzer for S3 alerts you to buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings that report the source and level of public or shared access.

In IAM Access Analyzer for S3, you can block all public access to a bucket with a single click. You can also drill down into bucket-level permission settings to configure granular levels of access. For

specific and verified use cases that require public or shared access, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket.

In rare cases, IAM Access Analyzer for S3 and Amazon S3 block public access evaluation might differ on whether a bucket is public. This behavior occurs because Amazon S3 block public access performs validation on the existence of actions in addition to evaluating public access. Suppose that the bucket policy contains an Action statement that allows public access for an action that isn't supported by Amazon S3 (for example, s3:NotASupportedAction). In this case, Amazon S3 block public access evaluates the bucket as public because such a statement could potentially make the bucket public if the action later becomes supported. In cases where Amazon S3 block public access and IAM Access Analyzer for S3 differ in their evaluations, we recommend reviewing the bucket policy and removing any unsupported actions.

For more information about IAM Access Analyzer for S3, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

Permissions

To use Amazon S3 Block Public Access features, you must have the following permissions.

Operation	Required permissions
GET bucket policy status	s3:GetBucketPolicyStatus
GET bucket Block Public Access settings	s3:GetBucketPublicAccessBlock
PUT bucket Block Public Access settings	s3:PutBucketPublicAccessBlock
DELETE bucket Block Public Access settings	s3:PutBucketPublicAccessBlock
GET account Block Public Access settings	s3:GetAccountPublicAccessBlock
PUT account Block Public Access settings	s3:PutAccountPublicAccessBlock
DELETE account Block Public Access settings	s3:PutAccountPublicAccessBlock
PUT access point Block Public Access settings	s3>CreateAccessPoint

Note

The DELETE operations require the same permissions as the PUT operations. There are no separate permissions for the DELETE operations.

Configuring block public access

For more information about configuring block public access for your AWS account, your Amazon S3 buckets, and your access points, see the following topics:

- [Configuring block public access settings for your account](#)
- [Configuring block public access settings for your S3 buckets](#)
- [Performing block public access operations on an access point](#)

Configuring block public access settings for your account

Important

If your account is managed by an organization-level Block Public Access policy, you cannot modify these account-level settings. Organization-level policies override account-level configurations. For more information on centralized management options, see [S3 policy](#) in the *AWS Organizations user guide*.

Amazon S3 Block Public Access provides settings for access points, buckets, organizations, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access. For more information, see [Blocking public access to your Amazon S3 storage](#).

Note

Account level settings override settings on individual objects. Configuring your account to block public access will override any public access settings made to individual objects within your account. When organization-level policies are active, account-level settings automatically inherit from the organization policy and cannot be modified directly.

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to configure block public access settings for all the buckets in your account when not managed by organization policies. For more information, see the sections below.

To configure block public access settings for your buckets, see [Configuring block public access settings for your S3 buckets](#). For information about access points, see [Performing block public access operations on an access point](#).

Using the S3 console

Amazon S3 block public access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit block public access settings for all the S3 buckets in your AWS account. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

To edit block public access settings for all the S3 buckets in an AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose **Block Public Access settings for this account**.
3. Choose **Edit** to change the block public access settings for all the buckets in your AWS account.
4. Choose the settings that you want to change, and then choose **Save changes**.
5. When you're asked for confirmation, enter **confirm**. Then choose **Confirm** to save your changes.

If you receive an error message that says, "This account does not allow changes to its account-level S3 Block Public Access settings due to an organizational S3 Block Public Access policy in effect," your account is managed by organization-level policies. Contact your organization administrator to modify these settings.

Using the AWS CLI

You can use Amazon S3 Block Public Access through the AWS CLI. For more information about setting up and using the AWS CLI, see [What is the AWS Command Line Interface?](#)

Account

To perform block public access operations on an account, use the AWS CLI service `s3control`. The account-level operations that use this service are as follows:

- PutPublicAccessBlock (for an account)
- GetPublicAccessBlock (for an account)
- DeletePublicAccessBlock (for an account)

Note

PutPublicAccessBlock and DeletePublicAccessBlock operations will return an "Access Denied" error when the account is managed by organization-level policies. Account-level GetPublicAccessBlock operations will return the enforced organization-level policy if present.

For additional information and examples, see [put-public-access-block](#) in the *AWS CLI Reference*.

Using the AWS SDKs

Java

The following examples show you how to use Amazon S3 Block Public Access with the AWS SDK for Java to put a public access block configuration on an Amazon S3 account.

Note

PutPublicAccessBlock and DeletePublicAccessBlock operations will fail with an "Access Denied" error if the account is managed by organization-level policies.

```
AWSS3ControlClientBuilder controlClientBuilder =
    AWSS3ControlClientBuilder.standard();
controlClientBuilder.setRegion(<region>);
controlClientBuilder.setCredentials(<credentials>);

AWSS3Control client = controlClientBuilder.build();
client.putPublicAccessBlock(new PutPublicAccessBlockRequest()
    .withAccountId(<account-id>)
    .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
        .withIgnorePublicAcls(<value>)
        .withBlockPublicAcls(<value>))
```

```
.withBlockPublicPolicy(<value>)
.withRestrictPublicBuckets(<value>)));
```

Important

This example pertains only to account-level operations, which use the `AWSS3Control` client class. For bucket-level operations, see the preceding example.

Other SDKs

For information about using the other AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Account-level operations
 - [`PutPublicAccessBlock`](#) - Fails when account is managed by organization policies
 - [`GetPublicAccessBlock`](#) - Returns effective configuration including organization policies.
 - [`DeletePublicAccessBlock`](#) - Fails when account is managed by organization policies.

You'll see following error message for restricted operations: "This account does not allow changes to its account-level S3 Block Public Access settings due to an organizational S3 Block Public Access policy in effect."

Configuring block public access settings for your S3 buckets

Amazon S3 Block Public Access provides settings for access points, buckets, organizations, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access. For more information, see [Blocking public access to your Amazon S3 storage](#).

Note

Bucket-level Block Public Access settings work alongside organization and account-level policies. S3 applies the most restrictive setting between bucket-level and effective account-level configurations (which may be enforced by organization policies if present).

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to grant public access to one or more buckets. You can also block public access to buckets that are already public. For more information, see the sections below.

To configure block public access settings for every bucket in your account, see [Configuring block public access settings for your account](#). For organization-wide centralized management, see [S3 policy](#) in the *AWS Organizations user guide*.

For information about configuring block public access for access points, see [Performing block public access operations on an access point](#).

Using the S3 console

Amazon S3 Block Public Access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit Block Public Access settings for one or more S3 buckets. For information about blocking public access using the AWS CLI, AWS SDKs, and the Amazon S3 REST APIs, see [Blocking public access to your Amazon S3 storage](#).

You can see if your bucket is publicly accessible from the **Buckets** list, in the **IAM Access Analyzer** column. For more information, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

If you see an **Error** when you list your buckets and their public access settings, you might not have the required permissions. Check to make sure you have the following permissions added to your user or role policy:

```
s3:GetAccountPublicAccessBlock  
s3:GetBucketPublicAccessBlock  
s3:GetBucketPolicyStatus  
s3:GetBucketLocation  
s3:GetBucketAcl  
s3>ListAccessPoints  
s3>ListAllMyBuckets
```

In some rare cases, requests can also fail because of an AWS Region outage.

To edit the Amazon S3 block public access settings for a single S3 bucket

Follow these steps if you need to change the public access settings for a single S3 bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Bucket name** list, choose the name of the bucket that you want.
3. Choose **Permissions**.
4. Choose **Edit** next to **Block public access (bucket settings)** to change the public access settings for the bucket. For more information about the four Amazon S3 Block Public Access Settings, see [Block public access settings](#).
5. Choose one of the settings, and then choose **Save changes**.
6. When you're asked for confirmation, enter **confirm**. Then choose **Confirm** to save your changes.

Important

Even if you disable bucket-level Block Public Access settings, your bucket may still be protected by account-level or organization-level policies. S3 always applies the most restrictive combination of settings across all levels.

You can also change Amazon S3 Block Public Access settings when you create a bucket. For more information, see [Creating a general purpose bucket](#).

Using the AWS CLI

To block public access on a bucket or to delete the public access block, use the AWS CLI service `s3api`. The bucket-level operations that use this service are as follows:

- `PutPublicAccessBlock` (for a bucket)
- `GetPublicAccessBlock` (for a bucket)
- `DeletePublicAccessBlock` (for a bucket)
- `GetBucketPolicyStatus`

For more information and examples, see [put-public-access-block](#) in the *AWS CLI Reference*.

Note

These bucket-level operations are not restricted by organization-level policies. However, the effective public access behavior will still be governed by the most restrictive combination of bucket, account, and organization settings. For more information about the hierarchy and policy interactions, see [the section called “Editing bucket public access settings”](#).

Using the AWS SDKs

Java

```
AmazonS3 client = AmazonS3ClientBuilder.standard()
    .withCredentials(<credentials>)
    .build();

client.setPublicAccessBlock(new SetPublicAccessBlockRequest()
    .withBucketName(<bucket-name>)
    .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
        .withBlockPublicAcls(<value>)
        .withIgnorePublicAcls(<value>)
        .withBlockPublicPolicy(<value>)
        .withRestrictPublicBuckets(<value>)));
```

⚠ Important

This example pertains only to bucket-level operations, which use the AmazonS3 client class. For account-level operations, see the following example.

Other SDKs

For information about using the other AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Bucket-level operations
 - [PutPublicAccessBlock](#)
 - [GetPublicAccessBlock](#)
 - [DeletePublicAccessBlock](#)
 - [GetBucketPolicyStatus](#)

Reviewing bucket access using IAM Access Analyzer for S3

IAM Access Analyzer for S3 provides external access findings for your S3 general purpose buckets that are configured to allow access to anyone on the internet (public) or other AWS accounts, including AWS accounts outside of your organization. For each bucket that's shared publicly or with other AWS accounts, you receive findings into the source and level of shared access. For example, IAM Access Analyzer for S3 might show that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. With these findings, you can take immediate and precise corrective action to restore your bucket access to what you intended.

The Amazon S3 console presents an **External access summary** in the S3 console next to your list of general purpose buckets. In the summary, you can click on the active findings for each AWS Region to see the details of the finding in the IAM Access Analyzer for S3 page. External access findings in **External access summary** are automatically updated once every 24 hours.

When reviewing a bucket that allows public access, on the IAM Access Analyzer for S3 page, you can block all public access to the bucket with a single click. We recommend that you block all public access to your buckets unless you require public access to support a specific use case. Before you block all public access, ensure that your applications will continue to work correctly without public access. For more information, see [Blocking public access to your Amazon S3 storage](#).

You can also drill down into bucket-level permission settings to configure granular levels of access. For specific and verified use cases that require public access, such as static website hosting, public downloads, or cross-account sharing, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket. You can revisit and modify

these bucket configurations at any time. You can also download your findings as a CSV report for auditing purposes.

IAM Access Analyzer for S3 is available at no extra cost on the Amazon S3 console. IAM Access Analyzer for S3 is powered by AWS Identity and Access Management (IAM) IAM Access Analyzer. To use IAM Access Analyzer for S3 in the Amazon S3 console, you must visit the IAM console and create an external access analyzer on a per-Region basis.

For more information about IAM Access Analyzer, see [What is IAM Access Analyzer?](#) in the *IAM User Guide*. For more information about IAM Access Analyzer for S3, review the following sections.

Important

- IAM Access Analyzer for S3 requires an account-level analyzer in each AWS Region where you have buckets. To use IAM Access Analyzer for S3, you must visit IAM Access Analyzer and create an analyzer that has an account as the zone of trust. For more information, see [Enabling IAM Access Analyzer](#) in *IAM User Guide*.
- IAM Access Analyzer for S3 doesn't analyze the access point policy that's attached to cross-account access points. This behavior occurs because the access point and its policy are outside the zone of trust, that is, the account. Buckets that delegate access to a cross-account access point are listed under **Buckets with public access** if you haven't applied the RestrictPublicBuckets block public access setting to the bucket or account. When you apply the RestrictPublicBuckets block public access setting, the bucket is reported under **Buckets with access from other AWS accounts — including third-party AWS accounts**.
- When a bucket policy or bucket ACL is added or modified, IAM Access Analyzer generates and updates findings based on the change within 30 minutes. Findings related to account level block public access settings might not be generated or updated for up to 6 hours after you change the settings. Findings related to Multi-Region Access Points might not be generated or updated for up to six hours after the Multi-Region Access Point is created, deleted, or you change its policy.

Topics

- [Reviewing a global summary of policies that grant external access to buckets](#)
- [Information provided by IAM Access Analyzer for S3](#)

- [Blocking all public access](#)
- [Reviewing and changing bucket access](#)
- [Archiving bucket findings](#)
- [Activating an archived bucket finding](#)
- [Viewing finding details](#)
- [Downloading an IAM Access Analyzer for S3 report](#)

Reviewing a global summary of policies that grant external access to buckets

You can use the **External access summary** to view a global summary of policies that grant external access to buckets across your AWS account directly from the S3 console. This summary helps you identify Amazon S3 general purpose buckets in any AWS Region that allow public access or access from other AWS accounts without needing to inspect policies in each AWS Region individually.

Enabling external access summary and IAM Access Analyzer for S3

To use the **External access summary** and IAM Access Analyzer for S3, you must complete the following prerequisite steps.

1. Grant the required permissions. For more information, see [Permissions Required to use IAM Access Analyzer](#) in the *IAM User Guide*.
2. Visit IAM to create an account-level analyzer for each Region where you want to use IAM Access Analyzer.

You can do this by creating an analyzer that has an account as the zone of trust in the IAM console or by using the AWS CLI or AWS SDKs. For more information, see [Enabling IAM Access Analyzer](#) in *IAM User Guide*.

Viewing buckets that allow external access

The **External access summary** displays findings and errors for external access that are provided by IAM Access Analyzer for S3 for general purpose buckets. Archived findings and findings for unused access are not included in the summary but can be viewed in the IAM console or IAM Access Analyzer for S3. For more information, see [View the IAM Access Analyzer findings dashboard](#) in the *IAM User Guide*.

Note

The **External access summary** only includes findings for external access analyzers for each of your AWS accounts, not your AWS Organization.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation panel, choose **General purpose buckets**.
3. Expand the **External access summary**. The console displays active public and cross-account access findings.

Note

If S3 experiences an issue loading bucket details, refresh the general purpose buckets list or view findings in IAM Access Analyzer for S3. For more information, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

4. To view a list of findings or errors for an AWS Region, choose the link to the Region. The IAM Access Analyzer for S3 page displays names of buckets that can be accessed publicly or by other AWS accounts. For more information, see [Information provided by IAM Access Analyzer for S3](#).

Updating access controls for buckets that allow external access

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation panel, choose **General purpose buckets**.
3. Expand the **External access summary**. The console displays active findings for buckets that can be accessed publicly or by other AWS accounts.

Note

If S3 experiences an issue loading bucket details, refresh the general purpose buckets list or view findings in IAM Access Analyzer for S3. For more information, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

- To view a list of findings or errors for an AWS Region, choose the link to the Region. The IAM Access Analyzer for S3 displays active findings for buckets that can be accessed publicly or by other AWS accounts.

 **Note**

External access findings in **External access summary** are automatically updated once every 24 hours.

- To block all public access for a bucket, see [Blocking all public access](#). To change the bucket access, see [Reviewing and changing bucket access](#).

Information provided by IAM Access Analyzer for S3

IAM Access Analyzer for S3 provides findings for buckets that can be accessed outside your AWS account. Buckets that are listed under **Public access findings** can be accessed by anyone on the internet. If IAM Access Analyzer for S3 identifies public buckets, you also see a warning at the top of the page that shows you the number of public buckets in your Region. Buckets listed under **Cross-account access findings** are shared conditionally with other AWS accounts, including accounts outside of your organization.

For each bucket, IAM Access Analyzer for S3 provides the following information:

- Bucket name**
- Shared through** - How the bucket is shared—through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy. Multi-Region Access Points and cross-account access points are reflected under access points. A bucket can be shared through both policies and ACLs. If you want to find and review the source for your bucket access, you can use the information in this column as a starting point for taking immediate and precise corrective action.
- Status** - The status of the bucket finding. IAM Access Analyzer for S3 displays findings for all public and shared buckets.
 - Active** - Finding has not been reviewed.
 - Archived** - Finding has been reviewed and confirmed as intended.
 - All** - All findings for buckets that are public or shared with other AWS accounts, including AWS accounts outside of your organization.

- **Access level** - Access permissions granted for the bucket:
 - **List** - List resources.
 - **Read** - Read but not edit resource contents and attributes.
 - **Write** - Create, delete, or modify resources.
 - **Permissions** - Grant or modify resource permissions.
 - **Tagging** - Update tags associated with the resource.
- **External principal** - The AWS account outside of your organization with access to the bucket.
- **Resources control policy (RCP) restriction** - The resource control policy (RCP) that applies to the bucket, if applicable. For more information, see [Resource control policies \(RCPs\)](#).

Blocking all public access

If you want to block all access to a bucket in a single click, you can use the **Block all public access** button in IAM Access Analyzer for S3. When you block all public access to a bucket, no public access is granted. We recommend that you block all public access to your buckets unless you require public access to support a specific and verified use case. Before you block all public access, ensure that your applications will continue to work correctly without public access.

If you don't want to block all public access to your bucket, you can edit your block public access settings on the Amazon S3 console to configure granular levels of access to your buckets. For more information, see [Blocking public access to your Amazon S3 storage](#).

In rare cases, IAM Access Analyzer for S3 and Amazon S3 block public access evaluation might differ on whether a bucket is public. This behavior occurs because Amazon S3 block public access performs validation on the existence of actions in addition to evaluating public access. Suppose that the bucket policy contains an Action statement that allows public access for an action that isn't supported by Amazon S3 (for example, s3:NotASupportedAction). In this case, Amazon S3 block public access evaluates the bucket as public because such a statement could potentially make the bucket public if the action later becomes supported. In cases where Amazon S3 block public access and IAM Access Analyzer for S3 differ in their evaluations, we recommend reviewing the bucket policy and removing any unsupported actions.

To block all public access to a bucket using IAM Access Analyzer for S3

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation pane on the left, under **Dashboards**, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **Block all public access**.
5. To confirm your intent to block all public access to the bucket, in **Block all public access (bucket settings)**, enter **confirm**.

Amazon S3 blocks all public access to your bucket. The status of the bucket finding updates to **resolved**, and the bucket disappears from the IAM Access Analyzer for S3 listing. If you want to review resolved buckets, open IAM Access Analyzer on the [IAM Console](#).

Reviewing and changing bucket access

If you did not intend to grant access to the public or other AWS accounts, including accounts outside of your organization, you can modify the bucket ACL, bucket policy, the Multi-Region Access Point policy, or the access point policy to remove the access to the bucket. The **Shared through** column shows all sources of bucket access: bucket policy, bucket ACL, and/or access point policy. Multi-Region Access Points and cross-account access points are reflected under access points.

To review and change a bucket policy, a bucket ACL, a Multi-Region Access Point, or an access point policy

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Access analyzer for S3**.
3. To see whether public access or shared access is granted through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy, look in the **Shared through** column.
4. Under **Buckets**, choose the name of the bucket with the bucket policy, bucket ACL, Multi-Region Access Point policy, or access point policy that you want to change or review.
5. If you want to change or view a bucket ACL:
 - a. Choose **Permissions**.
 - b. Choose **Access Control List**.
 - c. Review your bucket ACL, and make changes as required.

For more information, see [Configuring ACLs](#).

6. If you want to change or review a bucket policy:

- a. Choose **Permissions**.
- b. Choose **Bucket Policy**.
- c. Review or change your bucket policy as required.

For more information, see [Adding a bucket policy by using the Amazon S3 console](#).

7. If you want to change or view a Multi-Region Access Point policy:

- a. Choose **Multi-Region Access Point**.
- b. Choose the Multi-Region Access Point name.
- c. Review or change your Multi-Region Access Point policy as required.

For more information, see [Permissions](#).

8. If you want to review or change an access point policy:

- a. Choose **Access Points for general purpose buckets** or **Access Points for directory buckets**.
- b. Choose the access point name.
- c. Review or change access as required.

For more information, see [Managing your Amazon S3 access points for general purpose buckets](#).

If you edit or remove a bucket ACL, a bucket policy, or an access point policy to remove public or shared access, the status for the bucket findings updates to resolved. The resolved bucket findings disappear from the IAM Access Analyzer for S3 listing, but you can view them in IAM Access Analyzer.

Archiving bucket findings

If a bucket grants access to the public or other AWS accounts, including accounts outside of your organization, to support a specific use case (for example, a static website, public downloads, or cross-account sharing), you can archive the finding for the bucket. When you archive bucket findings, you acknowledge and record your intent for the bucket to remain public or shared.

Archived bucket findings remain in your IAM Access Analyzer for S3 listing so that you always know which buckets are public or shared.

To archive bucket findings in IAM Access Analyzer for S3

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **IAM Access Analyzer for S3**.
3. In IAM Access Analyzer for S3, choose an active bucket.
4. To acknowledge your intent for this bucket to be accessed by the public or other AWS accounts, including accounts outside of your organization, choose **Archive**.
5. Enter **confirm**, and choose **Archive**.

Activating an archived bucket finding

After you archive findings, you can always revisit them and change their status back to active, indicating that the bucket requires another review.

To activate an archived bucket finding in IAM Access Analyzer for S3

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Access analyzer for S3**.
3. Choose the archived bucket findings.
4. Choose **Mark as active**.

Viewing finding details

If you need to see more information about a finding, you can open the bucket finding details in IAM Access Analyzer on the [IAM Console](#).

To view finding details in IAM Access Analyzer for S3

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **View details**.

The finding details open in IAM Access Analyzer on the [IAM Console](#).

Downloading an IAM Access Analyzer for S3 report

You can download your bucket findings as a CSV report that you can use for auditing purposes. The report includes the same information that you see in IAM Access Analyzer for S3 on the Amazon S3 console.

To download a report

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane on the left, choose **Access analyzer for S3**.
3. In the Region filter, choose the Region.

IAM Access Analyzer for S3 updates to shows buckets for the chosen Region.

4. Choose **Download report**.

A CSV report is generated and saved to your computer.

Verifying bucket ownership with bucket owner condition

Amazon S3 bucket owner condition ensures that the buckets you use in your S3 operations belong to the AWS accounts that you expect.

Most S3 operations read from or write to specific S3 buckets. These operations include uploading, copying, and downloading objects, retrieving or modifying bucket configurations, and retrieving or modifying object configurations. When you perform these operations, you specify the bucket that you want to use by including its name with the request. For example, to retrieve an object from S3, you make a request that specifies the name of a bucket and the object key to retrieve from that bucket.

Because Amazon S3 identifies buckets based on their names, an application that uses an incorrect bucket name in a request could inadvertently perform operations against a different bucket than expected. To help avoid unintentional bucket interactions in situations like this, you can use *bucket owner condition*. Bucket owner condition enables you to verify that the target bucket is owned by the expected AWS account, providing an additional layer of assurance that your S3 operations are having the effects you intend.

Topics

- [When to use bucket owner condition](#)
- [Verifying a bucket owner](#)
- [Examples](#)
- [Restrictions and limitations](#)

When to use bucket owner condition

We recommend using bucket owner condition whenever you perform a supported S3 operation and know the account ID of the expected bucket owner. Bucket owner condition is available for all S3 object operations and most S3 bucket operations. For a list of S3 operations that don't support bucket owner condition, see [Restrictions and limitations](#).

To see the benefit of using bucket owner condition, consider the following scenario involving AWS customer Bea:

1. Bea develops an application that uses Amazon S3. During development, Bea uses her testing-only AWS account to create a bucket named `bea-data-test`, and configures her application to make requests to `bea-data-test`.
2. Bea deploys her application, but forgets to reconfigure the application to use a bucket in her production AWS account.
3. In production, Bea's application makes requests to `bea-data-test`, which succeed. This results in production data being written to the bucket in Bea's test account.

Bea can help protect against situations like this by using bucket owner condition. With bucket owner condition, Bea can include the AWS account ID of the expected bucket owner in her requests. Amazon S3 then checks the account ID of the bucket owner before processing each request. If the actual bucket owner doesn't match the expected bucket owner, the request fails.

If Bea uses bucket owner condition, the scenario described earlier won't result in Bea's application inadvertently writing to a test bucket. Instead, the requests that her application makes at step 3 will fail with an `Access Denied` error message. By using bucket owner condition, Bea helps eliminate the risk of accidentally interacting with buckets in the wrong AWS account.

Verifying a bucket owner

To use bucket owner condition, you include a parameter with your request that specifies the expected bucket owner. Most S3 operations involve only a single bucket, and require only this single parameter to use bucket owner condition. For `CopyObject` operations, this first parameter specifies the expected owner of the destination bucket, and you include a second parameter to specify the expected owner of the source bucket.

When you make a request that includes a bucket owner condition parameter, S3 checks the account ID of the bucket owner against the specified parameter before processing the request. If the parameter matches the bucket owner's account ID, S3 processes the request. If the parameter doesn't match the bucket owner's account ID, the request fails with an `Access Denied` error message.

You can use bucket owner condition with the AWS Command Line Interface (AWS CLI), AWS SDKs, and Amazon S3 REST APIs. When using bucket owner condition with the AWS CLI and Amazon S3 REST APIs, use the following parameter names.

Access method	Parameter for non-copy operations	Copy operation source parameter	Copy operation destination parameter
AWS CLI	--expected-bucket-owner	--expected-source-bucket-owner	--expected-bucket-owner
Amazon S3 REST APIs	x-amz-expected-bucket-owner header	x-amz-source-expected-bucket-owner header	x-amz-expected-bucket-owner header

The parameter names that are required to use bucket owner condition with the AWS SDKs vary depending on the language. To determine the required parameters, see the SDK documentation for your desired language. You can find the SDK documentation at [Tools to Build on AWS](#).

Examples

The following examples show how you can implement bucket owner condition in Amazon S3 using the AWS CLI or the AWS SDK for Java 2.x.

Example

Example: Upload an object

The following example uploads an object to S3 bucket `amzn-s3-demo-bucket1`, using bucket owner condition to ensure that `amzn-s3-demo-bucket1` is owned by AWS account 111122223333.

AWS CLI

```
aws s3api put-object \  
    --bucket amzn-s3-demo-bucket1 --key exampleobject --  
body example_file.txt \  
    --expected-bucket-owner 111122223333
```

AWS SDK for Java 2.x

```
public void putObjectExample() {  
    S3Client s3Client = S3Client.create();  
    PutObjectRequest request = PutObjectRequest.builder()  
        .bucket("amzn-s3-demo-bucket1")  
        .key("exampleobject")  
        .expectedBucketOwner("111122223333")  
        .build();  
    Path path = Paths.get("example_file.txt");  
    s3Client.putObject(request, path);  
}
```

Example

Example: Copy an object

The following example copies the object `object1` from S3 bucket `amzn-s3-demo-bucket1` to S3 bucket `amzn-s3-demo-bucket2`. It uses bucket owner condition to ensure that the buckets are owned by the expected accounts according to the following table.

Bucket	Expected owner
<code>amzn-s3-demo-bucket1</code>	111122223333
<code>amzn-s3-demo-bucket2</code>	444455556666

AWS CLI

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket1/object1 \
    --bucket amzn-s3-demo-bucket2 --key object1copy \
    --expected-source-bucket-owner 111122223333 --expected-
    bucket-owner 444455556666
```

AWS SDK for Java 2.x

```
public void copyObjectExample() {
    S3Client s3Client = S3Client.create();
    CopyObjectRequest request = CopyObjectRequest.builder()
        .copySource("amzn-s3-demo-bucket1/object1")
        .destinationBucket("amzn-s3-demo-bucket2")
        .destinationKey("object1copy")
        .expectedSourceBucketOwner("111122223333")
        .expectedBucketOwner("444455556666")
        .build();
    s3Client.copyObject(request);
}
```

Example

Example: Retrieve a bucket policy

The following example retrieves the access policy for S3 bucket *amzn-s3-demo-bucket1*, using bucket owner condition to ensure that *amzn-s3-demo-bucket1* is owned by AWS account 111122223333.

AWS CLI

```
aws s3api get-bucket-policy --bucket amzn-s3-demo-bucket1 --expected-bucket-
    owner 111122223333
```

AWS SDK for Java 2.x

```
public void getBucketPolicyExample() {
    S3Client s3Client = S3Client.create();
    GetBucketPolicyRequest request = GetBucketPolicyRequest.builder()
        .bucket("amzn-s3-demo-bucket1")
```

```
    .expectedBucketOwner("111122223333")
    .build();

try {
    GetBucketPolicyResponse response = s3Client.getBucketPolicy(request);
}
catch (S3Exception e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
}
}
```

Restrictions and limitations

Amazon S3 bucket owner condition has the following restrictions and limitations:

- The value of the bucket owner condition parameter must be an AWS account ID (12-digit numeric value). Service principals aren't supported.
- Bucket owner condition isn't available for [CreateBucket](#), [ListBuckets](#), or any of the operations included in [AWS S3 Control](#). Amazon S3 ignores any bucket owner condition parameters included with requests to these operations.
- Bucket owner condition only verifies that the account specified in the verification parameter owns the bucket. Bucket owner condition doesn't check the configuration of the bucket. It also doesn't guarantee that the bucket's configuration meets any specific conditions or matches any past state.

Controlling ownership of objects and disabling ACLs for your bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable [access control lists \(ACLs\)](#). By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you keep ACLs disabled except in circumstances where you must control access for

each object individually. With ACLs disabled, you can use policies to more easily control access to every object in your bucket, regardless of who uploaded the objects in your bucket.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

For the majority of modern use cases in S3, we recommend that you keep ACLs disabled by applying the Bucket owner enforced setting and using your bucket policy to share data with users outside of your account as needed. This approach simplifies permissions management. You can disable ACLs on both newly created and already existing buckets. For newly created buckets, ACLs are disabled by default. In the case of an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of an access evaluation, and access is granted or denied on the basis of policies. For existing buckets, you can re-enable ACLs at any time after you disable them, and your preexisting bucket and object ACLs are restored.

Before you disable ACLs, we recommend that you review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account. After you disable ACLs, your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs, for example, the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL expressed in XML. Existing applications that support bucket owner full control ACLs see no impact. PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return a 400 error with the error code `AccessControlListNotSupported`.

In contrast, a bucket with the Bucket owner preferred setting continues to accept and honor bucket and object ACLs. With this setting, new objects that are written with the bucket-owner-full-control canned ACL are automatically owned by the bucket owner rather than the object writer. All other ACL behaviors remain in place. To require all Amazon S3 PUT operations to include the bucket-owner-full-control canned ACL, you can [add a bucket policy](#) that allows only object uploads using this ACL.

To see which Object Ownership settings are applied to your buckets, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to find Object Ownership settings](#).

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Object Ownership settings

This table shows the impact that each Object Ownership setting has on ACLs, objects, object ownership, and object uploads.

Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
Bucket owner enforced (default)	All new and existing objects	Bucket owner owns every object.	ACLs are disabled and no longer affect access permissions to your bucket. Requests to set or update ACLs fail. However, requests to read ACLs are supported.	Uploads with bucket owner full control ACLs or uploads that don't specify an ACL

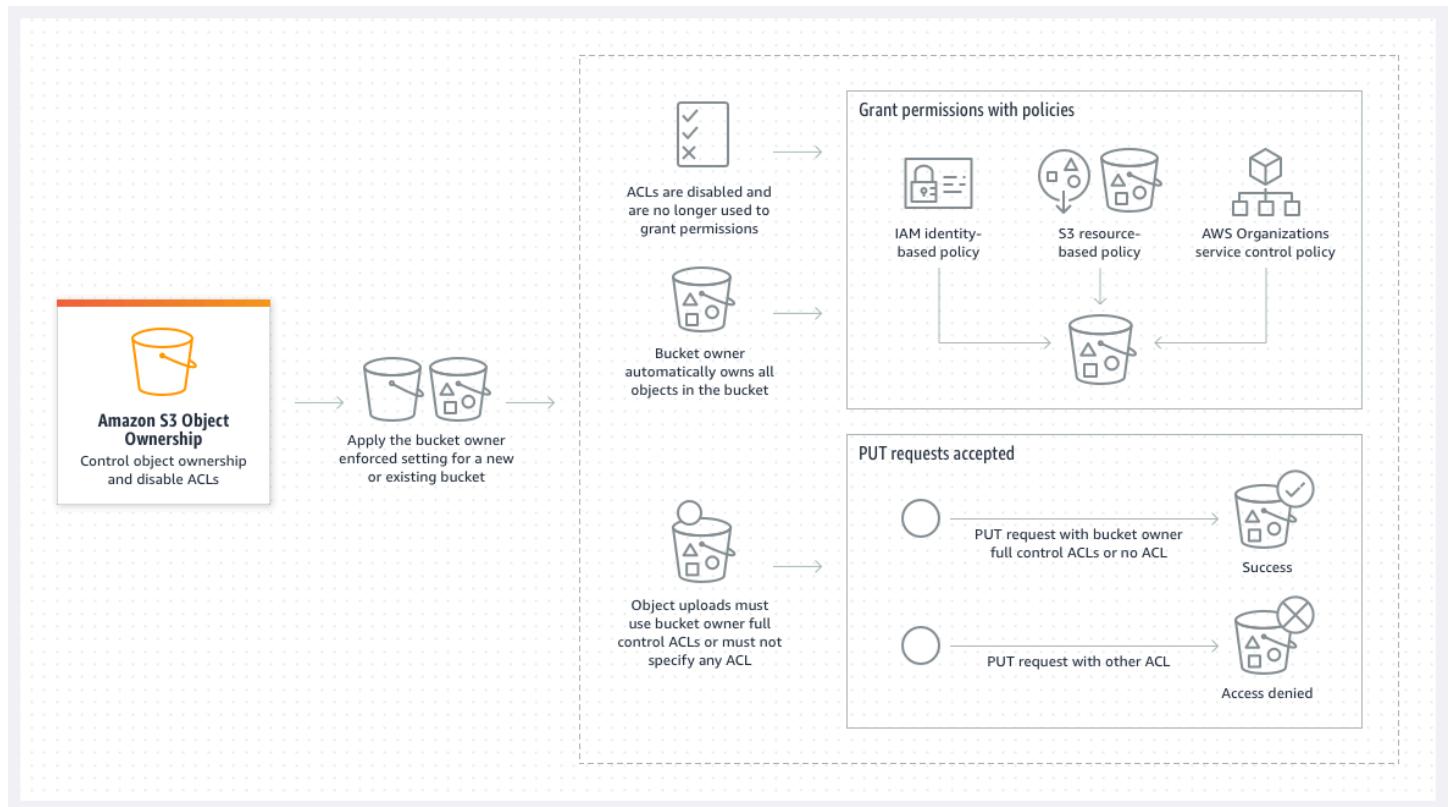

Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
			<p>Bucket owner has full ownership and control.</p> <p>Object writer no longer has full ownership and control.</p>	
Bucket owner preferred	New objects	<p>If an object upload includes the <code>bucket-owner-full-control</code> canned ACL, the bucket owner owns the object.</p> <p>Objects uploaded with other ACLs are owned by the writing account.</p>	<p>ACLs can be updated and can grant permissions.</p> <p>If an object upload includes the <code>bucket-owner-full-control</code> canned ACL, the bucket owner has full control access, and the object writer no longer has full control access.</p>	All uploads

Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
Object writer	New objects	Object writer owns the object.	ACLs can be updated and can grant permissions. Object writer has full control access.	All uploads

Changes introduced by disabling ACLs

When the Bucket owner enforced setting for Object Ownership is applied, ACLs are disabled and you automatically own and take full control over every object in the bucket without taking any additional actions. Bucket owner enforced is the default setting for all newly created buckets. After the Bucket owner enforced setting is applied, you will see three changes:

- All bucket ACLs and object ACLs are disabled, which gives full access to you, as the bucket owner. When you perform a read ACL request on your bucket or object, you will see that full access is given only to the bucket owner.
- You, as the bucket owner, automatically own and have full control over every object in your bucket.
- ACLs no longer affect access permissions to your bucket. As a result, access control for your data is based on policies, such as AWS Identity and Access Management (IAM) [identity-based policies](#), Amazon S3 [bucket policies](#), VPC endpoint policies, and Organizations [service control policies \(SCPs\)](#) or [resource control policies \(RCPs\)](#).

If you use S3 Versioning, the bucket owner owns and has full control over all object versions in your bucket. Applying the Bucket owner enforced setting does not add a new version of an object.

New objects can be uploaded to your bucket only if they use bucket owner full control ACLs or don't specify an ACL. Object uploads fail if they specify any other ACL. For more information, see [Troubleshooting](#).

Because the following example PutObject operation using the AWS Command Line Interface (AWS CLI) includes the `bucket-owner-full-control` canned ACL, the object can be uploaded to a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file --acl bucket-owner-full-control
```

Because the following PutObject operation doesn't specify an ACL, it also succeeds for a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file
```

Note

If other AWS accounts need access to objects after uploading, you must grant additional permissions to those accounts through bucket policies. For more information, see [Walkthroughs that use policies to manage access to your Amazon S3 resources](#).

Re-enabling ACLs

You can re-enable ACLs by changing from the Bucket owner enforced setting to another Object Ownership setting at any time. If you used object ACLs for permissions management before you applied the Bucket owner enforced setting and you didn't migrate these object ACL permissions to your bucket policy, after you re-enable ACLs, these permissions are restored. Additionally, objects written to the bucket while the Bucket owner enforced setting was applied are still owned by the bucket owner.

For example, if you change from the Bucket owner enforced setting back to the Object writer setting, you, as the bucket owner, no longer own and have full control over objects that were previously owned by other AWS accounts. Instead, the uploading accounts again own these objects. Objects owned by other accounts use ACLs for permissions, so you can't use policies to grant permissions to these objects. However, you, as the bucket owner, still own any objects that were written to the bucket while the Bucket owner enforced setting was applied. These objects are not owned by the object writer, even if you re-enable ACLs.

For instructions on enabling and managing ACLs using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs, see [Configuring ACLs](#).

Prerequisites for disabling ACLs

Before you disable ACLs for an existing bucket, complete the following prerequisites.

- [Review bucket and object ACLs and migrate ACL permissions](#)
- [Identify requests that required an ACL for authorization](#)
- [Review and update bucket policies that use ACL-related condition keys](#)

Object Ownership permissions

To apply, update, or delete an Object Ownership setting for a bucket, you need the `s3:PutBucketOwnershipControls` permission. To return the Object Ownership setting for a bucket, you need the `s3:GetBucketOwnershipControls` permission. For more information, see [Setting Object Ownership when you create a bucket](#) and [Viewing the Object Ownership setting for an S3 bucket](#).

Disabling ACLs for all new buckets

By default, all new buckets are created with the Bucket owner enforced setting applied and ACLs are disabled. We recommend keeping ACLs disabled. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM policies for access control instead of ACLs. Policies are a simplified and more flexible access control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources.

Replication and Object Ownership

When you use S3 replication and the source and destination buckets are owned by different AWS accounts, you can disable ACLs (with the Bucket owner enforced setting for Object Ownership) to change replica ownership to the AWS account that owns the destination bucket. This setting mimics the existing owner override behavior without the need of the `s3:ObjectOwnerOverrideToBucketOwner` permission. All objects that are replicated to the destination bucket with the Bucket owner enforced setting are owned by the destination bucket owner. For more information about the owner override option for replication configurations, see [Changing the replica owner](#).

Setting Object Ownership

You can apply an Object Ownership setting by using the Amazon S3 console, AWS CLI, AWS SDKs, Amazon S3 REST API, or AWS CloudFormation. The following REST API and AWS CLI commands support Object Ownership:

REST API	AWS CLI	Description
PutBucketOwnershipControls	put-bucket-ownership-controls	Creates or modifies the Object Ownership setting for an existing S3 bucket.
CreateBucket	create-bucket	Creates a bucket using the <code>x-amz-object-ownership</code> request header to specify the Object Ownership setting.
GetBucketOwnershipControls	get-bucket-ownership-controls	Retrieves the Object Ownership setting for an Amazon S3 bucket.
DeleteBucketOwnershipControls	delete-bucket-ownership-controls	Deletes the Object Ownership setting for an Amazon S3 bucket.

For more information about applying and working with Object Ownership settings, see the following topics.

Topics

- [Prerequisites for disabling ACLs](#)
- [Setting Object Ownership when you create a bucket](#)
- [Setting Object Ownership on an existing bucket](#)
- [Viewing the Object Ownership setting for an S3 bucket](#)
- [Disabling ACLs for all new buckets and enforcing Object Ownership](#)
- [Troubleshooting](#)

Prerequisites for disabling ACLs

A bucket access control list (ACL) in Amazon S3 is a mechanism that allows you to define granular permissions for individual objects within an S3 bucket, specifying which AWS accounts or groups can access and modify those objects. A majority of modern use cases in Amazon S3 no longer

require the use of ACLs. We recommend that you use AWS Identity and Access Management (IAM) and bucket policies to manage access, and to keep ACLs disabled, except in circumstances where you need to control access for each object individually.

If you have ACLs enabled on your bucket, before you disable ACLs, complete the following prerequisites:

Topics

- [Review bucket and object ACLs and migrate ACL permissions](#)
- [Identify requests that required an ACL for authorization](#)
- [Review and update bucket policies that use ACL-related condition keys](#)
- [Example use cases](#)

Review bucket and object ACLs and migrate ACL permissions

When you disable ACLs, permissions granted by bucket and object ACLs no longer affect access. Before you disable ACLs, review your bucket and object ACLs.

Each of your existing bucket and object ACLs has an equivalent in an IAM policy. The following bucket policy examples show you how READ and WRITE permissions for bucket and object ACLs map to IAM permissions. For more information about how each ACL translates to IAM permissions, see [Mapping of ACL permissions and access policy permissions](#).

Before you disable ACLs:

- If your bucket ACL grants access outside of your AWS account, first, you must migrate your bucket ACL permissions to your bucket policy.
- Next, reset your bucket ACL to the default private ACL.
- We also recommend that you review your object-level ACL permissions and migrate them to your bucket policy.

If your bucket ACLs grant read or write permissions to others outside of your account, before you can disable ACLs, you must migrate these permissions to your bucket policy. After you migrate these permissions, you can set **Object Ownership** to the *Bucket owner enforced* setting. If you don't migrate bucket ACLs that grant read or write access outside of your account, your request to apply the Bucket owner enforced setting fails and returns the [InvalidBucketAclWithObjectOwnership](#) error code.

If your bucket ACL grants access outside of your AWS account, before you disable ACLs, you must migrate your bucket ACL permissions to your bucket policy and reset your bucket ACL to the default private ACL. If you don't migrate and reset, your request to apply the Bucket owner enforced setting to disable ACLs fails and returns the [InvalidBucketAclWithObjectOwnership](#) error code. We also recommend that you review your object ACL permissions and migrate them to your bucket policy.

To review and migrate ACL permissions to bucket policies, see the following topics.

Topics

- [Bucket policies examples](#)
- [Using the S3 console to review and migrate ACL permissions](#)
- [Using the AWS CLI to review and migrate ACL permissions](#)

Bucket policies examples

These example bucket policies show you how to migrate READ and WRITE bucket and object ACL permissions for a third-party AWS account to a bucket policy. READ_ACP and WRITE_ACP ACLs are less relevant for policies because they grant ACL-related permissions (s3:GetBucketAcl, s3:GetObjectAcl, s3:PutBucketAcl, and s3:PutObjectAcl).

Example – READ ACL for a bucket

If your bucket had a READ ACL that grants AWS account **111122223333** permission to list the contents of your bucket, you can write a bucket policy that grants s3>ListBucket, s3>ListBucketVersions, s3>ListBucketMultipartUploads permissions for your bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Permission to list the objects in a bucket",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:root"  
                ]  
            }  
        }  
    ]  
}
```

```
        "arn:aws:iam::111122223333:root"
    ],
},
"Action": [
    "s3>ListBucket",
    "s3>ListBucketVersions",
    "s3>ListBucketMultipartUploads"
],
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
}
]
}
```

Example – READ ACLs for every object in a bucket

If every object in your bucket has a READ ACL that grants access to AWS account **111122223333**, you can write a bucket policy that grants s3:GetObject and s3:GetObjectVersion permissions to this account for every object in your bucket.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Read permission for every object in a bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root"
                ]
            },
            "Action": [
                "s3GetObject",
                "s3GetObjectVersion"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

This example resource element grants access to a specific object.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/OBJECT-KEY"
```

Example – WRITE ACL that grants permissions to write objects to a bucket

If your bucket has a WRITE ACL that grants AWS account **111122223333** permission to write objects to your bucket, you can write a bucket policy that grants s3:PutObject permission for your bucket.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Permission to write objects to a bucket",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::111122223333:root"
        ]
      },
      "Action": [
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
    }
  ]
}
```

Using the S3 console to review and migrate ACL permissions

To review a bucket's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket name.
3. Choose the **Permissions** tab.

4. Under **Access control list (ACL)**, review your bucket ACL permissions.

To review an object's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket name containing your object.
3. In the **Objects** list, choose your object name.
4. Choose the **Permissions** tab.
5. Under **Access control list (ACL)**, review your object ACL permissions.

To migrate ACL permissions and update your bucket ACL

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket name.
3. On the **Permissions** tab, under **Bucket policy**, choose **Edit**.
4. In the **Policy** box, add or update your bucket policy.

For example bucket policies, see [Bucket policies examples](#) and [Example use cases](#).

5. Choose **Save changes**.
6. [Update your bucket ACL](#) to remove ACL grants to other groups or AWS accounts.
7. [Apply the Bucket owner enforced setting](#) for Object Ownership.

Using the AWS CLI to review and migrate ACL permissions

1. To return the bucket ACL for your bucket, use the [get-bucket-acl](#) AWS CLI command:

```
aws s3api get-bucket-acl --bucket amzn-s3-demo-bucket
```

For example, this bucket ACL grants WRITE and READ access to a third-party account. In this ACL, the third-party account is identified by the [canonical user ID](#). To apply the Bucket owner enforced setting and disable ACLs, you must migrate these permissions for the third-party account to a bucket policy.

```
{  
    "Owner": {  
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
    },  
    "Grants": [  
        {  
            "Grantee": {  
                "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "FULL_CONTROL"  
        },  
        {  
            "Grantee": {  
                "ID":  
                    "72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "READ"  
        },  
        {  
            "Grantee": {  
                "ID":  
                    "72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "WRITE"  
        }  
    ]  
}
```

For other example ACLs, see [Example use cases](#).

2. Migrate your bucket ACL permissions to a bucket policy:

This example bucket policy grants s3:PutObject and s3>ListBucket permissions for a third-party account. In the bucket policy, the third-party account is identified by the AWS account ID ([111122223333](#)).

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy file://  
policy.json
```

```
policy.json:  
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PolicyForCrossAccountAllowUpload",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:root"  
                ]  
            },  
            "Action": [  
                "s3:PutObject",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3::::amzn-s3-demo-bucket",  
                "arn:aws:s3::::amzn-s3-demo-bucket/*"  
            ]  
        }  
    ]  
}
```

For more example bucket policies, see [Bucket policies examples](#) and [Example use cases](#).

3. To return the ACL for a specific object, use the [get-object-acl](#) AWS CLI command.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket --key EXAMPLE-OBJECT-KEY
```

4. If required, migrate object ACL permissions to your bucket policy.

This example resource element grants access to a specific object in a bucket policy.

```
"Resource": "arn:aws:s3::::amzn-s3-demo-bucket/EXAMPLE-OBJECT-KEY"
```

5. Reset the ACL for your bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

6. [Apply the Bucket owner enforced setting](#) for Object Ownership.

Identify requests that required an ACL for authorization

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. If the request required an ACL for authorization or if you have PUT requests that specify an ACL, the string is Yes. If no ACLs were required, or if you are setting a `bucket-owner-full-control` canned ACL, or if the requests are allowed by your bucket policy, the `aclRequired` value string is "-" in Amazon S3 server access logs and is absent in CloudTrail. For more information about the expected `aclRequired` values, see [aclRequired values for common Amazon S3 requests](#).

If you have `PutBucketAcl` or `PutObjectAcl` requests with headers that grant ACL-based permissions, with the exception of the `bucket-owner-full-control` canned ACL, you must remove those headers before you can disable ACLs. Otherwise, your requests will fail.

For all other requests that required an ACL for authorization, migrate those ACL permissions to bucket policies. Then, remove any bucket ACLs before you enable the bucket owner enforced setting.

 **Note**

Do not remove object ACLs. Otherwise, applications that rely on object ACLs for permissions will lose access.

If you see that no requests required an ACL for authorization, you can proceed to disable ACLs. For more information about identifying requests, see [Using Amazon S3 server access logs to identify requests](#) and [Identifying Amazon S3 requests using CloudTrail](#).

Review and update bucket policies that use ACL-related condition keys

After you apply the Bucket owner enforced setting to disable ACLs, new objects can be uploaded to your bucket only if the request uses bucket owner full control ACLs or doesn't specify an ACL. Before disabling ACLs, review your bucket policy for ACL-related condition keys.

If your bucket policy uses an ACL-related condition key to require the `bucket-owner-full-control` canned ACL (for example, `s3:x-amz-acl`), you don't need to update your bucket policy. The following bucket policy uses the `s3:x-amz-acl` to require the `bucket-owner-full-control` canned ACL for S3 `PutObject` requests. This policy *still* requires the object writer to

specify the bucket-owner-full-control canned ACL. However, buckets with ACLs disabled still accept this ACL, so requests continue to succeed with no client-side changes required.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "OnlyAllowWritesToMyBucketWithBucketOwnerFullControl",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/ExampleUser"  
                ]  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": "bucket-owner-full-control"  
                }  
            }  
        }  
    ]  
}
```

However, if your bucket policy uses an ACL-related condition key that requires a different ACL, you must remove this condition key. This example bucket policy requires the public-read ACL for S3 PutObject requests and therefore must be updated before disabling ACLs.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Only allow writes to my bucket with public read access",  
            "Effect": "Allow",  
            "Principal": "*"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Principal": {
            "AWS": [
                "arn:aws:iam::111122223333:user/ExampleUser"]
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "public-read"
                }
            }
        }
    }
}
```

Example use cases

The following examples show you how to migrate ACL permissions to bucket policies for specific use cases.

Topics

- [Grant access to the S3 log delivery group for server access logging](#)
- [Grant public read access to the objects in a bucket](#)
- [Grant Amazon ElastiCache \(Redis OSS\) access to your S3 bucket](#)

Grant access to the S3 log delivery group for server access logging

If you want to apply the Bucket owner enforced setting to disable ACLs for a server access logging destination bucket (also known as a *target bucket*), you must migrate bucket ACL permissions for the S3 log delivery group to the logging service principal (`logging.s3.amazonaws.com`) in a bucket policy. For more information about log delivery permissions, see [Permissions for log delivery](#).

This bucket ACL grants `WRITE` and `READ_ACP` access to the S3 log delivery group:

```
{
    "Owner": {
```

```
"ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
},
"Grants": [
{
    "Grantee": {
        "Type": "CanonicalUser",
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Permission": "FULL_CONTROL"
},
{
    "Grantee": {
        "Type": "Group",
        "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
    },
    "Permission": "WRITE"
},
{
    "Grantee": {
        "Type": "Group",
        "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
    },
    "Permission": "READ_ACP"
}
]
}
```

To migrate bucket ACL permissions for the S3 log delivery group to the logging service principal in a bucket policy

1. Add the following bucket policy to your destination bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy file://policy.json

policy.json:      {
    {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3ServerAccessLogsPolicy",
            "Effect": "Allow",
            "Principal": "acs.amazonaws.com/groups/s3/LogDelivery"
        }
    ]
}
```

```
        "Principal": {
            "Service": "logging.s3.amazonaws.com"
        },
        "Action": [
            "s3:PutObject"
        ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/EXAMPLE-LOGGING-PREFIX*",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:s3:::SOURCE-BUCKET-NAME"
            },
            "StringEquals": {
                "aws:SourceAccount": "SOURCE-AWS-ACCOUNT-ID"
            }
        }
    }
]
```

2. Reset the ACL for your destination bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. [Apply the Bucket owner enforced setting](#) for Object Ownership to your destination bucket.

Grant public read access to the objects in a bucket

If your object ACLs grant public read access to all of the objects in your bucket, you can migrate these ACL permissions to a bucket policy.

This object ACL grants public read access to an object in a bucket:

```
{
    "Owner": {
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },

```

```
        "Permission": "FULL_CONTROL"
    },
    {
        "Grantee": {
            "Type": "Group",
            "URI": "http://acs.amazonaws.com/groups/global/AllUsers"
        },
        "Permission": "READ"
    }
]
```

To migrate public read ACL permissions to a bucket policy

1. To grant public read access to all of the objects in your bucket, add the following bucket policy, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy  
file://policy.json
```

```
policy.json:  
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket/*"  
            ]  
        }  
    ]  
}
```

To grant public access to a specific object in a bucket policy, use the following format for the Resource element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/OBJECT-KEY"
```

To grant public access to all of the objects with a specific prefix, use the following format for the Resource element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/PREFIX/*"
```

2. Apply the Bucket owner enforced setting for Object Ownership.

Grant Amazon ElastiCache (Redis OSS) access to your S3 bucket

You can [export your ElastiCache \(Redis OSS\) backup](#) to an S3 bucket, which gives you access to the backup from outside ElastiCache. To export your backup to an S3 bucket, you must grant ElastiCache permissions to copy a snapshot to the bucket. If you've granted permissions to ElastiCache in a bucket ACL, you must migrate these permissions to a bucket policy before you apply the Bucket owner enforced setting to disable ACLs. For more information, see [Grant ElastiCache access to your Amazon S3 bucket](#) in the *Amazon ElastiCache User Guide*.

The following example shows the bucket ACL permissions that grant permissions to ElastiCache.

```
{
    "Owner": {
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "ID":
"852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "ID":
"540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
                "Type": "CanonicalUser"
            },
            "Permission": "READ"
        }
    ]
}
```

```
},
{
    "Grantee": {
        "ID": "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
        "Type": "CanonicalUser"
    },
    "Permission": "WRITE"
},
{
    "Grantee": {
        "ID": "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
        "Type": "CanonicalUser"
    },
    "Permission": "READ_ACP"
}
]
```

To migrate bucket ACL permissions for ElastiCache (Redis OSS) to a bucket policy

1. Add the following bucket policy to your bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy
file://policy.json

policy.json:
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Stmt15399483",
            "Effect": "Allow",
            "Principal": {
                "Service": "Region.elasticache-snapshot.amazonaws.com"
            },
            "Action": [
                "s3:PutObject",
                "s3:GetObject",
                "s3>ListBucket",
                "s3:GetBucketAcl",
                "s3>ListMultipartUploadParts",
            ]
        }
    ]
}
```

```
        "s3>ListBucketMultipartUploads"
    ],
    "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
    ]
}
```

2. Reset the ACL for your bucket to the default ACL:

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. [Apply the Bucket owner enforced setting](#) for Object Ownership.

Setting Object Ownership when you create a bucket

When you create a bucket, you can configure S3 Object Ownership. To set Object Ownership for an existing bucket, see [Setting Object Ownership on an existing bucket](#).

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Permissions: To apply the **Bucket owner enforced** setting or the **Bucket owner preferred** setting, you must have the following permissions: `s3:CreateBucket` and `s3:PutBucketOwnershipControls`. No additional permissions are needed when creating a bucket with the **Object writer** setting applied. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3 in the Service Authorization Reference](#).

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Important

A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you disable ACLs except in circumstances where you need to control access for each object individually. With Object Ownership, you can disable ACLs and rely on policies for access control. When you disable ACLs, you can easily maintain a bucket with objects uploaded by different AWS accounts. You, as the bucket owner, own all the objects in the bucket and can manage access to them using policies.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

- After you create a bucket, you can't change its Region.

- To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

- In the left navigation pane, choose **General purpose buckets**.
- Choose **Create bucket**. The **Create bucket** page opens.
- For **Bucket name**, enter a name for your bucket.

The bucket name must:

- Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (commercial Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions).
- Be between 3 and 63 characters long.
- Consist only of lowercase letters, numbers, periods (.), and hyphens (-). For best compatibility, we recommend that you avoid using periods (.) in bucket names, except for buckets that are used only for static website hosting.
- Begin and end with a letter or number.
- For a complete list of bucket-naming rules, see [General purpose bucket naming rules](#).

Important

- After you create the bucket, you can't change its name.
- Don't include sensitive information in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

- (Optional) Under **General configuration**, you can choose to copy an existing bucket's settings to your new bucket. If you don't want to copy the settings of an existing bucket, skip to the next step.

Note

This option:

- Isn't available in the AWS CLI and is only available in the Amazon S3 console

- Doesn't copy the bucket policy from the existing bucket to the new bucket

To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you want to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window reopens.

Under **Copy settings from existing bucket**, you now see the name of the bucket that you selected. The settings of your new bucket now match the settings of the bucket that you selected. If you want to remove the copied settings, choose **Restore defaults**. Review the remaining bucket settings on the **Create bucket** page. If you don't want to make any changes, you can skip to the final step.

7. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the general purpose bucket. ACLs no longer affect access permissions to data in the S3 general purpose bucket. The bucket uses policies exclusively to define access control.

By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you must control access for each object individually. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can [add a bucket policy](#) that allows only object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

 **Note**

The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

8. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

 **Note**

To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

9. (Optional) By default, **Bucket Versioning** is disabled. Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can recover more easily from both unintended user actions and application failures. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

To enable versioning on your bucket, choose **Enable**.

10. (Optional) Under **Tags**, you can choose to add tags to your bucket. With AWS cost allocation, you can use bucket tags to annotate billing for your use of a bucket. A tag is a key-value pair that represents a label that you assign to a bucket. For more information, see [the section called "Using cost allocation tags"](#).

To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

11. To configure **Default encryption**, under **Encryption type**, choose one of the following:

- **Server-side encryption with Amazon S3 managed keys (SSE-S3)**
- **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
- **Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**

⚠ Important

If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas in the AWS Key Management Service Developer Guide](#).

Buckets and new objects are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption configuration. For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about SSE-S3, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

For more information about using server-side encryption to encrypt your data, see [the section called “Data encryption”](#).

12. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**, do the following:
 - a. Under **AWS KMS key**, specify your KMS key in one of the following ways:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.
 - Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys in the AWS Key Management Service Developer Guide](#).
 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.

- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

⚠ Important

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that isn't listed, you must enter your KMS key ARN. If you want to use a KMS key that's owned by a different account, you must first have permission to use the key, and then you must enter the KMS key ARN. For more information about cross account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*. For more information about SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#). For more information about DSSE-KMS, see [the section called “Dual-layer server-side encryption \(DSSE-KMS\)”](#). When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

- b. When you configure your bucket to use default encryption with SSE-KMS, you can also use S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#). S3 Bucket Keys aren't supported for DSSE-KMS.

By default, S3 Bucket Keys are enabled in the Amazon S3 console. We recommend leaving S3 Bucket Keys enabled to lower your costs. To disable S3 Bucket Keys for your bucket, under **Bucket Key**, choose **Disable**.

13. (Optional) S3 Object Lock helps protect new objects from being deleted or overwritten. For more information, see [Locking objects with Object Lock](#). If you want to enable S3 Object Lock, do the following:

- a. Choose **Advanced settings**.

⚠️ Important

Enabling Object Lock automatically enables versioning for the bucket. After you've enabled and successfully created the bucket, you must also configure the Object Lock default retention and legal hold settings on the bucket's **Properties** tab.

- b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

ⓘ Note

To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning`, and `s3:PutBucketObjectLockConfiguration`.

14. Choose **Create bucket**.

Using the AWS CLI

To set Object Ownership when you create a new bucket, use the `create-bucket` AWS CLI command with the `--object-ownership` parameter.

This example applies the Bucket owner enforced setting for a new bucket using the AWS CLI:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket --region us-east-1 --object-ownership BucketOwnerEnforced
```

⚠️ Important

If you don't set Object Ownership when you create a bucket by using the AWS CLI, the default setting will be `ObjectWriter` (ACLs enabled).

Using the AWS SDK for Java

This example sets the Bucket owner enforced setting for a new bucket using the AWS SDK for Java:

```
// Build the ObjectOwnership for CreateBucket
```

```
CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
    .bucket(bucketName)
    .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
    .build()

// Send the request to Amazon S3
s3client.createBucket(createBucketRequest);
```

Using CloudFormation

To use the AWS::S3::Bucket CloudFormation resource to set Object Ownership when you create a new bucket, see [OwnershipControls within AWS::S3::Bucket](#) in the *AWS CloudFormation User Guide*.

Using the REST API

To apply the Bucket owner enforced setting for S3 Object Ownership, use the `CreateBucket` API operation with the `x-amz-object-ownership` request header set to `BucketOwnerEnforced`. For information and examples, see [CreateBucket](#) in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- [Bucket owner enforced](#) – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.
- [Bucket owner preferred](#) – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

Setting Object Ownership on an existing bucket

You can configure S3 Object Ownership on an existing S3 bucket. To apply Object Ownership when you create a bucket, see [Setting Object Ownership when you create a bucket](#).

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using

access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Prerequisites: Before you apply the Bucket owner enforced setting to disable ACLs, you must migrate bucket ACL permissions to bucket policies and reset your bucket ACLs to the default private ACL. We also recommend that you migrate object ACL permissions to bucket policies and edit bucket policies that require ACLs other than bucket owner full control ACLs. For more information, see [Prerequisites for disabling ACLs](#).

Permissions: To use this operation, you must have the `s3:PutBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an S3 Object Ownership setting to.

3. Choose the **Permissions** tab.
4. Under **Object Ownership**, choose **Edit**.
5. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

To require that all new buckets are created with ACLs disabled by using IAM or AWS Organizations policies, see [Disabling ACLs for all new buckets \(bucket owner enforced\)](#).

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

If you apply the bucket owner preferred setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can [add a bucket policy](#) that only allows object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

6. Choose **Save**.

Using the AWS CLI

To apply an Object Ownership setting for an existing bucket, use the `put-bucket-ownership-controls` command with the `--ownership-controls` parameter. Valid values for ownership are `BucketOwnerEnforced`, `BucketOwnerPreferred`, or `ObjectWriter`.

This example applies the Bucket owner enforced setting for an existing bucket by using the AWS CLI:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-controls="Rules=[{ObjectOwnership=BucketOwnerEnforced}]"]
```

For information about `put-bucket-ownership-controls`, see [put-bucket-ownership-controls](#) in the *AWS Command Line Interface User Guide*.

Using the AWS SDK for Java

This example applies the `BucketOwnerEnforced` setting for Object Ownership on an existing bucket by using the AWS SDK for Java:

```
// Build the ObjectOwnership for BucketOwnerEnforced
OwnershipControlsRule rule = OwnershipControlsRule.builder()
    .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
    .build();

OwnershipControls ownershipControls = OwnershipControls.builder()
    .rules(rule)
    .build()

// Build the PutBucketOwnershipControlsRequest
PutBucketOwnershipControlsRequest putBucketOwnershipControlsRequest =
    PutBucketOwnershipControlsRequest.builder()
        .bucket(BUCKET_NAME)
        .ownershipControls(ownershipControls)
        .build();

// Send the request to Amazon S3
s3client.putBucketOwnershipControls(putBucketOwnershipControlsRequest);
```

Using CloudFormation

To use CloudFormation to apply an Object Ownership setting for an existing bucket, see [AWS::S3::Bucket OwnershipControls](#) in the *AWS CloudFormation User Guide*.

Using the REST API

To use the REST API to apply an Object Ownership setting to an existing S3 bucket, use `PutBucketOwnershipControls`. For more information, see [PutBucketOwnershipControls](#) in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- [Bucket owner enforced](#) – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.

- [**Bucket owner preferred**](#) – Add an S3 bucket policy to require the bucket-owner-full-control canned ACL for all object uploads to your bucket.

Viewing the Object Ownership setting for an S3 bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the bucket-owner-full-control canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

You can view the S3 Object Ownership settings for an Amazon S3 bucket. To set Object Ownership for a new bucket, see [Setting Object Ownership when you create a bucket](#). To set Object Ownership for an existing bucket, see [Setting Object Ownership on an existing bucket](#).

Permissions: To use this operation, you must have the `s3:GetBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an Object Ownership setting to.
3. Choose the **Permissions** tab.
4. Under **Object Ownership**, you can view the Object Ownership settings for your bucket.

Using the AWS CLI

To retrieve the S3 Object Ownership setting for an S3 bucket, use the [get-bucket-ownership-controls](#) AWS CLI command.

```
aws s3api get-bucket-ownership-controls --bucket amzn-s3-demo-bucket
```

Using the REST API

To retrieve the Object Ownership setting for an S3 bucket, use the `GetBucketOwnershipControls` API operation. For more information, see [GetBucketOwnershipControls](#).

Disabling ACLs for all new buckets and enforcing Object Ownership

We recommend that you disable ACLs on your Amazon S3 buckets. You can do this by applying the Bucket owner enforced setting for S3 Object Ownership. When you apply this setting, ACLs are disabled and you automatically own and have full control over all objects in your bucket. To require that all new buckets are created with ACLs disabled, use AWS Identity and Access Management (IAM) policies or AWS Organizations service control policies (SCPs), as described in the next section.

To enforce object ownership for new objects without disabling ACLs, you can apply the Bucket owner preferred setting. When you apply this setting, we strongly recommend that you update your bucket policy to require the `bucket-owner-full-control` canned ACL for all PUT requests to your bucket. Make sure you also update your clients to send the `bucket-owner-full-control` canned ACL to your bucket from other accounts.

Topics

- [Disabling ACLs for all new buckets \(bucket owner enforced\)](#)
- [Requiring the bucket-owner-full-control canned ACL for Amazon S3 PUT operations \(bucket owner preferred\)](#)

Disabling ACLs for all new buckets (bucket owner enforced)

The following example IAM policy denies the s3:CreateBucket permission for a specific IAM user or role unless the Bucket owner enforced setting is applied for Object Ownership. The key-value pair in the Condition block specifies s3:x-amz-object-ownership as its key and the BucketOwnerEnforced setting as its value. In other words, the IAM user can create buckets only if they set the Bucket owner enforced setting for Object Ownership and disable ACLs. You can also use this policy as a boundary SCP for your AWS organization.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "RequireBucketOwnerFullControl",  
            "Action": "s3:CreateBucket",  
            "Effect": "Deny",  
            "Resource": "*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-object-ownership": "BucketOwnerEnforced"  
                }  
            }  
        }  
    ]  
}
```

Requiring the bucket-owner-full-control canned ACL for Amazon S3 PUT operations (bucket owner preferred)

With the Bucket owner preferred setting for Object Ownership, you, as the bucket owner, own and have full control over new objects that other accounts write to your bucket with the bucket-

owner-full-control canned ACL. However, if other accounts write objects to your bucket without the bucket-owner-full-control canned ACL, the object writer maintains full control access. You, as the bucket owner, can implement a bucket policy that allows writes only if they specify the bucket-owner-full-control canned ACL.

Note

If you have ACLs disabled with the Bucket owner enforced setting, you, as the bucket owner, automatically own and have full control over all the objects in your bucket. You don't need to use this section to update your bucket policy to enforce object ownership for the bucket owner.

The following bucket policy specifies that account **111122223333** can upload objects to **amzn-s3-demo-bucket** only when the object's ACL is set to bucket-owner-full-control. Be sure to replace **111122223333** with your account and **amzn-s3-demo-bucket** with the name of your bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "OnlyAllowWritesToMyBucketWithBucketOwnerFullControl",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/ExampleUser"  
                ]  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": "bucket-owner-full-control"  
                }  
            }  
        }  
    ]  
}
```

```
}
```

```
]
```

```
}
```

The following is an example copy operation that includes the bucket-owner-full-control canned ACL by using the AWS Command Line Interface (AWS CLI).

```
aws s3 cp file.txt s3://amzn-s3-demo-bucket --acl bucket-owner-full-control
```

After the bucket policy is put into effect, if the client does not include the bucket-owner-full-control canned ACL, the operation fails, and the uploader receives the following error:

An error occurred (AccessDenied) when calling the PutObject operation: Access Denied.

Note

If clients need access to objects after uploading, you must grant additional permissions to the uploading account. For information about granting accounts access to your resources, see [Walkthroughs that use policies to manage access to your Amazon S3 resources](#).

Troubleshooting

When you apply the Bucket owner enforced setting for S3 Object Ownership, access control lists (ACLs) are disabled and you, as the bucket owner, automatically own all objects in your bucket. ACLs no longer affect permissions for the objects in your bucket. You can use policies to grant permissions. All S3 PUT requests must either specify the bucket-owner-full-control canned ACL or not specify an ACL, or these requests will fail. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

If an invalid ACL is specified or bucket ACL permissions grant access outside of your AWS account, you might see the following error responses.

AccessControlListNotSupported

After you apply the Bucket owner enforced setting for Object Ownership, ACLs are disabled. Requests to set ACLs or update ACLs fail with a 400 error and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported. Requests

to read ACLs always return a response that shows full control for the bucket owner. In your PUT operations, you must either specify bucket owner full control ACLs or not specify an ACL. Otherwise, your PUT operations fail.

The following example put-object AWS CLI command includes the public-read canned ACL.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key object-key-name --body doc-example-body --acl public-read
```

If the bucket uses the Bucket owner enforced setting to disable ACLs, this operation fails, and the uploader receives the following error message:

An error occurred (AccessControlListNotSupported) when calling the PutObject operation: The bucket does not allow ACLs

InvalidBucketAclWithObjectOwnership

If you want to apply the Bucket owner enforced setting to disable ACLs, your bucket ACL must give full control only to the bucket owner. Your bucket ACL cannot give access to an external AWS account or any other group. For example, if your CreateBucket request sets Bucket owner enforced and specifies a bucket ACL that provides access to an external AWS account, your request fails with a 400 error and returns the InvalidBucketAclWithObjectOwnership error code. Similarly, if your PutBucketOwnershipControls request sets Bucket owner enforced on a bucket that has a bucket ACL that grants permissions to others, the request fails.

Example : Existing bucket ACL grants public read access

For example, if an existing bucket ACL grants public read access, you cannot apply the Bucket owner enforced setting for Object Ownership until you migrate these ACL permissions to a bucket policy and reset your bucket ACL to the default private ACL. For more information, see [Prerequisites for disabling ACLs](#).

This example bucket ACL grants public read access:

```
{  
    "Owner": {  
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
    },  
    "Grants": [  
        {  
            "Grantee": {  
                "Type": "Group",  
                "URI": "http://acs.amazonaws.com/groups/global/AllUsers"  
            },  
            "Permission": "Read"  
        }  
    ]  
}
```

```
{  
    "Grantee": {  
        "ID":  
"852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",  
        "Type": "CanonicalUser"  
    },  
    "Permission": "FULL_CONTROL"  
},  
{  
    "Grantee": {  
        "Type": "Group",  
        "URI": "http://acs.amazonaws.com/groups/global/AllUsers"  
    },  
    "Permission": "READ"  
}  
]  
}
```

The following example `put-bucket-ownership-controls` AWS CLI command applies the Bucket owner enforced setting for Object Ownership:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-  
controls Rules=[{ObjectOwnership=BucketOwnerEnforced}]
```

Because the bucket ACL grants public read access, the request fails and returns the following error code:

An error occurred (`InvalidBucketAclWithObjectOwnership`) when calling the `PutBucketOwnershipControls` operation: Bucket cannot have ACLs set with ObjectOwnership's `BucketOwnerEnforced` setting

Security in Amazon S3

Important

Starting in April 2026, AWS will disable server-side encryption with customer-provided keys (SSE-C) for all new buckets. In addition, SSE-C encryption will be disabled for all existing buckets in AWS accounts that do not have any SSE-C encrypted data. With these changes, the few applications that need SSE-C encryption must deliberately enable the use SSE-C via the [PutBucketEncryption](#) API after creating the bucket. In these cases, you might need to update automation scripts, CloudFormation templates, or other infrastructure configuration tools to configure these settings. For more information, see the [AWS Storage Blog post](#).

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

Security of the cloud

AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to Amazon S3, see [AWS Services in Scope by Compliance Program](#).

Security in the cloud

Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations. For Amazon S3, your responsibility includes the following areas:

- Managing your data, including [object ownership](#) and [encryption](#).
- Classifying your assets.

- [Managing access](#) to your data using [IAM roles](#) and other service configurations to apply the appropriate permissions.
- Enabling detective controls such as [AWS CloudTrail](#) or [Amazon GuardDuty](#) for Amazon S3.

This documentation will help you understand how to apply the shared responsibility model when using Amazon S3. The following topics show you how to configure Amazon S3 to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you monitor and secure your Amazon S3 resources.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Security best practices for Amazon S3

Important

Starting in April 2026, AWS will disable server-side encryption with customer-provided keys (SSE-C) for all new buckets. In addition, SSE-C encryption will be disabled for all existing buckets in AWS accounts that do not have any SSE-C encrypted data. With these changes, the few applications that need SSE-C encryption must deliberately enable the use SSE-C via the [PutBucketEncryption](#) API after creating the bucket. In these cases, you might need to update automation scripts, CloudFormation templates, or other infrastructure configuration tools to configure these settings. For more information, see the [AWS Storage Blog post](#).

Amazon S3 provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful recommendations rather than prescriptions.

Topics

- [Monitoring data security with managed AWS security services](#)

Amazon S3 security best practices

The following best practices for Amazon S3 can help prevent security incidents.

Disable access control lists (ACLs)

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of [access control lists \(ACLs\)](#). We recommend that you disable ACLs, except in circumstances where you must control access for each object individually. To disable ACLs and take ownership of every object in your bucket, apply the bucket owner enforced setting for S3 Object Ownership. When you disable ACLs, you can easily maintain a bucket with objects uploaded by different AWS accounts.

When ACLs are disabled access control for your data is based on policies, such as the following:

- AWS Identity and Access Management (IAM) user policies
- S3 bucket policies
- Virtual private cloud (VPC) endpoint policies
- AWS Organizations service control policies (SCPs)
- AWS Organizations resource control policies (RCPs)

Disabling ACLs simplifies permissions management and auditing. ACLs are disabled for new buckets by default. You can also disable ACLs for existing buckets. If you have an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of the access-evaluation process. Instead, access is granted or denied on the basis of policies.

Before you disable ACLs, make sure that you do the following:

- Review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account.
- Reset your bucket ACL to the default (full control to the bucket owner).

After you disable ACLs, the following behaviors occur:

- Your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs. These ACLs include the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL that are expressed in XML.
- Existing applications that support bucket owner full control ACLs see no impact.
- PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return an HTTP status code 400 (Bad Request) with the error code `AccessControlListNotSupported`.

For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Ensure that your Amazon S3 buckets use the correct policies and are not publicly accessible

Unless you explicitly require anyone on the internet to be able to read or write to your S3 bucket, make sure that your S3 bucket is not public. The following are some of the steps that you can take to block public access:

- Use S3 Block Public Access. With S3 Block Public Access, you can easily set up centralized controls to limit public access to your Amazon S3 resources. These centralized controls are enforced regardless of how the resources are created. For organizations managing multiple AWS accounts, you can now use organization-level enforcement through AWS Organizations to centrally manage S3 Block Public Access settings across your entire organization with a single policy configuration.

For more information, see [Blocking public access to your Amazon S3 storage](#).

- Identify Amazon S3 bucket policies that allow a wildcard identity such as "Principal": "*" (which effectively means "anyone"). Also look for policies that allow a wildcard action "*" (which effectively allows the user to perform any action in the Amazon S3 bucket).
- Similarly, look for Amazon S3 bucket access control lists (ACLs) that provide read, write, or full-access to "Everyone" or "Any authenticated AWS user."
- Use the `ListBuckets` API operation to scan all of your Amazon S3 buckets. Then use `GetBucketAcl`, `GetBucketWebsite`, and `GetBucketPolicy` to determine whether each bucket has compliant access controls and a compliant configuration.
- Use [AWS Trusted Advisor](#) to inspect your Amazon S3 implementation.
- Consider implementing ongoing detective controls by using the [`s3-bucket-public-read-prohibited`](#) and [`s3-bucket-public-write-prohibited`](#) managed AWS Config Rules.

For organizations with multiple AWS accounts, consider using organization-level Block Public Access management:

- Centralized policy management: Use AWS Organizations to create a single S3 Block Public Access policy that automatically applies to all member accounts or selected organizational units (OUs).
- Automatic inheritance: When you attach the policy at the root or OU level, new member accounts automatically inherit the Block Public Access settings without individual account setup.
- Simplified compliance: Organization-level policies eliminate the need to maintain complex Service Control Policies (SCPs) for Block Public Access enforcement and reduce operational overhead of managing individual account configurations.

- Audit capabilities: Use AWS CloudTrail to monitor policy attachment and enforcement across member accounts for compliance tracking.

For more information, see [Identity and Access Management for Amazon S3](#).

Disable server-side encryption with customer-provided keys (SSE-C) to your buckets

Most modern use cases in Amazon S3 no longer use SSE-C because it lacks the flexibility of server-side encryption with Amazon S3 managed keys (SSE-S3) or server-side encryption with AWS KMS keys (SSE-KMS). SSE-C's requirement to provide the encryption key each time you interact with your SSE-C encrypted data makes it impractical to share your SSE-C key with other users, roles, or AWS services who read data from your S3 buckets in order to operate on your data.

To limit the server-side encryption types you can use in your general purpose buckets, you can choose to block SSE-C write requests by updating your default encryption configuration for your buckets. This bucket-level configuration blocks requests to upload objects that specify SSE-C. When SSE-C is blocked for a bucket, any PutObject, CopyObject, PostObject, or Multipart Upload or replication requests that specify SSE-C encryption will be rejected with an HTTP 403 AccessDenied error.

To learn more about blocking SSE-C, see [the section called “Blocking or unblocking SSE-C”](#).

Create bucket names that aren't predictable

Bucket names must be unique across all AWS accounts in all of the AWS Regions within a partition. Once an AWS account creates a bucket, that bucket name can't be used by another AWS account in the same partition until the bucket is deleted.

We recommend that you create bucket names that aren't predictable. Don't write code that assumes your chosen bucket name is available unless you have already created the bucket. One method for creating bucket names that aren't predictable is to append a Globally Unique Identifier (GUID) to your bucket name, for example, amazon-s3-demo-bucket-a1b2c3d4-5678-90ab-cdef-example11111. For more information, see [Creating a bucket that uses a GUID in the bucket name](#).

We recommend that you don't delete your buckets. All AWS Accounts now have a default bucket quota of 10,000 buckets, reducing the need to delete empty buckets from your account. If you delete a bucket, be aware that another AWS account in the same partition can use the same bucket name for a new bucket and can therefore potentially receive requests that are intended for the deleted bucket. If you want to prevent this, or if you want to continue to use

the same bucket name, don't delete the bucket. We recommend that you empty the bucket and keep it. Instead of deleting the bucket, block any bucket requests as needed. For buckets no longer in active use, we recommend emptying the bucket of all objects to minimize costs while retaining the bucket itself. For more information, see [Deleting a general purpose bucket](#).

Implement least privilege access

When granting permissions, you decide who is getting what permissions to which Amazon S3 resources. You enable specific actions that you want to allow on those resources. Therefore, we recommend that you grant only the permissions that are required to perform a task. Implementing least privilege access is fundamental in reducing security risk and the impact that could result from errors or malicious intent.

The following tools are available to implement least privilege access:

- [Policy actions for Amazon S3](#) and [Permissions Boundaries for IAM Entities](#)
- [How Amazon S3 works with IAM](#)
- [Access control list \(ACL\) overview](#)

For guidance on what to consider when choosing one or more of the preceding mechanisms, see [Identity and Access Management for Amazon S3](#).

Use IAM roles for applications and AWS services that require Amazon S3 access

In order for applications running on Amazon EC2 or other AWS services to access Amazon S3 resources, they must include valid AWS credentials in their AWS API requests. We recommend not storing AWS credentials directly in the application or Amazon EC2 instance. These are long-term credentials that are not automatically rotated and could have a significant business impact if they are compromised.

Instead, use an IAM role to manage temporary credentials for applications or services that need to access Amazon S3. When you use a role, you don't have to distribute long-term credentials (such as a username and password or access keys) to an Amazon EC2 instance or AWS service, such as AWS Lambda. The role supplies temporary permissions that applications can use when they make calls to other AWS resources.

For more information, see the following topics in the *IAM User Guide*:

- [IAM Roles](#)
- [Common Scenarios for Roles: Users, Applications, and Services](#)

Consider encryption of data at rest

You have the following options for protecting data at rest in Amazon S3:

- **Server-side encryption** – All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

Amazon S3 also provides these server-side encryption options:

- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

For more information, see [Protecting data with server-side encryption](#).

- **Client-side encryption** – Encrypt data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, the encryption keys, and related tools. As with server-side encryption, client-side encryption can help reduce risk by encrypting the data with a key that is stored in a different mechanism than the mechanism that stores the data itself.

Amazon S3 provides multiple client-side encryption options. For more information, see [Protecting data by using client-side encryption](#).

Enforce encryption of data in transit

You can use HTTPS (TLS) to help prevent potential attackers from eavesdropping on or manipulating network traffic by using person-in-the-middle or similar attacks. We recommend allowing only encrypted connections over HTTPS (TLS) by using the [aws:SecureTransport](#) condition in your Amazon S3 bucket policies. For more information, see the example S3 bucket policy [Managing access based on HTTP or HTTPS requests](#). In addition to denying HTTP requests, we recommend that you set Amazon CloudWatch alarms on `tlsDetails.tlsVersion NOT EXISTS` that alert you if HTTP access attempts are made on your content. For more information on how to configure Amazon CloudWatch alarms, see [Creating CloudWatch alarms for CloudTrail events: examples](#) and [CloudTrail record contents](#) in the *AWS CloudTrail User Guide*.

⚠ Important

We recommend that your application not pin Amazon S3 TLS certificates as AWS doesn't support pinning of publicly-trusted certificates. S3 automatically renews certificates and renewal can happen any time before certificate expiry. Renewing a certificate generates a new public-private key pair. If you've pinned an S3 certificate which has been recently renewed with a new public key, you won't be able to connect to S3 until your application uses the new certificate.

Also consider implementing ongoing detective controls by using the [s3-bucket-ssl-requests-only](#) managed AWS Config rule.

Consider using S3 Object Lock

With S3 Object Lock, you can store objects by using a "Write Once Read Many" (WORM) model. S3 Object Lock can help prevent accidental or inappropriate deletion of data. For example, you can use S3 Object Lock to help protect your AWS CloudTrail logs.

For more information, see [Locking objects with Object Lock](#).

Enable S3 Versioning

S3 Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can easily recover from both unintended user actions and application failures.

Also consider implementing ongoing detective controls by using the [s3-bucket-versioning-enabled](#) managed AWS Config rule.

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Consider using S3 Cross-Region Replication

Although Amazon S3 stores your data across multiple geographically diverse Availability Zones by default, compliance requirements might dictate that you store data at even greater distances. With S3 Cross-Region Replication (CRR), you can replicate data between distant AWS Regions to help satisfy these requirements. CRR enables automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see [Replicating objects within and across Regions](#).

Note

CRR requires both the source and destination S3 buckets to have versioning enabled.

Also consider implementing ongoing detective controls by using the [s3-bucket-replication-enabled](#) managed AWS Config rule.

Consider using VPC endpoints for Amazon S3 access

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. VPC endpoints can help prevent traffic from traversing the open internet.

VPC endpoints for Amazon S3 provide multiple ways to control access to your Amazon S3 data:

- You can control the requests, users, or groups that are allowed through a specific VPC endpoint by using S3 bucket policies.
- You can control which VPCs or VPC endpoints have access to your S3 buckets by using S3 bucket policies.
- You can help prevent data exfiltration by using a VPC that does not have an internet gateway.

For more information, see [Controlling access from VPC endpoints with bucket policies](#).

Use managed AWS security services to monitor data security

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. These services can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of accounts.

For more information, see [Monitoring data security with managed AWS security services](#).

Amazon S3 monitoring and auditing best practices

The following best practices for Amazon S3 can help detect potential security weaknesses and incidents.

Identify and audit all of your Amazon S3 buckets

Identification of your IT assets is a crucial aspect of governance and security. You need to have visibility of all your Amazon S3 resources to assess their security posture and take action on potential areas of weakness. To audit your resources, we recommend doing the following:

- Use Tag Editor to identify and tag security-sensitive or audit-sensitive resources, then use those tags when you need to search for these resources. For more information, see [Searching for Resources to Tag](#) in the *Tagging AWS Resources User Guide*.
- Use S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. For more information, see [Cataloging and analyzing your data with S3 Inventory](#).
- Create resource groups for your Amazon S3 resources. For more information, see [What are resource groups?](#) in the *AWS Resource Groups User Guide*.

Implement monitoring by using AWS monitoring tools

Monitoring is an important part of maintaining the reliability, security, availability, and performance of Amazon S3 and your AWS solutions. AWS provides several tools and services to help you monitor Amazon S3 and your other AWS services. For example, you can monitor Amazon CloudWatch metrics for Amazon S3, particularly the PutRequests, GetRequests, 4xxErrors, and DeleteRequests metrics. For more information, see [Monitoring metrics with Amazon CloudWatch](#) and [Logging and monitoring in Amazon S3](#).

For a second example, see [Example: Amazon S3 Bucket Activity](#). This example describes how to create a CloudWatch alarm that is triggered when an Amazon S3 API call is made to PUT or DELETE a bucket policy, a bucket lifecycle, or a bucket replication configuration, or to PUT a bucket ACL.

Enable Amazon S3 server access logging

Server access logging provides detailed records of the requests that are made to a bucket. Server access logs can assist you in security and access audits, help you learn about your customer base, and understand your Amazon S3 bill. For instructions on enabling server access logging, see [Logging requests with server access logging](#).

Also consider implementing ongoing detective controls by using the [s3-bucket-logging-enabled](#) AWS Config managed rule.

Use AWS CloudTrail

AWS CloudTrail provides a record of actions taken by a user, a role, or an AWS service in Amazon S3. You can use information collected by CloudTrail to determine the following:

- The request that was made to Amazon S3
- The IP address from which the request was made
- Who made the request
- When the request was made
- Additional details about the request

For example, you can identify CloudTrail entries for PUT actions that affect data access, in particular PutBucketAcl, PutObjectAcl, PutBucketPolicy, and PutBucketWebsite.

When you set up your AWS account, CloudTrail is enabled by default. You can view recent events in the CloudTrail console. To create an ongoing record of activity and events for your Amazon S3 buckets, you can create a trail in the CloudTrail console. For more information, see [Logging data events](#) in the *AWS CloudTrail User Guide*.

When you create a trail, you can configure CloudTrail to log data events. Data events are records of resource operations performed on or within a resource. In Amazon S3, data events record object-level API activity for individual buckets. CloudTrail supports a subset of Amazon S3 object-level API operations, such as GetObject, DeleteObject, and PutObject. For more information about how CloudTrail works with Amazon S3, see [Logging Amazon S3 API calls using AWS CloudTrail](#). In the Amazon S3 console, you can also configure your S3 buckets to [Enabling CloudTrail event logging for S3 buckets and objects](#).

AWS Config provides a managed rule (`cloudtrail-s3-dataevents-enabled`) that you can use to confirm that at least one CloudTrail trail is logging data events for your S3 buckets. For more information, see [cloudtrail-s3-dataevents-enabled](#) in the *AWS Config Developer Guide*.

Enable AWS Config

Several of the best practices listed in this topic suggest creating AWS Config rules. AWS Config helps you to assess, audit, and evaluate the configurations of your AWS resources. AWS Config monitors resource configurations so that you can evaluate the recorded configurations against the desired secure configurations. With AWS Config, you can do the following:

- Review changes in configurations and relationships between AWS resources

- Investigate detailed resource-configuration histories
- Determine your overall compliance against the configurations specified in your internal guidelines

Using AWS Config can help you simplify compliance auditing, security analysis, change management, and operational troubleshooting. For more information, see [Setting Up AWS Config with the Console](#) in the *AWS Config Developer Guide*. When specifying the resource types to record, ensure that you include Amazon S3 resources.

⚠ Important

AWS Config managed rules only supports general purpose buckets when evaluating Amazon S3 resources. AWS Config doesn't record configuration changes for directory buckets. For more information, see [AWS Config Managed Rules](#) and [List of AWS Config Managed Rules](#) in the *AWS Config Developer Guide*.

For an example of how to use AWS Config, see [How to Use AWS Config to Monitor for and Respond to Amazon S3 Buckets Allowing Public Access](#) on the *AWS Security Blog*.

Use S3 Storage Lens

S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

With S3 Storage Lens, you can use metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and access-management best practices, and improve the performance of application workloads.

For example, you can identify buckets that don't have S3 Lifecycle rules to abort incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. For more information, see [Understanding Amazon S3 Storage Lens](#).

Monitor AWS security advisories

We recommend that you regularly check the security advisories posted in Trusted Advisor for your AWS account. In particular, look for warnings about Amazon S3 buckets with "open access permissions." You can do this programmatically by using [describe-trusted-advisor-checks](#).

Further, actively monitor the primary email address that's registered to each of your AWS accounts. AWS uses this email address to contact you about emerging security issues that might affect you.

AWS operational issues with broad impact are posted on the [AWS Health Dashboard - Service health](#). Operational issues are also posted to individual accounts through the AWS Health Dashboard. For more information, see the [AWS Health documentation](#).

Monitoring data security with managed AWS security services

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. They can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of AWS accounts.

AWS detection and response services can help you identify potential security misconfigurations, threats, or unexpected behaviors, so that you can quickly respond to potentially unauthorized or malicious activity in your environment. AWS data protection services can help you monitor and protect your data, accounts, and workloads from unauthorized access. They can also help you discover sensitive data, such as personally identifiable information (PII), in your Amazon S3 data estate.

To help you identify and evaluate data security and compliance risks, managed AWS security services generate findings to notify you of potential security events or issues with your Amazon S3 data. The findings provide relevant details that you can use to investigate, assess, and act upon these risks according to your incident-response workflows and policies. You can access findings data directly by using each service. You can also send the data to other applications, services, and systems, such as your security incident and event management system (SIEM).

To monitor the security of your Amazon S3 data, consider using these managed AWS security services.

Amazon GuardDuty

Amazon GuardDuty is a threat-detection service that continuously monitors your AWS accounts and workloads for malicious activity and delivers detailed security findings for visibility and remediation.

With the S3 protection feature in GuardDuty, you can configure GuardDuty to analyze AWS CloudTrail management and data events for your Amazon S3 resources. GuardDuty then monitors those events for malicious and suspicious activity. To inform the analysis and identify potential security risks, GuardDuty uses threat-intelligence feeds and machine learning.

GuardDuty can monitor different kinds of activity for your Amazon S3 resources. For example, CloudTrail management events for Amazon S3 include bucket-level operations, such as `ListBuckets`, `DeleteBucket`, and `PutBucketReplication`. CloudTrail data events for Amazon S3 include object-level operations, such as `GetObject`, `ListObjects`, and `PutObject`. If GuardDuty detects anomalous or potentially malicious activity, it generates a finding to notify you.

For more information, see [Amazon S3 Protection in Amazon GuardDuty](#) in the *Amazon GuardDuty User Guide*.

Amazon Detective

Amazon Detective simplifies the investigative process and helps you conduct faster, more effective security investigations. Detective provides prebuilt data aggregations, summaries, and context that can help you analyze and assess the nature and extent of possible security issues.

Detective automatically extracts time-based events, such as API calls from AWS CloudTrail and Amazon VPC Flow Logs for your AWS resources. It also ingests findings generated by Amazon GuardDuty. Detective then uses machine learning, statistical analysis, and graph theory to generate visualizations that help you conduct effective security investigations more quickly.

These visualizations provide a unified, interactive view of resource behaviors and the interactions between them over time. You can explore this behavior graph to examine potentially malicious actions, such as failed login attempts or suspicious API calls. You can also see how these actions affect resources, such as S3 buckets and objects.

For more information, see the [Amazon Detective Administration Guide](#).

IAM Access Analyzer

AWS Identity and Access Management Access Analyzer (IAM Access Analyzer) can help you identify resources that are shared with an external entity. You can also use IAM Access Analyzer to validate IAM policies against policy grammar and best practices, and generate IAM policies based on access activity in your AWS CloudTrail logs.

IAM Access Analyzer uses logic-based reasoning to analyze resource policies in your AWS environment, such as bucket policies. With IAM Access Analyzer for S3, you're alerted when an S3 bucket is configured to allow access to anyone on the internet or other AWS accounts, including accounts outside your organization. For example, IAM Access Analyzer for S3 can report that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. For each public or shared bucket, you receive findings that indicate the source and level of public or shared access. With these findings, you can take immediate and precise corrective action to restore bucket access to what you intended.

For more information, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

Amazon Macie

Amazon Macie is a security service that discovers sensitive data by using machine learning and pattern matching. Macie provides visibility into data security risks, and enables automated protection against those risks. With Macie, you can automate the discovery and reporting of sensitive data in your Amazon S3 data estate to gain a better understanding of the data that your organization stores in S3.

To detect sensitive data with Macie, you can use built-in criteria and techniques that are designed to detect a large and growing list of sensitive data types for many countries and regions. These sensitive data types include multiple types of personally identifiable information (PII), financial data, and credentials data. You can also use custom criteria that you define—regular expressions that define text patterns to match and, optionally, character sequences and proximity rules that refine the results.

If Macie detects sensitive data in an S3 object, Macie generates a security finding to notify you. This finding provides information about the affected object, the types and number of occurrences of the sensitive data that Macie found, and additional details to help you investigate the affected S3 bucket and object. For more information, see the [Amazon Macie User Guide](#).

AWS Security Hub CSPM

AWS Security Hub CSPM is a security-posture management service that performs security best-practice checks, aggregates alerts and findings from multiple sources into a single format, and enables automated remediation.

Security Hub CSPM collects and provides security findings data from integrated AWS Partner Network security solutions and AWS services, including Amazon Detective, Amazon GuardDuty, IAM Access Analyzer, and Amazon Macie. It also generates its own findings by running continuous, automated security checks based on AWS best practices and supported industry standards.

Security Hub CSPM then correlates and consolidates findings across providers to help you prioritize and process the most significant findings. It also provides support for custom actions, which you can use to invoke responses or remediation actions for specific classes of findings.

With Security Hub CSPM, you can assess the security and compliance status of your Amazon S3 resources, and you can do so as part of a broader analysis of your organization's security posture in individual AWS Regions and across multiple Regions. This includes analyzing security trends and identifying the highest-priority security issues. You can also aggregate findings from multiple AWS Regions, and monitor and process aggregated findings data from a single Region.

For more information, see [Amazon Simple Storage Service controls](#) in the *AWS Security Hub CSPM User Guide*.

Data protection in Amazon S3

Amazon S3 provides a highly durable storage infrastructure designed for mission-critical and primary data storage. S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive redundantly store objects on multiple devices across a minimum of three Availability Zones in an AWS Region. An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. Availability Zones are physically separated by a meaningful distance, many kilometers, from any other Availability Zone, although all are within 100 km (60 miles) of each other. The S3 One Zone-IA storage class stores data redundantly across multiple devices within a single Availability Zone. These services are designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy, and they also regularly verify the integrity of your data using checksums.

Amazon S3 standard storage offers the following features:

- Backed with the [Amazon S3 Service Level Agreement](#).
- Designed to provide 99.999999999% durability and 99.99% availability of objects over a given year.
- S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive are all designed to sustain data in the event of the loss of an entire Amazon S3 Availability Zone.

Amazon S3 further protects your data using versioning. You can use versioning to preserve, retrieve, and restore every version of every object that is stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. By default, requests retrieve the most recently written version. You can retrieve older versions of an object by specifying a version of the object in a request.

Apart from S3 Versioning, you can also use Amazon S3 Object Lock and S3 Replication to protect your data. For more information, see [Data protection in Amazon S3](#).

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management, so that each user is given only the permissions necessary to fulfill their job duties.

If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

The following security best practices also address data protection in Amazon S3:

- [Implement server-side encryption](#)
- [Enforce encryption of data in transit](#)
- [Consider using Macie with Amazon S3](#)
- [Identify and audit all your Amazon S3 buckets](#)
- [Monitor Amazon Web Services security advisories](#)

Protecting data with encryption

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

Data protection refers to protecting data while it's in transit (as it travels to and from Amazon S3) and at rest (while it is stored on disks in Amazon S3 data centers). You can protect data in transit by using Secure Socket Layer/Transport Layer Security (SSL/TLS) including hybrid post-quantum key exchange or client-side encryption. For protecting data at rest in Amazon S3, you have the following options:

- **Server-side encryption** – Amazon S3 encrypts your objects before saving them on disks in AWS data centers and then decrypts the objects when you download them.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see [Configuring default encryption](#).

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the [Copy objects](#) action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and the *AWS Storage Blog* post [How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations](#).

For more information about each option for server-side encryption, see [Protecting data with server-side encryption](#).

To configure server-side encryption, see:

- [Specifying server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#)
 - [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#)
 - [the section called “Specifying DSSE-KMS”](#)
 - [Specifying server-side encryption with customer-provided keys \(SSE-C\)](#)
- **Client-side encryption** – You encrypt your data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, encryption keys, and related tools.

To configure client-side encryption, see [Protecting data by using client-side encryption](#).

To see which percentage of your storage bytes are encrypted, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

For more information about server-side encryption, client-side encryption, and encryption in transit, review the following topics.

Topics

- [Protecting data with server-side encryption](#)

- [Protecting data by using client-side encryption](#)
- [Protecting data in transit with encryption](#)

Protecting data with server-side encryption

Important

Starting in April 2026, AWS will disable server-side encryption with customer-provided keys (SSE-C) for all new buckets. In addition, SSE-C encryption will be disabled for all existing buckets in AWS accounts that do not have any SSE-C encrypted data. With these changes, the few applications that need SSE-C encryption must deliberately enable the use SSE-C via the [PutBucketEncryption](#) API after creating the bucket. In these cases, you might need to update automation scripts, CloudFormation templates, or other infrastructure configuration tools to configure these settings. For more information, see the [AWS Storage Blog post](#).

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it. As long as you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted objects. For example, if you share your objects by using a presigned URL, that URL works the same way for both encrypted and unencrypted objects. Additionally, when you list objects in your bucket, the list API operations return a list of all objects, regardless of whether they are encrypted.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see [Configuring default encryption](#).

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the [Copy objects](#) action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and the *AWS Storage Blog* post [How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations](#).

 **Note**

You can't apply different types of server-side encryption to the same object simultaneously.

If you need to encrypt your existing objects, use S3 Batch Operations and S3 Inventory. For more information, see [Encrypting objects with Amazon S3 Batch Operations](#) and [Performing object operations in bulk with Batch Operations](#).

When storing data in Amazon S3 you have four mutually exclusive options for server-side encryption, depending on how you choose to manage the encryption keys and the number of encryption layers that you want to apply.

Server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 buckets have encryption configured by default. The default option for server-side encryption is with Amazon S3 managed keys (SSE-S3). Each object is encrypted with a unique key. As an additional safeguard, SSE-S3 encrypts the key itself with a root key that it regularly rotates. SSE-S3 uses one of the strongest block ciphers available, 256-bit Advanced Encryption Standard (AES-256), to encrypt your data. For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)

Server-side encryption with AWS KMS keys (SSE-KMS) is provided through an integration of the AWS KMS service with Amazon S3. With AWS KMS, you have more control over your keys. For example, you can view separate keys, edit control policies, and follow the keys in AWS CloudTrail. Additionally, you can create and manage customer managed keys or use AWS managed keys that are unique to you, your service, and your Region. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)

Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) is similar to SSE-KMS, but DSSE-KMS applies two independent layers of AES-256 encryption instead of one layer: first using a AWS KMS data encryption key, then using a separate Amazon S3-managed encryption key. Because both layers of encryption are applied to an object on the server side, you can use a wide range of AWS services and tools to analyze data in S3 while using an encryption method that can satisfy compliance requirements for multilayer encryption. For more information, see [Using dual-layer server-side encryption with AWS KMS keys \(DSSE-KMS\)](#).

Server-side encryption with customer-provided keys (SSE-C)

With server-side encryption with customer-provided keys (SSE-C), you manage the encryption keys, and Amazon S3 manages the encryption as it writes to disks and the decryption when you access your objects. For more information, see [Using server-side encryption with customer-provided keys \(SSE-C\)](#).

Note

When using access points for Amazon FSx file systems using S3 access points you have one option for server-side encryption.

Server-side encryption with Amazon FSx (SSE-FSx)

All Amazon FSx file systems have encryption configured by default and are encrypted at rest with keys managed using AWS Key Management Service. Data is automatically encrypted and decrypted by on the file system as data is being written to and read from the file system. These processes are handled transparently by Amazon FSx.

Setting default server-side encryption behavior for Amazon S3 buckets

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

All Amazon S3 buckets have encryption configured by default, and objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption setting applies to all objects in your Amazon S3 buckets.

If you need more control over your keys, such as managing key rotation and access policy grants, you can choose to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about editing KMS keys, see [Editing keys](#) in *AWS Key Management Service Developer Guide*.

Note

We've changed buckets to encrypt new object uploads automatically. If you previously created a bucket without default encryption, Amazon S3 will enable encryption by default for the bucket using SSE-S3. There will be no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or SSE-KMS configured. If you

want to encrypt your objects with SSE-KMS, you must change the encryption type in your bucket settings. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys to decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of encryption. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

To identify buckets that have SSE-KMS enabled for default encryption, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to protect your data](#).

When you use server-side encryption, Amazon S3 encrypts an object before saving it to disk and decrypts it when you download the object. For more information about protecting data using server-side encryption and encryption-key management, see [Protecting data with server-side encryption](#).

For more information about the permissions required for default encryption, see [PutBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

You can configure the Amazon S3 default encryption behavior for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

Encrypting existing objects

To encrypt your existing unencrypted Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation. You can use the [Batch Operations Copy operation](#) to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and the *AWS Storage Blog* post [Encrypting objects with Amazon S3 Batch Operations](#).

You can also encrypt existing objects by using the `CopyObject` API operation or the `copy-object` AWS CLI command. For more information, see the *AWS Storage Blog* post [Encrypting existing Amazon S3 objects with the AWS CLI](#).

Note

Amazon S3 buckets with default bucket encryption set to SSE-KMS cannot be used as destination buckets for [the section called “Logging server access”](#). Only SSE-S3 default encryption is supported for server access log destination buckets.

Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (aws/s3) is used.
- If you're uploading or accessing S3 objects by using AWS Identity and Access Management (IAM) principals that are in the same AWS account as your KMS key, you can use the AWS managed key (aws/s3).
- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.
- You must specify a key that you (the requester) have been granted Encrypt permission to. For more information, see [Allow key users to use a KMS key for cryptographic operations](#) in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see [Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?](#)

Using default encryption with replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the

entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.

- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

For more information about using default encryption with SSE-KMS, see [Replicating encrypted objects](#).

Using Amazon S3 Bucket Keys with default encryption

When you configure your bucket to use SSE-KMS as the default encryption behavior for new objects, you can also configure S3 Bucket Keys. S3 Bucket Keys decrease the number of transactions from Amazon S3 to AWS KMS to reduce the cost of SSE-KMS.

When you configure your bucket to use S3 Bucket Keys for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create a unique [data key](#) for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations.

For more information about using S3 Bucket Keys, see [Using Amazon S3 Bucket Keys](#).

Configuring default encryption

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

Amazon S3 buckets have bucket encryption enabled by default, and new objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption applies to all new objects in your Amazon S3 buckets, and comes at no cost to you.

If you need more control over your encryption keys, such as managing key rotation and access policy grants, you can elect to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#). For more information about DSSE-KMS, see [the section called “Dual-layer server-side encryption \(DSSE-KMS\)”](#).

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

When you set default bucket encryption to SSE-KMS, you can also configure an S3 Bucket Key to reduce your AWS KMS request costs. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

Note

If you use [PutBucketEncryption](#) to set your default bucket encryption to SSE-KMS, you should verify that your KMS key ID is correct. Amazon S3 does not validate the KMS key ID provided in PutBucketEncryption requests.

There are no additional charges for using default encryption for S3 buckets. Requests to configure the default encryption behavior incur standard Amazon S3 request charges. For information about pricing, see [Amazon S3 pricing](#). For SSE-KMS and DSSE-KMS, AWS KMS charges apply and are listed at [AWS KMS pricing](#).

Server-side encryption with customer-provided keys (SSE-C) is not supported for default encryption.

You can configure Amazon S3 default encryption for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

Changes to note before enabling default encryption

After you enable default encryption for a bucket, the following encryption behavior applies:

- There is no change to the encryption of the objects that existed in the bucket before default encryption was enabled.
- When you upload objects after enabling default encryption:
 - If your PUT request headers don't include encryption information, Amazon S3 uses the bucket's default encryption settings to encrypt the objects.
 - If your PUT request headers include encryption information, Amazon S3 uses the encryption information from the PUT request to encrypt objects before storing them in Amazon S3.
- If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

 **Note**

Objects uploaded before default encryption was enabled will not be encrypted. For information about encrypting existing objects, see [the section called "Setting default bucket encryption"](#).

Using the S3 console

To configure default encryption on an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. To configure encryption, under **Encryption type**, choose one of the following:
 - **Server-side encryption with Amazon S3 managed keys (SSE-S3)**
 - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
 - **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**

⚠ Important

If you use the SSE-KMS or DSSE-KMS options for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

Buckets and new objects are encrypted by default with SSE-S3, unless you specify another type of default encryption for your buckets. For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

For more information about using Amazon S3 server-side encryption to encrypt your data, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

7. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**, do the following:

- a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

⚠ Important

You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console only lists 100 KMS keys per Region. If you have more than 100 KMS keys in the same Region, you can only see the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter the KMS key ARN.

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 only supports symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

For more information about using SSE-KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#). For more information about using DSSE-KMS, see [the section called "Dual-layer server-side encryption \(DSSE-KMS\)"](#).

- b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable an S3 Bucket Key. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

ℹ Note

S3 Bucket Keys aren't supported for DSSE-KMS.

8. Choose **Save changes**.

Using the AWS CLI

These examples show you how to configure default encryption by using SSE-S3 or by using SSE-KMS with an S3 Bucket Key.

For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about using the AWS CLI to configure default encryption, see [put-bucket-encryption](#).

Example – Default encryption with SSE-S3

This example configures default bucket encryption with Amazon S3 managed keys.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-configuration '{  
    "Rules": [  
        {  
            "ApplyServerSideEncryptionByDefault": {  
                "SSEAlgorithm": "AES256"  
            }  
        }  
    ]  
}'
```

Example – Default encryption with SSE-KMS using an S3 Bucket Key

This example configures default bucket encryption with SSE-KMS using an S3 Bucket Key.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-configuration '{  
    "Rules": [  
        {  
            "ApplyServerSideEncryptionByDefault": {  
                "SSEAlgorithm": "aws:kms",  
                "KMSMasterKeyID": "KMS-Key-ARN"  
            },  
            "BucketKeyEnabled": true  
        }  
    ]  
}'
```

Using the REST API

Use the REST API PutBucketEncryption operation to enable default encryption and to set the type of server-side encryption to use—SSE-S3, SSE-KMS, or DSSE-KMS.

For more information, see [PutBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

Monitoring default encryption with AWS CloudTrail and Amazon EventBridge

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

You can track default encryption configuration requests for Amazon S3 buckets by using AWS CloudTrail events. The following API event names are used in CloudTrail logs:

- PutBucketEncryption
- GetBucketEncryption
- DeleteBucketEncryption

You can also create EventBridge rules to match the CloudTrail events for these API calls. For more information about CloudTrail events, see [Enable logging for objects in a bucket using the console](#). For more information about EventBridge events, see [Events from AWS services](#).

You can use CloudTrail logs for object-level Amazon S3 actions to track PUT and POST requests to Amazon S3. You can use these actions to verify whether default encryption is being used to encrypt objects when incoming PUT requests don't have encryption headers.

When Amazon S3 encrypts an object by using the default encryption settings, the log includes one of the following fields as the name-value pair: "SSEApplied": "Default_SSE_S3", "SSEApplied": "Default_SSE_KMS", or "SSEApplied": "Default_DSSE_KMS".

When Amazon S3 encrypts an object by using the PUT encryption headers, the log includes one of the following fields as the name-value pair: "SSEApplied": "SSE_S3", "SSEApplied": "SSE_KMS", "SSEApplied": "DSSE_KMS", or "SSEApplied": "SSE_C".

For multipart uploads, this information is included in your `InitiateMultipartUpload` API operation requests. For more information about using CloudTrail and CloudWatch, see [Logging and monitoring in Amazon S3](#).

Default encryption FAQ

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. SSE-S3, which uses 256-bit Advanced Encryption Standard (AES-256), is automatically applied to all new buckets and to any existing S3 bucket that doesn't already have default encryption configured. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

The following sections answer questions about this update.

Does Amazon S3 change the default encryption settings for my existing buckets that already have default encryption configured?

No. There are no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) configured. For more information about how to set the default encryption behavior for buckets, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about SSE-S3 and SSE-KMS encryption settings, see [Protecting data with server-side encryption](#).

Is default encryption enabled on my existing buckets that don't have default encryption configured?

Yes. Amazon S3 now configures default encryption on all existing unencrypted buckets to apply server-side encryption with S3 managed keys (SSE-S3) as the base level of encryption for new objects uploaded to these buckets. Objects that are already in an existing unencrypted bucket won't be automatically encrypted.

How can I view the default encryption status of new object uploads?

Currently, you can view the default encryption status of new object uploads in AWS CloudTrail logs, S3 Inventory, and S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

- To view your CloudTrail events, see [Viewing CloudTrail events in the CloudTrail console](#) in the *AWS CloudTrail User Guide*. CloudTrail logs provide API tracking for PUT and POST requests to Amazon S3. When default encryption is being used to encrypt objects in your buckets, the CloudTrail logs for PUT and POST API requests will include the following field as the name-value pair: "SSEApplied": "Default_SSE_S3".
- To view the automatic encryption status of new object uploads in S3 Inventory, configure an S3 Inventory report to include the **Encryption** metadata field, and then see the encryption status of each new object in the report. For more information, see [Setting up Amazon S3 Inventory](#).
- To view the automatic encryption status for new object uploads in S3 Storage Lens, configure an S3 Storage Lens dashboard and see the **Encrypted bytes** and **Encrypted object count** metrics in the **Data protection** category of the dashboard. For more information, see [Using the S3 console](#) and [Viewing S3 Storage Lens metrics on the dashboards](#).
- To view the automatic bucket-level encryption status in the Amazon S3 console, check the **Default encryption** of your Amazon S3 buckets in the Amazon S3 console. For more information, see [Configuring default encryption](#).
- To view the automatic encryption status as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs, check the response header `x-amz-server-side-encryption` when you use object action APIs, such as [PutObject](#) and [GetObject](#).

What do I have to do to take advantage of this change?

You are not required to make any changes to your existing applications. Because default encryption is enabled for all of your buckets, all new objects uploaded to Amazon S3 are automatically encrypted.

Can I disable encryption for the new objects being written to my bucket?

No. SSE-S3 is the new base level of encryption that's applied to all the new objects being uploaded to your bucket. You can no longer disable encryption for new object uploads.

Will my charges be affected?

No. Default encryption with SSE-S3 is available at no additional cost. You will be billed for storage, requests, and other S3 features, as usual. For pricing, see [Amazon S3 pricing](#).

Will Amazon S3 encrypt my existing objects that are unencrypted?

No. Beginning on January 5, 2023, Amazon S3 only automatically encrypts new object uploads. To encrypt existing objects, you can use S3 Batch Operations to create encrypted copies of your

objects. These encrypted copies will retain the existing object data and name and will be encrypted by using the encryption keys that you specify. For more details, see [Encrypting objects with Amazon S3 Batch Operations](#) in the *AWS Storage Blog*.

I did not enable encryption for my buckets before this release. Do I need to change the way that I access objects?

No. Default encryption with SSE-S3 automatically encrypts your data as it's written to Amazon S3 and decrypts it for you when you access it. There is no change in the way that you access objects that are automatically encrypted.

Do I need to change the way that I access my client-side encrypted objects?

No. All client-side encrypted objects that are encrypted before being uploaded into Amazon S3 arrive as encrypted ciphertext objects within Amazon S3. These objects will now have an additional layer of SSE-S3 encryption. Your workloads that use client-side encrypted objects will not require any changes to your client services or authorization settings.

Note

HashiCorp Terraform users that aren't using an updated version of the AWS Provider might see an unexpected drift after creating new S3 buckets with no customer defined encryption configuration. To avoid this drift, update your Terraform AWS Provider version to one of the following versions: any 4.x release, 3.76.1, or 2.70.4.

Using server-side encryption with Amazon S3 managed keys (SSE-S3)

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

All new object uploads to Amazon S3 buckets are encrypted by default with server-side encryption with Amazon S3 managed keys (SSE-S3).

Server-side encryption protects data at rest. Amazon S3 encrypts each object with a unique key. As an additional safeguard, it encrypts the key itself with a key that it rotates regularly. Amazon S3 server-side encryption uses 256-bit Advanced Encryption Standard Galois/Counter Mode (AES-GCM) to encrypt all uploaded objects.

There are no additional fees for using server-side encryption with Amazon S3 managed keys (SSE-S3). However, requests to configure the default encryption feature incur standard Amazon S3 request charges. For information about pricing, see [Amazon S3 pricing](#).

If you require your data uploads to be encrypted using only Amazon S3 managed keys, you can use the following bucket policy. For example, the following bucket policy denies permissions to upload an object unless the request includes the `x-amz-server-side-encryption` header to request server-side encryption:

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjectPolicy",  
    "Statement": [  
        {  
            "Sid": "DenyObjectsThatAreNotSSES3",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-server-side-encryption": "AES256"  
                }  
            }  
        }  
    ]  
}
```

Note

Server-side encryption encrypts only the object data, not the object metadata.

API support for server-side encryption

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see [Configuring default encryption](#).

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the [Copy objects](#) action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and the [AWS Storage Blog post How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations](#).

To configure server-side encryption by using the object creation REST APIs, you must provide the `x-amz-server-side-encryption` request header. For information about the REST APIs, see [Using the REST API](#).

The following Amazon S3 APIs support this header:

- **PUT operations** – Specify the request header when uploading data using the PUT API. For more information, see [PUT Object](#).
- **Initiate Multipart Upload** – Specify the header in the initiate request when uploading large objects using the multipart upload API operation. For more information, see [Initiate Multipart Upload](#).
- **COPY operations** – When you copy an object, you have both a source object and a target object. For more information, see [PUT Object - Copy](#).

 **Note**

When using a POST operation to upload an object, instead of providing the request header, you provide the same information in the form fields. For more information, see [POST Object](#).

The AWS SDKs also provide wrapper APIs that you can use to request server-side encryption. You can also use the AWS Management Console to upload objects and request server-side encryption.

For more general information, see [AWS KMS concepts](#) in the *AWS Key Management Service Developer Guide*.

Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys

(SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see [Configuring default encryption](#).

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the [Copy objects](#) action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and the *AWS Storage Blog* post [How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations](#).

You can specify SSE-S3 by using the S3 console, REST APIs, AWS SDKs, and AWS Command Line Interface (AWS CLI). For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

Using the S3 console

This topic describes how to set or change the type of encryption an object by using the AWS Management Console. When you copy an object by using the console, Amazon S3 copies the object as is. That means that if the source object is encrypted, the target object is also encrypted. You can use the console to add or change encryption for an object.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to change an object's encryption.
- For a list of additional permissions required to change an object's encryption, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object

becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.
 - Under **Encryption type**, choose **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).
8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Save changes**.

Note

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

At the time of object creation—that is, when you are uploading a new object or making a copy of an existing object—you can specify if you want Amazon S3 to encrypt your data with Amazon S3 managed keys (SSE-S3) by adding the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm AES256, which Amazon S3 supports. Amazon S3 confirms that your object is stored with SSE-S3 by returning the response header `x-amz-server-side-encryption`.

The following REST upload API operations accept the `x-amz-server-side-encryption` request header.

- [PUT Object](#)
- [PUT Object - Copy](#)
- [POST Object](#)
- [Initiate Multipart Upload](#)

When uploading large objects by using the multipart upload API operation, you can specify server-side encryption by adding the `x-amz-server-side-encryption` header to the Initiate Multipart Upload request. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored using SSE-S3.

- [PUT Object](#)
- [PUT Object - Copy](#)
- [POST Object](#)
- [Initiate Multipart Upload](#)
- [Upload Part](#)
- [Upload Part - Copy](#)
- [Complete Multipart Upload](#)
- [Get Object](#)
- [Head Object](#)

Note

Do not send encryption request headers for GET requests and HEAD requests if your object uses SSE-S3, or you'll get an HTTP status code 400 (Bad Request) error.

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use server-side encryption with Amazon S3 managed encryption keys (SSE-S3). This section provides examples of using the AWS SDKs in multiple languages. For information about other SDKs, go to [Sample Code and Libraries](#).

Java

When you use the AWS SDK for Java to upload an object, you can use SSE-S3 to encrypt it. To request server-side encryption, use the `ObjectMetadata` property of the `PutObjectRequest` to set the `x-amz-server-side-encryption` request header. When you call the `putObject()` method of the `AmazonS3Client`, Amazon S3 encrypts and saves the data.

You can also request SSE-S3 encryption when uploading objects with the multipart upload API operation:

- When using the high-level multipart upload API operation, you use the `TransferManager` methods to apply server-side encryption to objects as you upload them. You can use any of the upload methods that take `ObjectMetadata` as a parameter. For more information, see [Uploading an object using multipart upload](#).
- When using the low-level multipart upload API operation, you specify server-side encryption when you initiate the multipart upload. You add the `ObjectMetadata` property by calling the `InitiateMultipartUploadRequest.setObjectMetadata()` method. For more information, see [Using the AWS SDKs \(low-level API\)](#).

You can't directly change the encryption state of an object (encrypting an unencrypted object or decrypting an encrypted object). To change an object's encryption state, you make a copy of the object, specifying the desired encryption state for the copy, and then delete the original object. Amazon S3 encrypts the copied object only if you explicitly request server-side encryption. To request encryption of the copied object through the Java API, use the `ObjectMetadata` property to specify server-side encryption in the `CopyObjectRequest`.

Example Example

The following example shows how to set server-side encryption by using the AWS SDK for Java. It shows how to perform the following tasks:

- Upload a new object by using SSE-S3.
- Change an object's encryption state (in this example, encrypting a previously unencrypted object) by making a copy of the object.
- Check the encryption state of the object.

For more information about server-side encryption, see [Using the REST API](#). For instructions on creating and testing a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

        // Upload an object and encrypt it with SSE.
        uploadObjectWithSSEEncryption(s3Client, bucketName, keyNameToEncrypt);

        // Upload a new unencrypted object, then change its encryption state
        // to encrypted by making a copy.
        changeSSEEncryptionStatusByCopying(s3Client,
            bucketName,
            keyNameToCopyAndEncrypt,
            copiedObjectName);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}

private static void uploadObjectWithSSEEncryption(AmazonS3 s3Client, String
bucketName, String keyName) {
    String objectContent = "Test object encrypted with SSE";
    byte[] objectBytes = objectContent.getBytes();

    // Specify server-side encryption.
    ObjectMetadata objectMetadata = new ObjectMetadata();
    objectMetadata.setContentLength(objectBytes.length);

    objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
    PutObjectRequest putRequest = new PutObjectRequest(bucketName,
        keyName,
        new ByteArrayInputStream(objectBytes),
        objectMetadata);

    // Upload the object and check its encryption status.
    PutObjectResult putResult = s3Client.putObject(putRequest);
    System.out.println("Object '" + keyName + "' uploaded with SSE.");
    printEncryptionStatus(putResult);
}
```

```
private static void changeSSEEncryptionStatusByCopying(AmazonS3 s3Client,
    String bucketName,
    String sourceKey,
    String destKey) {
    // Upload a new, unencrypted object.
    PutObjectResult putResult = s3Client.putObject(bucketName, sourceKey,
"Object example to encrypt by copying");
    System.out.println("Unencrypted object \\" + sourceKey + "\\ uploaded.");
    printEncryptionStatus(putResult);

    // Make a copy of the object and use server-side encryption when storing the
    // copy.
    CopyObjectRequest request = new CopyObjectRequest(bucketName,
        sourceKey,
        bucketName,
        destKey);
    ObjectMetadata objectMetadata = new ObjectMetadata();

    objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
    request.setNewObjectMetadata(objectMetadata);

    // Perform the copy operation and display the copy's encryption status.
    CopyObjectResult response = s3Client.copyObject(request);
    System.out.println("Object \\" + destKey + "\\ uploaded with SSE.");
    printEncryptionStatus(response);

    // Delete the original, unencrypted object, leaving only the encrypted copy
in
    // Amazon S3.
    s3Client.deleteObject(bucketName, sourceKey);
    System.out.println("Unencrypted object \\" + sourceKey + "\\ deleted.");
}

private static void printEncryptionStatus(SSEResultBase response) {
    String encryptionStatus = response.getSSEAlgorithm();
    if (encryptionStatus == null) {
        encryptionStatus = "Not encrypted with SSE";
    }
    System.out.println("Object encryption status is: " + encryptionStatus);
}
```

.NET

When you upload an object, you can direct Amazon S3 to encrypt it. To change the encryption state of an existing object, you make a copy of the object and delete the source object. By default, the copy operation encrypts the target only if you explicitly request server-side encryption of the target object. To specify SSE-S3 in the `CopyObjectRequest`, add the following:

```
ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
```

For a working sample of how to copy an object, see [Using the AWS SDKs](#).

The following example uploads an object. In the request, the example directs Amazon S3 to encrypt the object. The example then retrieves object metadata and verifies the encryption method that was used. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SpecifyServerSideEncryptionTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** key name for object created ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            WritingAnObjectAsync().Wait();
        }

        static async Task WritingAnObjectAsync()
        {
```

```
try
{
    var putRequest = new PutObjectRequest
    {
        BucketName = bucketName,
        Key = keyName,
        ContentBody = "sample text",
        ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
    };

    var putResponse = await client.PutObjectAsync(putRequest);

    // Determine the encryption state of an object.
    GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest
    {
        BucketName = bucketName,
        Key = keyName
    };
    GetObjectMetadataResponse response = await
client.GetObjectMetadataAsync(metadataRequest);
    ServerSideEncryptionMethod objectEncryption =
response.ServerSideEncryptionMethod;

    Console.WriteLine("Encryption method used: {0}",
objectEncryption.ToString());
}
catch (AmazonS3Exception e)
{
    Console.WriteLine("Error encountered ***. Message:'{0}' when writing
an object", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
}
}
```

PHP

This topic shows how to use classes from version 3 of the AWS SDK for PHP to add SSE-S3 to objects that you upload to Amazon S3. For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

To upload an object to Amazon S3, use the [Aws\S3\S3Client::putObject\(\)](#) method. To add the x-amz-server-side-encryption request header to your upload request, specify the ServerSideEncryption parameter with the value AES256, as shown in the following code example. For information about server-side encryption requests, see [Using the REST API](#).

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

// $filepath should be an absolute path to a file on disk.
$filepath = '*** Your File Path ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Upload a file with server-side encryption.
$result = $s3->putObject([
    'Bucket'           => $bucket,
    'Key'              => $keyname,
    'SourceFile'       => $filepath,
    'ServerSideEncryption' => 'AES256',
]);
```

In response, Amazon S3 returns the x-amz-server-side-encryption header with the value of the encryption algorithm that was used to encrypt your object's data.

When you upload large objects by using the multipart upload API operation, you can specify SSE-S3 for the objects that you are uploading, as follows:

- When you're using the low-level multipart upload API operation, specify server-side encryption when you call the [Aws\S3\S3Client::createMultipartUpload\(\)](#) method. To add the x-amz-server-side-encryption request header to your request, specify the array parameter's ServerSideEncryption key with the value AES256. For more information about the low-level multipart upload API operation, see [Using the AWS SDKs \(low-level API\)](#).
- When you're using the high-level multipart upload API operation, specify server-side encryption by using the ServerSideEncryption parameter of the [CreateMultipartUpload](#) API operation. For an example of using the setOption() method with the high-level multipart upload API operation, see [Uploading an object using multipart upload](#).

To determine the encryption state of an existing object, retrieve the object metadata by calling the [Aws\S3\S3Client::headObject\(\)](#) method as shown in the following PHP code example.

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Check which server-side encryption algorithm is used.
$result = $s3->headObject([
    'Bucket' => $bucket,
    'Key'     => $keyname,
]);
echo $result['ServerSideEncryption'];
```

To change the encryption state of an existing object, make a copy of the object by using the [Aws\S3\S3Client::copyObject\(\)](#) method and delete the source object. By default, `copyObject()` does not encrypt the target unless you explicitly request server-side encryption of the destination object by using the `ServerSideEncryption` parameter with the value AES256. The following PHP code example makes a copy of an object and adds server-side encryption to the copied object.

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$sourceBucket = '*** Your Source Bucket Name ***';
$sourceKeyname = '*** Your Source Object Key ***';

$targetBucket = '*** Your Target Bucket Name ***';
$targetKeyname = '*** Your Target Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Copy an object and add server-side encryption.
$s3->copyObject([
    'Bucket'          => $targetBucket,
    'Key'             => $targetKeyname,
    'CopySource'      => "$sourceBucket/$sourceKeyname",
    'ServerSideEncryption' => 'AES256',
]);

```

For more information, see the following topics:

- [AWS SDK for PHP for Amazon S3 Aws\S3\S3Client Class](#)
- [AWS SDK for PHP Documentation](#)

Ruby

When using the AWS SDK for Ruby to upload an object, you can specify that the object be stored encrypted at rest with SSE-S3. When you read the object back, it is automatically decrypted.

The following AWS SDK for Ruby Version 3 example demonstrates how to specify that a file uploaded to Amazon S3 be encrypted at rest.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
```

```
class ObjectPutSseWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  def put_object_encrypted(object_content, encryption)
    @object.put(body: object_content, server_side_encryption: encryption)
    true
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't put your content to #{object.key}. Here's why: #{e.message}"
    false
  end
end

# Example usage:
def run_demo
  bucket_name = "amzn-s3-demo-bucket"
  object_key = "my-encrypted-content"
  object_content = "This is my super-secret content."
  encryption = "AES256"

  wrapper = ObjectPutSseWrapper.new(Aws::S3::Object.new(bucket_name,
  object_content))
  return unless wrapper.put_object_encrypted(object_content, encryption)

  puts "Put your content into #{bucket_name}:#{object_key} and encrypted it with
  #{encryption}."
end

run_demo if $PROGRAM_NAME == __FILE__
```

The following code example demonstrates how to determine the encryption state of an existing object.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectGetEncryptionWrapper
  attr_reader :object
```

```
# @param object [Aws::S3::Object] An existing Amazon S3 object.
def initialize(object)
  @object = object
end

# Gets the object into memory.
#
# @return [Aws::S3::Types::GetObjectOutput, nil] The retrieved object data if
# successful; otherwise nil.
def object
  @object.get
rescue Aws::Errors::ServiceError => e
  puts "Couldn't get object #{@object.key}. Here's why: #{e.message}"
end
end

# Example usage:
def run_demo
  bucket_name = "amzn-s3-demo-bucket"
  object_key = "my-object.txt"

  wrapper = ObjectGetEncryptionWrapper.new(Aws::S3::Object.new(bucket_name,
    object_key))
  obj_data = wrapper.get_object
  return unless obj_data

  encryption = obj_data.server_side_encryption.nil? ? 'no' :
  obj_data.server_side_encryption
  puts "Object #{object_key} uses #{encryption} encryption."
end

run_demo if $PROGRAM_NAME == __FILE__
```

If server-side encryption is not used for the object that is stored in Amazon S3, the method returns null.

To change the encryption state of an existing object, make a copy of the object and delete the source object. By default, the copy methods do not encrypt the target unless you explicitly request server-side encryption. You can request the encryption of the target object by specifying the `server_side_encryption` value in the option's hash argument, as shown in the following Ruby code example. The code example demonstrates how to copy an object and encrypt the copy with SSE-S3.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectCopyEncryptWrapper
  attr_reader :source_object

  # @param source_object [Aws::S3::Object] An existing Amazon S3 object. This is
  used as the source object for
  #                                         copy actions.
  def initialize(source_object)
    @source_object = source_object
  end

  # Copy the source object to the specified target bucket, rename it with the target
  key, and encrypt it.
  #
  # @param target_bucket [Aws::S3::Bucket] An existing Amazon S3 bucket where the
  object is copied.
  # @param target_object_key [String] The key to give the copy of the object.
  # @return [Aws::S3::Object, nil] The copied object when successful; otherwise,
  nil.
  def copy_object(target_bucket, target_object_key, encryption)
    @source_object.copy_to(bucket: target_bucket.name, key: target_object_key,
    server_side_encryption: encryption)
    target_bucket.object(target_object_key)
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't copy #{@source_object.key} to #{target_object_key}. Here's why:
    #{e.message}"
  end
end

# Example usage:
def run_demo
  source_bucket_name = "amzn-s3-demo-bucket1"
  source_key = "my-source-file.txt"
  target_bucket_name = "amzn-s3-demo-bucket2"
  target_key = "my-target-file.txt"
  target_encryption = "AES256"

  source_bucket = Aws::S3::Bucket.new(source_bucket_name)
  wrapper = ObjectCopyEncryptWrapper.new(source_bucket.object(source_key))
  target_bucket = Aws::S3::Bucket.new(target_bucket_name)
  target_object = wrapper.copy_object(target_bucket, target_key, target_encryption)
```

```
return unless target_object

puts "Copied #{source_key} from #{source_bucket_name} to
#{target_object.bucket_name}:#{target_object.key} and \"\
    encrypted the target with #{target_object.server_side_encryption}
encryption."
end

run_demo if $PROGRAM_NAME == __FILE__
```

Using the AWS CLI

To specify SSE-S3 when you upload an object by using the AWS CLI, use the following example.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key object-key-name --server-side-
encryption AES256 --body file path
```

For more information, see [put-object](#) in the *AWS CLI reference*. To specify SSE-S3 when you copy an object by using the AWS CLI, see [copy-object](#).

Using CloudFormation

For examples of setting up encryption using CloudFormation, see [Create a bucket with default encryption](#) and the [Create a bucket by using AWS KMS server-side encryption with an S3 Bucket Key](#) example in the `AWS::S3::Bucket ServerSideEncryptionRule` topic in the *AWS CloudFormation User Guide*.

Using server-side encryption with AWS KMS keys (SSE-KMS)

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

Server-side encryption is the encryption of data at its destination by the application or service that receives it.

Amazon S3 automatically enables server-side encryption with Amazon S3 managed keys (SSE-S3) for new object uploads.

Unless you specify otherwise, buckets use SSE-S3 by default to encrypt objects. However, you can choose to configure buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) instead. For more information, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#).

AWS KMS is a service that combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Amazon S3 uses server-side encryption with AWS KMS (SSE-KMS) to encrypt your S3 object data. Also, when SSE-KMS is requested for the object, the S3 checksum (as part of the object's metadata) is stored in encrypted form. For more information about checksum, see [Checking object integrity in Amazon S3](#).

If you use KMS keys, you can use AWS KMS through the [AWS Management Console](#) or the [AWS KMS API](#) to do the following:

- Centrally create, view, edit, monitor, enable or disable, rotate, and schedule deletion of KMS keys.
- Define the policies that control how and by whom KMS keys can be used.
- Audit KMS key usage for correct use. Auditing is supported by the [AWS KMS API](#) but not by the [AWS KMS Console](#);

The security controls in AWS KMS can help you meet encryption-related compliance requirements. You can use these KMS keys to protect your data in Amazon S3 buckets. When you use SSE-KMS encryption with an S3 bucket, the AWS KMS keys must be in the same Region as the bucket.

There are additional charges for using AWS KMS keys. For more information, see [AWS KMS key concepts](#) in the [AWS Key Management Service Developer Guide](#) and [AWS KMS pricing](#).

For instructions on allowing IAM users to access KMS-encrypted buckets see [My Amazon S3 bucket has default encryption using a custom AWS KMS key. How can I allow users to download from and upload to the bucket?](#) in the AWS re:Post Knowledge Center.

Permissions

To successfully make a PutObject request to encrypt an object with an AWS KMS key to Amazon S3, you need kms:GenerateDataKey permissions on the key. To download an object encrypted with an AWS KMS key, you need kms:Decrypt permissions for the key. To [perform a multipart upload](#) to encrypt an object with an AWS KMS key, you must have the kms:GenerateDataKey and kms:Decrypt permissions for the key.

Important

Carefully review the permissions that are granted in your KMS key policies. Always restrict customer-managed KMS key policy permissions only to the IAM principals and AWS services that must access the relevant AWS KMS key action. For more information, see [Key policies in AWS KMS](#).

Topics

- [AWS KMS keys](#)
- [Amazon S3 Bucket Keys](#)
- [Requiring server-side encryption](#)
- [Encryption context](#)
- [Sending requests for AWS KMS encrypted objects](#)
- [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#)
- [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#)

AWS KMS keys

When you use server-side encryption with AWS KMS (SSE-KMS), you can use the default [AWS managed key](#), or you can specify a [customer managed key](#) that you have already created. AWS KMS supports *envelope encryption*. S3 uses the AWS KMS features for *envelope encryption* to further protect your data. Envelope encryption is the practice of encrypting your plain text data with a data key, and then encrypting that data key with a KMS key. For more information about envelope encryption, see [Envelope encryption](#) in the *AWS Key Management Service Developer Guide*.

If you don't specify a customer managed key, Amazon S3 automatically creates an AWS managed key in your AWS account the first time that you add an object encrypted with SSE-KMS to a bucket. By default, Amazon S3 uses this KMS key for SSE-KMS.

Note

Objects encrypted using SSE-KMS with [AWS managed keys](#) can't be shared cross-account. If you need to share SSE-KMS data cross-account, you must use a [customer managed key](#) from AWS KMS.

If you want to use a customer managed key for SSE-KMS, create a symmetric encryption customer managed key before you configure SSE-KMS. Then, when you configure SSE-KMS for your bucket, specify the existing customer managed key. For more information about symmetric encryption key, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

Creating a customer managed key gives you more flexibility and control. For example, you can create, rotate, and disable customer managed keys. You can also define access controls and audit the customer managed key that you use to protect your data. For more information about customer managed and AWS managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

Note

When you use server-side encryption with a customer managed key that's stored in an external key store, unlike standard KMS keys, you are responsible for ensuring the availability and durability of your key material. For more information about external key stores and how they shift the shared responsibility model, see [External key stores](#) in the *AWS Key Management Service Developer Guide*.

Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (aws/s3) from the uploading account is used for encryption and required for decryption.
- AWS managed key (aws/s3) can be used as your KMS key for cross-account operations when the uploading and accessing AWS Identity and Access Management (IAM) principals are from the same AWS account.

- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.
- You must specify a key that you (the requester) have been granted Encrypt permission to. For more information, see [Allow key users to use a KMS key for cryptographic operations](#) in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see [Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?](#)

SSE-KMS encryption workflow

If you choose to encrypt your data using an AWS managed key or a customer managed key, AWS KMS and Amazon S3 perform the following envelope encryption actions:

1. Amazon S3 requests a plaintext [data key](#) and a copy of the key encrypted under the specified KMS key.
2. AWS KMS generates a data key, encrypts it under the KMS key, and sends both the plaintext data key and the encrypted data key to Amazon S3.
3. Amazon S3 encrypts the data using the data key and removes the plaintext key from memory as soon as possible after use.
4. Amazon S3 stores the encrypted data key as metadata with the encrypted data.

When you request that your data be decrypted, Amazon S3 and AWS KMS perform the following actions:

1. Amazon S3 sends the encrypted data key to AWS KMS in a Decrypt request.
2. AWS KMS decrypts the encrypted data key by using the same KMS key and returns the plaintext data key to Amazon S3.
3. Amazon S3 decrypts the encrypted data, using the plaintext data key, and removes the plaintext data key from memory as soon as possible.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the [AWS Key Management Service Developer Guide](#).

Auditing SSE-KMS encryption

To identify requests that specify SSE-KMS, you can use the **All SSE-KMS requests** and **% all SSE-KMS requests** metrics in Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can also use the SSE-KMS enabled bucket count and % SSE-KMS enabled buckets to understand the count of buckets that (SSE-KMS) for [default bucket encryption](#). For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

To audit the usage of your AWS KMS keys for your SSE-KMS encrypted data, you can use AWS CloudTrail logs. You can get insight into your [cryptographic operations](#), such as [GenerateDataKey](#) and [Decrypt](#). CloudTrail supports numerous [attribute values](#) for filtering your search, including event name, user name, and event source.

Amazon S3 Bucket Keys

When you configure server-side encryption using AWS KMS (SSE-KMS), you can configure your buckets to use S3 Bucket Keys for SSE-KMS. Using a bucket-level key for SSE-KMS can reduce your AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS.

When you configure a bucket to use an S3 Bucket Key for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create unique [data keys](#) for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, further reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations. For more information about using S3 Bucket Keys, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

Requiring server-side encryption

To require server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object (s3:PutObject) permission to everyone if the request does not include an x-amz-server-side-encryption-aws-kms-key-id header that requests server-side encryption with SSE-KMS.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjectPolicy",  
    "Statement": [  
        {  
            "Sid": "DenyObjectsThatAreNotSSEKMS",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
            "Condition": {  
                "Null": {  
                    "s3:x-amz-server-side-encryption-aws-kms-key-id": "true"  
                }  
            }  
        }  
    ]  
}
```

To require that a particular AWS KMS key be used to encrypt the objects in a bucket, you can use the s3:x-amz-server-side-encryption-aws-kms-key-id condition key.

To specify the KMS key, you must use a key Amazon Resource Name (ARN) that is in the arn:aws:kms:*region:acct-id:key/key-id* format. AWS Identity and Access Management does not validate if the string for s3:x-amz-server-side-encryption-aws-kms-key-id exists.

Note

When you upload an object, you can specify the KMS key by using the `x-amz-server-side-encryption-aws-kms-key-id` header or rely on your [default bucket encryption configuration](#). If your `PutObject` request specifies `aws:kms` in the `x-amz-server-side-encryption` header, but does not specify the `x-amz-server-side-encryption-aws-kms-key-id` header, then Amazon S3 assumes that you want to use the AWS managed key. Regardless, the AWS KMS key ID that Amazon S3 uses for object encryption must match the AWS KMS key ID in the policy, otherwise Amazon S3 denies the request.

For a complete list of Amazon S3 specific condition keys, see [Condition keys for Amazon S3](#) in the *Service Authorization Reference*.

Encryption context

An *encryption context* is a set of key-value pairs that contains additional contextual information about the data. The encryption context is not encrypted. When an encryption context is specified for an encryption operation, Amazon S3 must specify the same encryption context for the decryption operation. Otherwise, the decryption fails. AWS KMS uses the encryption context as [additional authenticated data](#) (AAD) to support [authenticated encryption](#). For more information about the encryption context, see [Encryption context](#) in the *AWS Key Management Service Developer Guide*.

By default, Amazon S3 uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair:

- **If you use SSE-KMS without enabling an S3 Bucket Key**, the object ARN is used as the encryption context.

`arn:aws:s3:::object_ARN`

- **If you use SSE-KMS and enable an S3 Bucket Key**, the bucket ARN is used as the encryption context. For more information about S3 Bucket Keys, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

`arn:aws:s3:::bucket_ARN`

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header in an [s3:PutObject](#) request. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context. When it processes your PUT request, Amazon S3 appends the default encryption context of `aws:s3:arn` to the one that you provide.

You can use the encryption context to identify and categorize your cryptographic operations. You can also use the default encryption context ARN value to track relevant requests in AWS CloudTrail by viewing which Amazon S3 ARN was used with which encryption key.

In the `requestParameters` field of a CloudTrail log file, the encryption context looks similar to the following one.

```
"encryptionContext": {  
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1/file_name"  
}
```

When you use SSE-KMS with the optional S3 Bucket Keys feature, the encryption context value is the ARN of the bucket.

```
"encryptionContext": {  
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1"  
}
```

Sending requests for AWS KMS encrypted objects

Important

All GET and PUT requests for AWS KMS encrypted objects must be made using Secure Sockets Layer (SSL) or Transport Layer Security (TLS). Requests must also be signed using valid credentials, such as AWS Signature Version 4 (or AWS Signature Version 2).

AWS Signature Version 4 is the process of adding authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) and [Signature Version 4 signing process](#).

⚠ Important

If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests. Otherwise, you'll get an HTTP 400 Bad Request error.

Topics

- [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#)
- [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#)

Specifying server-side encryption with AWS KMS (SSE-KMS)

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see [Configuring default encryption](#).

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the [Copy objects](#) action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and the [AWS Storage Blog post How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations](#).

You can specify SSE-KMS by using the Amazon S3 console, REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Note

If you want to use a KMS key that's owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

Using the S3 console

This topic describes how to set or change the type of encryption of an object to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) by using the Amazon S3 console.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to change an object's encryption.
- For a list of additional permissions required to change an object's encryption, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To add or change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.

Important

If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.
 - a. Under **Encryption type**, choose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**.
 - b. Under **AWS KMS key**, do one of the following to choose your KMS key:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.
 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Save changes**.

 **Note**

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of server-side encryption with AWS KMS keys (SSE-KMS) to encrypt your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms`. Amazon S3 confirms that your object is stored using SSE-KMS by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id`
- `x-amz-server-side-encryption-context`
- `x-amz-server-side-encryption-bucket-key-enabled`

Topics

- [Amazon S3 REST API operations that support SSE-KMS](#)
- [Encryption context \(x-amz-server-side-encryption-context\)](#)
- [AWS KMS key ID \(x-amz-server-side-encryption-aws-kms-key-id\)](#)
- [S3 Bucket Keys \(x-amz-server-side-encryption-aws-bucket-key-enabled\)](#)

Amazon S3 REST API operations that support SSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- [**PutObject**](#) – When you upload data by using the PUT API operation, you can specify these request headers.
- [**CopyObject**](#) – When you copy an object, you have both a source object and a target object. When you pass SSE-KMS headers with the CopyObject operation, they're applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object isn't encrypted unless you explicitly request server-side encryption.
- [**POST Object**](#) – When you use a POST operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- [**CreateMultipartUpload**](#) – When you upload large objects by using the multipart upload API operation, you can specify these headers. You specify these headers in the CreateMultipartUpload request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored by using server-side encryption.

- [PutObject](#)
- [CopyObject](#)
- [POST Object](#)
- [CreateMultipartUpload](#)
- [UploadPart](#)
- [UploadPartCopy](#)
- [CompleteMultipartUpload](#)
- [GetObject](#)
- [HeadObject](#)

Important

- All GET and PUT requests for an object protected by AWS KMS fail if you don't make these requests by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
- If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 BadRequest error.

Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair. If you use SSE-KMS without enabling an S3 Bucket Key, you use the object ARN as your encryption context; for example, `arn:aws:s3:::object_ARN`. However, if you use SSE-KMS and enable an S3 Bucket Key, you use the bucket ARN for your encryption context; for example, `arn:aws:s3:::bucket_ARN`.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context isn't encrypted, make sure it doesn't include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see [Encryption context](#). For general information about the encryption context, see [AWS Key Management Service Concepts - Encryption context](#) in the *AWS Key Management Service Developer Guide*.

AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (aws/s3) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

S3 Bucket Keys (`x-amz-server-side-encryption-aws-bucket-key-enabled`)

You can use the `x-amz-server-side-encryption-aws-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level. S3 Bucket Keys reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

If you specify the `x-amz-server-side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-bucket-key-enabled` header, your object uses the S3 Bucket Key settings for the destination bucket to encrypt your object. For more information, see [Configuring an S3 Bucket Key at the object level](#).

Using the AWS CLI

To use the following example AWS CLI commands, replace the *user input placeholders* with your own information.

When you upload a new object or copy an existing object, you can specify the use of server-side encryption with AWS KMS keys to encrypt your data. To do this, add the `--server-side-encryption` parameter to the command.

encryption aws:kms header to the request. Use the --ssekms-key-id *example-key-id* to add your [customer managed AWS KMS key](#) that you created. If you specify --server-side-encryption aws:kms, but don't provide an AWS KMS key ID, Amazon S3 will use an AWS managed key.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms --ssekms-key-id example-key-id --body filepath
```

You can additionally enable or disable Amazon S3 Bucket Keys on your PUT or COPY operations by adding --bucket-key-enabled or --no-bucket-key-enabled. Amazon S3 Bucket Keys can reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms --bucket-key-enabled --body filepath
```

You can encrypt an unencrypted object to use SSE-KMS by copying the object back in place.

```
aws s3api copy-object --bucket amzn-s3-demo-bucket --key example-object-key --body filepath --bucket amzn-s3-demo-bucket --key example-object-key --sse aws:kms --sse-kms-key-id example-key-id --body filepath
```

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use AWS KMS keys for server-side encryption. The following examples show how to use SSE-KMS with the AWS SDKs for Java and .NET. For information about other SDKs, see [Sample code and libraries](#) on the AWS Developer Center.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the [AWS Key Management Service Developer Guide](#).

CopyObject operation

When copying objects, you add the same request properties (`ServerSideEncryptionMethod` and `ServerSideEncryptionKeyManagementServiceKeyId`) to request Amazon S3 to use an AWS KMS key. For more information about copying objects, see [Copying, moving, and renaming objects](#).

PUT operation

Java

When uploading an object by using the AWS SDK for Java, you can request Amazon S3 to use an AWS KMS key by adding the `SSEAwsKeyManagementParams` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,  
    keyName, file).withSSEAwsKeyManagementParams(new SSEAwsKeyManagementParams());
```

In this case, Amazon S3 uses the AWS managed key (aws/s3). For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#). You can optionally create a symmetric encryption KMS key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,  
    keyName, file).withSSEAwsKeyManagementParams(new  
    SSEAwsKeyManagementParams(keyID));
```

For more information about creating customer managed keys, see [Programming the AWS KMS API](#) in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see [Uploading objects](#).
- For multipart uploads that use the high-level or low-level multipart upload API operations, see [Uploading an object using multipart upload](#).

.NET

When uploading an object by using the AWS SDK for .NET, you can request Amazon S3 to use an AWS KMS key by adding the `ServerSideEncryptionMethod` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest
{
    BucketName = amzn-s3-demo-bucket,
    Key = keyName,
    // other properties
    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS
};
```

In this case, Amazon S3 uses the AWS managed key. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#). You can optionally create your own symmetric encryption customer managed key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest1 = new PutObjectRequest
{
    BucketName = amzn-s3-demo-bucket,
    Key = keyName,
    // other properties
    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS,
    ServerSideEncryptionKeyManagementServiceKeyId = keyId
};
```

For more information about creating customer managed keys, see [Programming the AWS KMS API](#) in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see [Uploading objects](#).
- For multipart uploads that use the high-level or low-level multipart upload API operations, see [Uploading an object using multipart upload](#).

Presigned URLs

Java

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
ClientConfiguration clientConfiguration = new ClientConfiguration();
clientConfiguration.setSignerOverride("AWSS3V4SignerType");
AmazonS3Client s3client = new AmazonS3Client(
    new ProfileCredentialsProvider(), clientConfiguration);
...
```

For a code example, see [Sharing objects with presigned URLs](#).

.NET

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
AWSConfigs.S3Config.UseSignatureVersion4 = true;
```

For a code example, see [Sharing objects with presigned URLs](#).

Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys

Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). Using a bucket-level key for SSE-KMS can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. With a few clicks in the AWS Management Console, and without any changes to your client applications, you can configure your bucket to use an S3 Bucket Key for SSE-KMS encryption on new objects.

Note

S3 Bucket Keys aren't supported for dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS).

S3 Bucket Keys for SSE-KMS

Workloads that access millions or billions of objects encrypted with SSE-KMS can generate large volumes of requests to AWS KMS. When you use SSE-KMS to protect your data without an S3 Bucket Key, Amazon S3 uses an individual AWS KMS [data key](#) for every object. In this case, Amazon S3 makes a call to AWS KMS every time a request is made against a KMS-encrypted object. For information about how SSE-KMS works, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

When you configure your bucket to use an S3 Bucket Key for SSE-KMS, AWS generates a short-lived bucket-level key from AWS KMS, then temporarily keeps it in S3. This bucket-level key will create data keys for new objects during its lifecycle. S3 Bucket Keys are used for a limited time period within Amazon S3, reducing the need for S3 to make requests to AWS KMS to complete encryption operations. This reduces traffic from S3 to AWS KMS, allowing you to access AWS KMS-encrypted objects in Amazon S3 at a fraction of the previous cost.

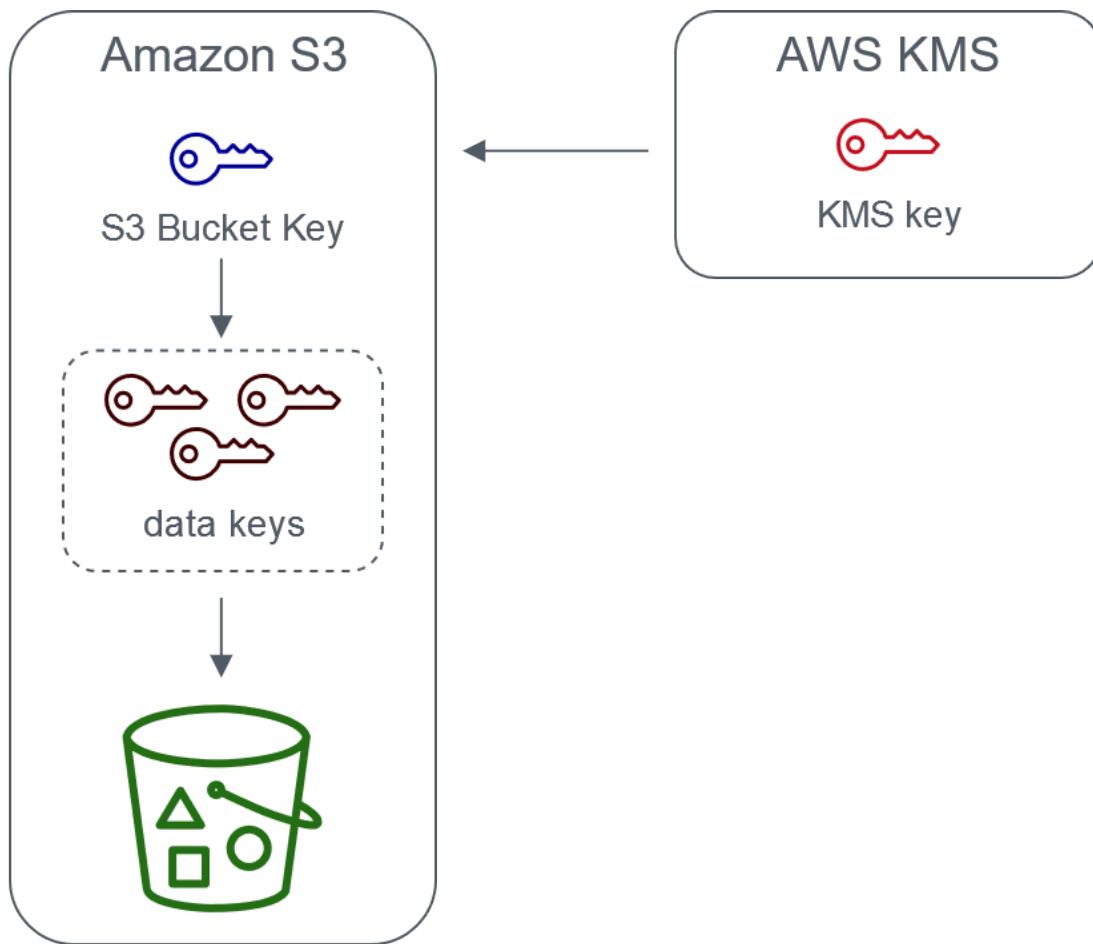

Unique bucket-level keys are fetched at least once per requester to ensure that the requester's access to the key is captured in an AWS KMS CloudTrail event. Amazon S3 treats callers as different requesters when they use different roles or accounts, or the same role with different scoping policies. AWS KMS request savings reflect the number of requesters, request patterns, and relative age of the objects requested. For example, a fewer number of requesters, requesting multiple objects in a limited time window, and encrypted with the same bucket-level key, results in greater savings.

 **Note**

Using S3 Bucket Keys allows you to save on AWS KMS request costs by decreasing your requests to AWS KMS for Encrypt, GenerateDataKey, and Decrypt operations through the use of a bucket-level key. By design, subsequent requests that take advantage of this bucket-level key do not result in AWS KMS API requests or validate access against the AWS KMS key policy.

When you configure an S3 Bucket Key, objects that are already in the bucket do not use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a CopyObject operation. For more information, see [Configuring an S3 Bucket Key at the object level](#).

Amazon S3 will only share an S3 Bucket Key for objects encrypted by the same AWS KMS key. S3 Bucket Keys are compatible with KMS keys created by AWS KMS, [imported key material](#), and [key material backed by custom key stores](#).

Server-side encryption with AWS Key Management service using an S3 Bucket Key

Configuring S3 Bucket Keys

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects through the Amazon S3 console, AWS SDKs, AWS CLI, or REST API. With S3 Bucket Keys enabled on your bucket, objects uploaded with a different specified SSE-KMS key will use their own S3 Bucket Keys. Regardless of your S3 Bucket Key setting, you can include the `x-amz-server-side-encryption-bucket-key-enabled` header with a `true` or `false` value in your request, to override the bucket setting.

Before you configure your bucket to use an S3 Bucket Key, review [Changes to note before enabling an S3 Bucket Key](#).

Configuring an S3 Bucket Key using the Amazon S3 console

When you create a new bucket, you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also configure an existing bucket to use an S3 Bucket Key for SSE-KMS on new objects by updating your bucket properties.

For more information, see [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#).

REST API, AWS CLI, and AWS SDK support for S3 Bucket Keys

You can use the REST API, AWS CLI, or AWS SDK to configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also enable an S3 Bucket Key at the object level.

For more information, see the following:

- [Configuring an S3 Bucket Key at the object level](#)
- [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#)

The following API operations support S3 Bucket Keys for SSE-KMS:

- [PutBucketEncryption](#)
 - ServerSideEncryptionRule accepts the BucketKeyEnabled parameter for enabling and disabling an S3 Bucket Key.
- [GetBucketEncryption](#)
 - ServerSideEncryptionRule returns the settings for BucketKeyEnabled.
- [PutObject](#), [CopyObject](#), [CreateMultipartUpload](#), and [POST Object](#)
 - The x-amz-server-side-encryption-bucket-key-enabled request header enables or disables an S3 Bucket Key at the object level.
- [HeadObject](#), [GetObject](#), [UploadPartCopy](#), [UploadPart](#), and [CompleteMultipartUpload](#)
 - The x-amz-server-side-encryption-bucket-key-enabled response header indicates if an S3 Bucket Key is enabled or disabled for an object.

Working with CloudFormation

In CloudFormation, the AWS::S3::Bucket resource includes an encryption property called BucketKeyEnabled that you can use to enable or disable an S3 Bucket Key.

For more information, see [Using CloudFormation](#).

Changes to note before enabling an S3 Bucket Key

Before you enable an S3 Bucket Key, note the following related changes:

IAM or AWS KMS key policies

If your existing AWS Identity and Access Management (IAM) policies or AWS KMS key policies use your object Amazon Resource Name (ARN) as the encryption context to refine or limit access to your KMS key, these policies won't work with an S3 Bucket Key. S3 Bucket Keys use the bucket ARN as encryption context. Before you enable an S3 Bucket Key, update your IAM policies or AWS KMS key policies to use your bucket ARN as the encryption context.

For more information about the encryption context and S3 Bucket Keys, see [Encryption context](#).

CloudTrail events for AWS KMS

After you enable an S3 Bucket Key, your AWS KMS CloudTrail events log your bucket ARN instead of your object ARN. Additionally, you see fewer KMS CloudTrail events for SSE-KMS objects in your logs. Because key material is time-limited in Amazon S3, fewer requests are made to AWS KMS.

Using an S3 Bucket Key with replication

You can use S3 Bucket Keys with Same-Region Replication (SRR) and Cross-Region Replication (CRR).

When Amazon S3 replicates an encrypted object, it generally preserves the encryption settings of the replica object in the destination bucket. However, if the source object is not encrypted and your destination bucket uses default encryption or an S3 Bucket Key, Amazon S3 encrypts the object with the destination bucket's configuration.

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

Example Example 1 – Source object uses S3 Bucket Keys; destination bucket uses default encryption

If your source object uses an S3 Bucket Key but your destination bucket uses default encryption with SSE-KMS, the replica object maintains its S3 Bucket Key encryption settings in the destination bucket. The destination bucket still uses default encryption with SSE-KMS.

Example Example 2 – Source object is not encrypted; destination bucket uses an S3 Bucket Key with SSE-KMS

If your source object is not encrypted and the destination bucket uses an S3 Bucket Key with SSE-KMS, the replica object is encrypted by using an S3 Bucket Key with SSE-KMS in the destination bucket. This results in the ETag of the source object being different from the ETag of the replica object. You must update applications that use the ETag to accommodate for this difference.

Working with S3 Bucket Keys

For more information about enabling and working with S3 Bucket Keys, see the following sections:

- [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#)
- [Configuring an S3 Bucket Key at the object level](#)
- [Viewing the settings for an S3 Bucket Key](#)

Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects

When you configure server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. S3 Bucket Keys decrease the request traffic from Amazon S3 to AWS KMS and reduce the cost of SSE-KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects by using the Amazon S3 console, REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or CloudFormation. If you want to enable or disable an S3 Bucket Key for existing objects, you can use a CopyObject operation. For more information, see [Configuring an S3 Bucket Key at the object level](#) and [Using Batch Operations to enable S3 Bucket Keys for SSE-KMS](#).

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket Amazon Resource Name (ARN) and not the object ARN, for example, `arn:aws:s3:::bucket_ARN`. You need to update your IAM policies to use the bucket ARN for the encryption context. For more information, see [S3 Bucket Keys and replication](#).

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

Prerequisites

Before you configure your bucket to use an S3 Bucket Key, review [Changes to note before enabling an S3 Bucket Key](#).

Using the S3 console

In the S3 console, you can enable or disable an S3 Bucket Key for a new or existing bucket. Objects in the S3 console inherit their S3 Bucket Key setting from the bucket configuration. When you enable an S3 Bucket Key for your bucket, new objects that you upload to the bucket use an S3 Bucket Key for SSE-KMS.

Uploading, copying, or modifying objects in buckets that have an S3 Bucket Key enabled

If you upload, modify, or copy an object in a bucket that has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object might be updated to align with the bucket configuration.

If an object already has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object don't change when you copy or modify the object. However, if you modify or copy an object that doesn't have an S3 Bucket Key enabled, and the destination bucket has an S3 Bucket Key configuration, the object inherits the destination bucket's S3 Bucket Key settings. For example, if your source object doesn't have an S3 Bucket Key enabled but the destination bucket has S3 Bucket Key enabled, an S3 Bucket Key is enabled for the object.

To enable an S3 Bucket Key when you create a new bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. Enter your bucket name, and choose your AWS Region.
5. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.
6. Under **AWS KMS key**, do one of the following to choose your KMS key:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*.

7. Under **Bucket Key**, choose **Enable**.
8. Choose **Create bucket**.

Amazon S3 creates your bucket with an S3 Bucket Key enabled. New objects that you upload to the bucket will use an S3 Bucket Key.

To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

To enable an S3 Bucket Key for an existing bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.
7. Under **AWS KMS key**, do one of the following to choose your KMS key:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating Keys in the AWS Key Management Service Developer Guide](#).

8. Under **Bucket Key**, choose **Enable**.
9. Choose **Save changes**.

Amazon S3 enables an S3 Bucket Key for new objects added to your bucket. Existing objects don't use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see [Configuring an S3 Bucket Key at the object level](#).

To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

Using the REST API

You can use [PutBucketEncryption](#) to enable or disable an S3 Bucket Key for your bucket. To configure an S3 Bucket Key with `PutBucketEncryption`, use the [ServerSideEncryptionRule](#) data type, which includes default encryption with SSE-KMS. You can also optionally use a customer managed key by specifying the KMS key ID for the customer managed key.

For more information and example syntax, see [PutBucketEncryption](#).

Using the AWS SDK for Java

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();

ServerSideEncryptionByDefault serverSideEncryptionByDefault = new
    ServerSideEncryptionByDefault()
    .withSSEAlgorithm(SSEAlgorithm.KMS);
ServerSideEncryptionRule rule = new ServerSideEncryptionRule()
    .withApplyServerSideEncryptionByDefault(serverSideEncryptionByDefault)
    .withBucketKeyEnabled(true);
ServerSideEncryptionConfiguration serverSideEncryptionConfiguration =
```

```
new ServerSideEncryptionConfiguration().withRules(Collections.singleton(rule));

SetBucketEncryptionRequest setBucketEncryptionRequest = new
SetBucketEncryptionRequest()
.withServerSideEncryptionConfiguration(serverSideEncryptionConfiguration)
.withBucketName(bucketName);

s3client.setBucketEncryption(setBucketEncryptionRequest);
```

Using the AWS CLI

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS CLI. Replace the *user input placeholders* with your own information.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-configuration '{
    "Rules": [
        {
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "aws:kms",
                "KMSMasterKeyID": "KMS-Key-ARN"
            },
            "BucketKeyEnabled": true
        }
    ]
}'
```

Using CloudFormation

For more information about configuring an S3 Bucket Key with CloudFormation, see [AWS::S3::Bucket ServerSideEncryptionRule](#) in the *AWS CloudFormation User Guide*.

Configuring an S3 Bucket Key at the object level

When you perform a PUT or COPY operation using the REST API, AWS SDKs, or AWS CLI, you can enable or disable an S3 Bucket Key at the object level by adding the `x-amz-server-side-encryption-bucket-key-enabled` request header with a `true` or `false` value. S3 Bucket Keys reduce the cost of server-side encryption using AWS Key Management Service (AWS KMS) (SSE-KMS) by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

When you configure an S3 Bucket Key for an object using a PUT or COPY operation, Amazon S3 only updates the settings for that object. The S3 Bucket Key settings for the destination bucket do not change. If you submit a PUT or COPY request for a KMS-encrypted object into a bucket with S3 Bucket Keys enabled, your object level operation will automatically use S3 Bucket Keys unless you disable the keys in the request header. If you don't specify an S3 Bucket Key for your object, Amazon S3 applies the S3 Bucket Key settings for the destination bucket to the object.

Prerequisite:

Before you configure your object to use an S3 Bucket Key, review [Changes to note before enabling an S3 Bucket Key](#).

Topics

- [Amazon S3 Batch Operations](#)
- [Using the REST API](#)
- [Using the AWS SDK for Java \(PutObject\)](#)
- [Using the AWS CLI \(PutObject\)](#)

Amazon S3 Batch Operations

To encrypt your existing Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation.

You can use the [S3 Batch Operations Copy operation](#) to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and [Encrypting objects with Amazon S3 Batch Operations](#).

Using the REST API

When you use SSE-KMS, you can enable an S3 Bucket Key for an object by using the following API operations:

- [PutObject](#) – When you upload an object, you can specify the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level.

- [CopyObject](#) – When you copy an object and configure SSE-KMS, you can specify the x-amz-server-side-encryption-bucket-key-enabled request header to enable or disable an S3 Bucket Key for your object.
- [POST Object](#) – When you use a POST operation to upload an object and configure SSE-KMS, you can use the x-amz-server-side-encryption-bucket-key-enabled form field to enable or disable an S3 Bucket Key for your object.
- [CreateMultipartUpload](#) – When you upload large objects by using the CreateMultipartUpload API operation and configure SSE-KMS, you can use the x-amz-server-side-encryption-bucket-key-enabled request header to enable or disable an S3 Bucket Key for your object.

To enable an S3 Bucket Key at the object level, include the x-amz-server-side-encryption-bucket-key-enabled request header. For more information about SSE-KMS and the REST API, see [Using the REST API](#).

Using the AWS SDK for Java (PutObject)

You can use the following example to configure an S3 Bucket Key at the object level using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();

String bucketName = "amzn-s3-demo-bucket1";
String keyName = "key name for object";
String contents = "file contents";

PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName, keyName,
    contents)
    .withBucketKeyEnabled(true);

s3client.putObject(putObjectRequest);
```

Using the AWS CLI (PutObject)

You can use the following AWS CLI example to configure an S3 Bucket Key at the object level as part of a PutObject request.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key object key name --server-side-  
encryption aws:kms --bucket-key-enabled --body filepath
```

Viewing the settings for an S3 Bucket Key

You can view the settings for an S3 Bucket Key at the bucket or object level by using the Amazon S3 console, REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

S3 Bucket Keys decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of server-side encryption using AWS Key Management Service (SSE-KMS). For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

To view the S3 Bucket Key settings for a bucket or an object that has inherited S3 Bucket Key settings from the bucket configuration, you need permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see [GetBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

Using the S3 console

In the S3 console, you can view the S3 Bucket Key settings for your bucket or object. S3 Bucket Key settings are inherited from the bucket configuration unless the source objects already has an S3 Bucket Key configured.

Objects and folders in the same bucket can have different S3 Bucket Key settings. For example, if you upload an object using the REST API and enable an S3 Bucket Key for the object, the object retains its S3 Bucket Key setting in the destination bucket, even if S3 Bucket Key is disabled in the destination bucket. As another example, if you enable an S3 Bucket Key for an existing bucket, objects that are already in the bucket do not use an S3 Bucket Key. However, new objects have an S3 Bucket Key enabled.

To view the S3 Bucket Key setting for your bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose **Properties**.
5. In the **Default encryption** section, under **Bucket Key**, you see the S3 Bucket Key setting for your bucket.

If you can't see the S3 Bucket Key setting, you might not have permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see [GetBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

To view the S3 Bucket Key setting for your object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
3. In the **Objects** list, choose your object name.
4. On the **Details** tab, under **Server-side encryption settings**, choose **Edit**.

Under **Bucket Key**, you see the S3 Bucket Key setting for your object. You cannot edit this setting.

Using the AWS CLI

To return bucket-level S3 Bucket Key settings

To use this example, replace each *user input placeholder* with your own information.

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
```

For more information, see [get-bucket-encryption](#) in the *AWS CLI Command Reference*.

To return object-level S3 Bucket Key settings

To use this example, replace each *user input placeholder* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-bucket1 --key my_images.tar.bz2
```

For more information, see [head-object](#) in the *AWS CLI Command Reference*.

Using the REST API

To return bucket-level S3 Bucket Key settings

To return encryption information for a bucket, including the settings for an S3 Bucket Key, use the `GetBucketEncryption` operation. S3 Bucket Key settings are returned in the response body in the `ServerSideEncryptionConfiguration` element with the `BucketKeyEnabled` setting. For more information, see [GetBucketEncryption](#) in the *Amazon S3 API Reference*.

To return object-level settings for an S3 Bucket Key

To return the S3 Bucket Key status for an object, use the `HeadObject` operation. `HeadObject` returns the `x-amz-server-side-encryption-bucket-key-enabled` response header to show whether an S3 Bucket Key is enabled or disabled for the object. For more information, see [HeadObject](#) in the *Amazon S3 API Reference*.

The following API operations also return the `x-amz-server-side-encryption-bucket-key-enabled` response header if an S3 Bucket Key is configured for an object:

- [PutObject](#)
- [PostObject](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)
- [UploadPartCopy](#)
- [UploadPart](#)
- [CompleteMultipartUpload](#)
- [GetObject](#)

Using dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

Using dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. DSSE-KMS helps you more easily fulfill compliance standards that require you to apply multilayer encryption to your data and have full control of your encryption keys.

The "dual" in DSSE-KMS refers to two independent layers of AES-256 encryption that are applied to your data:

- *First layer:* Your data is encrypted using a unique data encryption key (DEK) generated by AWS KMS
- *Second layer:* The already-encrypted data is encrypted again using a separate AES-256 encryption key managed by Amazon S3

This differs from standard SSE-KMS, which applies only a single layer of encryption. The dual-layer approach provides enhanced security by ensuring that even if one encryption layer were compromised, your data would remain protected by the second layer. This additional security comes with increased processing overhead and AWS KMS API calls, which accounts for the higher cost compared to standard SSE-KMS. For more information about DSSE-KMS pricing, see [AWS KMS key concepts](#) in the AWS Key Management Service Developer Guide and [AWS KMS pricing](#).

When you use DSSE-KMS with an Amazon S3 bucket, the AWS KMS keys must be in the same Region as the bucket. Also, when DSSE-KMS is requested for the object, the S3 checksum that's part of the object's metadata is stored in encrypted form. For more information about checksums, see [Checking object integrity in Amazon S3](#).

 **Note**

S3 Bucket Keys aren't supported for DSSE-KMS.

The key differences between DSSE-KMS and standard SSE-KMS are:

- **Encryption layers:** DSSE-KMS applies two independent layers of AES-256 encryption, while standard SSE-KMS applies one layer
- **Security:** DSSE-KMS provides enhanced protection against potential encryption vulnerabilities
- **Compliance:** DSSE-KMS helps meet regulatory requirements that mandate multilayer encryption
- **Performance:** DSSE-KMS has slightly higher latency due to additional encryption processing
- **Cost:** DSSE-KMS incurs higher charges due to increased computational overhead and additional AWS KMS operations

Requiring dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

To require dual-layer server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object

(s3:PutObject) permission to everyone if the request does not include an x-amz-server-side-encryption header that requests server-side encryption with DSSE-KMS.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjectPolicy",  
    "Statement": [{  
        "Sid": "DenyUnEncryptedObjectUploads",  
        "Effect": "Deny",  
        "Principal": {  
            "AWS": "arn:aws:iam::111122223333:root"  
        },  
        "Action": "s3:PutObject",  
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
        "Condition": {  
            "StringNotEquals": {  
                "s3:x-amz-server-side-encryption": "aws:kms:dsse"  
            }  
        }  
    }]  
}
```

Topics

- [Specifying dual-layer server-side encryption with AWS KMS keys \(DSSE-KMS\)](#)

Specifying dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

You can apply encryption when you are either uploading a new object or copying an existing object.

You can specify DSSE-KMS by using the Amazon S3 console, Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the

multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Note

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

Using the S3 console

This section describes how to set or change the type of encryption of an object to use dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) by using the Amazon S3 console.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to change an object's encryption.
- For a list of additional permissions required to change an object's encryption, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To add or change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.
 - a. Under **Encryption type**, choose **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**.
 - b. Under **AWS KMS key**, do one of the following to choose your KMS key:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

⚠ Important

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you

must first have permission to use the key, and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see [Identifying asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

8. For **Bucket Key**, choose **Disable**. S3 Bucket Keys aren't supported for DSSE-KMS.
9. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
10. Choose **Save changes**.

 **Note**

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) to encrypt your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms:dsse`. Amazon S3 confirms that your object is stored with DSSE-KMS encryption by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms:dsse`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id`: *SSEKMSKeyId*
- `x-amz-server-side-encryption-context`: *SSEKMSEncryptionContext*

Topics

- [Amazon S3 REST API operations that support DSSE-KMS](#)
- [Encryption context \(x-amz-server-side-encryption-context\)](#)
- [AWS KMS key ID \(x-amz-server-side-encryption-aws-kms-key-id\)](#)

Amazon S3 REST API operations that support DSSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- [PutObject](#) – When you upload data by using the PUT API operation, you can specify these request headers.
- [CopyObject](#) – When you copy an object, you have both a source object and a target object. When you pass DSSE-KMS headers with the CopyObject operation, they are applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.
- [POST Object](#) – When you use a POST operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- [CreateMultipartUpload](#) – When you upload large objects by using a multipart upload, you can specify these headers in the CreateMultipartUpload request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored with server-side encryption.

- [PutObject](#)
- [CopyObject](#)
- [POST Object](#)
- [CreateMultipartUpload](#)
- [UploadPart](#)
- [UploadPartCopy](#)
- [CompleteMultipartUpload](#)
- [GetObject](#)
- [HeadObject](#)

Important

- All GET and PUT requests for an object that's protected by AWS KMS fail if you don't make them by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
- If your object uses DSSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 (Bad Request) error.

Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms:dsse`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object's Amazon Resource Name (ARN) as the encryption context pair; for example, `arn:aws:s3:::object_ARN`.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see [Encryption context](#). For general information about the encryption context, see [AWS Key Management Service Concepts - Encryption context](#) in the [AWS Key Management Service Developer Guide](#).

AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-side-encryption:aws:kms:dsse` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (aws/s3) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

⚠️ Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the [AWS Key Management Service Developer Guide](#).

Using the AWS CLI

When you upload a new object or copy an existing object, you can specify the use of DSSE-KMS to encrypt your data. To do this, add the `--server-side-encryption aws:kms:dsse` parameter to the request. Use the `--ssekms-key-id example-key-id` parameter to add your [customer managed AWS KMS key](#) that you created. If you specify `--server-side-encryption aws:kms:dsse`, but do not provide an AWS KMS key ID, then Amazon S3 will use the AWS managed key (aws/s3).

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms:dsse --ssekms-key-id example-key-id --body filepath
```

You can encrypt an unencrypted object to use DSSE-KMS by copying the object back in place.

```
aws s3api copy-object --bucket amzn-s3-demo-bucket --key example-object-key --copy-source amzn-s3-demo-bucket/example-object-key --server-side-encryption aws:kms:dsse --ssekms-key-id example-key-id
```

Using server-side encryption with customer-provided keys (SSE-C)

Server-side encryption is about protecting data at rest. Server-side encryption encrypts only the object data, not the object metadata. You can use server-side encryption with customer-provided keys (SSE-C) in your general purpose buckets to encrypt your data with your own encryption keys. With the encryption key that you provide as part of your request, Amazon S3 manages data encryption as it writes to disks and data decryption when you access your objects. Therefore, you don't need to maintain any code to perform data encryption and decryption. The only thing that you need to do is manage the encryption keys that you provide.

Most modern use cases in Amazon S3 no longer use SSE-C because it lacks the flexibility of server-side encryption with Amazon S3 managed keys (SSE-S3) or server-side encryption with AWS

KMS keys (SSE-KMS). SSE-C's requirement to provide the encryption key each time you interact with your SSE-C encrypted data makes it impractical to share your SSE-C key with other users, roles, or AWS services who read data from your S3 buckets in order to operate on your data. Due to the widespread support for SSE-KMS across AWS, most modern workloads do not use SSE-C encryption because it lacks the flexibility of SSE-KMS. To learn more about SSE-KMS, see [the section called "KMS keys stored in AWS KMS \(SSE-KMS\)"](#).

If you want to prevent SSE-C encryption from being used for objects written to your bucket, you can block SSE-C encryption when changing your bucket's default encryption configuration. When SSE-C is blocked for a general purpose bucket, any PutObject, CopyObject, PostObject, Multipart Upload or replication requests that specify SSE-C encryption will be rejected with an HTTP 403 AccessDenied error. To learn more about blocking SSE-C, see [the section called "Blocking or unblocking SSE-C"](#).

There are no additional charges for using SSE-C. However, requests to configure and use SSE-C incur standard Amazon S3 request charges. For information about pricing, see [Amazon S3 pricing](#).

Important

Starting in April 2026, AWS will disable server-side encryption with customer-provided keys (SSE-C) for all new buckets. In addition, SSE-C encryption will be disabled for all existing buckets in AWS accounts that do not have any SSE-C encrypted data. With these changes, the few applications that need SSE-C encryption must deliberately enable the use SSE-C via the [PutBucketEncryption](#) API after creating the bucket. In these cases, you might need to update automation scripts, CloudFormation templates, or other infrastructure configuration tools to configure these settings. For more information, see the [AWS Storage Blog post](#).

Considerations before using SSE-C

- S3 never stores the encryption key when you use SSE-C. You must supply the encryption key every time you want anyone to download your SSE-C encrypted data from S3.
 - You manage a mapping of which encryption key was used to encrypt which object. You are responsible for tracking which encryption key you provided for which object. That also means if you lose the encryption key, you lose the object.
 - Because you manage encryption keys on the client side, you manage any additional safeguards, such as key rotation, on the client side.

- This design can make it difficult to share your SSE-C key with other users, roles, or AWS services you to operate on your data. Due to the widespread support for SSE-KMS across AWS, most modern workloads do not use SSE-C because it lacks the flexibility of SSE-KMS. To learn more about SSE-KMS, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).
- This means that objects encrypted with SSE-C cannot be natively decrypted by AWS managed services.
- You must use HTTPS when specifying SSE-C headers on your requests.
 - Amazon S3 rejects any requests made over HTTP when using SSE-C. For security considerations, we recommend that you consider any key that you erroneously send over HTTP to be compromised. Discard the key and rotate as appropriate.
- If your bucket is versioning-enabled, each object version that you upload can have its own encryption key. You are responsible for tracking which encryption key was used for which object version.
- SSE-C is not supported in the Amazon S3 Console. You cannot use the Amazon S3 console to upload an object and specify SSE-C encryption. You also cannot use the console to update (for example, change the storage class or add metadata) an existing object stored using SSE-C.

Topics

- [Specifying server-side encryption with customer-provided keys \(SSE-C\)](#)
- [Blocking or unblocking SSE-C for a general purpose bucket](#)
- [Default SSE-C setting for new buckets FAQ](#)

Specifying server-side encryption with customer-provided keys (SSE-C)

To use server-side encryption with customer provided keys (SSE-C) first make sure that SSE-C is not a blocked encryption type in your Amazon S3 general purpose bucket's default encryption configuration. If blocked, you can enable this encryption type by updating your default encryption configuration for the bucket. Then, you can use SSE-C in your upload requests by passing the required headers. See [Amazon S3 actions that support writing data with SSE-C](#), and make sure to include the [S3 API headers required for SSE-C object encryption and decryption requests](#).

When you upload an object specifying SSE-C, Amazon S3 uses the encryption key that you provide to apply AES-256 encryption to your data. Amazon S3 then removes the encryption key from memory. When you retrieve an object, you must provide the same encryption key as part of your

request. Amazon S3 first verifies that the encryption key that you provided matches, and then it decrypts the object before returning the object data to you.

Before using SSE-C, make sure you have reviewed the [Considerations before using SSE-C](#).

 **Note**

Amazon S3 does not store the encryption key that you provide. Instead, it stores a randomly salted Hash-based Message Authentication Code (HMAC) value of the encryption key to validate future requests. The salted HMAC value cannot be used to derive the value of the encryption key or to decrypt the contents of the encrypted object. That means if you lose the encryption key, you lose the object.

Topics

- [SSE-C Actions and Required Headers](#)
- [Example bucket policy to enforce SSE-C encryption](#)
- [Presigned URLs and SSE-C](#)
- [Making requests with SSE-C](#)
- [Using the REST API](#)
- [Using the AWS SDKs to specify SSE-C for PUT, GET, Head, and Copy operations](#)
- [Using the AWS SDKs to specify SSE-C for multipart uploads](#)

SSE-C Actions and Required Headers

Specifying SSE-C on supported S3 APIs requires passing specific request parameters.

 **Note**

The PutBucketEncryption API in Amazon S3 is used to configure default server-side encryption for a bucket. However, PutBucketEncryption does not support enabling SSE-C as a default encryption method for a bucket. SSE-C is an object-level encryption method where you provide the encryption key to Amazon S3 with each object upload or download request. Amazon S3 uses this key to encrypt or decrypt the object during the request and then discards the key. This means SSE-C is enabled on a per-object basis, not as a default bucket setting.

Amazon S3 actions that support writing data with SSE-C

You can request server-side encryption with customer provided keys (SSE-C) when writing objects to a general purpose bucket by using the following API operations or actions:

- [CopyObject](#)
- [CreateMultipartUpload](#)
- [CompleteMultipartUpload](#)
- [POST Object](#)
- [PutObject](#)
- [UploadPart](#)
- [UploadPartCopy](#)

 **Note**

S3 Replication supports objects that are encrypted with SSE-C. For more information about replicating encrypted objects, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

S3 API headers required for SSE-C object encryption and decryption requests

You must provide the following three API headers to encrypt or decrypt objects with SSE-C:

- `x-amz-server-side-encryption-customer-algorithm` Use this header to specify the encryption algorithm. The header value must be AES256.
- `x-amz-server-side-encryption-customer-key` Use this header to provide the 256-bit, base64-encoded encryption key for Amazon S3 to use to encrypt or decrypt your data.
- `x-amz-server-side-encryption-customer-key-MD5` Use this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure that the encryption key was transmitted without error.

S3 API headers required for requests to copy source objects encrypted with SSE-C

You must provide the following three API headers to copy source objects encrypted with SSE-C:

- **x-amz-copy-source-server-side-encryption-customer-algorithm** Include this header to specify the algorithm Amazon S3 should use to decrypt the source object. This value must be AES256.
- **x-amz-copy-source-server-side-encryption-customer-key** Include this header to provide the base64-encoded encryption key for Amazon S3 to use to decrypt the source object. This encryption key must be the one that you provided Amazon S3 when you created the source object. Otherwise, Amazon S3 cannot decrypt the object.
- **x-amz-copy-source-server-side-encryption-customer-key-MD5** Include this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321.

Example bucket policy to enforce SSE-C encryption

To require SSE-C for all objects written to an Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies upload object (`s3:PutObject`) permissions for all requests that don't include the `x-amz-server-side-encryption-customer-algorithm` header requesting SSE-C.

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjectPolicy",  
    "Statement": [  
        {  
            "Sid": "RequireSSECObjectUploads",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "Null": {  
                    "s3:x-amz-server-side-encryption-customer-algorithm": "true"  
                }  
            }  
        }  
    ]  
}
```

Important

If you use a bucket policy to require SSE-C on `s3:PutObject`, you must include the `x-amz-server-side-encryption-customer-algorithm` header in all multipart upload requests (`CreateMultipartUpload`, `UploadPart`, and `CompleteMultipartUpload`).

Presigned URLs and SSE-C

You can generate a presigned URL that can be used for operations such as uploading a new object, retrieving an existing object, or retrieving object metadata. Presigned URLs support SSE-C as follows:

- When creating a presigned URL, you must specify the algorithm by using the `x-amz-server-side-encryption-customer-algorithm` header in the signature calculation.
- When using the presigned URL to upload a new object, retrieve an existing object, or retrieve only object metadata, you must provide all the encryption headers in your client application's request.

Note

For non-SSE-C objects, you can generate a presigned URL and directly paste that URL into a browser to access the data.

However, you cannot do this for SSE-C objects, because in addition to the presigned URL, you also must include HTTP headers that are specific to SSE-C objects. Therefore, you can use presigned URLs for SSE-C objects only programmatically.

For more information about presigned URLs, see [Download and upload objects with presigned URLs](#).

Making requests with SSE-C

At the time of object creation with the REST API, you can specify server-side encryption with customer-provided keys (SSE-C). When you use SSE-C, you must provide encryption key information using the [S3 API headers required for requests to copy source objects encrypted with SSE-C](#). You can use AWS SDK wrapper libraries to add these headers to your request. If you need to, you can make the Amazon S3 REST API calls directly in your application.

Important

Before specifying server-side encryption with customer provided keys (SSE-C), make sure that SSE-C encryption is not blocked for your general purpose bucket. For more information, see [Blocking or unblocking SSE-C for a general purpose bucket](#).

Note

You cannot use the Amazon S3 console to upload an object and request SSE-C. You also cannot use the console to update (for example, change the storage class or add metadata) an existing object stored using SSE-C. For more information, see [S3 API headers required for SSE-C object encryption and decryption requests](#).

Using the REST API

Amazon S3 REST APIs that support SSE-C

The following Amazon S3 APIs support server-side encryption with customer-provided encryption keys (SSE-C).

- **GET operation** – When retrieving objects using the GET API (see [GET Object](#)), you can specify the request headers.
- **HEAD operation** – To retrieve object metadata using the HEAD API (see [HEAD Object](#)), you can specify these request headers.
- **PUT operation** – When uploading data using the PUT Object API (see [PUT Object](#)), you can specify these request headers.
- **Multipart Upload** – When uploading large objects using the multipart upload API, you can specify these headers. You specify these headers in the initiate request (see [Initiate Multipart Upload](#)) and each subsequent part upload request (see [Upload Part](#) or [UploadPartCopy](#)). For each part upload request, the encryption information must be the same as what you provided in the initiate multipart upload request.
- **POST operation** – When using a POST operation to upload an object (see [POST Object](#)), instead of the request headers, you provide the same information in the form fields.
- **Copy operation** – When you copy an object (see [CopyObject](#)), you have both a source object and a target object:

- If you want to specify the target object's encryption type, you must provide the `x-amz-server-side-encryption` request header.
- If you want the target object encrypted using SSE-C, you must provide encryption information using the S3 API [S3 API headers required for SSE-C object encryption and decryption requests](#).
- If the source object is encrypted using SSE-C, you must provide encryption key information using the S3 API headers [S3 API headers required for requests to copy source objects encrypted with SSE-C](#).

Using the AWS SDKs to specify SSE-C for PUT, GET, Head, and Copy operations

The following examples show how to request server-side encryption with customer-provided keys (SSE-C) for objects. The examples perform the following operations. Each operation shows how to specify SSE-C-related headers in the request:

- **Put object** – Uploads an object and requests server-side encryption using a customer-provided encryption key.
- **Get object** – Downloads the object uploaded in the previous step. In the request, you provide the same encryption information you provided when you uploaded the object. Amazon S3 needs this information to decrypt the object so that it can return it to you.
- **Get object metadata** – Retrieves the object's metadata. You provide the same encryption information used when the object was created.
- **Copy object** – Makes a copy of the previously-uploaded object. Because the source object is stored using SSE-C, you must provide its encryption information in your copy request. By default, Amazon S3 encrypts the copy of the object only if you explicitly request it. This example directs Amazon S3 to store an encrypted copy of the object.

Java

Note

This example shows how to upload an object in a single operation. When using the Multipart Upload API to upload large objects, you provide encryption information in the same way shown in this example. For examples of multipart uploads that use the AWS SDK for Java, see [Uploading an object using multipart upload](#).

To add the required encryption information, you include an `SSECustomerKey` in your request. For more information about the `SSECustomerKey` class, see the REST API section.

For instructions on creating and testing a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

Example

```

};
    await client.CopyObjectAsync(copyRequest);
}
}
```

```
}
```

Using the AWS SDKs to specify SSE-C for multipart uploads

The example in the preceding section shows how to request server-side encryption with customer-provided key (SSE-C) in the PUT, GET, Head, and Copy operations. This section describes other Amazon S3 APIs that support SSE-C.

Java

To upload large objects, you can use multipart upload APIs. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#). You can use either high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using the high-level TransferManager API, you provide the encryption-specific headers in the PutObjectRequest. For more information, see [Uploading an object using multipart upload](#).
- When using the low-level API, you provide encryption-related information in the InitiateMultipartUploadRequest, followed by identical encryption information in each UploadPartRequest. You do not need to provide any encryption-specific headers in your CompleteMultipartUploadRequest. For examples, see [Using the AWS SDKs \(low-level API\)](#).

The following example uses TransferManager to create objects and shows how to provide SSE-C related information. The example does the following:

- Creates an object using the TransferManager.upload() method. In the PutObjectRequest instance, you provide encryption key information in the request. Amazon S3 encrypts the object using the customer-provided key.
- Makes a copy of the object by calling the TransferManager.copy() method. The example directs Amazon S3 to encrypt the object copy using a new SSECustomerKey. Because the source object is encrypted using SSE-C, the CopyObjectRequest also provides the encryption key of the source object so that Amazon S3 can decrypt the object before copying it.

Example

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.CopyObjectRequest;
import com.amazonaws.services.s3.model.PutObjectRequest;
import com.amazonaws.services.s3.model.SSECustomerKey;
import com.amazonaws.services.s3.transfer.Copy;
import com.amazonaws.services.s3.transfer.TransferManager;
import com.amazonaws.services.s3.transfer.TransferManagerBuilder;
import com.amazonaws.services.s3.transfer.Upload;

import javax.crypto.KeyGenerator;
import java.io.File;
import java.security.SecureRandom;

public class ServerSideEncryptionCopyObjectUsingHLwithSSEC {

    public static void main(String[] args) throws Exception {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String fileToUpload = "*** File path ***";
        String keyName = "*** New object key name ***";
        String targetKeyName = "*** Key name for object copy ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withRegion(clientRegion)
                .withCredentials(new ProfileCredentialsProvider())
                .build();
            TransferManager tm = TransferManagerBuilder.standard()
                .withS3Client(s3Client)
                .build();

            // Create an object from a file.
            PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName,
keyName, new File(fileToUpload));

            // Create an encryption key.
```

```
        KeyGenerator keyGenerator = KeyGenerator.getInstance("AES");
        keyGenerator.init(256, new SecureRandom());
        SSECustomerKey sseCustomerEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());

        // Upload the object. TransferManager uploads asynchronously, so this
call
        // returns immediately.
        putObjectRequest.setSSECustomerKey(sseCustomerEncryptionKey);
        Upload upload = tm.upload(putObjectRequest);

        // Optionally, wait for the upload to finish before continuing.
        upload.waitForCompletion();
        System.out.println("Object created.");

        // Copy the object and store the copy using SSE-C with a new key.
        CopyObjectRequest copyObjectRequest = new CopyObjectRequest(bucketName,
keyName, bucketName, targetKeyName);
        SSECustomerKey sseTargetObjectEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());
        copyObjectRequest.setSourceSSECustomerKey(sseCustomerEncryptionKey);

copyObjectRequest.setDestinationSSECustomerKey(sseTargetObjectEncryptionKey);

        // Copy the object. TransferManager copies asynchronously, so this call
returns
        // immediately.
        Copy copy = tm.copy(copyObjectRequest);

        // Optionally, wait for the upload to finish before continuing.
        copy.waitForCompletion();
        System.out.println("Copy complete.");
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

.NET

To upload large objects, you can use multipart upload API (see [Uploading and copying objects using multipart upload in Amazon S3](#)). AWS SDK for .NET provides both high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using high-level Transfer-Utility API, you provide the encryption-specific headers in the TransferUtilityUploadRequest as shown. For code examples, see [Uploading an object using multipart upload](#).

```
TransferUtilityUploadRequest request = new TransferUtilityUploadRequest()
{
    FilePath = filePath,
    BucketName = existingBucketName,
    Key = keyName,
    // Provide encryption information.
    ServerSideEncryptionCustomerMethod =
    ServerSideEncryptionCustomerMethod.AES256,
    ServerSideEncryptionCustomerProvidedKey = base64Key,
};
```

- When using the low-level API, you provide encryption-related information in the initiate multipart upload request, followed by identical encryption information in the subsequent upload part requests. You do not need to provide any encryption-specific headers in your complete multipart upload request. For examples, see [Using the AWS SDKs \(low-level API\)](#).

The following is a low-level multipart upload example that makes a copy of an existing large object. In the example, the object to be copied is stored in Amazon S3 using SSE-C, and you want to save the target object also using SSE-C. In the example, you do the following:

- Initiate a multipart upload request by providing an encryption key and related information.
- Provide source and target object encryption keys and related information in the CopyPartRequest.
- Obtain the size of the source object to be copied by retrieving the object metadata.
- Upload the objects in 5 MB parts.

Example

```
using Amazon;
```

```
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.IO;
using System.Security.Cryptography;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SSECLowLevelMPUcopyObjectTest
    {
        private const string existingBucketName = "*** bucket name ***";
        private const string sourceKeyName      = "*** source object key name
***";
        private const string targetKeyName      = "*** key name for the target
object ***";
        private const string filePath           = @ "*** file path ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            CopyObjClientEncryptionKeyAsync().Wait();

    Key = sourceKeyName,
    UploadId = initResponse.UploadId,
    //PartETags = new List<PartETag>(uploadResponses)

};

    completeRequest.AddPartETags(uploadResponses);

    CompleteMultipartUploadResponse completeUploadResponse =
        await s3Client.CompleteMultipartUploadAsync(completeRequest);

}
catch (Exception exception)
{
```

```
        Console.WriteLine("Exception occurred: {0}", exception.Message);
        AbortMultipartUploadRequest abortMPURequest = new
    AbortMultipartUploadRequest
    {
        BucketName = existingBucketName,
        Key = sourceKeyName,
        UploadId = initResponse.UploadId
    };
    await s3Client.AbortMultipartUploadAsync(abortMPURequest);
}
}
}
```

Blocking or unblocking SSE-C for a general purpose bucket

Most modern use cases in Amazon S3 no longer use server-side encryption with customer-provided keys (SSE-C) because it lacks the flexibility of server-side encryption with Amazon S3 managed keys (SSE-S3) or server-side encryption with AWS KMS keys (SSE-KMS). SSE-C's requirement to provide the encryption key each time you interact with your SSE-C encrypted data makes it impractical to share your SSE-C key with other users, roles, or AWS services who read data from your S3 buckets in order to operate on your data.

To limit the server-side encryption types you can use in your general purpose buckets, you can choose to block SSE-C write requests by updating your default encryption configuration for your buckets. This bucket-level configuration blocks requests to upload objects that specify SSE-C. When SSE-C is blocked for a bucket, any PutObject, CopyObject, PostObject, or Multipart Upload or replication requests that specify SSE-C encryption will be rejected with an HTTP 403 AccessDenied error.

This setting is a parameter on the PutBucketEncryption API and can also be updated using the S3 Console, AWS CLI, and AWS SDKs, if you have the s3:PutEncryptionConfiguration permission.

Valid values are SSE-C, which blocks SSE-C encryption for the general purpose bucket, and NONE, which allows the use SSE-C for writes to the bucket.

Important

Starting in April 2026, AWS will disable server-side encryption with customer-provided keys (SSE-C) for all new buckets. In addition, SSE-C encryption will be disabled for all existing buckets in AWS accounts that do not have any SSE-C encrypted data. With these changes, the few applications that need SSE-C encryption must deliberately enable the use of SSE-C via the [PutBucketEncryption](#) API after creating the bucket. In these cases, you might need to update automation scripts, CloudFormation templates, or other infrastructure configuration tools to configure these settings. For more information, see the [AWS Storage Blog post](#).

Permissions

Use the PutBucketEncryption API or the S3 Console, AWS SDKs, or AWS CLI to block or unblock encryption types for a general purpose bucket. You must have the following permission:

- `s3:PutEncryptionConfiguration`

Use the GetBucketEncryption API or the S3 Console, AWS SDKs, or AWS CLI to view blocked encryption types for a general purpose bucket. You must have the following permission:

- `s3:GetEncryptionConfiguration`

Considerations before blocking SSE-C encryption

After you block SSE-C for any bucket, the following encryption behavior applies:

- There is no change to the encryption of the objects that existed in the bucket before you blocked SSE-C encryption.
- After you block SSE-C encryption, you can continue to make `GetObject` and `HeadObject` requests on pre-existing objects encrypted with SSE-C as long as you provide the required SSE-C headers on the requests.
- When SSE-C is blocked for a bucket, any `PutObject`, `CopyObject`, `PostObject`, or `Multipart Upload` requests that specify SSE-C encryption will be rejected with an HTTP 403 `AccessDenied` error.

- If a destination bucket for replication has SSE-C blocked and the source objects being replicated are encrypted with SSE-C, the replication will fail with an HTTP 403 AccessDenied error.

If you want to review if you're using SSE-C encryption in any of your buckets before blocking this encryption type, you can use tools such as [AWS CloudTrail](#) to monitor access to your data. This [blog post](#) shows you how to audit encryption methods for object uploads in real time. You can also reference this [re:Post article](#) to guide you through the querying S3 Inventory reports to see if you have any SSE-C encrypted objects.

Steps

You can block or unblock server-side encryption with customer-provided keys (SSE-C) for a general purpose bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To block or unblock SSE-C encryption for a bucket using the Amazon S3 console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **general purpose buckets**.
3. Select the bucket that you would like to block SSE-C encryption for.
4. Select the **Properties** tab for the bucket.
5. Navigate to the **Default Encryption** properties panel for the bucket and select **Edit**.
6. In the **Blocked encryption types** section, check the box next to **Server-side encryption with customer-provided keys (SSE-C)** to block SSE-C encryption or uncheck this box to allow SSE-C.
7. Select **Save Changes**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to block or unblock SSE-C encryption for a general purpose bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request to block SSE-C encryption for a general purpose bucket:

```
aws s3api put-bucket-encryption \
--bucket amzn-s3-demo-bucket \
--server-side-encryption-configuration '{
    "Rules": [
        {
            "BlockEncryptionTypes": {
                "EncryptionType": "SSE-C"
            }
        }
    ]
}'
```

Request to enable the use of SSE-C encryption on a general purpose bucket:

```
aws s3api put-bucket-encryption \
--bucket amzn-s3-demo-bucket \
--server-side-encryption-configuration '{
    "Rules": [
        {
            "BlockEncryptionTypes": {
                "EncryptionType": "NONE"
            }
        }
    ]
}'
```

Using the AWS SDKs

SDK for Java 2.x

The following examples show you how to block or unblock SSE-C encryption writes to your general purpose buckets by using the AWS SDKs

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and blocking SSE-C

```
S3Client s3Client = ...;
ServerSideEncryptionByDefault defaultSse = ServerSideEncryptionByDefault
    .builder()
    .sseAlgorithm(ServerSideEncryption.AES256)
    .build();
BlockedEncryptionTypes blockedEncryptionTypes = BlockedEncryptionTypes
    .builder()
    .encryptionType(EncryptionType.SSE_C)
```

```
.build();
ServerSideEncryptionRule rule = ServerSideEncryptionRule.builder()
    .applyServerSideEncryptionByDefault(defaultSse)
    .blockedEncryptionTypes(blockedEncryptionTypes)
    .build();
s3Client.putBucketEncryption(be -> be
    .bucket(bucketName)
    .serverSideEncryptionConfiguration(c -> c.rules(rule)));
```

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and unblocking SSE-C

```
S3Client s3Client = ...;
ServerSideEncryptionByDefault defaultSse = ServerSideEncryptionByDefault
    .builder()
    .sseAlgorithm(ServerSideEncryption.AES256)
    .build();
BlockedEncryptionTypes blockedEncryptionTypes = BlockedEncryptionTypes
    .builder()
    .encryptionType(EncryptionType.NONE)
    .build();
ServerSideEncryptionRule rule = ServerSideEncryptionRule.builder()
    .applyServerSideEncryptionByDefault(defaultSse)
    .blockedEncryptionTypes(blockedEncryptionTypes)
    .build();
s3Client.putBucketEncryption(be -> be
    .bucket(bucketName)
    .serverSideEncryptionConfiguration(c -> c.rules(rule)));
```

SDK for Python Boto3

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and blocking SSE-C

```
s3 = boto3.client("s3")
s3.put_bucket_encryption(
    Bucket="amzn-s3-demo-bucket",
    ServerSideEncryptionConfiguration={
        "Rules": [
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "AES256"
            },
        ]
    }
);
```

```
        "BlockedEncryptionTypes": {  
            "EncryptionType": ["SSE-C"]  
        }  
    }]  
}  
)
```

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and unblocking SSE-C

```
s3 = boto3.client("s3")  
s3.put_bucket_encryption(  
    Bucket="amzn-s3-demo-bucket",  
    ServerSideEncryptionConfiguration={  
        "Rules": [  
            {"ApplyServerSideEncryptionByDefault": {  
                "SSEAlgorithm": "AES256"  
            },  
            "BlockedEncryptionTypes": {  
                "EncryptionType": ["NONE"]  
            }  
        ]  
    }  
)
```

Using the REST API

For information about the Amazon S3 REST API support for blocking or unblocking SSE-C encryption for a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [BlockedEncryptionTypes](#) data type used in the [ServerSideEncryptionRule](#) data type of the [PutBucketEncryption](#) and [GetBucketEncryption](#) API operations.

Default SSE-C setting for new buckets FAQ

Important

Starting in April 2026, AWS will disable server-side encryption with customer-provided keys (SSE-C) for all new buckets. In addition, SSE-C encryption will be disabled for all existing

buckets in AWS accounts that do not have any SSE-C encrypted data. With these changes, the few applications that need SSE-C encryption must deliberately enable the use SSE-C via the [PutBucketEncryption](#) API after creating the bucket. In these cases, you might need to update automation scripts, CloudFormation templates, or other infrastructure configuration tools to configure these settings. For more information, see the [AWS Storage Blog post](#).

The following sections answer questions about this update.

1. In April 2026, will the new SSE-C setting take effect for all newly created buckets?

Yes. During April 2026, the new default setting will gradually be rolled out across all AWS Regions.

2. How long will it take before this rollout covers all AWS Regions?

This update will take several weeks to roll out. We will publish a What's New post when we start to deploy this update.

3. How will I know that the update is complete?

You can easily determine if the change has completed in your AWS Region by creating a new bucket and calling the [GetBucketEncryption](#) API operation to determine if SSE-C encryption is disabled. After the update is complete, all new general purpose buckets will automatically have SSE-C encryption disabled by default. You can adjust these settings after creating your S3 bucket by calling the [PutBucketEncryption](#) API operation.

4. Will Amazon S3 update my existing bucket configurations?

If your AWS account does not have any SSE-C encrypted objects, AWS will disable SSE-C encryption on all of your existing buckets. If any bucket in your AWS account has SSE-C encrypted objects, AWS will not change the bucket configurations on any of your buckets in that account. After the CreateBucket change is complete for your AWS Region, the new default setting will apply to all new general purpose buckets.

5. Can I disable SSE-C encryption for my buckets before the update is complete?

Yes. You can disable SSE-C encryption for any bucket by calling the [PutBucketEncryption](#) API operation and specifying the new BlockedEncryptionTypes header.

6. Can I use SSE-C to encrypt data in my new buckets?

Yes. Most modern use cases in Amazon S3 no longer use SSE-C because it lacks the flexibility of server-side encryption with Amazon S3 managed keys (SSE-S3) or server-side encryption with AWS KMS keys (SSE-KMS). If you need to use SSE-C encryption in a new bucket, you can create the new bucket and then enable the use of SSE-C encryption in a separate PutBucketEncryption request.

Example

```
aws s3api create-bucket \
bucket amzn-s3-demo-bucket \
region us-east-1 \

aws s3api put-bucket-encryption \
-- bucket amzn-s3-demo-bucket \
-- server-side-encryption-configuration \
'{ \Rules\: [{ \
  \
  \ApplyServerSideEncryptionByDefault\: { \
    \SSEAlgorithm\: \AES256\, \
  }, \
  \BlockedEncryptionTypes\: [ \
    \EncryptionType\:\NONE\] \
} \
}'] \
}'
```

Note

You must have the `s3:PutEncryptionConfiguration` permission to call the `PutBucketEncryption` API.

7. How does blocking SSE-C affect requests to my bucket?

When SSE-C is blocked for a bucket, any `PutObject`, `CopyObject`, `PostObject`, or `Multipart Upload` or replication requests that specify SSE-C encryption will be rejected with an HTTP 403 `AccessDenied` error.

Protecting data by using client-side encryption

Client-side encryption is the act of encrypting your data locally to help ensure its security in transit and at rest. To encrypt your objects before you send them to Amazon S3, use the Amazon S3 Encryption Client. When your objects are encrypted in this manner, your objects aren't exposed to any third party, including AWS. Amazon S3 receives your objects already encrypted; Amazon S3 does not play a role in encrypting or decrypting your objects. You can use both the Amazon S3 Encryption Client and [server-side encryption](#) to encrypt your data. When you send encrypted objects to Amazon S3, Amazon S3 doesn't recognize the objects as being encrypted, it only detects typical objects.

The Amazon S3 Encryption Client works as an intermediary between you and Amazon S3. After you instantiate the Amazon S3 Encryption Client, your objects are automatically encrypted and decrypted as part of your Amazon S3 PutObject and GetObject requests. Your objects are all encrypted with a unique data key. The Amazon S3 Encryption Client does not use or interact with bucket keys, even if you specify a KMS key as your wrapping key.

The *Amazon S3 Encryption Client Developer Guide* focuses on versions 3.0 and later of the Amazon S3 Encryption Client. For more information, see [What is the Amazon S3 Encryption Client?](#) in the *Amazon S3 Encryption Client Developer Guide*.

For more information about previous versions of the Amazon S3 Encryption client, see the AWS SDK Developer Guide for your programming language.

- [AWS SDK for Java](#)
- [AWS SDK for .NET](#)
- [AWS SDK for Go](#)
- [AWS SDK for PHP](#)
- [AWS SDK for Ruby](#)
- [AWS SDK for C++](#)

Protecting data in transit with encryption

Amazon S3 supports both HTTP and HTTPS protocols for data transmission. HTTP transmits data in plain text, while HTTPS adds a security layer by encrypting data using Transport Layer Security (TLS). TLS protects against eavesdropping, data tampering, and man-in-the-middle attacks. While

HTTP traffic is accepted, most implementations use encryption in transit with HTTPS and TLS to protect data as it travels between clients and Amazon S3.

TLS 1.2 and TLS 1.3 Support

Amazon S3 supports TLS 1.2 and TLS 1.3 for HTTPS connections across all API endpoints for all AWS Regions. S3 automatically negotiates the strongest TLS protection supported by your client software, and the S3 endpoint you are accessing. Current AWS tools (2014 or later) including the AWS SDKs and AWS CLI automatically default to TLS 1.3 with no action required on your part. You can override this automatic negotiation through client configuration settings to specify a particular TLS version if backward compatibility to TLS 1.2 is needed. When using TLS 1.3, you can optionally configure hybrid post quantum key exchange (ML-KEM) to make quantum-resistant requests to Amazon S3. For more information, see [the section called “Configure PQ-TLS client”](#).

 **Note**

TLS 1.3 is supported in all S3 endpoints, except for AWS PrivateLink for Amazon S3 and Multi-Region Access Points.

Monitoring TLS usage

You can use either Amazon S3 server access logs or AWS CloudTrail to monitor requests to Amazon S3 buckets. Both logging options record the TLS version and cipher suite used in each request.

- **Amazon S3 server access logs** – Server access logging provides detailed records for the requests that are made to a bucket. For example, access log information can be useful in security and access audits. For more information, see [Amazon S3 server access log format](#).
- **AWS CloudTrail** – [AWS CloudTrail](#) is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. For more information, see [Amazon S3 CloudTrail events](#).

Enforcing encryption in transit

It's a security best practice to enforce encryption of data in transit to Amazon S3. You can enforce HTTPS-only communication or the use of specific TLS version through various policy mechanisms. These include IAM resource-based policies for S3 buckets ([bucket policies](#)), [Service Control Policies \(SCPs\)](#), [Resource Control Policies \(RCPs\)](#), and [VPC endpoint policies](#).

Bucket policy examples for enforcing encryption in transit

You can use the [S3 condition key](#) `s3:TlsVersion` to restrict access to Amazon S3 buckets based on the TLS version that's used by the client. For more information, see [Example 6: Requiring a minimum TLS version](#).

Example bucket policy enforcing TLS 1.3 using the S3:TlsVersion condition key

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyInsecureConnections",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:*",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket1",  
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"  
            ],  
            "Condition": {  
                "NumericLessThan": {  
                    "s3:TlsVersion": "1.3"  
                }  
            }  
        }  
    ]  
}
```

You can use the `aws:SecureTransport` [global condition key](#) in your S3 bucket policy to check whether the request was sent through HTTPS (TLS). Unlike the previous example, this condition does not check for a specific TLS version. For more information, see [Restrict access to only HTTPS requests](#).

Example bucket policy enforcing HTTPS using the aws:SecureTransport global condition key

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "RestrictToTLSRequestsOnly",  
            "Action": "s3:*,
```

```
"Effect": "Deny",
"Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket1",
    "arn:aws:s3:::amzn-s3-demo-bucket1/*"
],
"Condition": {
    "Bool": {
        "aws:SecureTransport": "false"
    }
},
"Principal": "*"
}
]
```

Example policy based on both keys and more examples

You can use both types of condition keys in the previous examples in one policy. For more information and additional enforcement approaches, see the AWS Storage Blog article [Enforcing encryption in transit with TLS1.2 or higher with Amazon S3](#).

Using hybrid post-quantum TLS with Amazon S3

Amazon S3 supports a hybrid post-quantum key exchange option for the TLS network encryption protocol. You can use this TLS option when you make requests to Amazon S3 endpoints utilizing TLS 1.3. The classic cipher suites that S3 supports for TLS sessions make brute force attacks on the key exchange mechanisms infeasible with current technology. However, if a cryptographically relevant quantum computer becomes practical in the future, the classic cipher suites used in TLS key exchange mechanisms will be susceptible to these attacks. At present, the industry is aligned on hybrid post-quantum key exchange that combines classic and post-quantum elements to ensure that your TLS connection is at least as strong as it would be with classic cipher suites. Amazon S3 supports hybrid PQ-TLS, in compliance with the industry-standard IANA specification, today.

If you're developing applications that rely on the long-term confidentiality of data passed over a TLS connection, you should consider a plan to migrate to post-quantum cryptography before large-scale quantum computers become available for use. As part of the shared responsibility model, S3 enables quantum-safe cryptography on our service endpoints. As browsers and applications enable PQ-TLS on their side, S3 will choose the strongest possible configuration to secure data in transit.

Supported endpoint types and AWS Regions

Post-quantum TLS for Amazon S3 is available in all AWS Regions. For a list of S3 endpoints for each AWS Region, see [Amazon Simple Storage Service endpoints and quotas](#) in the *Amazon Web Services General Reference*.

 **Note**

Hybrid post-quantum TLS is supported for all S3 endpoints except for AWS PrivateLink for Amazon S3, Multi-Region Access Points, and S3 Vectors.

Using hybrid post-quantum TLS with Amazon S3

You must configure the client that makes requests to Amazon S3 to support hybrid post-quantum TLS. When setting up your HTTP client test environment or production environments, be aware of the following information:

Encryption in Transit

Hybrid post-quantum TLS is only used for encryption in transit. This protects your data while it is traveling from your client to the S3 endpoint. This new support combined with Amazon S3's server-side encryption by default utilizing AES-256 algorithms offers customers quantum-resistant encryption both in-transit and at-rest. For more information about server-side encryption in Amazon S3, see [Protecting data with server-side encryption](#).

Supported Clients

The use of hybrid post-quantum TLS requires using a client that supports this functionality. AWS SDKs and tools have cryptographic capabilities and configuration that differ across languages and runtimes. To learn more about post-quantum cryptography for specific tools, see [Enabling hybrid post-quantum TLS](#).

 **Note**

PQ-TLS key exchange details for requests to Amazon S3 are not available in AWS CloudTrail events or S3 server access logs.

Learn more about post-quantum TLS

For more information about using hybrid post-quantum TLS, see the following resources.

- To learn about post-quantum cryptography at AWS, including links to blog posts and research papers, see [Post-Quantum Cryptography for AWS](#).
- For information about s2n-tls, see [Introducing s2n-tls, a New Open Source TLS Implementation](#) and [Using s2n-tls](#).
- For information about the AWS Common Runtime HTTP Client, see [Configuring the AWS CRT-based HTTP client](#) in the *AWS SDK for Java 2.x Developer Guide*.
- For information about the post-quantum cryptography project at the National Institute for Standards and Technology (NIST), see [Post-Quantum Cryptography](#).
- For information about NIST post-quantum cryptography standardization, see [NIST's Post-Quantum Cryptography Standardization](#).

Configuring hybrid post-quantum TLS for your client

To use PQ-TLS with Amazon S3, you need to configure your client to support post-quantum key exchange algorithms. Also ensure that your client supports the hybrid approach, which combines traditional elliptic curve cryptography with post-quantum algorithms like ML-KEM (Module-Lattice-Based Key Encapsulation Mechanism).

The specific configuration depends on your client library and programming language. For more information, see [Enabling hybrid post-quantum TLS](#).

Client configuration example: AWS SDK for Java 2

In this procedure, add a Maven dependency for the AWS Common Runtime HTTP Client. Next, configure an HTTP client that prefers post-quantum TLS. Then, create an Amazon S3 client that uses the HTTP client.

Note

The AWS Common Runtime HTTP Client, which has been available as a preview, became generally available in February 2023. In that release, the `tlsCipherPreference` class and the `tlsCipherPreference()` method parameter are replaced by the `postQuantumTlsEnabled()` method parameter. If you were using this example during the preview, you need to update your code.

1. Add the AWS Common Runtime client to your Maven dependencies. We recommend using the latest available version.

For example, this statement adds version 2.30.22 of the AWS Common Runtime client to your Maven dependencies.

```
<dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>aws-crt-client</artifactId>
    <version>2.30.22</version>
</dependency>
```

2. To enable the hybrid post-quantum cipher suites, add the AWS SDK for Java 2.x to your project and initialize it. Then enable the hybrid post-quantum cipher suites on your HTTP client as shown in the following example.

This code uses the `postQuantumTlsEnabled()` method parameter to configure an [AWS common runtime HTTP client](#) that prefers the recommended hybrid post-quantum cipher suite, ECDH with ML-KEM. Then it uses the configured HTTP client to build an instance of the Amazon S3 asynchronous client, [S3AsyncClient](#). After this code completes, all [Amazon S3 API](#) requests on the `S3AsyncClient` instance use hybrid post-quantum TLS.

⚠ Important

As of v2.35.11, callers no longer need to set `.postQuantumTlsEnabled(true)` to enable hybrid post-quantum TLS for your client. All versions newer than v2.35.11 enable post-quantum TLS by default.

```
// Configure HTTP client
SdkAsyncHttpClient awsCrtHttpClient = AwsCrtAsyncHttpClient.builder()
    .postQuantumTlsEnabled(true)
    .build();

// Create the Amazon S3 async client
S3AsyncClient s3Async = S3AsyncClient.builder()
    .httpClient(awsCrtHttpClient)
    .build();
```

3. Test your Amazon S3 calls with hybrid post-quantum TLS.

When you call Amazon S3 API operations on the configured Amazon S3 client, your calls are transmitted to the Amazon S3 endpoint using hybrid post-quantum TLS. To test your configuration, call an Amazon S3 API, such as [ListBuckets](#).

```
ListBucketsResponse response = s3Async.listBuckets();
```

Test your hybrid post-quantum TLS configuration

Consider running the following tests with hybrid cipher suites on your applications that call Amazon S3.

- Run load tests and benchmarks. The hybrid cipher suites perform differently than traditional key exchange algorithms. You might need to adjust your connection timeouts to allow for the longer handshake times. If you're running inside an AWS Lambda function, extend the execution timeout setting.
- Try connecting from different locations. Depending on the network path your request takes, you might discover that intermediate hosts, proxies, or firewalls with deep packet inspection (DPI) block the request. This might result from using the new cipher suites in the [ClientHello](#) part of the TLS handshake, or from the larger key exchange messages. If you have trouble resolving these issues, work with your security team or IT administrators to update the relevant configuration and unblock the new TLS cipher suites.

Internet traffic privacy

This topic describes how Amazon S3 secures connections from the service to other locations.

Traffic between service and on-premises clients and applications

The following connections can be combined with AWS PrivateLink to provide connectivity between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
- An Direct Connect connection. For more information, see [What is Direct Connect?](#)

Access to Amazon S3 via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend utilizing TLS 1.3 with hybrid post-quantum

key exchange. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the [AWS Security Token Service \(STS\)](#) to generate temporary security credentials to sign requests.

Traffic between AWS resources in the same Region

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. The VPC routes requests to Amazon S3 and routes responses back to the VPC. For more information, see [VPC Endpoints](#) in the *VPC User Guide*. For example bucket policies that you can use to control S3 bucket access from VPC endpoints, see [Controlling access from VPC endpoints with bucket policies](#).

AWS PrivateLink for Amazon S3

With AWS PrivateLink for Amazon S3, you can provision *interface VPC endpoints* (interface endpoints) in your virtual private cloud (VPC). These endpoints are directly accessible from applications that are on premises over VPN and Direct Connect, or in a different AWS Region over VPC peering.

Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your VPC. Requests to Amazon S3 over interface endpoints stay on the Amazon network. You can also access interface endpoints in your VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (Site-to-Site VPN). For more information about how to connect your VPC with your on-premises network, see the [Direct Connect User Guide](#) and the [AWS Site-to-Site VPN User Guide](#).

For general information about interface endpoints, see [Interface VPC endpoints \(AWS PrivateLink\)](#) in the *AWS PrivateLink Guide*.

- [Creating a VPC endpoint policy for Amazon S3](#)

Types of VPC endpoints for Amazon S3

You can use two types of VPC endpoints to access Amazon S3: *gateway endpoints* and *interface endpoints* (by using AWS PrivateLink). A *gateway endpoint* is a gateway that you specify in your route table to access Amazon S3 from your VPC over the AWS network. *Interface endpoints* extend the functionality of gateway endpoints by using private IP addresses to route requests to Amazon S3 from within your VPC, on premises, or from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway. For more information, see [What is VPC peering?](#) and [Transit Gateway vs VPC peering](#).

Interface endpoints are compatible with gateway endpoints. If you have an existing gateway endpoint in the VPC, you can use both types of endpoints in the same VPC.

Gateway endpoints for Amazon S3	Interface endpoints for Amazon S3
In both cases, your network traffic remains on the AWS network.	
Use Amazon S3 public IP addresses	Use private IP addresses from your VPC to access Amazon S3
Use the same Amazon S3 DNS names	Require endpoint-specific Amazon S3 DNS names
Do not allow access from on premises	Allow access from on premises
Do not allow access from another AWS Region	Allow access from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway
Not billed	Billed

For more information, see [Gateway endpoints](#) and [interface VPC endpoints](#) in the *AWS PrivateLink Guide*.

Restrictions and limitations of AWS PrivateLink for Amazon S3

VPC limitations apply to AWS PrivateLink for Amazon S3. For more information, see [Interface endpoint considerations](#) and [AWS PrivateLink quotas](#) in the *AWS PrivateLink Guide*. In addition, the following restrictions apply.

Interface endpoints for Amazon S3 does not support the following:

- [Federal Information Processing Standard \(FIPS\) endpoints](#)
- [Website endpoints](#)
- [Legacy global endpoints](#)
- [S3 dash Region endpoints](#)
- Using [CopyObject](#) or [UploadPartCopy](#) between buckets in different AWS Regions
- Transport Layer Security (TLS) 1.0
- Transport Layer Security (TLS) 1.1
- Transport Layer Security (TLS) 1.3
- Hybrid post-quantum Transport Layer Security (TLS)

Creating a VPC endpoint

To create a VPC interface endpoint, see [Create a VPC endpoint](#) in the *AWS PrivateLink Guide*. To create a VPC gateway endpoint, see [Create a gateway endpoint](#) in the *AWS PrivateLink Guide*.

Accessing Amazon S3 interface endpoints

When you create an interface endpoint, Amazon S3 generates two types of endpoint-specific, S3 DNS names: *Regional* and *zonal*.

- A *Regional* DNS name includes a unique VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for VPC endpoint ID `vpce-1a2b3c4d`, the DNS name generated might be similar to `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, `vpce-1a2b3c4d-5e6f-us-east-1a.s3.us-east-1.vpce.amazonaws.com`. You might use this option if your

architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

Endpoint-specific S3 DNS names can be resolved from the S3 public DNS domain.

VPC endpoints for Amazon S3 support different types of IP addressing, including: IPv4, IPv6, and Dualstack. See [IP Address types for VPC endpoints](#) and [DNS record IP types for VPC endpoints](#).

IP Address types for VPC endpoints

VPC endpoints for Amazon S3 support different types of IP addressing, including:

- **IPv4**

VPC endpoints can be configured to use only IPv4 addresses for connectivity.

- **IPv6**

VPC endpoints can be configured to use only IPv6 addresses for connectivity.

- **Dual-stack**

VPC endpoints can be configured in dual-stack mode, supporting both IPv4 and IPv6 addresses simultaneously. This provides flexibility to access Amazon S3 over either IPv4 or IPv6 networks.

The IP address type you choose for your VPC endpoint will depend on the networking requirements of your applications and infrastructure. Considerations may include the IP addressing schemes used in your VPC, on-premises networks, and across the internet connectivity to Amazon S3. For more information, see IP address types for [interface endpoints](#) and [gateway endpoints](#) in the *Amazon Virtual Private Cloud* guide.

DNS record IP types for VPC endpoints

Depending on your IP address type, when you call a VPC endpoint, the AWS service can return A records, AAAA records, or both A and AAAA records. You can customize which record types your AWS service returns by modifying the DNS record IP type. The following table shows the supported DNS record IP types and the IP address types:

Supported IP address types	DNS record IP types
IPv4	IPv4

Supported IP address types	DNS record IP types
IPv6	IPv6
Dualstack	Dualstack, IPv4, IPv6, Service-defined

Configuring the service-defined DNS record IP type for Amazon S3

If you create a gateway endpoint for Amazon S3 and configure the DNS record IP type as service-defined and use the regional service endpoint, (such as s3.us-east-2.amazonaws.com), Amazon S3 returns A records to your clients. In contrast, if you create a gateway endpoint and are using a dual-stack service endpoint, (such as s3.dualstack.us-east-2.amazonaws.com) and select the DNS record IP type as service-defined, Amazon S3 returns both A and AAAA records to your clients.

Similarly, if you create an interface endpoint with Private DNS enabled and choose service-defined as the DNS record type, for the regional service endpoint, (such as, s3.us-east-2.amazonaws.com), Amazon S3 returns A records to your client. Whereas, for a dualstack service endpoint, (such as, s3.dualstack.us-east-2.amazonaws.com), Amazon S3 returns both A and AAAA records. For more information, see DNS record IP type for [interface endpoints](#) and [gateway endpoints](#) in the *VPC User Guide*.

The following table shows the supported DNS record IP types for gateway and interface endpoints:

IP address type	Supported DNS record IP types for S3 Gateway endpoints	Supported DNS record IP types for S3 Interface endpoints
IPv4	IPv4, service-defined*	IPv4
IPv6	IPv6, service-defined*	IPv6
Dualstack	IPv4, IPv6, Dualstack, service-defined*	Dualstack*, IPv4, IPv6, service-defined

* Represents the default DNS record IP type.

To enable IPv6 connectivity on an existing S3 gateway or interface endpoint, update the IP address type for the endpoint to **Dualstack**. When updated, Amazon S3 automatically updates the routing tables with IPv6 addresses for gateway endpoints. Then you can use the dualstack service endpoint, such as `s3.dualstack.us-east-2.amazonaws.com`, and Amazon S3 will return both A and AAAA records for dualstack S3 DNS queries. If you want to use IPV6 with the regional service endpoint, such as `s3.us-east-2.amazonaws.com`, modify the IP address type for the endpoint to **Dualstack**; and the DNS record IP type to **Dualstack**. Then Amazon S3 will return both A and AAAA records for the regional S3 DNS queries.

Considerations

- If your gateway endpoint has the default configuration of IP address type as IPv4 and DNS record IP type as service-defined, then the dualstack service endpoint (such as `s3.dualstack.us-east-2.amazonaws.com`), traffic that uses AAAA records won't be routed through the gateway endpoint. Instead, this traffic will be dropped or routed over an IPv6-compatible path if one is present. For example, if your virtual private cloud (VPC) has an internet gateway, your IPv6 traffic will be routed over the internet gateway in your VPC in this scenario. If you want to ensure your traffic is always routed over a VPC endpoint, you can use an Amazon S3 bucket policy that restricts access to a specific bucket if a specified VPC endpoint is not used. For more information, see [Restricting access to a specific VPC endpoint](#).
- If your interface endpoint has the default configuration of IP address type, which is IPv4, and DNS record IP type as IPv4, dualstack service endpoints, such as `ass3.dualstack.us-east-2.amazonaws.com`, are not supported. Traffic that uses the A or AAAA records of the dualstack service endpoints won't be routed through the interface endpoint. Instead, this traffic will be dropped or routed over another compatible path if one is present.
- Creating or modifying a gateway endpoint with a DNS record IP type other than service-defined requires both the `enableDnsSupport` and `enableDnsHostnames` VPC attributes to be set to true.

Private DNS

Private DNS options for VPC interface endpoints simplify routing S3 traffic over VPC endpoints and help you take advantage of the lowest-cost network path available to your application. You can

use private DNS options to route Regional S3 traffic without updating your S3 clients to use the endpoint-specific DNS names of your interface endpoints, or managing DNS infrastructure. With private DNS names enabled, Regional S3 DNS queries resolve to the private IP addresses of AWS PrivateLink for the following endpoints:

- Regional bucket endpoints (for example, s3.us-east-1.amazonaws.com)
- Control endpoints (for example, s3-control.us-east-1.amazonaws.com)
- Access point endpoints (for example, s3-accesspoint.us-east-1.amazonaws.com)

If you have a gateway endpoint in your VPC, you can automatically route in-VPC requests over your existing S3 gateway endpoint and on-premises requests over your interface endpoint. This approach allows you to optimize your networking costs by using gateway endpoints, which are not billed, for your in-VPC traffic. Your on-premises applications can use AWS PrivateLink with the help of the inbound Resolver endpoint. Amazon provides a DNS server, called the Route 53 Resolver, for your VPC. An inbound Resolver endpoint forwards DNS queries from the on-premises network to Route 53 Resolver.

Important

To take advantage of the lowest cost network path when using **Enable private DNS only for inbound endpoints**, a gateway endpoint must be present in your VPC. The presence of a gateway endpoint helps ensure that in-VPC traffic always routes over the AWS private network when the **Enable private DNS only for inbound endpoints** option is selected.

You must maintain this gateway endpoint while you have the **Enable private DNS only for inbound endpoints** option selected. If you want to delete your gateway endpoint you must first clear **Enable private DNS only for inbound endpoints**.

If you want to update an existing interface endpoint to **Enable private DNS only for inbound endpoints**, first confirm that your VPC has an S3 gateway endpoint. For more information about gateway endpoints and managing private DNS names, see [Gateway VPC endpoints](#) and [Manage DNS names](#) respectively in the *AWS PrivateLink Guide*.

When enabling **Private DNS for inbound resolver only**, the dnsRecordIpType of the gateway endpoint must either match that of interface endpoint or be **service defined**.

The **Enable private DNS only for inbound endpoints** option is available only for services that support gateway endpoints.

For more information about creating a VPC endpoint that uses **Enable private DNS only for inbound endpoints**, see [Create an interface endpoint](#) in the *AWS PrivateLink Guide*.

Using the VPC console

In the console you have two options: **Enable DNS name** and **Enable private DNS only for inbound endpoints**. **Enable DNS name** is an option supported by AWS PrivateLink. By using the **Enable DNS name** option, you can use Amazon's private connectivity to Amazon S3, while making requests to the default public endpoint DNS names. When this option is enabled, customers can take advantage of the lowest cost network path available to their application.

When you enable private DNS names on an existing or new VPC interface endpoint for Amazon S3, the **Enable private DNS only for inbound endpoints** option is selected by default. If this option is selected, your applications use only interface endpoints for your on-premises traffic. This in-VPC traffic automatically uses the lower-cost gateway endpoints. Alternatively, you can clear **Enable private DNS only for inbound endpoints** to route all S3 requests over your interface endpoint.

Using the AWS CLI

If you don't specify a value for `PrivateDnsOnlyForInboundResolverEndpoint`, it will default to `true`. However, before your VPC applies your settings, it performs a check to make sure that you have a gateway endpoint present in the VPC. If a gateway endpoint is present in the VPC, the call succeeds. If not, you will see the following error message:

To set `PrivateDnsOnlyForInboundResolverEndpoint` to `true`, the VPC `vpce_id` must have a gateway endpoint for the service.

For a new VPC Interface endpoint

Use the `private-dns-enabled` and `dns-options` attributes to enable private DNS through the command line. The `PrivateDnsOnlyForInboundResolverEndpoint` option in the `dns-options` attribute must be set to `true`. Replace the `user input placeholders` with your own information.

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name s3-service-name \
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface \
```

```
--private-dns-enabled \
--ip-address-type ip-address-type \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true \
--security-group-ids client-sg-id
```

For an existing VPC endpoint

If you want to use private DNS for an existing VPC endpoint, use the following example command and replace the *user input placeholders* with your own information.

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=false
```

If you want to update an existing VPC endpoint to enable private DNS only for the Inbound Resolver, use the following example and replace the sample values with your own.

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true
```

Accessing buckets, access points, and Amazon S3 Control API operations from S3 interface endpoints

You can use the AWS CLI or AWS SDKs to access buckets, S3 access points, and Amazon S3 Control API operations through S3 interface endpoints.

The following image shows the VPC console **Details** tab, where you can find the DNS name of a VPC endpoint. In this example, the *VPC endpoint ID (vpce-id)* is `vpce-0e25b8cdd720f900e` and the *DNS name* is `*.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com`.

Details	Subnets	Security Groups	Policy	Notifications	Tags	
Endpoint ID	vpce-0e25b8cdd720f900e				VPC ID	vpc-0c0ccb9d87b1734bd VPCStack VPC
Status	available				Status message	
Creation time	January 8, 2021 at 1:30:11 AM UTC-8				Service name	com.amazonaws.us-east-1.s3
Endpoint type	Interface				DNS names	*.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com (Z7HUB22UULQXV)

When using the DNS name to access a resource, replace * with the appropriate value. The appropriate values to use in place of * are as follows:

- bucket
- accesspoint
- control

For example, to access a bucket, use a *DNS name* like this:

bucket.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com

For examples of how to use DNS names to access buckets, access points, and Amazon S3 Control API operations, see the following sections of [AWS CLI examples](#) and [AWS SDK examples](#).

For more information about how to view your endpoint-specific DNS names, see [Viewing endpoint service private DNS name configuration](#) in the *VPC User Guide*.

AWS CLI examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints in AWS CLI commands, use the --region and --endpoint-url parameters.

Example: Use an endpoint URL to list objects in your bucket

In the following example, replace the bucket name *my-bucket*, Region *us-east-1*, and the DNS name of the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
aws s3 ls s3://my-bucket --region us-east-1 --endpoint-url  
https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

Example: Use an endpoint URL to list objects from an access point

- **Method 1 – Using the Amazon Resource Name (ARN) of the access point with the access point endpoint**

Replace the ARN `us-east-1:123456789012:accesspoint/accesspointexemplename`, the Region `us-east-1`, and the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` with your own information.

```
aws s3api list-objects-v2 --bucket arn:aws:s3:us-east-1:123456789012:accesspoint/accesspointexemplename --region us-east-1 --endpoint-url https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

If you can't run the command successfully, update your AWS CLI to the latest version and try again. For more information on the update instructions, see [Installing or updating the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

- **Method 2 – Using the alias of the access point with the regional bucket endpoint**

In the following example, replace the access point alias `accesspointexemplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias`, the Region `us-east-1`, and the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` with your own information.

```
aws s3api list-objects-v2 --bucket accesspointexemplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias --region us-east-1 --endpoint-url https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

- **Method 3 – Using the alias of the access point with the access point endpoint**

First, to construct an S3 endpoint with the bucket included as part of the hostname, set the addressing style to `virtual` for `aws s3api` to use. For more information about AWS `configure`, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

```
aws configure set default.s3.addressing_style virtual
```

Then, in the following example, replace the access point alias `accesspointexemplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias`, the Region `us-east-1`, and the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` with your own information. For more information about access point alias, see [Access point aliases](#).

```
aws s3api list-objects-v2 --  
bucket accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias --  
region us-east-1 --endpoint-url https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

Example: Use an endpoint URL to list jobs with an S3 control API operation

In the following example, replace the Region *us-east-1*, the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com*, and the account ID *12345678* with your own information.

```
aws s3control --region us-east-1 --endpoint-url  
https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com list-jobs --  
account-id 12345678
```

AWS SDK examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then configure your clients to use an endpoint URL for accessing a bucket, access point, or Amazon S3 Control API operations through S3 interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
s3_client = session.client(  
    service_name='s3',  
    region_name='us-east-1',  
    endpoint_url='https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'  
)
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
ap_client = session.client(  
    service_name='s3',  
    region_name='us-east-1',  
    endpoint_url='https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-  
east-1.vpce.amazonaws.com'  
)
```

Example: Use an endpoint URL to access the Amazon S3 Control API

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
control_client = session.client(  
    service_name='s3control',  
    region_name='us-east-1',  
    endpoint_url='https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'  
)
```

SDK for Java 1.x

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
// bucket client  
final AmazonS3 s3 = AmazonS3ClientBuilder.standard().withEndpointConfiguration(  
    new AwsClientBuilder.EndpointConfiguration(  
        "https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",  
        Regions.DEFAULT_REGION.getName()  
    )  
.build();  
List<Bucket> buckets = s3.listBuckets();
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and ARN *us-east-1:123456789012:accesspoint/prod* with your own information.

```
// accesspoint client
```

```
final AmazonS3 s3accesspoint =
    AmazonS3ClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
            "https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",
            Regions.DEFAULT_REGION.getName()
        )
    ).build();
ObjectListing objects = s3accesspoint.listObjects("arn:aws:s3:us-east-1:123456789012:accesspoint/prod");
```

Example: Use an endpoint URL to access an Amazon S3 Control API operation

In the following example, replace the VPC endpoint ID **vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com** with your own information.

```
// control client
final AWSS3Control s3control =
    AWSS3ControlClient.builder().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
            "https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",
            Regions.DEFAULT_REGION.getName()
        )
    ).build();
final ListJobsResult jobs = s3control.listJobs(new ListJobsRequest());
```

SDK for Java 2.x

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the VPC endpoint ID **vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com** and the Region **Region.US_EAST_1** with your own information.

```
// bucket client
Region region = Region.US_EAST_1;
s3Client = S3Client.builder().region(region)

.endpointOverride(URI.create("https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
    .build()
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` and the Region `Region.US_EAST_1` with your own information.

```
// accesspoint client
Region region = Region.US_EAST_1;
S3Client s3Client = S3Client.builder().region(region)

.endpointOverride(URI.create("https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
.build()
```

Example: Use an endpoint URL to access the Amazon S3 Control API

In the following example, replace the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` and the Region `Region.US_EAST_1` with your own information.

```
// control client
Region region = Region.US_EAST_1;
S3ControlClient s3ControlClient = S3ControlClient.builder().region(region)

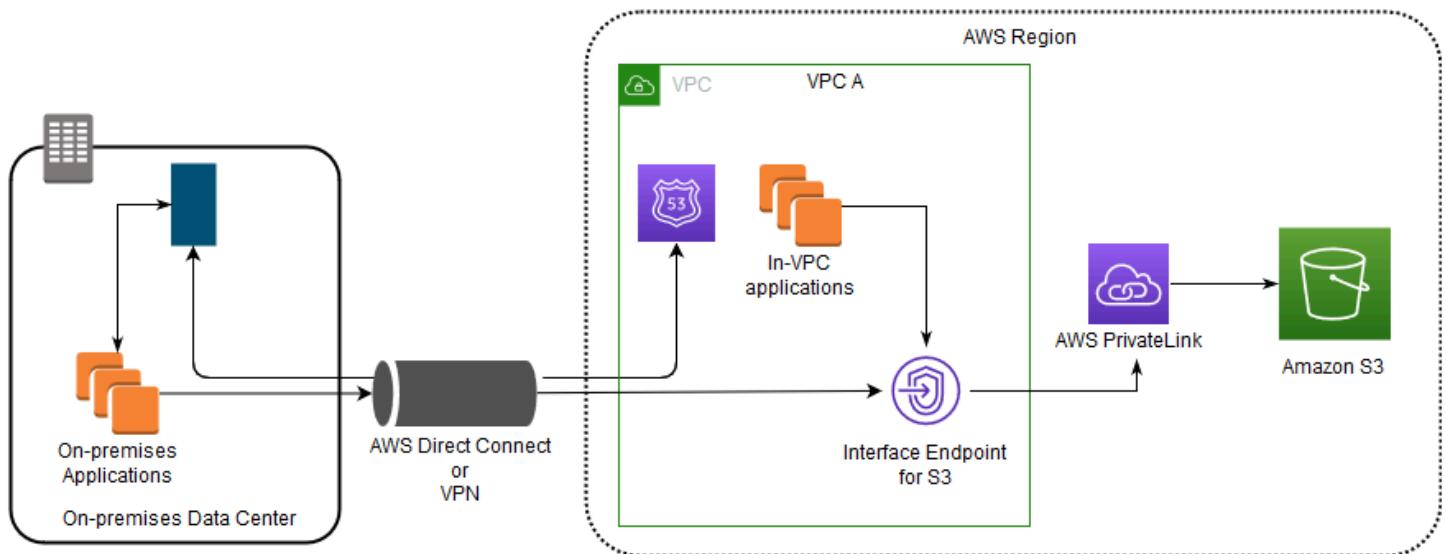

.endpointOverride(URI.create("https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
.build()
```

Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for Amazon S3, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public Amazon S3 DNS domain.

Using interface endpoints to access Amazon S3 without a gateway endpoint or an internet gateway in the VPC

Interface endpoints in your VPC can route both in-VPC applications and on-premises applications to Amazon S3 over the Amazon network, as illustrated in the following diagram.

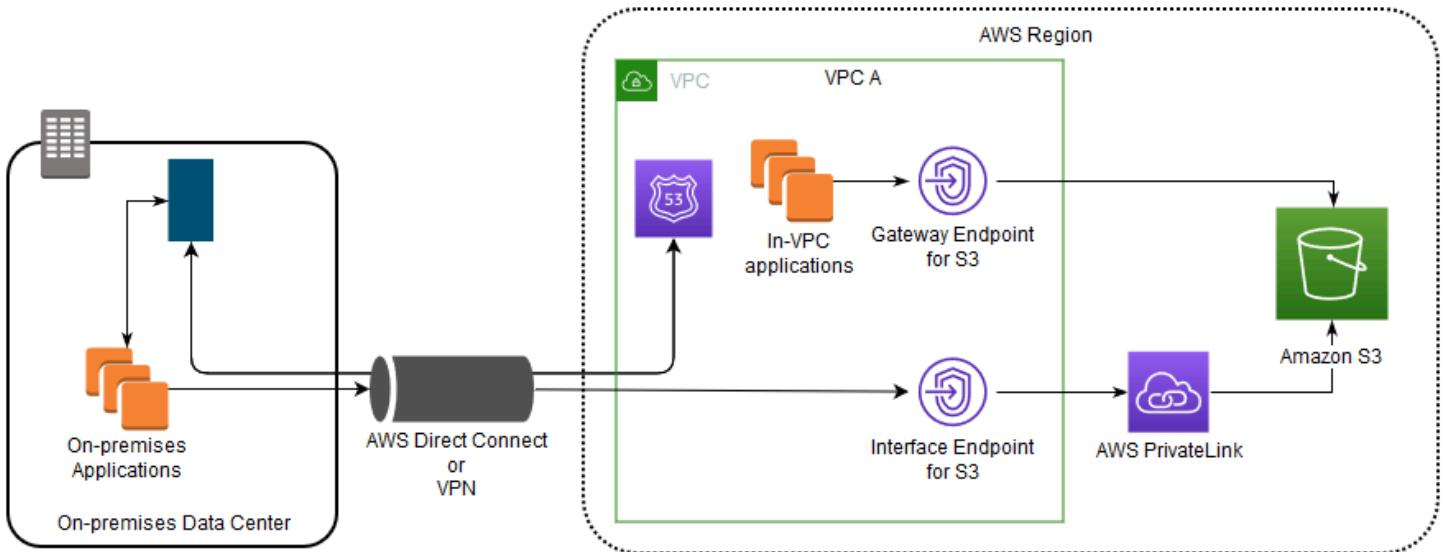

The diagram illustrates the following:

- Your on-premises network uses Direct Connect or Site-to-Site VPN to connect to VPC A.
- Your applications on-premises and in VPC A use endpoint-specific DNS names to access Amazon S3 through the S3 interface endpoint.
- On-premises applications send data to the interface endpoint in the VPC through Direct Connect (or Site-to-Site VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.
- In-VPC applications also send traffic to the interface endpoint. AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.

Using gateway endpoints and interface endpoints together in the same VPC to access Amazon S3

You can create interface endpoints and retain the existing gateway endpoint in the same VPC, as the following diagram shows. By taking this approach, you allow in-VPC applications to continue accessing Amazon S3 through the gateway endpoint, which is not billed. Then, only your on-premises applications would use interface endpoints to access Amazon S3. To access Amazon S3 this way, you must update your on-premises applications to use endpoint-specific DNS names for Amazon S3.

The diagram illustrates the following:

- On-premises applications use endpoint-specific DNS names to send data to the interface endpoint within the VPC through Direct Connect (or Site-to-Site VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.
- Using default Regional Amazon S3 names, in-VPC applications send data to the gateway endpoint that connects to Amazon S3 over the AWS network.

For more information about gateway endpoints, see [Gateway VPC endpoints](#) in the *VPC User Guide*.

Creating a VPC endpoint policy for Amazon S3

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon S3. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

You can also use Amazon S3 bucket policies to restrict access to specific buckets from a specific VPC endpoint by using the `aws:sourceVpc` condition in your bucket policy. The following examples show policies that restrict access to a bucket or to an endpoint.

Topics

- [Example: Restricting access to a specific bucket from a VPC endpoint](#)

- [Example: Restricting access to buckets in a specific account from a VPC endpoint](#)
- [Example: Restricting access to a specific VPC endpoint in the S3 bucket policy](#)

Example: Restricting access to a specific bucket from a VPC endpoint

You can create an endpoint policy that restricts access to only specific Amazon S3 buckets. This type of policy is useful if you have other AWS services in your VPC that use buckets. The following bucket policy restricts access to only the *amzn-s3-demo-bucket1*. To use this endpoint policy, replace *amzn-s3-demo-bucket1* with the name of your bucket.

JSON

            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket1",  
                        "arn:aws:s3:::amzn-s3-demo-bucket1/*"]  
        }  
    ]  
}
```

Example: Restricting access to buckets in a specific account from a VPC endpoint

You can create an endpoint policy that restricts access to only the S3 buckets in a specific AWS account. To prevent clients within your VPC from accessing buckets that you don't own, use the following statement in your endpoint policy. The following example statement creates a policy that restricts access to resources owned by a single AWS account ID, *111122223333*.

```
{  
    "Statement": [  
        {
```

```
"Sid": "Access-to-bucket-in-specific-account-only",
"Principal": "*",
>Action": [
    "s3:GetObject",
    "s3:PutObject"
],
"Effect": "Deny",
"Resource": "arn:aws:s3:::*",
"Condition": {
    "StringNotEquals": {
        "aws:ResourceAccount": "111122223333"
    }
}
]
}
```

Note

To specify the AWS account ID of the resource being accessed, you can use either the `aws:ResourceAccount` or the `s3:ResourceAccount` key in your IAM policy. However, be aware that some AWS services rely on access to AWS managed buckets. Therefore, using the `aws:ResourceAccount` or `s3:ResourceAccount` key in your IAM policy might also affect access to these resources.

Example: Restricting access to a specific VPC endpoint in the S3 bucket policy

The following Amazon S3 bucket policy allows access to a specific bucket, `amzn-s3-demo-bucket2`, from only the VPC endpoint `vpce-1a2b3c4d`. The policy denies all access to the bucket if the specified endpoint is not being used. The `aws:sourceVpc` condition specifies the endpoint and doesn't require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the endpoint ID. To use this bucket policy, replace `amzn-s3-demo-bucket2` and `vpce-1a2b3c4d` with your bucket name and endpoint.

Important

- When applying the following Amazon S3 bucket policy to restrict access to only certain VPC endpoints, you might block your access to the bucket without intending to do so. Bucket policies that are intended to specifically limit bucket access to connections

originating from your VPC endpoint can block all connections to the bucket. For information about how to fix this issue, see [My bucket policy has the wrong VPC or VPC endpoint ID. How can I fix the policy so that I can access the bucket?](#) in the *Support Knowledge Center*.

- Before using the following example policy, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- This policy disables *console* access to the specified bucket, because console requests don't originate from the specified VPC endpoint.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909152",  
    "Statement": [  
        { "Sid": "Access-to-specific-VPCE-only",  
            "Principal": "*",  
            "Action": "s3:*",  
            "Effect": "Deny",  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket2",  
                        "arn:aws:s3:::amzn-s3-demo-bucket2/*"],  
            "Condition": {"StringNotEquals": {"aws:sourceVpce": "vpce-1a2b3c4d"}}  
        }  
    ]  
}
```

For more policy examples, see [Endpoints for Amazon S3](#) in the *VPC User Guide*.

For more information about VPC connectivity, see [Network-to-VPC connectivity options](#) in the AWS whitepaper [Amazon Virtual Private Cloud Connectivity Options](#).

Compliance validation for Amazon S3

The security and compliance of Amazon S3 is assessed by third-party auditors as part of multiple AWS compliance programs, including the following:

- System and Organization Controls (SOC)
- Payment Card Industry Data Security Standard (PCI DSS)
- Federal Risk and Authorization Management Program (FedRAMP)
- Health Insurance Portability and Accountability Act (HIPAA)

AWS provides a frequently updated list of AWS services in scope of specific compliance programs at [AWS Services in Scope by Compliance Program](#).

Third-party audit reports are available for you to download using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

For more information about AWS compliance programs, see [AWS Compliance Programs](#).

Your compliance responsibility when using Amazon S3 is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. If your use of Amazon S3 is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- [Security and Compliance Quick Start Guides](#) that discuss architectural considerations and steps for deploying security- and compliance-focused baseline environments on AWS.
- [Architecting for HIPAA Security and Compliance](#) outlines how companies use AWS to help them meet HIPAA requirements.
- [AWS Compliance Resources](#) provide several different workbooks and guides that might apply to your industry and location.
- [AWS Config](#) can be used to assess how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) provides you with a comprehensive view of your security state within AWS and helps you check your compliance with security industry standards and best practices.
- [Locking objects with Object Lock](#) can help you meet technical requirements of financial services regulators (such as the SEC, FINRA, and CFTC) that require write once, read many (WORM) data storage for certain types of books and records information.

- [Cataloging and analyzing your data with S3 Inventory](#) can help you audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs.

Resilience in Amazon S3

The AWS global infrastructure is built around Regions and Availability Zones. AWS Regions provide multiple, physically separated and isolated Availability Zones that are connected with low latency, high throughput, and highly redundant networking. These Availability Zones offer you an effective way to design and operate applications and databases. They are more highly available, fault tolerant, and scalable than traditional single data center infrastructures or multi-data center infrastructures. If you specifically need to replicate your data over greater geographic distances, you can use [Replicating objects within and across Regions](#), which enables automatic, asynchronous copying of objects across buckets in different AWS Regions.

Each AWS Region has multiple Availability Zones. You can deploy your applications across multiple Availability Zones in the same Region for fault tolerance and low latency. Availability Zones are connected to each other with fast, private fiber-optic networking, enabling you to easily architect applications that automatically fail over between Availability Zones without interruption.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](#).

In addition to the AWS global infrastructure, Amazon S3 offers several features to help support your data resiliency and backup needs.

Lifecycle configuration

A lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. With lifecycle configuration rules, you can tell Amazon S3 to transition objects to less expensive storage classes, archive them, or delete them. For more information, see [Managing the lifecycle of objects](#).

Versioning

Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

S3 Object Lock

You can use S3 Object Lock to store objects using a *write once, read many* (WORM) model. Using S3 Object Lock, you can prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. S3 Object Lock enables you to meet regulatory requirements

that require WORM storage or simply to add an additional layer of protection against object changes and deletion. For more information, see [Locking objects with Object Lock](#).

Storage classes

Amazon S3 offers a range of storage classes to choose from depending on the requirements of your workload. The S3 Standard-IA and S3 One Zone-IA storage classes are designed for data you access about once a month and need milliseconds access. The S3 Glacier Instant Retrieval storage class is designed for long-lived archive data accessed with milliseconds access that you access about once a quarter. For archive data that does not require immediate access, such as backups, you can use the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see [Understanding and managing Amazon S3 storage classes](#).

The following security best practices also address resilience:

- [Enable versioning](#)
- [Consider Amazon S3 cross-region replication](#)
- [Identify and audit all your Amazon S3 buckets](#)

Encryption of Amazon S3 backups

If you are storing backups using Amazon S3, the encryption of your backups depends on the configuration of those buckets. Amazon S3 provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The default encryption supports keys stored in AWS KMS (SSE-KMS). For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

For more information about Versioning and Object Lock, see the following topics: [Retaining multiple versions of objects with S3 Versioning](#) [Locking objects with Object Lock](#)

Infrastructure security in Amazon S3

As a managed service, Amazon S3 is protected by the AWS global network security procedures that are described in the security pillar of the [AWS Well-Architected Framework](#).

Access to Amazon S3 via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend also supporting TLS 1.3 and hybrid post-quantum key exchange. To learn about post-quantum cryptography at AWS, including links to blog posts and research papers, see [Post-Quantum Cryptography for AWS](#).

 **Note**

TLS 1.3 is supported in all S3 endpoints, except for AWS PrivateLink for Amazon S3 and Multi-Region Access Points.

Clients must also support cipher suites with Perfect Forward Secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Additionally, requests must be signed using AWS Signature V4 or AWS Signature V2, requiring valid credentials to be provided.

These APIs are callable from any network location. However, Amazon S3 does support resource-based access policies, which can include restrictions based on the source IP address. You can also use Amazon S3 bucket policies to control access to buckets from specific virtual private cloud (VPC) endpoints, or specific VPCs. Effectively, this isolates network access to a given Amazon S3 bucket from only the specific VPC within the AWS network. For more information, see [Controlling access from VPC endpoints with bucket policies](#).

The following security best practices also address infrastructure security in Amazon S3:

- [Consider VPC endpoints for Amazon S3 access](#)
- [Identify and audit all your Amazon S3 buckets](#)

Configuration and vulnerability analysis in Amazon S3

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- [Compliance validation for Amazon S3](#)
- [Shared Responsibility Model](#)
- [Amazon Web Services: Overview of Security Processes](#)

The following security best practices also address configuration and vulnerability analysis in Amazon S3:

- [Identify and audit all your Amazon S3 buckets](#)
- [Enable AWS Config](#)

Access management

Amazon S3 provides a variety of access management tools. The following is a list of these features and tools. You do not need all of these access management tools, but you must use one or more to grant access to your Amazon S3 buckets, objects, and other [S3 resources](#). Proper application of these tools can help make sure that your resources are accessible only to the intended users.

The most commonly used access management tool is an *access policy*. An access policy can be a *resource-based policy* that is attached to an AWS resource, such as a bucket policy for a bucket. An access policy can also be an *identity-based policy* that is attached to an AWS Identity and Access Management (IAM) identity, such as an IAM user, group, or role. An access policy describes who has access to what things. Write an access policy to grant AWS accounts and IAM users, groups, and roles permission to perform operations on a resource. For example, you can grant PUT Object permission to another AWS account so that the other account can upload objects to your bucket.

The following are the access management tools available in Amazon S3. For a more comprehensive guide on Amazon S3 access control, see [Access control in Amazon S3](#).

Bucket policy

An Amazon S3 bucket policy is a JSON-formatted [AWS Identity and Access Management \(IAM\) resource-based policy](#) that is attached to a particular bucket. Use bucket policies to grant other

AWS accounts or IAM identities permissions for the bucket and the objects in it. Many S3 access management use cases can be met by using a bucket policy. With bucket policies, you can personalize bucket access to help make sure that only the identities that you have approved can access resources and perform actions within them. For more information, see [Bucket policies for Amazon S3](#).

Identity-based policy

An identity-based or IAM user policy is a type of [AWS Identity and Access Management \(IAM\) policy](#). An identity-based policy is a JSON-formatted policy that is attached to IAM users, groups, or roles in your AWS account. You can use identity-based policies to grant an IAM identity access to your buckets or objects. You can create IAM users, groups, and roles in your account and attach access policies to them. You can then grant access to AWS resources, including Amazon S3 resources. For more information, see [Identity-based policies for Amazon S3](#).

S3 Access Grants

Use S3 Access Grants to create access grants to your Amazon S3 data for both identities in corporate identity directories, such as Active Directory, and to AWS Identity and Access Management (IAM) identities. S3 Access Grants helps you manage data permissions at scale. Additionally, S3 Access Grants logs end-user identity and the application used to access the S3 data in AWS CloudTrail. This provides a detailed audit history down to the end-user identity for all access to the data in your S3 buckets. For more information, see [Managing access with S3 Access Grants](#).

Access Points

Amazon S3 Access Points simplifies managing data access at scale for applications that use shared datasets on S3. Access Points are named network endpoints that are attached to a bucket. You can use access points to perform S3 object operations at scale, such as uploading and retrieving objects. A bucket can have up to 10,000 access points attached, and for each access point, you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. S3 Access Points can be associated with buckets in the same account or in another trusted account. Access Points policies are resource-based policies that are evaluated in conjunction with the underlying bucket policy. For more information, see [Managing access to shared datasets with access points](#).

Access control list (ACL)

An ACL is a list of grants identifying the grantee and the permission granted. ACLs grant basic read or write permissions to other AWS accounts. ACLs use an Amazon S3-specific XML schema. An ACL is a type of [AWS Identity and Access Management \(IAM\) policy](#). An object ACL is used to manage access to an object, and a bucket ACL is used to manage access to a bucket. With bucket policies, there is a single policy for the entire bucket, but object ACLs are specified for each object. We recommend that you keep ACLs turned off, except in circumstances where you must individually control access for each object. For more information about using ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Warning

The majority of modern use cases in Amazon S3 do not require the use of ACLs.

Object Ownership

To manage access to your objects, you must be the owner of the object. You can use the Object Ownership bucket-level setting to control ownership of objects uploaded to your bucket. Also, use Object Ownership to turn on ACLs. By default, Object Ownership is set to the *Bucket owner enforced setting* and all ACLs are turned off. When ACLs are turned off, the bucket owner owns all of the objects in the bucket and exclusively manages access to data. To manage access, the bucket owner uses policies or another access management tool, excluding ACLs. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

For a more comprehensive guide on Amazon S3 access control and additional best practices, see [Access control in Amazon S3](#).

Amazon Simple Storage Service data inventory

Amazon S3

Amazon S3 provides scalable object storage in the AWS Cloud. It allows you to store and retrieve any amount of data from anywhere on the web. Based on its unique architecture, S3 is designed to exceed 99.99999999% (11 nines) data durability. Additionally, S3 stores data redundantly across a minimum of 3 Availability Zones by default, providing built-in resilience against widespread disaster. Customers can store data in a single Availability Zone to minimize storage cost or latency, in multiple Availability Zones for resilience against the permanent loss of an entire data center, or in multiple AWS Regions to meet geographic resilience requirements.

Key Characteristics

Geographic location

Amazon S3 is hosted in multiple locations worldwide. You select locations for your data that put them close to your customers.

Buckets

A bucket is a container for objects stored in Amazon S3. Every object is contained within a bucket.

Objects

Objects are the fundamental entities stored in Amazon S3. Objects consist of object data and metadata.

Storage Classes

Amazon S3 offers different storage classes optimized for different use cases.

Storage Management

Amazon S3 has storage management features that you can use to manage costs and adhere to compliance requirements.

Access management and security

Amazon S3 provides features for auditing and managing access to your buckets and objects.

Geographic location

Amazon S3 is available in every AWS Region worldwide. Each Region is a separate geographic area.

Why this matters

After you determine where you want to store your data, you can decide whether to deploy functionally equivalent storage in the same locations or different locations, depending on your needs.

To get a summary of your Amazon S3 buckets across all Regions

Use the following AWS CLI command:

```
aws s3api list-buckets /  
--max-items 100 /  
--page-size 100
```

For more information, see [list-buckets](#) in the AWS CLI Command Reference.

Buckets

Amazon S3 buckets are containers for objects. Each bucket has a unique name across all of AWS. Amazon S3 supports four types of buckets: general purpose buckets, Directory buckets, table buckets, and vector buckets. Each type of bucket provides a unique set of features for different use cases. For more information on the different bucket types, see [Buckets](#) in the Amazon S3 User Guide.

Why these matter

After you list your buckets, you can validate your buckets settings for functionally equivalent storage systems by reviewing the various bucket configuration settings.

To list bucket configurations

```
aws s3api get-bucket-versioning --bucket amzn-s3-demo-bucket1  
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1  
aws s3api get-bucket-logging --bucket amzn-s3-demo-bucket1
```

For more information, see [get-bucket-versioning](#) in the AWS CLI Command Reference.

Objects

Objects are the fundamental entities stored in Amazon S3. Each object consists of data, a key (name), and metadata.

Why these matter

Understanding your object characteristics helps plan for equivalent storage capacity and performance requirements in functionally equivalent systems.

To list objects and their properties

```
aws s3api list-objects-v2 --bucket amzn-s3-demo-bucket1 /
```

```
--query 'Contents[].{Key: Key, Size: Size, LastModified: LastModified}'
```

For more information, see [list-objects-v2](#) in the AWS CLI Command Reference.

Storage Classes

- Amazon S3 Standard
- Amazon S3 Intelligent-Tiering
- Amazon S3 Standard-IA
- Amazon S3 One Zone-IA
- Amazon S3 Glacier Instant Retrieval
- Amazon S3 Glacier Flexible Retrieval
- Amazon S3 Glacier Deep Archive
- Amazon S3 Express One Zone

Why these matter

Understanding your storage class usage helps determine appropriate storage tiers in functionally equivalent systems. For more information, see [Understanding and managing Amazon S3 storage classes](#) in the Amazon S3 User Guide.

To review setorage class selection and usage

You can use Amazon S3 Storage Lens to review your storage class selection and usage. For more information, see [Understanding and manage Amazon S3 storage classes](#) in the Amazon S3 User Guide.

Storage management

Why this matters

Understanding your storage management usage helps plan for equivalent features to manage costs and adhere to compliance requirements in functionally equivalent systems.

To review storage managment feature selection and usage

You can use Amazon S3 Storage Lens to review your usage of storage management features. For more information, see [Amazon S3 Storage Lens metrics glossary](#) in the Amazon S3 User Guide.

Access management and security

Why these matter

Understanding your access management and security settings help you plan for equivalent features to manage access and security requirements in functionally equivalent systems.

To review your access management and security settings

After you list your buckets, you can validate your buckets security and access settings for functionally equivalent storage systems by reviewing the various bucket configuration settings.

```
aws s3api get-public-access-block --bucket amzn-s3-demo-bucket1  
aws s3api get-bucket-acl --bucket amzn-s3-demo-bucket1  
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1  
aws s3api get-bucket-policy --bucket amzn-s3-demo-bucket1
```

Data Transfer

You can transfer data from Amazon S3 using several methods:

- AWS CLI
- AWS SDK
- Amazon S3 REST API
- Third-party tools

Example using AWS CLI

To download an entire bucket:

```
aws s3 sync s3://amzn-s3-demo-bucket1 /local/path
```

For more information, see [sync](#) in the AWS CLI Command Reference.

To download specific objects:

```
aws s3 cp s3://amzn-s3-demo-bucket1/path/to/object /local/path
```

For more information, see [cp](#) in the AWS CLI Command Reference.

Related Resources

The following are additional characteristics of Amazon S3:

- [Access control in Amazon S3](#)
- [Security in Amazon S3](#)
- [Data protection in Amazon S3](#)
- [Logging and monitoring in Amazon S3](#)

Data protection in Amazon S3

In addition to the resilience offered by the AWS global infrastructure, Amazon S3 offers a number of features to help protect your data against accidental deletions or Regional failures.

S3 Replication

You can use live replication to enable automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. You can replicate objects to a single destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Regions or within the same Region as the source bucket. To enable failover controls, you can configure replication to be two-way (bidirectional) so that your source and destination buckets can be kept in sync during a Regional failure. For more information, see [the section called “Replicating objects within and across Regions”](#).

Multi-Region Access Points and failover controls

Amazon S3 Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, Multi-Region Access Points provide built-in network resilience with acceleration of internet-based requests to Amazon S3. Application requests made to a Multi-Region Access Point global endpoint use [AWS Global Accelerator](#) to automatically route over the AWS global network to the closest-proximity S3 bucket with an active routing status. For more information about Multi-Region Access Points, see [the section called “Managing multi-region traffic”](#).

With Amazon S3 Multi-Region Access Point failover controls, you can maintain business continuity during Regional traffic disruptions, while also giving your applications a multi-Region architecture to fulfill compliance and redundancy needs. If your Regional traffic gets disrupted, you can use Multi-Region Access Point failover controls to select which AWS Regions behind an Amazon S3 Multi-Region Access Point will process data-access and storage requests.

To support failover, you can set up your Multi-Region Access Point in an active-passive configuration, with traffic flowing to the active Region during normal conditions, and a passive Region on standby for failover. If you have S3 Cross-Region Replication (CRR) enabled with

two-way replication rules, you can keep your buckets synchronized during a failover. For more information about failover controls, see [the section called “Failover configuration”](#).

S3 Versioning

Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

S3 Object Lock

You can use S3 Object Lock to store objects using a *write once, read many* (WORM) model. Using S3 Object Lock, you can prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. S3 Object Lock enables you to meet regulatory requirements that require WORM storage or simply to add an additional layer of protection against object changes and deletion. For more information, see [Locking objects with Object Lock](#).

AWS Backup

Amazon S3 is natively integrated with AWS Backup, a fully managed, policy-based service that you can use to centrally define backup policies to protect your data in Amazon S3. After you define your backup policies and assign Amazon S3 resources to the policies, AWS Backup automates the creation of Amazon S3 backups and securely stores the backups in an encrypted backup vault that you designate in your backup plan. For more information, see [the section called “Backing up your data”](#).

For a tutorial on using some of these features together to protect your data, see [Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication](#).

Important

In addition to using the preceding features to protect your data, we recommend reviewing the recommendations in [the section called “Security best practices”](#).

Topics

- [Replicating objects within and across Regions](#)

- [Managing multi-Region traffic with Multi-Region Access Points](#)
- [Retaining multiple versions of objects with S3 Versioning](#)
- [Locking objects with Object Lock](#)
- [Backing up your Amazon S3 data](#)

Replicating objects within and across Regions

You can use replication to enable automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. You can replicate objects to a single destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Regions or within the same Region as the source bucket.

There are two types of replication: *live replication* and *on-demand replication*.

- **Live replication – To automatically replicate new and updated objects** as they are written to the source bucket, use live replication. Live replication doesn't replicate any objects that existed in the bucket before you set up replication. To replicate objects that existed before you set up replication, use on-demand replication.
- **On-demand replication – To replicate existing objects** from the source bucket to one or more destination buckets on demand, use S3 Batch Replication. For more information about replicating existing objects, see [When to use S3 Batch Replication](#).

There are two forms of live replication: *Cross-Region Replication (CRR)* and *Same-Region Replication (SRR)*.

- **Cross-Region Replication (CRR)** – You can use CRR to replicate objects across Amazon S3 buckets in different AWS Regions. For more information about CRR, see [the section called "When to use Cross-Region Replication"](#).
- **Same-Region Replication (SRR)** – You can use SRR to copy objects across Amazon S3 buckets in the same AWS Region. For more information about SRR, see [the section called "When to use Same-Region Replication"](#).

Topics

- [Why use replication?](#)

- [When to use Cross-Region Replication](#)
- [When to use Same-Region Replication](#)
- [When to use two-way replication \(bi-directional replication\)](#)
- [When to use S3 Batch Replication](#)
- [Workload requirements and live replication](#)
- [What does Amazon S3 replicate?](#)
- [Requirements and considerations for replication](#)
- [Setting up live replication overview](#)
- [Managing or pausing live replication](#)
- [Replicating existing objects with Batch Replication](#)
- [Troubleshooting replication](#)
- [Monitoring replication with metrics, event notifications, and statuses](#)

Why use replication?

Replication can help you do the following:

- **Replicate objects while retaining metadata** – You can use replication to make copies of your objects that retain all metadata, such as the original object creation times and version IDs. This capability is important if you must ensure that your replica is identical to the source object.
- **Replicate objects into different storage classes** – You can use replication to directly put objects into S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or another storage class in the destination buckets. You can also replicate your data to the same storage class and use lifecycle configurations on the destination buckets to move your objects to a colder storage class as they age.
- **Maintain object copies under different ownership** – Regardless of who owns the source object, you can tell Amazon S3 to change replica ownership to the AWS account that owns the destination bucket. This is referred to as the *owner override* option. You can use this option to restrict access to object replicas.
- **Keep objects stored over multiple AWS Regions** – To ensure geographic differences in where your data is kept, you can set multiple destination buckets across different AWS Regions. This feature might help you meet certain compliance requirements.
- **Replicate objects within 15 minutes** – To replicate your data in the same AWS Region or across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3

RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called “Using S3 Replication Time Control”](#).

 **Note**

S3 RTC does not apply to Batch Replication. Batch Replication is an on-demand replication job, and can be tracked with S3 Batch Operations. For more information, see [Tracking job status and completion reports](#).

- **Sync buckets, replicate existing objects, and replicate previously failed or replicated objects** – To sync buckets and replicate existing objects, use Batch Replication as an on-demand replication action. For more information about when to use Batch Replication, see [When to use S3 Batch Replication](#).
- **Replicate objects and fail over to a bucket in another AWS Region** – To keep all metadata and objects in sync across buckets during data replication, use two-way replication (also known as bi-directional replication) rules before configuring Amazon S3 Multi-Region Access Point failover controls. Two-way replication rules help ensure that when data is written to the S3 bucket that traffic fails over to, that data is then replicated back to the source bucket.

When to use Cross-Region Replication

S3 Cross-Region Replication (CRR) is used to copy objects across Amazon S3 buckets in different AWS Regions. CRR can help you do the following:

- **Meet compliance requirements** – Although Amazon S3 stores your data across multiple geographically distant Availability Zones by default, compliance requirements might dictate that you store data at even greater distances. To satisfy these requirements, use Cross-Region Replication to replicate data between distant AWS Regions.
- **Minimize latency** – If your customers are in two geographic locations, you can minimize latency in accessing objects by maintaining object copies in AWS Regions that are geographically closer to your users.
- **Increase operational efficiency** – If you have compute clusters in two different AWS Regions that analyze the same set of objects, you might choose to maintain object copies in those Regions.

When to use Same-Region Replication

Same-Region Replication (SRR) is used to copy objects across Amazon S3 buckets in the same AWS Region. SRR can help you do the following:

- **Aggregate logs into a single bucket** – If you store logs in multiple buckets or across multiple accounts, you can easily replicate logs into a single, in-Region bucket. Doing so allows for simpler processing of logs in a single location.
- **Configure live replication between production and test accounts** – If you or your customers have production and test accounts that use the same data, you can replicate objects between those multiple accounts, while maintaining object metadata.
- **Abide by data sovereignty laws** – You might be required to store multiple copies of your data in separate AWS accounts within a certain Region. Same-Region Replication can help you automatically replicate critical data when compliance regulations don't allow the data to leave your country.

When to use two-way replication (bi-directional replication)

- **Build shared datasets across multiple AWS Regions** – With replica modification sync, you can easily replicate metadata changes, such as object access control lists (ACLs), object tags, or object locks, on replication objects. This two-way replication is important if you want to keep all objects and object metadata changes in sync. You can [enable replica modification sync](#) on a new or existing replication rule when performing two-way replication between two or more buckets in the same or different AWS Regions.
- **Keep data synchronized across Regions during failover** – You can synchronize data in buckets between AWS Regions by configuring two-way replication rules with S3 Cross-Region Replication (CRR) directly from a Multi-Region Access Point. To make an informed decision on when to initiate failover, you can also enable S3 replication metrics so that you can monitor the replication in Amazon CloudWatch, in S3 Replication Time Control (S3 RTC), or from the Multi-Region Access Point.
- **Make your application highly available** – Even in the event of a Regional traffic disruption, you can use two-way replication rules to keep all metadata and objects in sync across buckets during data replication.

When to use S3 Batch Replication

Batch Replication replicates existing objects to different buckets as an on-demand option. Unlike live replication, these jobs can be run as needed. Batch Replication can help you do the following:

- **Replicate existing objects** – You can use Batch Replication to replicate objects that were added to the bucket before Same-Region Replication or Cross-Region Replication were configured.
- **Replicate objects that previously failed to replicate** – You can filter a Batch Replication job to attempt to replicate objects with a replication status of **FAILED**.
- **Replicate objects that were already replicated** – You might be required to store multiple copies of your data in separate AWS accounts or AWS Regions. Batch Replication can replicate existing objects to newly added destinations.
- **Replicate replicas of objects that were created from a replication rule** – Replication configurations create replicas of objects in destination buckets. Replicas of objects can be replicated only with Batch Replication.

Workload requirements and live replication

Depending on your workload requirements, some types of live replication will be better suited to your use case than others. Use the following table to determine which type of replication to use for your situation, and whether to use S3 Replication Time Control (S3 RTC) for your workload. S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement, or SLA). For more information, see [the section called “Using S3 Replication Time Control”](#).

Workload requirement	S3 RTC (15-minute SLA)	Cross-Region Replication (CRR)	Same-Region Replication (SRR)
Replicate objects between different AWS accounts	Yes	Yes	Yes
Replicate objects within the same AWS Region within	No	No	Yes

Workload requirement	S3 RTC (15-minute SLA)	Cross-Region Replication (CRR)	Same-Region Replication (SRR)
24-48 hours (not SLA backed)			
Replicate objects between different AWS Regions within 24-48 hours (not SLA backed)	No	Yes	No
Predictable replication time: Backed by SLA to replicate 99.9 percent of objects within 15 minutes	Yes	No	No

What does Amazon S3 replicate?

Amazon S3 replicates only specific items in buckets that are configured for replication.

Topics

- [What is replicated with replication configurations?](#)
- [What isn't replicated with replication configurations?](#)

What is replicated with replication configurations?

By default, Amazon S3 replicates the following:

- Objects created after you add a replication configuration.
- Unencrypted objects.
- Objects encrypted using customer provided keys (SSE-C), objects encrypted at rest under an Amazon S3 managed key (SSE-S3) or a KMS key stored in AWS Key Management Service (SSE-KMS). For more information, see [the section called “Replicating encrypted objects”](#).

- Object metadata from the source objects to the replicas. For information about replicating metadata from the replicas to the source objects, see [Replicating metadata changes with replica modification sync](#).
- Only objects in the source bucket for which the bucket owner has permissions to read objects and access control lists (ACLs).

For more information about resource ownership, see [Amazon S3 bucket and object ownership](#).

- Object ACL updates, unless you direct Amazon S3 to change the replica ownership when source and destination buckets aren't owned by the same accounts.

For more information, see [Changing the replica owner](#).

It can take a while until Amazon S3 can bring the two ACLs in sync. This change in ownership applies only to objects created after you add a replication configuration to the bucket.

- Object tags, if there are any.
- S3 Object Lock retention information, if there is any.

When Amazon S3 replicates objects that have retention information applied, it applies those same retention controls to your replicas, overriding the default retention period configured on your destination buckets. If you don't have retention controls applied to the objects in your source bucket, and you replicate into destination buckets that have a default retention period set, the destination bucket's default retention period is applied to your object replicas. For more information, see [Locking objects with Object Lock](#).

How delete operations affect replication

If you delete an object from the source bucket, the following actions occur by default:

- If you make a DELETE request without specifying an object version ID, Amazon S3 adds a delete marker. Amazon S3 deals with the delete marker as follows:
 - If you are using the latest version of the replication configuration (that is, you specify the `Filter` element in a replication configuration rule), Amazon S3 does not replicate the delete marker by default. However, you can add *delete marker replication* to non-tag-based rules. For more information, see [Replicating delete markers between buckets](#).
 - If you don't specify the `Filter` element, Amazon S3 assumes that the replication configuration is version V1, and it replicates delete markers that resulted from user actions.

However, if Amazon S3 deletes an object due to a lifecycle action, the delete marker is not replicated to the destination buckets.

- If you specify an object version ID to delete in a DELETE request, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination buckets. In other words, it doesn't delete the same object version from the destination buckets. This protects data from malicious deletions.

What isn't replicated with replication configurations?

By default, Amazon S3 doesn't replicate the following:

- Objects in the source bucket that are replicas that were created by another replication rule. For example, suppose you configure replication where bucket A is the source and bucket B is the destination. Now suppose that you add another replication configuration where bucket B is the source and bucket C is the destination. In this case, objects in bucket B that are replicas of objects in bucket A are not replicated to bucket C.

To replicate objects that are replicas, use Batch Replication. Learn more about configuring Batch Replication at [Replicating existing objects](#).

- Objects in the source bucket that have already been replicated to a different destination. For example, if you change the destination bucket in an existing replication configuration, Amazon S3 won't replicate the objects again.

To replicate previously replicated objects, use Batch Replication. Learn more about configuring Batch Replication at [Replicating existing objects](#).

- Batch Replication does not support re-replicating objects that were deleted with the version ID of the object from the destination bucket. To re-replicate these objects, you can copy the source objects in place with a Batch Copy job. Copying those objects in place creates new versions of the objects in the source bucket and initiates replication automatically to the destination. For more information about how to use Batch Copy, see, [Examples that use Batch Operations to copy objects](#).
- By default, when replicating from a different AWS account, delete markers added to the source bucket are not replicated.

For information about how to replicate delete markers, see [Replicating delete markers between buckets](#).

- Objects that are stored in the S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, S3 Intelligent-Tiering Archive Access, or S3 Intelligent-Tiering Deep Archive Access storage classes or tiers. You cannot replicate these objects until you restore them and copy them to a different storage class.

To learn more about S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive, see [Storage classes for rarely accessed objects](#).

To learn more about the S3 Intelligent-Tiering, see [Managing storage costs with Amazon S3 Intelligent-Tiering](#).

- Objects in the source bucket that the bucket owner doesn't have sufficient permissions to replicate.

For information about how an object owner can grant permissions to a bucket owner, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).

- Updates to bucket-level subresources.

For example, if you change the lifecycle configuration or add a notification configuration to your source bucket, these changes are not applied to the destination bucket. This feature makes it possible to have different configurations on source and destination buckets.

- Actions performed by lifecycle configuration.

For example, if lifecycle configuration is enabled only on your source bucket, Amazon S3 creates delete markers for expired objects but doesn't replicate those markers. If you want the same lifecycle configuration applied to both the source and destination buckets, enable the same lifecycle configuration on both. For more information about lifecycle configuration, see [Managing the lifecycle of objects](#).

- When you're using tag-based replication rules with live replication, new objects must be tagged with the matching replication rule tag in the PutObject operation. Otherwise, the objects won't be replicated. If objects are tagged after the PutObject operation, those objects also won't be replicated.

To replicate objects that have been tagged after the PutObject operation, you must use S3 Batch Replication. For more information about Batch Replication, see [Replicating existing objects](#).

Requirements and considerations for replication

Amazon S3 replication requires the following:

- The source bucket owner must have the source and destination AWS Regions enabled for their account. The destination bucket owner must have the destination Region enabled for their account.

For more information about enabling or disabling an AWS Region, see [Specify which AWS Regions your account can use in the AWS Account Management Reference Guide](#).

- Both source and destination buckets must have versioning enabled. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).
- Amazon S3 must have permissions to replicate objects from the source bucket to the destination bucket or buckets on your behalf. For more information about these permissions, see [Setting up permissions for live replication](#).
- If the owner of the source bucket doesn't own the object in the bucket, the object owner must grant the bucket owner READ and READ_ACP permissions with the object access control list (ACL). For more information, see [Access control list \(ACL\) overview](#).
- If the source bucket has S3 Object Lock enabled, the destination buckets must also have S3 Object Lock enabled.

To enable replication on a bucket that has Object Lock enabled, you must use the AWS Command Line Interface, REST API, or AWS SDKs. For more general information, see [Locking objects with Object Lock](#).

 **Note**

You must grant two new permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two new permissions are s3:GetObjectRetention and s3:GetObjectLegalHold. If the role has an s3:Get* permission, it satisfies the requirement. For more information, see [Setting up permissions for live replication](#).

For more information, see [Setting up live replication overview](#).

If you are setting the replication configuration in a *cross-account scenario*, where the source and destination buckets are owned by different AWS accounts, the following additional requirement applies:

- The owner of the destination buckets must grant the owner of the source bucket permissions to replicate objects with a bucket policy. For more information, see [\(Optional\) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts](#).
- The destination buckets cannot be configured as Requester Pays buckets. For more information, see [Using Requester Pays general purpose buckets for storage transfers and usage](#).

Considerations for replication

Before you create a replication configuration, be aware of the following considerations.

Topics

- [Lifecycle configuration and object replicas](#)
- [Versioning configuration and replication configuration](#)
- [Using S3 Replication with S3 Intelligent-Tiering](#)
- [Logging configuration and replication configuration](#)
- [CRR and the destination Region](#)
- [S3 Batch Replication](#)
- [S3 Replication Time Control](#)

Lifecycle configuration and object replicas

The time it takes for Amazon S3 to replicate an object depends on the size of the object. For large objects, it can take several hours. Although it might take a while before a replica is available in the destination, it takes the same amount of time to create the replica as it took to create the corresponding object in the source bucket. If a lifecycle configuration is enabled on a destination bucket, the lifecycle rules honor the original creation time of the object, not when the replica became available in the destination bucket.

Replication configuration requires the bucket to be versioning-enabled. When you enable versioning on a bucket, keep the following in mind:

- If you have an object Expiration lifecycle configuration, after you enable versioning, add a NonCurrentVersionExpiration policy to maintain the same permanent delete behavior as before you enabled versioning.
- If you have a Transition lifecycle configuration, after you enable versioning, consider adding a NonCurrentVersionTransition policy.

Versioning configuration and replication configuration

Both the source and destination buckets must be versioning-enabled when you configure replication on a bucket. After you enable versioning on both the source and destination buckets and configure replication on the source bucket, you will encounter the following issues:

- If you attempt to disable versioning on the source bucket, Amazon S3 returns an error. You must remove the replication configuration before you can disable versioning on the source bucket.
- If you disable versioning on the destination bucket, replication fails. The source object has the replication status FAILED.

Using S3 Replication with S3 Intelligent-Tiering

S3 Intelligent-Tiering is a storage class that is designed to optimize storage costs by automatically moving data to the most cost-effective access tier. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

Replicating objects stored in S3 Intelligent-Tiering with S3 Batch Replication or invoking [CopyObject](#) or [UploadPartCopy](#) constitutes access. In these cases, the source objects of the copy or replication operations are tiered up.

For more information about S3 Intelligent-Tiering see, [Managing storage costs with Amazon S3 Intelligent-Tiering](#).

Logging configuration and replication configuration

If Amazon S3 delivers logs to a bucket that has replication enabled, it replicates the log objects.

If [server access logs](#) or [AWS CloudTrail logs](#) are enabled on your source or destination bucket, Amazon S3 includes replication-related requests in the logs. For example, Amazon S3 logs each object that it replicates.

CRR and the destination Region

Amazon S3 Cross-Region Replication (CRR) is used to copy objects across S3 buckets in different AWS Regions. You might choose the Region for your destination bucket based on either your business needs or cost considerations. For example, inter-Region data transfer charges vary depending on the Regions that you choose.

Suppose that you chose US East (N. Virginia) (us-east-1) as the Region for your source bucket. If you choose US West (Oregon) (us-west-2) as the Region for your destination buckets, you pay more than if you choose the US East (Ohio) (us-east-2) Region. For pricing information, see "Data Transfer Pricing" in [Amazon S3 pricing](#).

There are no data transfer charges associated with Same-Region Replication (SRR).

S3 Batch Replication

For information about considerations for Batch Replication, see [S3 Batch Replication considerations](#).

S3 Replication Time Control

For information about best practices and considerations for S3 Replication Time Control (S3 RTC), see [Best practices and guidelines for S3 RTC](#).

Setting up live replication overview

Note

Objects that existed before you set up replication aren't replicated automatically. In other words, Amazon S3 doesn't replicate objects retroactively. To replicate objects that were created before your replication configuration, use S3 Batch Replication. For more information about configuring Batch Replication, see [Replicating existing objects](#).

To enable live replication—Same-Region Replication (SRR) or Cross-Region Replication (CRR)—add a replication configuration to your source bucket. This configuration tells Amazon S3 to replicate objects as specified. In the replication configuration, you must provide the following:

- **The destination buckets** – The bucket or buckets where you want Amazon S3 to replicate the objects.

- **The objects that you want to replicate** – You can replicate all objects in the source bucket or a subset of objects. You identify a subset by providing a [key name prefix](#), one or more object tags, or both in the configuration.

For example, if you configure a replication rule to replicate only objects with the key name prefix Tax/, Amazon S3 replicates objects with keys such as Tax/doc1 or Tax/doc2. But it doesn't replicate objects with the key Legal/doc3. If you specify both a prefix and one or more tags, Amazon S3 replicates only objects that have the specific key prefix and tags.

- **An AWS Identity and Access Management (IAM) role** – Amazon S3 assumes this IAM role to replicate objects on your behalf. For more information about creating this IAM role and managing permissions, see [Setting up permissions for live replication](#).

In addition to these minimum requirements, you can choose the following options:

- **Replica storage class** – By default, Amazon S3 stores object replicas using the same storage class as the source object. You can specify a different storage class for the replicas.
- **Replica ownership** – Amazon S3 assumes that an object replica continues to be owned by the owner of the source object. So when it replicates objects, it also replicates the corresponding object access control list (ACL) or S3 Object Ownership setting. If the source and destination buckets are owned by different AWS accounts, you can configure replication to change the owner of a replica to the AWS account that owns the destination bucket. For more information, see [the section called "Changing the replica owner"](#).

You can configure replication by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API. For detailed walkthroughs of how to set up replication, see [the section called "Replication walkthroughs"](#).

Amazon S3 provides REST API operations to support setting up replication rules. For more information, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PutBucketReplication](#)
- [GetBucketReplication](#)
- [DeleteBucketReplication](#)

Topics

- [Replication configuration file elements](#)

- [Setting up permissions for live replication](#)
- [Examples for configuring live replication](#)

Replication configuration file elements

Amazon S3 stores a replication configuration as XML. If you're configuring replication programmatically through the Amazon S3 REST API, you specify the various elements of your replication configuration in this XML file. If you're configuring replication through the AWS Command Line Interface (AWS CLI), you specify your replication configuration using JSON format. For JSON examples, see the walkthroughs in [the section called "Replication walkthroughs"](#).

Note

The latest version of the replication configuration XML format is V2. XML V2 replication configurations are those that contain the `<Filter>` element for rules, and rules that specify S3 Replication Time Control (S3 RTC).

To see your replication configuration version, you can use the `GetBucketReplication` API operation. For more information, see [GetBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

For backward compatibility, Amazon S3 continues to support the XML V1 replication configuration format. If you've used the XML V1 replication configuration format, see [Backward compatibility considerations](#) for backward compatibility considerations.

In the replication configuration XML file, you must specify an AWS Identity and Access Management (IAM) role and one or more rules, as shown in the following example:

```
<ReplicationConfiguration>
  <Role>IAM-role-ARN</Role>
  <Rule>
    ...
  </Rule>
  <Rule>
    ...
  </Rule>
  ...
</ReplicationConfiguration>
```

Amazon S3 can't replicate objects without your permission. You grant permissions to Amazon S3 with the IAM role that you specify in the replication configuration. Amazon S3 assumes this IAM role to replicate objects on your behalf. You must grant the required permissions to the IAM role first. For more information about managing permissions, see [Setting up permissions for live replication](#).

You add only one rule in a replication configuration in the following scenarios:

- You want to replicate all objects.
- You want to replicate only one subset of objects. You identify the object subset by adding a filter in the rule. In the filter, you specify an object key prefix, tags, or a combination of both to identify the subset of objects that the rule applies to. The filters target objects that match the exact values that you specify.

If you want to replicate different subsets of objects, you add multiple rules in a replication configuration. In each rule, you specify a filter that selects a different subset. For example, you might choose to replicate objects that have either tax/ or document/ key prefixes. To do this, you add two rules, one that specifies the tax/ key prefix filter and another that specifies the document/ key prefix. For more information about object key prefixes, see [Organizing objects using prefixes](#).

The following sections provide additional information.

Topics

- [Basic rule configuration](#)
- [Optional: Specifying a filter](#)
- [Additional destination configurations](#)
- [Example replication configurations](#)
- [Backward compatibility considerations](#)

Basic rule configuration

Each rule must include the rule's status and priority. The rule must also indicate whether to replicate delete markers.

- The <Status> element indicates whether the rule is enabled or disabled by using the values Enabled or Disabled. If a rule is disabled, Amazon S3 doesn't perform the actions specified in the rule.
- The <Priority> element indicates which rule has precedence whenever two or more replication rules conflict. Amazon S3 attempts to replicate objects according to all replication rules. However, if there are two or more rules with the same destination bucket, then objects are replicated according to the rule with the highest priority. The higher the number, the higher the priority.
- The <DeleteMarkerReplication> element indicates whether to replicate delete markers by using the values Enabled or Disabled.

In the <Destination> element configuration, you must provide the name of the destination bucket or buckets where you want Amazon S3 to replicate objects.

The following example shows the minimum requirements for a V2 rule. For backward compatibility, Amazon S3 continues to support the XML V1 format. For more information, see [Backward compatibility considerations](#).

```
...
<Rule>
    <ID>Rule-1</ID>
    <Status>Enabled-or-Disabled</Status>
    <Filter>
        <Prefix></Prefix>
    </Filter>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
        <Status>Enabled-or-Disabled</Status>
    </DeleteMarkerReplication>
    <Destination>
        <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
</Rule>
<Rule>
    ...
</Rule>
...
...
```

You can also specify other configuration options. For example, you might choose to use a storage class for object replicas that differs from the class for the source object.

Optional: Specifying a filter

To choose a subset of objects that the rule applies to, add an optional filter. You can filter by object key prefix, object tags, or a combination of both. If you filter on both a key prefix and object tags, Amazon S3 combines the filters by using a logical AND operator. In other words, the rule applies to a subset of objects with both a specific key prefix and specific tags.

Filter based on object key prefix

To specify a rule with a filter based on an object key prefix, use the following XML. You can specify only one prefix per rule.

```
<Rule>
  ...
  <Filter>
    <Prefix>key-prefix</Prefix>
  </Filter>
  ...
</Rule>
...
```

Filter based on object tags

To specify a rule with a filter based on object tags, use the following XML. You can specify one or more object tags.

```
<Rule>
  ...
  <Filter>
    <And>
      <Tag>
        <Key>key1</Key>
        <Value>value1</Value>
      </Tag>
      <Tag>
        <Key>key2</Key>
        <Value>value2</Value>
      </Tag>
      ...
    </And>
  </Filter>
</Rule>
```

```
</And>
</Filter>
...
</Rule>
...
```

Filter with a key prefix and object tags

To specify a rule filter with a combination of a key prefix and object tags, use the following XML. You wrap these filters in an `<And>` parent element. Amazon S3 performs a logical AND operation to combine these filters. In other words, the rule applies to a subset of objects with both a specific key prefix and specific tags.

```
<Rule>
...
<Filter>
  <And>
    <Prefix>key-prefix</Prefix>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
    ...
  </And>
</Filter>
...
</Rule>
...
```

Note

- If you specify a rule with an empty `<Filter>` element, your rule applies to all objects in your bucket.
- When you're using tag-based replication rules with live replication, new objects must be tagged with the matching replication rule tag in the `PutObject` operation. Otherwise, the objects won't be replicated. If objects are tagged after the `PutObject` operation, those objects also won't be replicated.

To replicate objects that have been tagged after the PutObject operation, you must use S3 Batch Replication. For more information about Batch Replication, see [Replicating existing objects](#).

Additional destination configurations

In the destination configuration, you specify the bucket or buckets where you want Amazon S3 to replicate objects. You can set configurations to replicate objects from one source bucket to one or more destination buckets.

```
...
<Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
</Destination>
...
```

You can add the following options in the `<Destination>` element.

Topics

- [Specify storage class](#)
- [Add multiple destination buckets](#)
- [Specify different parameters for each replication rule with multiple destination buckets](#)
- [Change replica ownership](#)
- [Enable S3 Replication Time Control](#)
- [Replicate objects created with server-side encryption by using AWS KMS](#)

Specify storage class

You can specify the storage class for the object replicas. By default, Amazon S3 uses the storage class of the source object to create object replicas, as in the following example.

```
...
<Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
        <StorageClass>storage-class</StorageClass>
</Destination>
```

...

Add multiple destination buckets

You can add multiple destination buckets in a single replication configuration, as follows.

```
...
<Rule>
  <ID>Rule-1</ID>
  <Status>Enabled-or-Disabled</Status>
  <Priority>integer</Priority>
  <DeleteMarkerReplication>
    <Status>Enabled-or-Disabled</Status>
  </DeleteMarkerReplication>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket1</Bucket>
  </Destination>
</Rule>
<Rule>
  <ID>Rule-2</ID>
  <Status>Enabled-or-Disabled</Status>
  <Priority>integer</Priority>
  <DeleteMarkerReplication>
    <Status>Enabled-or-Disabled</Status>
  </DeleteMarkerReplication>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket2</Bucket>
  </Destination>
</Rule>
...
...
```

Specify different parameters for each replication rule with multiple destination buckets

When adding multiple destination buckets in a single replication configuration, you can specify different parameters for each replication rule, as follows.

```
...
<Rule>
  <ID>Rule-1</ID>
  <Status>Enabled-or-Disabled</Status>
  <Priority>integer</Priority>
  <DeleteMarkerReplication>
    <Status>Disabled</Status>
```

```
</DeleteMarkerReplication>
<Metrics>
<Status>Enabled</Status>
<EventThreshold>
<Minutes>15</Minutes>
</EventThreshold>
</Metrics>
<Destination>
<Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket1</Bucket>
</Destination>
</Rule>
<Rule>
<ID>Rule-2</ID>
<Status>Enabled-or-Disabled</Status>
<Priority>integer</Priority>
<DeleteMarkerReplication>
<Status>Enabled</Status>
</DeleteMarkerReplication>
<Metrics>
<Status>Enabled</Status>
<EventThreshold>
<Minutes>15</Minutes>
</EventThreshold>
</Metrics>
<ReplicationTime>
<Status>Enabled</Status>
<Time>
<Minutes>15</Minutes>
</Time>
</ReplicationTime>
<Destination>
<Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket2</Bucket>
</Destination>
</Rule>
...
...
```

Change replica ownership

When the source and destination buckets aren't owned by the same accounts, you can change the ownership of the replica to the AWS account that owns the destination bucket. To do so, add the `<AccessControlTranslation>` element. This element takes the value `Destination`.

...

```
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <Account>destination-bucket-owner-account-id</Account>
  <AccessControlTranslation>
    <Owner>Destination</Owner>
  </AccessControlTranslation>
</Destination>
...
...
```

If you don't add the `<AccessControlTranslation>` element to the replication configuration, the replicas are owned by the same AWS account that owns the source object. For more information, see [Changing the replica owner](#).

Enable S3 Replication Time Control

You can enable S3 Replication Time Control (S3 RTC) in your replication configuration. S3 RTC replicates most objects in seconds and 99.99 percent of objects within 15 minutes (backed by a service-level agreement).

Note

Only a value of `<Minutes>15</Minutes>` is accepted for the `<EventThreshold>` and `<Time>` elements.

```
...
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <Metrics>
    <Status>Enabled</Status>
    <EventThreshold>
      <Minutes>15</Minutes>
    </EventThreshold>
  </Metrics>
  <ReplicationTime>
    <Status>Enabled</Status>
    <Time>
      <Minutes>15</Minutes>
    </Time>
  </ReplicationTime>
</Destination>
```

...

For more information, see [Meeting compliance requirements with S3 Replication Time Control](#). For API examples, see [PutBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

Replicate objects created with server-side encryption by using AWS KMS

Your source bucket might contain objects that were created with server-side encryption by using AWS Key Management Service (AWS KMS) keys (SSE-KMS). By default, Amazon S3 doesn't replicate these objects. You can optionally direct Amazon S3 to replicate these objects. To do so, first explicitly opt into this feature by adding the <SourceSelectionCriteria> element. Then provide the AWS KMS key (for the AWS Region of the destination bucket) to use for encrypting object replicas. The following example shows how to specify these elements.

```
...
<SourceSelectionCriteria>
  <SseKmsEncryptedObjects>
    <Status>Enabled</Status>
  </SseKmsEncryptedObjects>
</SourceSelectionCriteria>
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <EncryptionConfiguration>
    <ReplicaKmsKeyID>AWS KMS key ID to use for encrypting object replicas</ReplicaKmsKeyID>
  </EncryptionConfiguration>
</Destination>
...

```

For more information, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

Example replication configurations

To get started, you can add the following example replication configurations to your bucket, as appropriate.

Important

To add a replication configuration to a bucket, you must have the `iam:PassRole` permission. This permission allows you to pass the IAM role that grants Amazon S3 replication permissions. You specify the IAM role by providing the Amazon Resource Name

(ARN) that is used in the <Role> element in the replication configuration XML. For more information, see [Granting a User Permissions to Pass a Role to an AWS service](#) in the *IAM User Guide*.

Example 1: Replication configuration with one rule

The following basic replication configuration specifies one rule. The rule specifies an IAM role that Amazon S3 can assume and a single destination bucket for object replicas. The <Status> element value of Enabled indicates that the rule is in effect.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>

    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

To choose a subset of objects to replicate, you can add a filter. In the following configuration, the filter specifies an object key prefix. This rule applies to objects that have the prefix *Tax/* in their key names.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>

    <Filter>
      <Prefix>Tax/</Prefix>
    </Filter>
```

```
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
</Destination>

</Rule>
</ReplicationConfiguration>
```

If you specify the `<Filter>` element, you must also include the `<Priority>` and `<DeleteMarkerReplication>` elements. In this example, the value that you set for the `<Priority>` element is irrelevant because there is only one rule.

In the following configuration, the filter specifies one prefix and two tags. The rule applies to the subset of objects that have the specified key prefix and tags. Specifically, it applies to objects that have the `Tax/` prefix in their key names and the two specified object tags. In this example, the value that you set for the `<Priority>` element is irrelevant because there is only one rule.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>

    <Filter>
      <And>
        <Prefix>Tax/</Prefix>
        <Tag>
          <Tag>
            <Key>tagA</Key>
            <Value>valueA</Value>
          </Tag>
        </Tag>
        <Tag>
          <Tag>
            <Key>tagB</Key>
            <Value>valueB</Value>
          </Tag>
        </Tag>
      </And>
    </Filter>
  </Rule>
</ReplicationConfiguration>
```

```
</Filter>

<Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
</Destination>

</Rule>
</ReplicationConfiguration>
```

You can specify a storage class for the object replicas as follows:

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <Role>arn:aws:iam::account-id:role/role-name</Role>
    <Rule>
        <Status>Enabled</Status>
        <Destination>
            <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
            <StorageClass>storage-class</StorageClass>
        </Destination>
    </Rule>
</ReplicationConfiguration>
```

You can specify any storage class that Amazon S3 supports.

Example 2: Replication configuration with two rules

Example

In the following replication configuration, the rules specify the following:

- Each rule filters on a different key prefix so that each rule applies to a distinct subset of objects. In this example, Amazon S3 replicates objects with the key names *Tax/doc1.pdf* and *Project/project1.txt*, but it doesn't replicate objects with the key name *PersonalDoc/documentA*.
- Although both rules specify a value for the *<Priority>* element, the rule priority is irrelevant because the rules apply to two distinct sets of objects. The next example shows what happens when rule priority is applied.

- The second rule specifies the S3 Standard-IA storage class for object replicas. Amazon S3 uses the specified storage class for those object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
    ...
  </Rule>
  <Rule>
    <Status>Enabled</Status>
    <Priority>2</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Project</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
      <StorageClass>STANDARD_IA</StorageClass>
    </Destination>
    ...
  </Rule>
</ReplicationConfiguration>
```

Example 3: Replication configuration with two rules with overlapping prefixes

In this configuration, the two rules specify filters with overlapping key prefixes, *star* and *starship*. Both rules apply to objects with the key name *starship-x*. In this case, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority.

```
<ReplicationConfiguration>

<Role>arn:aws:iam::account-id:role/role-name</Role>

<Rule>
  <Status>Enabled</Status>
  <Priority>1</Priority>
  <DeleteMarkerReplication>
    <Status>string</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>star</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  </Destination>
</Rule>
<Rule>
  <Status>Enabled</Status>
  <Priority>2</Priority>
  <DeleteMarkerReplication>
    <Status>string</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>starship</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  </Destination>
</Rule>
</ReplicationConfiguration>
```

Example 4: Example walkthroughs

For example walkthroughs, see [Examples for configuring live replication](#).

For more information about the XML structure of replication configuration, see [PutBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

Backward compatibility considerations

The latest version of the replication configuration XML format is V2. XML V2 replication configurations are those that contain the `<Filter>` element for rules, and rules that specify S3 Replication Time Control (S3 RTC).

To see your replication configuration version, you can use the `GetBucketReplication` API operation. For more information, see [GetBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

For backward compatibility, Amazon S3 continues to support the XML V1 replication configuration format. If you've used the XML V1 replication configuration format, consider the following issues that affect backward compatibility:

- The replication configuration XML V2 format includes the `<Filter>` element for rules. With the `<Filter>` element, you can specify object filters based on the object key prefix, tags, or both to scope the objects that the rule applies to. The replication configuration XML V1 format supports filtering based only on the key prefix. In that case, you add the `<Prefix>` element directly as a child element of the `<Rule>` element, as in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Prefix>key-prefix</Prefix>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

- When you delete an object from your source bucket without specifying an object version ID, Amazon S3 adds a delete marker. If you use the replication configuration XML V1 format, Amazon S3 replicates only delete markers that result from user actions. In other words, Amazon S3 replicates the delete marker only if a user deletes an object. If an expired object is removed by Amazon S3 (as part of a lifecycle action), Amazon S3 doesn't replicate the delete marker.

In the replication configuration XML V2 format, you can enable delete marker replication for non-tag-based rules. For more information, see [Replicating delete markers between buckets](#).

Setting up permissions for live replication

When setting up live replication in Amazon S3, you must acquire the necessary permissions as follows:

- You must grant the AWS Identity and Access Management (IAM) principal (user or role) who will be creating replication rules a certain set of permissions.
- Amazon S3 needs permissions to replicate objects on your behalf. You grant these permissions by creating an IAM role and then specifying that role in your replication configuration.
- When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must also grant the source bucket owner permissions to store the replicas.

 **Note**

If you're using S3 Batch Operations to replicate objects on demand instead of setting up live replication, a different IAM role and policies are required for S3 Batch Replication. For a Batch Replication IAM role and policy examples, see [Configuring an IAM role for S3 Batch Replication](#).

Topics

- [Step 1: Granting permissions to the IAM principal who's creating replication rules](#)
- [Step 2: Creating an IAM role for Amazon S3 to assume](#)
- [\(Optional\) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts](#)
- [\(Optional\) Step 4: Granting permissions to change replica ownership](#)

Step 1: Granting permissions to the IAM principal who's creating replication rules

The IAM user or role that you will use to create replication rules needs permissions to create replication rules for one- or two-way replications. If the user or role doesn't have these

permissions, you won't be able to create replication rules. For more information, see [IAM Identities](#) in the *IAM User Guide*.

The user or role needs the following actions:

- `iam:AttachRolePolicy`
- `iam>CreatePolicy`
- `iam>CreateServiceLinkedRole`
- `iam:PassRole`
- `iam:PutRolePolicy`
- `s3:GetBucketVersioning`
- `s3:GetObjectVersionAcl`
- `s3:GetObjectVersionForReplication`
- `s3:GetReplicationConfiguration`
- `s3:PutReplicationConfiguration`

Following is a sample IAM policy that includes these actions.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetAccessPoint",  
                "s3:GetAccountPublicAccessBlock",  
                "s3:GetBucketAcl",  
                "s3:GetBucketLocation",  
                "s3:GetBucketPolicyStatus",  
                "s3:GetBucketPublicAccessBlock",  
                "s3>ListAccessPoints",  
                "s3>ListAllMyBuckets",  
                "s3:PutReplicationConfiguration",  
                "s3:GetReplicationConfiguration",  
                "s3:GetBucketVersioning",  
                "s3:PutBucketVersioning"  
            ]  
        }  
    ]  
}
```

```
        "s3:GetObjectVersionForReplication",
        "s3:GetObjectVersionAcl",
        "s3:GetObject",
        "s3>ListBucket",
        "s3:GetObjectVersion",
        "s3:GetBucketOwnershipControls",
        "s3:PutBucketOwnershipControls",
        "s3:GetObjectLegalHold",
        "s3:GetObjectRetention",
        "s3:GetBucketObjectLockConfiguration"
    ],
    "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket1-*",
        "arn:aws:s3:::amzn-s3-demo-bucket2-*/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3>List*AccessPoint*",
        "s3:GetMultiRegion*"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": [
        "iam:Get*",
        "iam>CreateServiceLinkedRole",
        "iam>CreateRole",
        "iam:PassRole"
    ],
    "Resource": "arn:aws:iam::*:role/service-role/s3*"
},
{
    "Effect": "Allow",
    "Action": [
        "iam>List*"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": [
```

```
        "iam:AttachRolePolicy",
        "iam:PutRolePolicy",
        "iam:CreatePolicy"
    ],
    "Resource": [
        "arn:aws:iam::*:policy/service-role/s3*",
        "arn:aws:iam::*:role/service-role/s3*"
    ]
}
}
```

Step 2: Creating an IAM role for Amazon S3 to assume

By default, all Amazon S3 resources—buckets, objects, and related subresources—are private, and only the resource owner can access the resource. Amazon S3 needs permissions to read and replicate objects from the source bucket. You grant these permissions by creating an IAM role and specifying that role in your replication configuration.

This section explains the trust policy and the minimum required permissions policy that are attached to this IAM role. The example walkthroughs provide step-by-step instructions to create an IAM role. For more information, see [Examples for configuring live replication](#).

Note

If you're using the console to create your replication configuration, we recommend that you skip this section and instead have the console create this IAM role and the necessary trust and permission policies for you.

The *trust policy* identifies which principal identities can assume the IAM role. The *permissions policy* specifies which actions the IAM role can perform, on which resources, and under what conditions.

- The following example shows a *trust policy* where you identify Amazon S3 as the AWS service principal that can assume the role:

JSON

```
{
```

```
"Version":"2012-10-17",
"Statement": [
    {
        "Effect":"Allow",
        "Principal": {
            "Service": "s3.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
]
```

- The following example shows a *trust policy* where you identify Amazon S3 and S3 Batch Operations as service principals that can assume the role. Use this approach if you're creating a Batch Replication job. For more information, see [Create a Batch Replication job for new replication rules or destinations](#).

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "s3.amazonaws.com",
                    "batchoperations.s3.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

For more information about IAM roles, see [IAM roles](#) in the *IAM User Guide*.

- The following example shows the *permissions policy*, where you grant the IAM role permissions to perform replication tasks on your behalf. When Amazon S3 assumes the role, it has the permissions that you specify in this policy. In this policy, **amzn-s3-demo-source-bucket** is the source bucket, and **amzn-s3-demo-destination-bucket** is the destination bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetReplicationConfiguration",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3GetObjectVersionForReplication",  
                "s3GetObjectVersionAcl",  
                "s3GetObjectVersionTagging"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete",  
                "s3:ReplicateTags"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        }  
    ]  
}
```

The permissions policy grants permissions for the following actions:

- `s3:GetReplicationConfiguration` and `s3>ListBucket` – Permissions for these actions on the *amzn-s3-demo-source-bucket* bucket allow Amazon S3 to retrieve the replication

configuration and list the bucket content. (The current permissions model requires the s3:ListBucket permission for accessing delete markers.)

- s3:GetObjectVersionForReplication and s3:GetObjectVersionAcl – Permissions for these actions are granted on all objects to allow Amazon S3 to get a specific object version and access control list (ACL) associated with the objects.
- s3:ReplicateObject and s3:ReplicateDelete – Permissions for these actions on all objects in the *amzn-s3-demo-destination-bucket* bucket allow Amazon S3 to replicate objects or delete markers to the destination bucket. For information about delete markers, see [How delete operations affect replication](#).

 **Note**

Permissions for the s3:ReplicateObject action on the *amzn-s3-demo-destination-bucket* bucket also allow replication of metadata such as object tags and ACLs. Therefore, you don't need to explicitly grant permission for the s3:ReplicateTags action.

- s3:GetObjectVersionTagging – Permissions for this action on objects in the *amzn-s3-demo-source-bucket* bucket allow Amazon S3 to read object tags for replication. For more information about object tags, see [Categorizing your objects using tags](#). If Amazon S3 doesn't have the s3:GetObjectVersionTagging permission, it replicates the objects, but not the object tags.

For a list of Amazon S3 actions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

 **Important**

The AWS account that owns the IAM role must have permissions for the actions that it grants to the IAM role.

For example, suppose that the source bucket contains objects owned by another AWS account. The owner of the objects must explicitly grant the AWS account that owns the IAM role the required permissions through the objects' access control lists (ACLs).

Otherwise, Amazon S3 can't access the objects, and replication of the objects fails. For information about ACL permissions, see [Access control list \(ACL\) overview](#).

The permissions described here are related to the minimum replication configuration. If you choose to add optional replication configurations, you must grant additional permissions to Amazon S3:

- To replicate encrypted objects, you also need to grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called "Replicating encrypted objects"](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called "Using Object Lock with S3 Replication"](#).

(Optional) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts

When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must also add a bucket policy to grant the owner of the source bucket permissions to perform replication actions, as shown in the following example. In this example policy, `amzn-s3-demo-destination-bucket` is the destination bucket.

You can also use the Amazon S3 console to automatically generate this bucket policy for you. For more information, see [Enable receiving replicated objects from a source bucket](#).

Note

The ARN format of the role might appear different. If the role was created by using the console, the ARN format is `arn:aws:iam::account-ID:role/service-role/role-name`. If the role was created by using the AWS CLI, the ARN format is `arn:aws:iam::account-ID:role/role-name`. For more information, see [IAM roles](#) in the *IAM User Guide*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "PolicyForDestinationBucket",  
    "Statement": [  
        {  
            "Sid": "Permissions on objects",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:role/service-role/source-  
account-IAM-role"  
            },  
            "Action": [  
                "s3:ReplicateDelete",  
                "s3:ReplicateObject"  
            ],  
            "Resource": "arn:aws:s3::::amzn-s3-demo-destination-bucket/*"  
        },  
        {  
            "Sid": "Permissions on bucket",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:role/service-role/source-  
account-IAM-role"  
            },  
            "Action": [  
                "s3>List*",  
                "s3:GetBucketVersioning",  
                "s3:PutBucketVersioning"  
            ],  
            "Resource": "arn:aws:s3::::amzn-s3-demo-destination-bucket"  
        }  
    ]  
}
```

For an example, see [Configuring replication for buckets in different accounts](#).

If objects in the source bucket are tagged, note the following:

- If the source bucket owner grants Amazon S3 permission for the `s3:GetObjectVersionTagging` and `s3:ReplicateTags` actions to replicate object tags (through the IAM role), Amazon S3 replicates the tags along with the objects. For information about the IAM role, see [Step 2: Creating an IAM role for Amazon S3 to assume](#).
- If the owner of the destination bucket doesn't want to replicate the tags, they can add the following statement to the destination bucket policy to explicitly deny permission for the `s3:ReplicateTags` action. In this policy, `amzn-s3-demo-destination-bucket` is the destination bucket.

```
...
"Statement": [
  {
    "Effect": "Deny",
    "Principal": {
      "AWS": "arn:aws:iam::source-bucket-account-id:role/service-role/source-
account-IAM-role"
    },
    "Action": "s3:ReplicateTags",
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
  }
]
...
...
```

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called “Replicating encrypted objects”](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).

Enable receiving replicated objects from a source bucket

Instead of manually adding the preceding policy to your destination bucket, you can quickly generate the policies needed to enable receiving replicated objects from a source bucket through the Amazon S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to use as a destination bucket.
4. Choose the **Management** tab, and scroll down to **Replication rules**.
5. For **Actions**, choose **Receive replicated objects**.

Follow the prompts and enter the AWS account ID of the source bucket account, and then choose **Generate policies**. The console generates an Amazon S3 bucket policy and a KMS key policy.

6. To add this policy to your existing bucket policy, either choose **Apply settings** or choose **Copy** to manually copy the changes.
7. (Optional) Copy the AWS KMS policy to your desired KMS key policy in the AWS Key Management Service console.

(Optional) Step 4: Granting permissions to change replica ownership

When different AWS accounts own the source and destination buckets, you can tell Amazon S3 to change the ownership of the replica to the AWS account that owns the destination bucket. To override the ownership of replicas, you must either grant some additional permissions or adjust the S3 Object Ownership settings for the destination bucket. For more information about owner override, see [Changing the replica owner](#).

Examples for configuring live replication

The following examples provide step-by-step walkthroughs that show how to configure live replication for common use cases.

Note

Live replication refers to Same-Region Replication (SRR) and Cross-Region Replication (CRR). Live replication doesn't replicate any objects that existed in the bucket before you set up replication. To replicate objects that existed before you set up replication, use

on-demand replication. To sync buckets and replicate existing objects on demand, see [Replicating existing objects](#).

These examples demonstrate how to create a replication configuration by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDKs (AWS SDK for Java and AWS SDK for .NET examples are shown).

For information about installing and configuring the AWS CLI, see the following topics in the *AWS Command Line Interface User Guide*:

- [Get started with the AWS CLI](#)
- [Configure the AWS CLI](#) – You must set up at least one profile. If you are exploring cross-account scenarios, set up two profiles.

For information about the AWS SDKs, see [AWS SDK for Java](#) and [AWS SDK for .NET](#).

 **Tip**

For a step-by-step tutorial that demonstrates how to use live replication to replicate data, see [Tutorial: Replicating data within and between AWS Regions using S3 Replication](#).

Topics

- [Configuring replication for buckets in the same account](#)
- [Configuring replication for buckets in different accounts](#)
- [Meeting compliance requirements with S3 Replication Time Control](#)
- [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#)
- [Replicating metadata changes with replica modification sync](#)
- [Replicating delete markers between buckets](#)

Configuring replication for buckets in the same account

Live replication is the automatic, asynchronous copying of objects across general purpose buckets in the same or different AWS Regions. Live replication copies newly created objects and object

updates from a source bucket to a destination bucket or buckets. For more information, see [Replicating objects within and across Regions](#).

When you configure replication, you add replication rules to the source bucket. Replication rules define which source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination bucket can be in the same AWS account as the source bucket, or it can be in a different account.

If you specify an object version ID to delete, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination bucket. In other words, it doesn't delete the same object version from the destination bucket. This protects data from malicious deletions.

When you add a replication rule to a bucket, the rule is enabled by default, so it starts working as soon as you save it.

In this example, you set up live replication for source and destination buckets that are owned by the same AWS account. Examples are provided for using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDK for Java and AWS SDK for .NET.

Prerequisites

Before you use the following procedures, make sure that you've set up the necessary permissions for replication, depending on whether the source and destination buckets are owned by the same or different accounts. For more information, see [the section called "Setting up permissions"](#).

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called "Replicating encrypted objects"](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called "Using Object Lock with S3 Replication"](#).

Using the S3 console

To configure a replication rule when the destination bucket is in the same AWS account as the source bucket, follow these steps.

If the destination bucket is in a different account from the source bucket, you must add a bucket policy to the destination bucket to grant the owner of the source bucket account permission to replicate objects in the destination bucket. For more information, see [\(Optional\) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want.
4. Choose the **Management** tab, scroll down to **Replication rules**, and then choose **Create replication rule**.
5. In the **Replication rule configuration** section, under **Replication rule name**, enter a name for your rule to help identify the rule later. The name is required and must be unique within the bucket.
6. Under **Status**, **Enabled** is selected by default. An enabled rule starts to work as soon as you save it. If you want to enable the rule later, choose **Disabled**.
7. If the bucket has existing replication rules, you are instructed to set a priority for the rule. You must set a priority for the rule to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see [Replication configuration file elements](#).
8. Under **Source bucket**, you have the following options for setting the replication source:
 - To replicate the whole bucket, choose **Apply to all objects in the bucket**.
 - To replicate all objects that have the same prefix, choose **Limit the scope of this rule using one or more filters**. This limits replication to all objects that have names that begin with the prefix that you specify (for example pictures). Enter a prefix in the **Prefix** box.

Note

If you enter a prefix that is the name of a folder, you must use **/** (forward slash) as the last character (for example, `pictures/`).

- To replicate all objects with one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. Repeat the procedure to add another tag. You can combine a prefix and tags. For more information about object tags, see [Categorizing your objects using tags](#).

The new replication configuration XML schema supports prefix and tag filtering and the prioritization of rules. For more information about the new schema, see [Backward compatibility considerations](#). For more information about the XML used with the Amazon S3 API that works behind the user interface, see [Replication configuration file elements](#). The new schema is described as *replication configuration XML V2*.

9. Under **Destination**, choose the bucket where you want Amazon S3 to replicate objects.

Note

The number of destination buckets is limited to the number of AWS Regions in a given partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (Standard Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions). To request an increase in your destination bucket quota, you can use [service quotas](#).

- To replicate to a bucket or buckets in your account, choose **Choose a bucket in this account**, and enter or browse for the destination bucket names.
- To replicate to a bucket or buckets in a different AWS account, choose **Specify a bucket in another account**, and enter the destination bucket account ID and bucket name.

If the destination is in a different account from the source bucket, you must add a bucket policy to the destination buckets to grant the owner of the source bucket account permission to replicate objects. For more information, see [\(Optional\) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts](#).

Optionally, if you want to help standardize ownership of new objects in the destination bucket, choose **Change object ownership to the destination bucket owner**. For more information about this option, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

 **Note**

If versioning is not enabled on the destination bucket, you get a warning that contains an **Enable versioning** button. Choose this button to enable versioning on the bucket.

10. Set up an AWS Identity and Access Management (IAM) role that Amazon S3 can assume to replicate objects on your behalf.

To set up an IAM role, in the **IAM role** section, select one of the following from the **IAM role** dropdown list:

- We highly recommend that you choose **Create new role** to have Amazon S3 create a new IAM role for you. When you save the rule, a new policy is generated for the IAM role that matches the source and destination buckets that you choose.
- You can choose to use an existing IAM role. If you do, you must choose a role that grants Amazon S3 the necessary permissions for replication. Replication fails if this role does not grant Amazon S3 sufficient permissions to follow your replication rule.

 **Important**

When you add a replication rule to a bucket, you must have the `iam:PassRole` permission to be able to pass the IAM role that grants Amazon S3 replication permissions. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

11. To replicate objects in the source bucket that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), under **Encryption**, select **Replicate objects encrypted with AWS KMS**. Under **AWS KMS keys for encrypting destination objects** are the source keys that you allow replication to use. All source KMS keys are included by default. To narrow the KMS key selection, you can choose an alias or key ID.

Objects encrypted by AWS KMS keys that you do not select are not replicated. A KMS key or a group of KMS keys is chosen for you, but you can choose the KMS keys if you want. For information about using AWS KMS with replication, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

Important

When you replicate objects that are encrypted with AWS KMS, the AWS KMS request rate doubles in the source Region and increases in the destination Region by the same amount. These increased call rates to AWS KMS are due to the way that data is re-encrypted by using the KMS key that you define for the replication destination Region. AWS KMS has a request rate quota that is per calling account per Region. For information about the quota defaults, see [AWS KMS Quotas - Requests per Second: Varies in the AWS Key Management Service Developer Guide](#).

If your current Amazon S3 PUT object request rate during replication is more than half the default AWS KMS rate limit for your account, we recommend that you request an increase to your AWS KMS request rate quota. To request an increase, create a case in the Support Center at [Contact Us](#). For example, suppose that your current PUT object request rate is 1,000 requests per second and you use AWS KMS to encrypt your objects. In this case, we recommend that you ask Support to increase your AWS KMS rate limit to 2,500 requests per second, in both your source and destination Regions (if different), to ensure that there is no throttling by AWS KMS.

To see your PUT object request rate in the source bucket, view PutRequests in the Amazon CloudWatch request metrics for Amazon S3. For information about viewing CloudWatch metrics, see [Using the S3 console](#).

If you chose to replicate objects encrypted with AWS KMS, do the following:

- Under **AWS KMS key for encrypting destination objects**, specify your KMS key in one of the following ways:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key Amazon Resource Name (ARN), choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears. This encrypts the replicas in the destination bucket. You can find the ARN for your KMS key in the [IAM Console](#), under **Encryption keys**.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

Important

You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console lists only 100 KMS keys per Region. If you have more than 100 KMS keys in the same Region, you can see only the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN.

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

12. Under **Destination storage class**, if you want to replicate your data into a specific storage class in the destination, choose **Change the storage class for the replicated objects**. Then choose the storage class that you want to use for the replicated objects in the destination. If you don't

choose this option, the storage class for replicated objects is the same class as the original objects.

13. You have the following additional options while setting the **Additional replication options**:

- If you want to enable S3 Replication Time Control (S3 RTC) in your replication configuration, select **Replication Time Control (RTC)**. For more information about this option, see [Meeting compliance requirements with S3 Replication Time Control](#).
- If you want to enable S3 Replication metrics in your replication configuration, select **Replication metrics and events**. For more information, see [Monitoring replication with metrics, event notifications, and statuses](#).
- If you want to enable delete marker replication in your replication configuration, select **Delete marker replication**. For more information, see [Replicating delete markers between buckets](#).
- If you want to enable Amazon S3 replica modification sync in your replication configuration, select **Replica modification sync**. For more information, see [Replicating metadata changes with replica modification sync](#).

 **Note**

When you use S3 RTC or S3 Replication metrics, additional fees apply.

14. To finish, choose **Save**.
15. After you save your rule, you can edit, enable, disable, or delete your rule by selecting your rule and choosing **Edit rule**.

Using the AWS CLI

To use the AWS CLI to set up replication when the source and destination buckets are owned by the same AWS account, you do the following:

- Create source and destination buckets.
- Enable versioning on the buckets.
- Create an AWS Identity and Access Management (IAM) role that gives Amazon S3 permission to replicate objects.
- Add the replication configuration to the source bucket.

To verify your setup, you test it.

To set up replication when the source and destination buckets are owned by the same AWS account

1. Set a credentials profile for the AWS CLI. This example uses the profile name acctA. For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

Important

The profile that you use for this example must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile that you use has the `iam:PassRole` permission. For more information, see [Grant a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*. If you use administrator credentials to create a named profile, you can perform all the tasks.

2. Create a source bucket and enable versioning on it by using the following AWS CLI commands. To use these commands, replace the *user input placeholders* with your own information.

The following `create-bucket` command creates a source bucket named *amzn-s3-demo-source-bucket* in the US East (N. Virginia) (us-east-1) Region:

```
aws s3api create-bucket \
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

The following `put-bucket-versioning` command enables S3 Versioning on the *amzn-s3-demo-source-bucket* bucket:

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Create a destination bucket and enable versioning on it by using the following AWS CLI commands. To use these commands, replace the *user input placeholders* with your own information.

 **Note**

To set up a replication configuration when both source and destination buckets are in the same AWS account, you use the same profile for the source and destination buckets. This example uses `acctA`.

To test a replication configuration when the buckets are owned by different AWS accounts, specify different profiles for each account. For example, use an `acctB` profile for the destination bucket.

The following `create-bucket` command creates a destination bucket named *amzn-s3-demo-destination-bucket* in the US West (Oregon) (`us-west-2`) Region:

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctA
```

The following `put-bucket-versioning` command enables S3 Versioning on the *amzn-s3-demo-destination-bucket* bucket:

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

4. Create an IAM role. You specify this role in the replication configuration that you add to the source bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create a role.
- Attach a permissions policy to the role.

- a. Create the IAM role.
 - i. Copy the following trust policy and save it to a file named s3-role-trust-policy.json in the current directory on your local computer. This policy grants the Amazon S3 service principal permissions to assume the role.

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Principal": {  
        "Service": "s3.amazonaws.com"  
      },  
      "Action": "sts:AssumeRole"  
    }  
  ]  
}
```

- ii. Run the following command to create a role.

```
$ aws iam create-role \
--role-name replicationRole \
--assume-role-policy-document file://s3-role-trust-policy.json \
--profile acctA
```

- b. Attach a permissions policy to the role.

- i. Copy the following permissions policy and save it to a file named s3-role-permissions-policy.json in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions.

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [
```

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:GetObjectVersionForReplication",  
        "s3:GetObjectVersionAcl",  
        "s3:GetObjectVersionTagging"  
    ],  
    "Resource": [  
        "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
    ]  
},  
{  
    "Effect": "Allow",  
    "Action": [  
        "s3>ListBucket",  
        "s3:GetReplicationConfiguration"  
    ],  
    "Resource": [  
        "arn:aws:s3:::amzn-s3-demo-source-bucket"  
    ]  
},  
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:ReplicateObject",  
        "s3:ReplicateDelete",  
        "s3:ReplicateTags"  
    ],  
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
}  
]  
}
```

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called “Replicating encrypted objects”](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access

Management (IAM) role that you use to set up replication. The two additional permissions are s3:GetObjectRetention and s3:GetObjectLegalHold. If the role has an s3:Get* permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).

- ii. Run the following command to create a policy and attach it to the role. Replace the *user input placeholders* with your own information.

```
$ aws iam put-role-policy \
--role-name replicationRole \
--policy-document file://s3-role-permissions-policy.json \
--policy-name replicationRolePolicy \
--profile acctA
```

5. Add a replication configuration to the source bucket.

- a. Although the Amazon S3 API requires that you specify the replication configuration as XML, the AWS CLI requires that you specify the replication configuration as JSON. Save the following JSON in a file called `replication.json` to the local directory on your computer.

```
{
  "Role": "IAM-role-ARN",
  "Rules": [
    {
      "Status": "Enabled",
      "Priority": 1,
      "DeleteMarkerReplication": { "Status": "Disabled" },
      "Filter" : { "Prefix": "Tax" },
      "Destination": {
        "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket"
      }
    }
  ]
}
```

- b. Update the JSON by replacing the values for the `amzn-s3-demo-destination-bucket` and `IAM-role-ARN` with your own information. Save the changes.

- c. Run the following put-bucket-replication command to add the replication configuration to your source bucket. Be sure to provide the source bucket name:

```
$ aws s3api put-bucket-replication \
--replication-configuration file://replication.json \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

To retrieve the replication configuration, use the get-bucket-replication command:

```
$ aws s3api get-bucket-replication \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

6. Test the setup in the Amazon S3 console, by doing the following steps:

- a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- b. In the left navigation pane, choose **Buckets**. In the **General purpose buckets** list, choose the source bucket.
- c. In the source bucket, create a folder named *Tax*.
- d. Add sample objects to the *Tax* folder in the source bucket.

 **Note**

The amount of time that it takes for Amazon S3 to replicate an object depends on the size of the object. For information about how to see the status of replication, see [Getting replication status information](#).

In the destination bucket, verify the following:

- That Amazon S3 replicated the objects.
- That the objects are replicas. On the **Properties** tab for your objects, scroll down to the **Object management overview** section. Under **Management configurations**, see the value under **Replication status**. Make sure that this value is set to **REPLICA**.

- That the replicas are owned by the source bucket account. You can verify the object ownership on the **Permissions** tab for your objects.

If the source and destination buckets are owned by different accounts, you can add an optional configuration to tell Amazon S3 to change the replica ownership to the destination account. For an example, see [How to change the replica owner](#).

Using the AWS SDKs

Use the following code examples to add a replication configuration to a bucket with the AWS SDK for Java and AWS SDK for .NET, respectively.

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called “Replicating encrypted objects”](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).

Java

To add a replication configuration to a bucket and then retrieve and verify the configuration using the AWS SDK for Java, you can use the `S3Client` to manage replication settings programmatically.

For examples of how to configure replication with the AWS SDK for Java, see [Set replication configuration on a bucket](#) in the *Amazon S3 API Reference*.

C#

The following AWS SDK for .NET code example adds a replication configuration to a bucket and then retrieves it. To use this code, provide the names for your buckets and the Amazon

Resource Name (ARN) for your IAM role. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CrossRegionReplicationTest
    {
        private const string sourceBucket = "*** source bucket ***";
        // Bucket ARN example - arn:aws:s3:::destinationbucket
        private const string destinationBucketArn = "*** destination bucket ARN
***";
        private const string roleArn = "*** IAM Role ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint sourceBucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        public static void Main()
        {
            s3Client = new AmazonS3Client(sourceBucketRegion);
            EnableReplicationAsync().Wait();
        }
        static async Task EnableReplicationAsync()
        {
            try
            {
                ReplicationConfiguration replConfig = new ReplicationConfiguration
                {
                    Role = roleArn,
                    Rules =
                    {
                        new ReplicationRule
                        {
                            Prefix = "Tax",
                            Status = ReplicationRuleStatus.Enabled,
                            Destination = new ReplicationDestination
                            {

```

```
        BucketArn = destinationBucketArn
    }
}
};

PutBucketReplicationRequest putRequest = new
PutBucketReplicationRequest
{
    BucketName = sourceBucket,
    Configuration = replConfig
};

PutBucketReplicationResponse putResponse = await
s3Client.PutBucketReplicationAsync(putRequest);

        // Verify configuration by retrieving it.
        await RetrieveReplicationConfigurationAsync(s3Client);
}

catch (AmazonS3Exception e)
{
    Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
}
}

private static async Task RetrieveReplicationConfigurationAsync(IAmazonS3
client)
{
    // Retrieve the configuration.
    GetBucketReplicationRequest getRequest = new GetBucketReplicationRequest
    {
        BucketName = sourceBucket
    };
    GetBucketReplicationResponse getResponse = await
client.GetBucketReplicationAsync(getRequest);
    // Print.
    Console.WriteLine("Printing replication configuration information...");
    Console.WriteLine("Role ARN: {0}", getResponse.Configuration.Role);
    foreach (var rule in getResponse.Configuration.Rules)
```

```
        {
            Console.WriteLine("ID: {0}", rule.Id);
            Console.WriteLine("Prefix: {0}", rule.Prefix);
            Console.WriteLine("Status: {0}", rule.Status);
        }
    }
}
```

Configuring replication for buckets in different accounts

Live replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. Live replication copies newly created objects and object updates from a source bucket to a destination bucket or buckets. For more information, see [Replicating objects within and across Regions](#).

When you configure replication, you add replication rules to the source bucket. Replication rules define which source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination bucket can be in the same AWS account as the source bucket, or it can be in a different account.

If you specify an object version ID to delete, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination bucket. In other words, it doesn't delete the same object version from the destination bucket. This protects data from malicious deletions.

When you add a replication rule to a bucket, the rule is enabled by default, so it starts working as soon as you save it.

Setting up live replication when the source and destination buckets are owned by different AWS accounts is similar to setting up replication when both buckets are owned by the same account. However, there are several differences when you're configuring replication in a cross-account scenario:

- The destination bucket owner must grant the source bucket owner permission to replicate objects in the destination bucket policy.
- If you're replicating objects that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) in a cross-account scenario, the owner of

the KMS key must grant the source bucket owner permission to use the KMS key. For more information, see [Granting additional permissions for cross-account scenarios](#).

- By default, replicated objects are owned by the source bucket owner. In a cross-account scenario, you might want to configure replication to change the ownership of the replicated objects to the owner of the destination bucket. For more information, see [Changing the replica owner](#).

To configure replication when the source and destination buckets are owned by different AWS accounts

1. In this example, you create source and destination buckets in two different AWS accounts. You must have two credential profiles set for the AWS CLI. This example uses acctA and acctB for those profile names. For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.
2. Follow the step-by-step instructions in [Configuring replication for buckets in the same account](#) with the following changes:
 - For all AWS CLI commands related to source bucket activities (such as creating the source bucket, enabling versioning, and creating the IAM role), use the acctA profile. Use the acctB profile to create the destination bucket.
 - Make sure that the permissions policy for the IAM role specifies the source and destination buckets that you created for this example.
3. In the console, add the following bucket policy on the destination bucket to allow the owner of the source bucket to replicate objects. For instructions, see [Adding a bucket policy by using the Amazon S3 console](#). Be sure to edit the policy by providing the AWS account ID of the source bucket owner, the IAM role name, and the destination bucket name.

Note

To use the following example, replace the *user input placeholders* with your own information. Replace *amzn-s3-demo-destination-bucket* with your destination bucket name. Replace *source-bucket-account-ID:role/service-role/source-account-IAM-role* in the IAM Amazon Resource Name (ARN) with the IAM role that you're using for this replication configuration.

If you created the IAM service role manually, set the role path in the IAM ARN as `role/service-role/`, as shown in the following policy example. For more information, see [IAM ARNs](#) in the *IAM User Guide*.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "",  
    "Statement": [  
        {  
            "Sid": "Set-permissions-for-objects",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:role/service-role/source-account-IAM-role"  
            },  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        },  
        {  
            "Sid": "Set-permissions-on-bucket",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111122223333:role/service-role/source-account-IAM-role"  
            },  
            "Action": [  
                "s3:GetBucketVersioning",  
                "s3:PutBucketVersioning"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket"  
        }  
    ]  
}
```

4. (Optional) If you're replicating objects that are encrypted with SSE-KMS, the owner of the KMS key must grant the source bucket owner permission to use the KMS key. For more information, see [Granting additional permissions for cross-account scenarios](#).
5. (Optional) In replication, the owner of the source object owns the replica by default. When the source and destination buckets are owned by different AWS accounts, you can add optional configuration settings to change replica ownership to the AWS account that owns the destination buckets. This includes granting the `ObjectOwnerOverrideToBucketOwner` permission. For more information, see [Changing the replica owner](#).

Changing the replica owner

In replication, the owner of the source object also owns the replica by default. However, when the source and destination buckets are owned by different AWS accounts, you might want to change the replica ownership. For example, you might want to change the ownership to restrict access to object replicas. In your replication configuration, you can add optional configuration settings to change replica ownership to the AWS account that owns the destination buckets.

To change the replica owner, you do the following:

- Add the `owner override` option to the replication configuration to tell Amazon S3 to change replica ownership.
- Grant Amazon S3 the `s3:ObjectOwnerOverrideToBucketOwner` permission to change replica ownership.
- Add the `s3:ObjectOwnerOverrideToBucketOwner` permission in the destination bucket policy to allow changing replica ownership. The `s3:ObjectOwnerOverrideToBucketOwner` permission allows the owner of the destination buckets to accept the ownership of object replicas.

For more information, see [the section called “Considerations for the ownership override option”](#) and [Adding the owner override option to the replication configuration](#). For a working example with step-by-step instructions, see [How to change the replica owner](#).

Important

Instead of using the owner override option, you can use the bucket owner enforced setting for Object Ownership. When you use replication and the source and destination buckets are owned by different AWS accounts, the bucket owner of the destination bucket can use the

bucket owner enforced setting for Object Ownership to change replica ownership to the AWS account that owns the destination bucket. This setting disables object access control lists (ACLs).

The bucket owner enforced setting mimics the existing owner override behavior without the need of the `s3:ObjectOwnerOverrideToBucketOwner` permission. All objects that are replicated to the destination bucket with the bucket owner enforced setting are owned by the destination bucket owner. For more information about Object Ownership, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Considerations for the ownership override option

When you configure the ownership override option, the following considerations apply:

- By default, the owner of the source object also owns the replica. Amazon S3 replicates the object version and the ACL associated with it.

If you add the owner override option to your replication configuration, Amazon S3 replicates only the object version, not the ACL. In addition, Amazon S3 doesn't replicate subsequent changes to the source object ACL. Amazon S3 sets the ACL on the replica that grants full control to the destination bucket owner.

- When you update a replication configuration to enable or disable the owner override, the following behavior occurs:
 - If you add the owner override option to the replication configuration:

When Amazon S3 replicates an object version, it discards the ACL that's associated with the source object. Instead, Amazon S3 sets the ACL on the replica, giving full control to the owner of the destination bucket. Amazon S3 doesn't replicate subsequent changes to the source object ACL. However, this ACL change doesn't apply to object versions that were replicated before you set the owner override option. ACL updates on source objects that were replicated before the owner override was set continue to be replicated (because the object and its replicas continue to have the same owner).

- If you remove the owner override option from the replication configuration:

Amazon S3 replicates new objects that appear in the source bucket and the associated ACLs to the destination buckets. For objects that were replicated before you removed the owner override, Amazon S3 doesn't replicate the ACLs because the object ownership change that

Amazon S3 made remains in effect. That is, ACLs put on the object version that were replicated when the owner override was set continue to be not replicated.

Adding the owner override option to the replication configuration

Warning

Add the owner override option only when the source and destination buckets are owned by different AWS accounts. Amazon S3 doesn't check if the buckets are owned by the same or different accounts. If you add the owner override when both buckets are owned by same AWS account, Amazon S3 applies the owner override. This option grants full permissions to the owner of the destination bucket and doesn't replicate subsequent updates to the source objects' access control lists (ACLs). The replica owner can directly change the ACL associated with a replica with a PutObjectAcl request, but not through replication.

To specify the owner override option, add the following to each Destination element:

- The AccessControlTranslation element, which tells Amazon S3 to change replica ownership
- The Account element, which specifies the AWS account of the destination bucket owner

```
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    ...
    <Destination>
        ...
        <AccessControlTranslation>
            <Owner>Destination</Owner>
        </AccessControlTranslation>
        <Account>destination-bucket-owner-account-id</Account>
    </Destination>
</Rule>
</ReplicationConfiguration>
```

The following example replication configuration tells Amazon S3 to replicate objects that have the **Tax** key prefix to the **amzn-s3-demo-destination-bucket** destination bucket and change ownership of the replicas. To use this example, replace the **user input placeholders** with your own information.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <ID>Rule-1</ID>
    <Priority>1</Priority>
    <Status>Enabled</Status>
    <DeleteMarkerReplication>
      <Status>Disabled</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
      <Account>destination-bucket-owner-account-id</Account>
      <AccessControlTranslation>
        <Owner>Destination</Owner>
      </AccessControlTranslation>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

Granting Amazon S3 permission to change replica ownership

Grant Amazon S3 permissions to change replica ownership by adding permission for the `s3:ObjectOwnerOverrideToBucketOwner` action in the permissions policy that's associated with the AWS Identity and Access Management (IAM) role. This role is the IAM role that you specified in the replication configuration that allows Amazon S3 to assume and replicate objects on your behalf. To use the following example, replace `amzn-s3-demo-destination-bucket` with the name of the destination bucket.

```
...
{
  "Effect": "Allow",
  "Action": [
    "s3:ObjectOwnerOverrideToBucketOwner"
  ],
  "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
}
```

Adding permission in the destination bucket policy to allow changing replica ownership

The owner of the destination bucket must grant the owner of the source bucket permission to change replica ownership. The owner of the destination bucket grants the owner of the source bucket permission for the `s3:ObjectOwnerOverrideToBucketOwner` action. This permission allows the destination bucket owner to accept ownership of the object replicas. The following example bucket policy statement shows how to do this. To use this example, replace the *user input placeholders* with your own information.

```
...
{
    "Sid": "1",
    "Effect": "Allow",
    "Principal": {"AWS": "source-bucket-account-id"},
    "Action": ["s3:ObjectOwnerOverrideToBucketOwner"],
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
}
...
```

How to change the replica owner

When the source and destination buckets in a replication configuration are owned by different AWS accounts, you can tell Amazon S3 to change replica ownership to the AWS account that owns the destination bucket. The following examples show how to use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDKs to change replica ownership.

Using the S3 console

For step-by-step instructions, see [Configuring replication for buckets in the same account](#).

This topic provides instructions for setting up a replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

The following procedure shows how to change replica ownership by using the AWS CLI. In this procedure, you do the following:

- Create the source and destination buckets.
- Enable versioning on the buckets.
- Create an AWS Identity and Access Management (IAM) role that gives Amazon S3 permission to replicate objects.

- Add the replication configuration to the source bucket.
- In the replication configuration, you direct Amazon S3 to change the replica ownership.
- You test your replication configuration.

To change replica ownership when the source and destination buckets are owned by different AWS accounts (AWS CLI)

To use the example AWS CLI commands in this procedure, replace the *user input placeholders* with your own information.

1. In this example, you create the source and destination buckets in two different AWS accounts. To work with these two accounts, configure the AWS CLI with two named profiles. This example uses profiles named *acctA* and *acctB*, respectively. For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

Important

The profiles that you use for this procedure must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile that you use has the `iam:PassRole` permission. If you use administrator user credentials to create a named profile, then you can perform all of the tasks in this procedure. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

2. Create the source bucket and enable versioning. This example creates a source bucket named *amzn-s3-demo-source-bucket* in the US East (N. Virginia) (us-east-1) Region.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Create a destination bucket and enable versioning. This example creates a destination bucket named *amzn-s3-demo-destination-bucket* in the US West (Oregon) (us-west-2) Region. Use an AWS account profile that's different from the one that you used for the source bucket.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctB
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
--versioning-configuration Status=Enabled \
--profile acctB
```

4. You must add permissions to your destination bucket policy to allow changing the replica ownership.
- a. Save the following policy to a file named *destination-bucket-policy.json*. Make sure to replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "destination_bucket_policy_sid",  
            "Principal": {  
                "AWS": "source-bucket-owner-account-id"  
            },  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete",  
                "s3:ObjectOwnerOverrideToBucketOwner",  
                "s3:ReplicateTags",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
            ]  
        }  
    ]  
}
```

```
"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
```

```
]
```

```
}
```

```
[
```

```
}
```

- b. Add the preceding policy to the destination bucket by using the following put-bucket-policy command:

```
aws s3api put-bucket-policy --region ${destination-region} --bucket ${amzn-s3-demo-destination-bucket} --policy file://destination_bucket_policy.json
```

5. Create an IAM role. You specify this role in the replication configuration that you add to the source bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create the role.
- Attach a permissions policy to the role.

- a. Create the IAM role.

- i. Copy the following trust policy and save it to a file named *s3-role-trust-policy.json* in the current directory on your local computer. This policy grants Amazon S3 permissions to assume the role.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

- ii. Run the following AWS CLI `create-role` command to create the IAM role:

```
$ aws iam create-role \
--role-name replicationRole \
--assume-role-policy-document file://s3-role-trust-policy.json \
--profile acctA
```

Make note of the Amazon Resource Name (ARN) of the IAM role that you created. You will need this ARN in a later step.

- b. Attach a permissions policy to the role.

- i. Copy the following permissions policy and save it to a file named *s3-role-perm-pol-changeowner.json* in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions. In the following steps, you attach this policy to the IAM role that you created earlier.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectVersionForReplication",
                "s3:GetObjectVersionAcl"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3>ListBucket",
                "s3:GetReplicationConfiguration"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket"
            ]
        }
    ]
}
```

```
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:ReplicateObject",
            "s3:ReplicateDelete",
            "s3:ObjectOwnerOverrideToBucketOwner",
            "s3:ReplicateTags",
            "s3:GetObjectVersionTagging"
        ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
    }
]
```

- ii. To attach the preceding permissions policy to the role, run the following `put-role-policy` command:

```
$ aws iam put-role-policy \
--role-name replicationRole \
--policy-document file://s3-role-perm-pol-changeowner.json \
--policy-name replicationRolechangeownerPolicy \
--profile acctA
```

6. Add a replication configuration to your source bucket.

- a. The AWS CLI requires specifying the replication configuration as JSON. Save the following JSON in a file named *replication.json* in the current directory on your local computer. In the configuration, the `AccessControlTranslation` specifies the change in replica ownership from the source bucket owner to the destination bucket owner.

```
{
    "Role": "IAM-role-ARN",
    "Rules": [
        {
            "Status": "Enabled",
            "Priority": 1,
            "DeleteMarkerReplication": {
                "Status": "Disabled"
            },
            "Filter": {},
            "Status": "Enabled",
        }
    ]
}
```

```
    "Destination":{  
        "Bucket":"arn:aws:s3:::amzn-s3-demo-destination-bucket",  
        "Account":"destination-bucket-owner-account-id",  
        "AccessControlTranslation":{  
            "Owner":"Destination"  
        }  
    }  
}  
]
```

- b. Edit the JSON by providing values for the destination bucket name, the destination bucket owner account ID, and the *IAM-role-ARN*. Replace *IAM-role-ARN* with the ARN of the IAM role that you created earlier. Save the changes.
- c. To add the replication configuration to the source bucket, run the following command:

```
$ aws s3api put-bucket-replication \  
--replication-configuration file://replication.json \  
--bucket amzn-s3-demo-source-bucket \  
--profile acctA
```

7. Test your replication configuration by checking replica ownership in the Amazon S3 console.
 - a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 - b. Add objects to the source bucket. Verify that the destination bucket contains the object replicas and that the ownership of the replicas has changed to the AWS account that owns the destination bucket.

Using the AWS SDKs

For a code example to add a replication configuration, see [Using the AWS SDKs](#). You must modify the replication configuration appropriately. For conceptual information, see [Changing the replica owner](#).

Meeting compliance requirements with S3 Replication Time Control

S3 Replication Time Control (S3 RTC) helps you meet compliance or business requirements for data replication and provides visibility into Amazon S3 replication times. S3 RTC replicates most objects that you upload to Amazon S3 in seconds, and 99.9 percent of those objects within 15 minutes.

By default, S3 RTC includes two ways to track the progress of replication:

- **S3 Replication metrics** – You can use S3 Replication metrics to monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination Region, and the total number of operations that failed replication. You can then monitor each dataset that you replicate separately. You can also enable S3 Replication metrics independently of S3 RTC. For more information, see [the section called "Using S3 Replication metrics"](#).

Replication rules with S3 Replication Time Control (S3 RTC) enabled publish S3 Replication metrics. Replication metrics are available within 15 minutes of enabling S3 RTC. Replication metrics are available through the Amazon S3 console, the Amazon S3 API, the AWS SDKs, the AWS Command Line Interface (AWS CLI), and Amazon CloudWatch. For more information about CloudWatch metrics, see [Monitoring metrics with Amazon CloudWatch](#). For more information about viewing replication metrics through the Amazon S3 console, see [Viewing replication metrics](#).

S3 Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics. For information, see [Amazon CloudWatch pricing](#).

- **Amazon S3 Event Notifications** – S3 RTC provides OperationMissedThreshold and OperationReplicatedAfterThreshold events that notify the bucket owner if object replication exceeds or occurs after the 15-minute threshold. With S3 RTC, Amazon S3 Event Notifications can notify you in the rare instance when objects don't replicate within 15 minutes and when those objects replicate after the 15-minute threshold.

Replication events are available within 15 minutes of enabling S3 RTC. Amazon S3 Event Notifications are available through Amazon SQS, Amazon SNS, or AWS Lambda. For more information, see [the section called "Receiving replication failure events"](#).

Best practices and guidelines for S3 RTC

When replicating data in Amazon S3 with S3 Replication Time Control (S3 RTC) enabled, follow these best practice guidelines to optimize replication performance for your workloads.

Topics

- [Amazon S3 Replication and request rate performance guidelines](#)
- [Estimating your replication request rates](#)

- [Exceeding S3 RTC data transfer rate quotas](#)
- [AWS KMS encrypted object replication request rates](#)

Amazon S3 Replication and request rate performance guidelines

When uploading and retrieving storage from Amazon S3, your applications can achieve thousands of transactions per second in request performance. For example, an application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per prefix in an S3 bucket, including the requests that S3 Replication makes on your behalf. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by parallelizing reads. For example, if you create 10 prefixes in an S3 bucket to parallelize reads, you can scale your read performance to 55,000 read requests per second.

Amazon S3 automatically scales in response to sustained request rates above these guidelines, or sustained request rates concurrent with LIST requests. While Amazon S3 is internally optimizing for the new request rate, you might receive HTTP 503 request responses temporarily until the optimization is complete. This behavior might occur with increases in request per second rates, or when you first enable S3 RTC. During these periods, your replication latency might increase. The S3 RTC service level agreement (SLA) doesn't apply to time periods when Amazon S3 performance guidelines on requests per second are exceeded.

The S3 RTC SLA also doesn't apply during time periods where your replication data transfer rate exceeds the default 1 gigabit per second (Gbps) quota. If you expect your replication transfer rate to exceed 1 Gbps, you can contact [AWS Support Center](#) or use [Service Quotas](#) to request an increase in your replication transfer rate quota.

Estimating your replication request rates

Your total request rate including the requests that Amazon S3 replication makes on your behalf must be within the Amazon S3 request rate guidelines for both the replication source and destination buckets. For each object replicated, Amazon S3 replication makes up to five GET/HEAD requests and one PUT request to the source bucket, and one PUT request to each destination bucket.

For example, if you expect to replicate 100 objects per second, Amazon S3 replication might perform an additional 100 PUT requests on your behalf for a total of 200 PUT requests per second to the source S3 bucket. Amazon S3 replication also might perform up to 500 GET/HEAD requests (5 GET/HEAD requests for each object that's replicated.)

Note

You incur costs for only one PUT request per object replicated. For more information, see the pricing information in the [Amazon S3 FAQs about replication](#).

Exceeding S3 RTC data transfer rate quotas

If you expect your S3 RTC data transfer rate to exceed the default 1 Gbps quota, contact [AWS Support Center](#) or use [Service Quotas](#) to request an increase in your replication transfer rate quota.

AWS KMS encrypted object replication request rates

When you replicate objects that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), AWS KMS requests per second quotas apply. AWS KMS might reject an otherwise valid request because your request rate exceeds the quota for the number of requests per second. When a request is throttled, AWS KMS returns a ThrottlingException error. The AWS KMS request rate quota applies to requests that you make directly and to requests made by Amazon S3 replication on your behalf.

For example, if you expect to replicate 1,000 objects per second, you can subtract 2,000 requests from your AWS KMS request rate quota. The resulting request rate per second is available for your AWS KMS workloads excluding replication. You can use [AWS KMS request metrics in Amazon CloudWatch](#) to monitor the total AWS KMS request rate on your AWS account.

To request an increase to your AWS KMS requests per second quota, contact [AWS Support Center](#) or use [Service Quotas](#).

Enabling S3 Replication Time Control

You can start using S3 Replication Time Control (S3 RTC) with a new or existing replication rule. You can choose to apply your replication rule to an entire bucket, or to objects with a specific prefix or tag. When you enable S3 RTC, S3 Replication metrics are also enabled on your replication rule.

You can configure S3 RTC by using the Amazon S3 console, the Amazon S3 API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI).

Using the S3 console

For step-by-step instructions, see [Configuring replication for buckets in the same account](#). This topic provides instructions for enabling S3 RTC in your replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

To use the AWS CLI to replicate objects with S3 RTC enabled, you create buckets, enable versioning on the buckets, create an IAM role that gives Amazon S3 permission to replicate objects, and add the replication configuration to the source bucket. The replication configuration must have S3 RTC enabled, as shown in the following example.

For step-by-step instructions for setting up your replication configuration by using the AWS CLI, see [Configuring replication for buckets in the same account](#).

The following example replication configuration enables and sets the `ReplicationTime` and `EventThreshold` values for a replication rule. Enabling and setting these values enables S3 RTC on the rule.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "DeleteMarkerReplication": {  
                "Status": "Disabled"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
                "Metrics": {  
                    "Status": "Enabled",  
                    "EventThreshold": {  
                        "Minutes": 15  
                    }  
                },  
                "ReplicationTime": {  
                    "Status": "Enabled",  
                    "Time": {  
                        "Minutes": 15  
                    }  
                }  
            }  
        }  
    ]  
}
```

```
        }
    },
    "Priority": 1
}
],
"Role": "IAM-Role-ARN"
}
```

Important

Metrics:EventThreshold:Minutes and ReplicationTime:Time:Minutes can only have 15 as a valid value.

Using the AWS SDK for Java

The following Java example adds replication configuration with S3 Replication Time Control (S3 RTC) enabled.

```
import software.amazon.awssdk.auth.credentials.AwsBasicCredentials;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.model.DeleteMarkerReplication;
import software.amazon.awssdk.services.s3.model.Destination;
import software.amazon.awssdk.services.s3.model.Metrics;
import software.amazon.awssdk.services.s3.model.MetricsStatus;
import software.amazon.awssdk.services.s3.model.PutBucketReplicationRequest;
import software.amazon.awssdk.services.s3.model.ReplicationConfiguration;
import software.amazon.awssdk.services.s3.model.ReplicationRule;
import software.amazon.awssdk.services.s3.model.ReplicationRuleFilter;
import software.amazon.awssdk.services.s3.model.ReplicationTime;
import software.amazon.awssdk.services.s3.model.ReplicationTimeStatus;
import software.amazon.awssdk.services.s3.model.ReplicationTimeValue;

public class Main {

    public static void main(String[] args) {
        S3Client s3 = S3Client.builder()
            .region(Region.US_EAST_1)
            .credentialsProvider(() -> AwsBasicCredentials.create(
                "AWS_ACCESS_KEY_ID",
                "AWS_SECRET_ACCESS_KEY"))
    }
}
```

```
.build();

ReplicationConfiguration replicationConfig = ReplicationConfiguration
    .builder()
    .rules(
        ReplicationRule
            .builder()
            .status("Enabled")

    .bucket("source_bucket")
    .replicationConfiguration(replicationConfig)
    .build();

s3.putBucketReplication(putBucketReplicationRequest);
}

}
```

Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C)

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

There are some special considerations when you're replicating objects that have been encrypted by using server-side encryption. Amazon S3 supports the following types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

For more information about server-side encryption, see [the section called “Server-side encryption”](#).

This topic explains the permissions that you need to direct Amazon S3 to replicate objects that have been encrypted by using server-side encryption. This topic also provides additional configuration elements that you can add and example AWS Identity and Access Management (IAM) policies that grant the necessary permissions for replicating encrypted objects.

For an example with step-by-step instructions, see [Enabling replication for encrypted objects](#). For information about creating a replication configuration, see [Replicating objects within and across Regions](#).

 **Note**

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Topics

- [How default bucket encryption affects replication](#)
- [Replicating objects encrypted with SSE-C](#)
- [Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS](#)
- [Enabling replication for encrypted objects](#)

How default bucket encryption affects replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.
- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

Replicating objects encrypted with SSE-C

By using server-side encryption with customer-provided keys (SSE-C), you can manage your own proprietary encryption keys. With SSE-C, you manage the keys while Amazon S3 manages the encryption and decryption process. You must provide an encryption key as part of your request, but you don't need to write any code to perform object encryption or decryption. When you upload an object, Amazon S3 encrypts the object by using the key that you provided. Amazon S3 then purges that key from memory. When you retrieve an object, you must provide the same encryption key as part of your request. For more information, see [the section called "Customer-provided encryption keys \(SSE-C\)"](#).

S3 Replication supports objects that are encrypted with SSE-C. You can configure SSE-C object replication in the Amazon S3 console or with the AWS SDKs in the same way that you configure replication for unencrypted objects. There aren't additional SSE-C permissions beyond what are currently required for replication.

S3 Replication automatically replicates newly uploaded SSE-C encrypted objects if they are eligible, as specified in your S3 Replication configuration. To replicate existing objects in your buckets, use S3 Batch Replication. For more information about replicating objects, see [the section called "Setting up live replication"](#) and [the section called "Replicating existing objects"](#).

There are no additional charges for replicating SSE-C objects. For details about replication pricing, see [Amazon S3 pricing](#).

Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS

By default, Amazon S3 doesn't replicate objects that are encrypted with SSE-KMS or DSSE-KMS. This section explains the additional configuration elements that you can add to direct Amazon S3 to replicate these objects.

For an example with step-by-step instructions, see [Enabling replication for encrypted objects](#). For information about creating a replication configuration, see [Replicating objects within and across Regions](#).

Specifying additional information in the replication configuration

In the replication configuration, you do the following:

- In the Destination element in your replication configuration, add the ID of the symmetric AWS KMS customer managed key that you want Amazon S3 to use to encrypt object replicas, as shown in the following example replication configuration.

- Explicitly opt in by enabling replication of objects encrypted by using KMS keys (SSE-KMS or DSSE-KMS). To opt in, add the `SourceSelectionCriteria` element, as shown in the following example replication configuration.

```
<ReplicationConfiguration>
  <Rule>
    ...
    <SourceSelectionCriteria>
      <SseKmsEncryptedObjects>
        <Status>Enabled</Status>
      </SseKmsEncryptedObjects>
    </SourceSelectionCriteria>

    <Destination>
      ...
      <EncryptionConfiguration>
        <ReplicaKmsKeyID>AWS KMS key ARN or Key Alias ARN that's in the same AWS Region as the destination bucket.</ReplicaKmsKeyID>
      </EncryptionConfiguration>
    </Destination>
    ...
  </Rule>
</ReplicationConfiguration>
```

Important

- The KMS key must have been created in the same AWS Region as the destination bucket.
- The KMS key *must* be valid. The `PutBucketReplication` API operation doesn't check the validity of KMS keys. If you use a KMS key that isn't valid, you will receive the `HTTP 200 OK` status code in response, but replication fails.

The following example shows a replication configuration that includes optional configuration elements. This replication configuration has one rule. The rule applies to objects with the `Tax` key prefix. Amazon S3 uses the specified AWS KMS key ID to encrypt these object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration>
```

```
<Role>arn:aws:iam::account-id:role/role-name</Role>
<Rule>
  <ID>Rule-1</ID>
  <Priority>1</Priority>
  <Status>Enabled</Status>
  <DeleteMarkerReplication>
    <Status>Disabled</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>Tax</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    <EncryptionConfiguration>
      <ReplicaKmsKeyId>AWS KMS key ARN or Key Alias ARN that's in the same AWS Region as the destination bucket.</ReplicaKmsKeyId>
    </EncryptionConfiguration>
  </Destination>
  <SourceSelectionCriteria>
    <SseKmsEncryptedObjects>
      <Status>Enabled</Status>
    </SseKmsEncryptedObjects>
  </SourceSelectionCriteria>
  </Rule>
</ReplicationConfiguration>
```

Granting additional permissions for the IAM role

To replicate objects that are encrypted at rest by using SSE-S3, SSE-KMS, or DSSE-KMS, grant the following additional permissions to the AWS Identity and Access Management (IAM) role that you specify in the replication configuration. You grant these permissions by updating the permissions policy that's associated with the IAM role.

- **s3:GetObjectVersionForReplication action for source objects** – This action allows Amazon S3 to replicate both unencrypted objects and objects created with server-side encryption by using SSE-S3, SSE-KMS, or DSSE-KMS.

Note

We recommend that you use the s3:GetObjectVersionForReplication action instead of the s3:GetObjectVersion action because s3:GetObjectVersionForReplication provides Amazon S3 with only the minimum

permissions necessary for replication. In addition, the `s3:GetObjectVersion` action allows replication of unencrypted and SSE-S3-encrypted objects, but not of objects that are encrypted by using KMS keys (SSE-KMS or DSSE-KMS).

- **kms:Decrypt and kms:Encrypt AWS KMS actions for the KMS keys**

- You must grant `kms:Decrypt` permissions for the AWS KMS key that's used to decrypt the source object.
- You must grant `kms:Encrypt` permissions for the AWS KMS key that's used to encrypt the object replica.
- **kms:GenerateDataKey action for replicating plaintext objects** – If you're replicating plaintext objects to a bucket with SSE-KMS or DSSE-KMS encryption enabled by default, you must include the `kms:GenerateDataKey` permission for the destination encryption context and the KMS key in the IAM policy.

We recommend that you restrict these permissions only to the destination buckets and objects by using AWS KMS condition keys. The AWS account that owns the IAM role must have permissions for the `kms:Encrypt` and `kms:Decrypt` actions for the KMS keys that are listed in the policy. If the KMS keys are owned by another AWS account, the owner of the KMS keys must grant these permissions to the AWS account that owns the IAM role. For more information about managing access to these KMS keys, see [Using IAM policies with AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

S3 Bucket Keys and replication

To use replication with an S3 Bucket Key, the AWS KMS key policy for the KMS key that's used to encrypt the object replica must include the `kms:Decrypt` permission for the calling principal. The call to `kms:Decrypt` verifies the integrity of the S3 Bucket Key before using it. For more information, see [Using an S3 Bucket Key with replication](#).

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN (for example, `arn:aws:s3:::bucket_ARN`). You must update your IAM policies to use the bucket ARN for the encryption context:

```
"kms:EncryptionContext:aws:s3:arn": [
    "arn:aws:s3:::bucket_ARN"
]
```

For more information, see [Encryption context \(x-amz-server-side-encryption-context\)](#) (in the "Using the REST API" section) and [Changes to note before enabling an S3 Bucket Key](#).

Example policies: Using SSE-S3 and SSE-KMS with replication

The following example IAM policies show statements for using SSE-S3 and SSE-KMS with replication.

Example – Using SSE-KMS with separate destination buckets

The following example policy shows statements for using SSE-KMS with separate destination buckets.

Example – Replicating objects created with SSE-S3 and SSE-KMS

The following is a complete IAM policy that grants the necessary permissions to replicate unencrypted objects, objects created with SSE-S3, and objects created with SSE-KMS.

            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket"
            ]
        }
    },
    "Resource": [
        "arn:aws:kms:us-east-1:111122223333:key/key-id"
    ]
}
]
```

Granting additional permissions for cross-account scenarios

In a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, you can use a KMS key to encrypt object replicas. However, the KMS key owner must grant the source bucket owner permission to use the KMS key.

Note

If you need to replicate SSE-KMS data cross-account, then your replication rule must specify a [customer managed key](#) from AWS KMS for the destination account. [AWS managed keys](#) don't allow cross-account use, and therefore can't be used to perform cross-account replication.

To grant the source bucket owner permission to use the KMS key (AWS KMS console)

1. Sign in to the AWS Management Console and open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**.
4. Choose the KMS key.
5. Under the **General configuration** section, choose the **Key policy** tab.
6. Scroll down to **Other AWS accounts**.
7. Choose **Add other AWS accounts**.

The **Other AWS accounts** dialog box appears.

8. In the dialog box, choose **Add another AWS account**. For **arn:aws:iam::**, enter the source bucket account ID.
9. Choose **Save changes**.

To grant the source bucket owner permission to use the KMS key (AWS CLI)

- For information about the `put-key-policy` AWS Command Line Interface (AWS CLI) command, see [put-key-policy](#) in the *AWS CLI Command Reference*. For information about the underlying `PutKeyPolicy` API operation, see [PutKeyPolicy](#) in the *AWS Key Management Service API Reference*.

AWS KMS transaction quota considerations

When you add many new objects with AWS KMS encryption after enabling Cross-Region Replication (CRR), you might experience throttling (HTTP 503 Service Unavailable errors).

Throttling occurs when the number of AWS KMS transactions per second exceeds the current quota. For more information, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

To request a quota increase, use Service Quotas. For more information, see [Requesting a quota increase](#). If Service Quotas isn't supported in your Region, [open an AWS Support case](#).

Enabling replication for encrypted objects

By default, Amazon S3 doesn't replicate objects that are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). To replicate objects encrypted with SSE-KMS or DSS-KMS, you must modify the bucket replication configuration to tell Amazon S3 to replicate these objects. This example explains how to use the Amazon S3 console and the AWS Command Line Interface (AWS CLI) to change the bucket replication configuration to enable replicating encrypted objects.

Note

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN. You must update your IAM policies to use the bucket ARN for the encryption context. For more information, see [S3 Bucket Keys and replication](#).

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Using the S3 console

For step-by-step instructions, see [Configuring replication for buckets in the same account](#). This topic provides instructions for setting a replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

To replicate encrypted objects with the AWS CLI, you do the following:

- Create source and destination buckets and enable versioning on these buckets.
- Create an AWS Identity and Access Management (IAM) service role that gives Amazon S3 permission to replicate objects. The IAM role's permissions include the necessary permissions to replicate the encrypted objects.
- Add a replication configuration to the source bucket. The replication configuration provides information related to replicating objects that are encrypted by using KMS keys.
- Add encrypted objects to the source bucket.
- Test the setup to confirm that your encrypted objects are being replicated to the destination bucket.

The following procedures walk you through this process.

To replicate server-side encrypted objects (AWS CLI)

To use the examples in this procedure, replace the *user input placeholders* with your own information.

1. In this example, you create both the source (*amzn-s3-demo-source-bucket*) and destination (*amzn-s3-demo-destination-bucket*) buckets in the same AWS account. You also set a credentials profile for the AWS CLI. This example uses the profile name *acctA*.

For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

2. Use the following commands to create the *amzn-s3-demo-source-bucket* bucket and enable versioning on it. The following example commands create the *amzn-s3-demo-source-bucket* bucket in the US East (N. Virginia) (us-east-1) Region.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Use the following commands to create the *amzn-s3-demo-destination-bucket* bucket and enable versioning on it. The following example commands create the *amzn-s3-demo-destination-bucket* bucket in the US West (Oregon) (us-west-2) Region.

 **Note**

To set up a replication configuration when both *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets are in the same AWS account, you use the same profile. This example uses *acctA*. To configure replication when the buckets are owned by different AWS accounts, you specify different profiles for each.

```
aws s3api create-bucket \  
--bucket amzn-s3-demo-destination-bucket \  
--region us-west-2 \  
--create-bucket-configuration LocationConstraint=us-west-2 \  
--profile acctA
```

```
aws s3api put-bucket-versioning \  
--bucket amzn-s3-demo-destination-bucket \  
--versioning-configuration Status=Enabled \  
--profile acctA
```

4. Next, you create an IAM service role. You will specify this role in the replication configuration that you add to the *amzn-s3-demo-source-bucket* bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create a service role.
- Attach a permissions policy to the role.

- a. To create an IAM service role, do the following:

- i. Copy the following trust policy and save it to a file called *s3-role-trust-policy-kmsobj*.json in the current directory on your local computer. This policy grants the Amazon S3 service principal permissions to assume the role so that Amazon S3 can perform tasks on your behalf.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- ii. Use the following command to create the role:

```
$ aws iam create-role \  
--role-name replicationRolekmsobj \  
--assume-role-policy-document file://s3-role-trust-policy-kmsobj.json \  
--profile accta
```

- b. Next, you attach a permissions policy to the role. This policy grants permissions for various Amazon S3 bucket and object actions.
 - i. Copy the following permissions policy and save it to a file named *s3-role-permissions-policykmsobj.json* in the current directory on your local computer. You will create an IAM role and attach the policy to it later.

⚠ Important

In the permissions policy, you specify the AWS KMS key IDs that will be used for encryption of the *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets. You must create two separate KMS keys for the *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets. AWS KMS keys aren't shared outside the AWS Region in which they were created.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "s3>ListBucket",  
                "s3:GetReplicationConfiguration",  
                "s3:GetObjectVersionForReplication",  
                "s3:GetObjectVersionAcl",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3::::amzn-s3-demo-source-bucket",  
                "arn:aws:s3::::amzn-s3-demo-source-bucket/*"  
            ]  
        },  
        {  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete",  
                "s3:ReplicateTags"  
            ],  
            "Effect": "Allow",  
            "Condition": {  
                "StringLikeIfExists": {  
                    "s3:x-amz-server-side-encryption": [  
                        "aws:kms",  
                        "AES256",  
                        "aws:kms:dsse"  
                    ],  
                    "s3:x-amz-server-side-encryption-aws-kms-key-id": [  
                        "AWS KMS key IDs(in ARN format) to use for  
                        encrypting object replicas"  
                    ]  
                }  
            },  
            "Resource": "arn:aws:s3::::amzn-s3-demo-destination-bucket/*"  
        },  
    ]  
}
```

```
{  
    "Action": [  
        "kms:Decrypt"  
    ],  
    "Effect": "Allow",  
    "Condition": {  
        "StringLike": {  
            "kms:ViaService": "s3.us-east-1.amazonaws.com",  
            "kms:EncryptionContext:aws:s3:arn": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
            ]  
        }  
    },  
    "Resource": [  
        "arn:aws:kms:us-east-1:111122223333:key/key-id"  
    ]  
},  
{  
    "Action": [  
        "kms:Encrypt"  
    ],  
    "Effect": "Allow",  
    "Condition": {  
        "StringLike": {  
            "kms:ViaService": "s3.us-west-2.amazonaws.com",  
            "kms:EncryptionContext:aws:s3:arn": [  
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
            ]  
        }  
    },  
    "Resource": [  
        "arn:aws:kms:us-west-2:111122223333:key/key-id"  
    ]  
}  
]  
}
```

- ii. Create a policy and attach it to the role.

```
$ aws iam put-role-policy \  
--role-name replicationRolekmsobj \  
--policy-document file://s3-role-permissions-policykmsobj.json \  
--policy-name replicationRolechangeownerPolicy \  
$
```

```
--profile acctA
```

5. Next, add the following replication configuration to the *amzn-s3-demo-source-bucket* bucket. It tells Amazon S3 to replicate objects with the *Tax/* prefix to the *amzn-s3-demo-destination-bucket* bucket.

⚠ Important

In the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if you have the `iam:PassRole` permission. The profile that you specify in the CLI command must have this permission. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

```
<ReplicationConfiguration>
  <Role>IAM-Role-ARN</Role>
  <Rule>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>Disabled</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <SourceSelectionCriteria>
      <SseKmsEncryptedObjects>
        <Status>Enabled</Status>
      </SseKmsEncryptedObjects>
    </SourceSelectionCriteria>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
      <EncryptionConfiguration>
        <ReplicaKmsKeyId>AWS KMS key IDs to use for encrypting object replicas</ReplicaKmsKeyId>
      </EncryptionConfiguration>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

To add a replication configuration to the *amzn-s3-demo-source-bucket* bucket, do the following:

- a. The AWS CLI requires you to specify the replication configuration as JSON. Save the following JSON in a file (*replication.json*) in the current directory on your local computer.

```
{  
    "Role": "IAM-Role-ARN",  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Priority": 1,  
            "DeleteMarkerReplication": {  
                "Status": "Disabled"  
            },  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
                "EncryptionConfiguration": {  
                    "ReplicaKmsKeyId": "AWS KMS key IDs (in ARN format) to use for  
                    encrypting object replicas"  
                }  
            },  
            "SourceSelectionCriteria": {  
                "SseKmsEncryptedObjects": {  
                    "Status": "Enabled"  
                }  
            }  
        }  
    ]  
}
```

- b. Edit the JSON to provide values for the *amzn-s3-demo-destination-bucket* bucket, *AWS KMS key IDs (in ARN format)*, and *IAM-role-ARN*. Save the changes.
- c. Use the following command to add the replication configuration to your *amzn-s3-demo-source-bucket* bucket. Be sure to provide the *amzn-s3-demo-source-bucket* bucket name.

```
$ aws s3api put-bucket-replication \
--replication-configuration file://replication.json \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

6. Test the configuration to verify that encrypted objects are replicated. In the Amazon S3 console, do the following:
 - a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 - b. In the *amzn-s3-demo-source-bucket* bucket, create a folder named *Tax*.
 - c. Add sample objects to the folder. Be sure to choose the encryption option and specify your KMS key to encrypt the objects.
 - d. Verify that the *amzn-s3-demo-destination-bucket* bucket contains the object replicas and that they are encrypted by using the KMS key that you specified in the configuration. For more information, see [the section called “Getting replication status”](#).

Using the AWS SDKs

For a code example that shows how to add a replication configuration, see [Using the AWS SDKs](#). You must modify the replication configuration appropriately.

Replicating metadata changes with replica modification sync

Amazon S3 replica modification sync can help you keep object metadata such as tags, access control lists (ACLs), and Object Lock settings replicated between replicas and source objects. By default, Amazon S3 replicates metadata from the source objects to the replicas only. When replica modification sync is enabled, Amazon S3 replicates metadata changes made to the replica copies back to the source object, making the replication bidirectional (two-way replication).

Enabling replica modification sync

You can use Amazon S3 replica modification sync with new or existing replication rules. You can apply it to an entire bucket or to objects that have a specific prefix.

To enable replica modification sync by using the Amazon S3 console, see [Examples for configuring live replication](#). This topic provides instructions for enabling replica modification sync in your

replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable replica modification sync by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the bucket containing the replicas with ReplicaModifications enabled. To set up two-way replication, create a replication rule from the source bucket (*amzn-s3-demo-source-bucket*) to the bucket containing the replicas (*amzn-s3-demo-destination-bucket*). Then, create a second replication rule from the bucket containing the replicas (*amzn-s3-demo-destination-bucket*) to the source bucket (*amzn-s3-demo-source-bucket*). The source and destination buckets can be in the same or different AWS Regions.

 **Note**

You must enable replica modification sync on both the source and destination buckets to replicate replica metadata changes like object access control lists (ACLs), object tags, or Object Lock settings on the replicated objects. Like all replication rules, you can apply these rules to the entire bucket or to a subset of objects filtered by prefix or object tags.

In the following example configuration, Amazon S3 replicates metadata changes under the prefix *Tax* to the bucket *amzn-s3-demo-source-bucket*, which contains the source objects.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "SourceSelectionCriteria": {  
                "ReplicaModifications": {  
                    "Status": "Enabled"  
                }  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-source-bucket"  
            },  
            "Priority": 1  
        }  
    ]  
}
```

```
],  
"Role": "IAM-Role-ARN"  
}
```

For full instructions on creating replication rules by using the AWS CLI, see [Configuring replication for buckets in the same account](#).

Replicating delete markers between buckets

By default, when S3 Replication is enabled and an object is deleted in the source bucket, Amazon S3 adds a delete marker in the source bucket only. This action helps protect data in the destination buckets from accidental or malicious deletions. If you have *delete marker replication* enabled, these markers are copied to the destination buckets, and Amazon S3 behaves as if the object was deleted in both the source and destination buckets. For more information about how delete markers work, see [Working with delete markers](#).

Note

- Delete marker replication isn't supported for tag-based replication rules. Delete marker replication also doesn't adhere to the 15-minute service-level agreement (SLA) that's granted when you're using S3 Replication Time Control (S3 RTC).
- If you're not using the latest replication configuration XML version, delete operations affect replication differently. For more information, see [How delete operations affect replication](#).
- If you enable delete marker replication and your source bucket has an S3 Lifecycle expiration rule, the delete markers added by the S3 Lifecycle expiration rule won't be replicated to the destination bucket.

Enabling delete marker replication

You can start using delete marker replication with a new or existing replication rule. You can apply delete marker replication to an entire bucket or to objects that have a specific prefix.

To enable delete marker replication by using the Amazon S3 console, see [Using the S3 console](#). This topic provides instructions for enabling delete marker replication in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable delete marker replication by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with DeleteMarkerReplication enabled, as shown in the following example configuration.

In the following example replication configuration, delete markers are replicated to the destination bucket *amzn-s3-demo-destination-bucket* for objects under the prefix *Tax*.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "DeleteMarkerReplication": {  
                "Status": "Enabled"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket"  
            },  
            "Priority": 1  
        }  
    ],  
    "Role": "IAM-Role-ARN"  
}
```

For full instructions on creating replication rules through the AWS CLI, see [Configuring replication for buckets in the same account](#).

Managing or pausing live replication

Live replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. After you set up your replication configuration, Amazon S3 replicates newly created objects and object updates from a source bucket to one or more specified destination buckets.

You use the Amazon S3 console to add replication rules to the source bucket. Replication rules define the source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. For more information about replication, see [Replicating objects within and across Regions](#).

You can manage replication rules on the **Replication** page in the Amazon S3 console. You can add, view, edit, enable, disable, or delete replication rules. You can also change the priority of your replication rules. For information about adding replication rules to a bucket, see [Using the S3 console](#).

To manage the replication rules for a bucket by using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. On the **General purpose buckets** tab, choose the name of the bucket that you want.
4. Choose the **Management** tab, and then scroll down to **Replication rules**.
5. You can change your replication rules in the following ways:
 - To enable or disable a replication rule, choose the option button to the left of the rule. On the **Actions** menu, choose **Enable rule** or **Disable rule**. You can also disable, enable, or delete all the rules in the bucket from the **Actions** menu.

Note

If you disable a replication rule and then later re-enable the rule, any new or changed objects that weren't replicated while the rule was disabled are *not* automatically replicated when the rule is re-enabled. To replicate those objects, you must use S3 Batch Replication. For more information, see [the section called "Replicating existing objects"](#).

- To change the priority of a rule, choose the option button to the left of the rule, and then choose **Edit rule**.

You set rule priorities to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see [Replication configuration file elements](#).

Pausing or stopping replication

To temporarily pause replication and have it automatically resume later, you can use the `aws:s3:bucket-pause-replication` action in AWS Fault Injection Service. For more

information, see [aws:s3:bucket-pause-replication](#) and [Pause S3 Replication](#) in the *AWS Fault Injection Service User Guide*.

To stop replication in Amazon S3, we recommend disabling your replication rules. If you disable a replication rule and then later re-enable the rule, any new or changed objects that weren't replicated while the rule was disabled are *not* automatically replicated when the rule is re-enabled. To replicate those objects, you must use S3 Batch Replication. For more information, see [the section called "Replicating existing objects"](#).

Replication will also stop if you remove the AWS Identity and Access Management (IAM) role, the AWS Key Management Service (AWS KMS) permissions, or the bucket policy permissions that grant Amazon S3 the required permissions. However, we don't recommend these approaches because they cause replication to fail. Amazon S3 reports the replication status for affected objects as FAILED. If permissions are later restored, objects marked as FAILED are *not* automatically replicated. To replicate those objects, you must use S3 Batch Replication.

Replicating existing objects with Batch Replication

S3 Batch Replication differs from live replication, which continuously and automatically replicates new objects across Amazon S3 buckets. Instead, S3 Batch Replication occurs on demand on existing objects. You can use S3 Batch Replication to replicate the following types of objects:

- Objects that existed before a replication configuration was in place
- Objects that have previously been replicated
- Objects that have failed replication

You can replicate these objects on demand by using a Batch Operations job.

To get started with Batch Replication, you can:

- **Initiate Batch Replication for a new replication rule or destination** – You can create a one-time Batch Replication job when you're creating the first rule in a new replication configuration or when you're adding a new destination bucket to an existing configuration through the Amazon S3 console.
- **Initiate Batch Replication for an existing replication configuration** – You can create a new Batch Replication job by using S3 Batch Operations through the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

When the Batch Replication job finishes, you receive a completion report. For more information about how to use this report to examine the job, see [Tracking job status and completion reports](#).

S3 Batch Replication considerations

Before using S3 Batch Replication, review the following list of considerations:

- Your source bucket must have an existing replication configuration. To enable replication, see [Setting up live replication overview](#) and [Examples for configuring live replication](#).
- If you have S3 Lifecycle configured for your bucket, we recommend disabling your lifecycle rules while the Batch Replication job is active. Doing so helps ensure parity between the source and destination buckets. Otherwise, these buckets could diverge, and the destination bucket won't be an exact replica of the source bucket. For example, consider the following scenario:
 - Your source bucket has multiple versions of an object and a delete marker on that object.
 - Your source and destination buckets have a lifecycle configuration to remove expired delete markers.

In this scenario, Batch Replication might replicate the delete marker to the destination bucket before replicating the object versions. This behavior could result in your lifecycle configuration marking the delete marker as expired and the delete marker being removed from the destination bucket before the object versions are replicated.

- The AWS Identity and Access Management (IAM) role that you specify to run the Batch Operations job must have the necessary permissions to perform the underlying Batch Replication operation. For more information about creating IAM roles, see [Configuring an IAM role for S3 Batch Replication](#).
- Batch Replication requires a manifest, which can be generated by Amazon S3. The generated manifest must be stored in the same AWS Region as the source bucket. If you choose not to generate the manifest, you can supply an Amazon S3 Inventory report or CSV file that contains the objects that you want to replicate. For more information, see [the section called “Specifying a manifest for a Batch Replication job”](#).
- Batch Replication doesn't support re-replicating objects that were deleted by specifying the version ID of the object from the destination bucket. To re-replicate these objects, you can copy the source objects in place with a Batch Copy job. Copying those objects in place creates new versions of the objects in the source bucket and automatically initiates replication to the destination bucket. Deleting and recreating the destination bucket doesn't initiate replication.

For more information about Batch Copy, see [Examples that use Batch Operations to copy objects](#).

- If you're using a replication rule on the source bucket, make sure to [update your replication configuration](#) by granting the IAM role that's attached to the replication rule the proper permissions to replicate objects. This IAM role must have the necessary permissions to perform replication on both the source and destination buckets.
- If you submit multiple Batch Replication jobs for the same bucket within a short time frame, Amazon S3 runs those jobs concurrently.
- If you submit multiple Batch Replication jobs for two different buckets, be aware that Amazon S3 might not run all jobs concurrently. If you exceed the number of Batch Replication jobs that can run at one time on your account, Amazon S3 pauses the lower priority jobs to work on the higher priority ones. After the higher priority jobs are completed, any paused jobs become active again.
- Batch Replication isn't supported for objects that are stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.
- To batch replicate S3 Intelligent-Tiering objects that are stored in the Archive Access or Deep Archive Access storage tiers, you must first initiate a [restore](#) request and wait until the objects are moved to the Frequent Access tier.
- A single Batch Replication job can support a manifest with up to 20 billion objects.

Specifying a manifest for a Batch Replication job

A manifest is an Amazon S3 object that contains the object keys that you want Amazon S3 to act upon. If you want to create a Batch Replication job, you must supply either a user-generated manifest or have Amazon S3 generate a manifest based on your replication configuration.

If you supply a user-generated manifest, it must be in the form of an Amazon S3 Inventory report or a CSV file. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID that's specified in the manifest will be replicated. To learn more about specifying a manifest, see [Specifying a manifest](#).

If you choose to have Amazon S3 generate a manifest file on your behalf, the objects listed use the same source bucket, prefix, and tags as your replication configurations on the source bucket. With a generated manifest, Amazon S3 replicates all eligible versions of your objects.

Note

If you choose to have Amazon S3 generate the manifest, the manifest must be stored in the same AWS Region as the source bucket.

Filters for a Batch Replication job

When creating your Batch Replication job, you can optionally specify additional filters, such as the object creation date and replication status, to reduce the scope of the job.

You can filter objects to replicate based on the `ObjectReplicationStatuses` value, by providing one or more of the following values:

- "NONE" – Indicates that Amazon S3 has never attempted to replicate the object before.
- "FAILED" – Indicates that Amazon S3 has attempted, but failed, to replicate the object before.
- "COMPLETED" – Indicates that Amazon S3 has successfully replicated the object before.
- "REPLICA" – Indicates that this object is a replica that Amazon S3 has replicated from another source bucket.

For more information about replication statuses, see [Getting replication status information](#).

If you don't filter your Batch Replication job, Batch Operations attempts to replicate all objects (no matter their `ObjectReplicationStatus`) in your manifest that match the rules in your replication configuration, except for certain objects that aren't replicated by default. For more information, see [the section called "What isn't replicated with replication configurations?"](#)

Depending on your goal, you might set `ObjectReplicationStatuses` to one or more of the following values:

- To replicate only existing objects that have never been replicated, only include "NONE".
- To retry replicating only objects that previously failed to replicate, only include "FAILED".
- To both replicate existing objects and retry replicating objects that previously failed to replicate, include both "NONE" and "FAILED".
- To backfill a destination bucket with objects that have been replicated to another destination, include "COMPLETED".
- To replicate objects that were previously replicated, include "REPLICA".

Batch Replication completion report

When you create a Batch Replication job, you can request a CSV completion report. This report shows the objects, replication success or failure codes, outputs, and descriptions. For more information about job tracking and completion reports, see [Completion reports](#).

For a list of replication failure codes and descriptions, see [Amazon S3 replication failure reasons](#).

For information about troubleshooting Batch Replication, see [Batch Replication errors](#).

Getting started with Batch Replication

To learn more about how to use Batch Replication, see [Tutorial: Replicating existing objects in your Amazon S3 buckets with S3 Batch Replication](#).

Configuring an IAM role for S3 Batch Replication

Because Amazon S3 Batch Replication is a type of Batch Operations job, you must create an AWS Identity and Access Management (IAM) role to grant Batch Operations permissions to perform actions on your behalf. You also must attach a Batch Replication IAM policy to the Batch Operations IAM role.

Use the following procedures to create a policy and an IAM role that give Batch Operations permission to initiate a Batch Replication job.

To create a policy for Batch Replication

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Under **Access management**, choose **Policies**.
3. Choose **Create policy**.
4. On the **Specify permissions** page, choose **JSON**.
5. Insert one of the following policies, depending on whether your manifest is generated by Amazon S3 or whether you are supplying your own manifest. For more information about manifests, see [Specifying a manifest for a Batch Replication job](#).

Before using these policies, replace the *user input placeholders* in the following policies with the names of your replication source bucket, manifest bucket, and completion report bucket.

Note

Your IAM role for Batch Replication needs different permissions, depending on whether you are generating a manifest or supplying one, so make sure that you choose the appropriate policy from the following examples.

Policy if using and storing an Amazon S3 generated manifest

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "s3:InitiateReplication"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
            ]  
        },  
        {  
            "Action": [  
                "s3:GetReplicationConfiguration",  
                "s3:PutInventoryConfiguration"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket"  
            ]  
        },  
        {  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"  
            ]  
        }  
    ]  
}
```

```
    "Resource": [
        "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*",
        "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
    ]
}
]
```

Policy if using a user-supplied manifest

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "s3:InitiateReplication"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
            ]
        },
        {
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*"
            ]
        }
    ]
}
```

```
        ]
    }
]
```

6. Choose **Next**.
7. Specify a name for the policy, and then choose **Create policy**.

To create an IAM role for Batch Replication

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Under **Access management**, choose **Roles**.
3. Choose **Create role**.
4. Choose **AWS service** as the type of trusted entity. In the **Use case** section, choose **S3** as the service, and **S3 Batch Operations** as the use case.
5. Choose **Next**. The **Add permissions** page appears. In the search box, search for the policy that you created in the preceding procedure. Select the checkbox next to the policy name, then choose **Next**.
6. On the **Name, review, and create** page, specify a name for your IAM role.
7. In the **Step 1: Trust identities** section, verify that your IAM role is using the following trust policy:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "batchoperations.s3.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

8. In the **Step 2: Add permissions** section, verify that your IAM role is using the policy that you created earlier.
9. Choose **Create role**.

Create a Batch Replication job for new replication rules or destinations

In Amazon S3, live replication doesn't replicate any objects that already existed in your source bucket before you created a replication configuration. Live replication automatically replicates only new and updated objects that are written to the bucket after the replication configuration is created. To replicate already existing objects, you can use S3 Batch Replication to replicate these objects on demand.

When you create the first rule in a new live replication configuration or add a new destination bucket to an existing replication configuration through the Amazon S3 console, you can optionally create a Batch Replication job. You can use this Batch Replication job to replicate existing objects in the source bucket to the destination bucket.

To use Batch Replication for an existing configuration without adding a new destination bucket, see [Create a Batch Replication job for existing replication rules](#).

Prerequisites

Before creating your Batch Replication job, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

Using Batch Replication for a new replication rule or destination through the Amazon S3 console

When you create the first rule in a new replication configuration or add a new destination bucket to an existing configuration through the Amazon S3 console, you can choose to create a Batch Replication job to replicate existing objects in the source bucket.

To create a Batch Replication job when creating or updating a replication configuration

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.

3. In the **General purpose buckets** list, choose the name of the bucket that contains the objects that you want to replicate.
4. To create a new replication rule or edit an existing rule, choose the **Management** tab, and scroll down to **Replication rules**:
 - To create a new replication rule, choose **Create replication rule**. For examples of how to set up a basic replication rule, see [Examples for configuring live replication](#).
 - To edit an existing replication rule, select the option button next to the rule name, and then choose **Edit rule**.
5. Create your new replication rule or edit the destination for your existing replication rule, and choose **Save**.

After you create the first rule in a new replication configuration or edit an existing configuration to add a new destination, a **Replicate existing objects?** dialog appears, giving you the option to create a Batch Replication job.

6. If you want to create and run this job now, choose **Yes, replicate existing objects**.
If you want to create a Batch Replication job at a later time, choose **No, do not replicate existing objects**.
7. If you chose **Yes, replicate existing objects**, the **Create Batch Operations job** page appears. The S3 Batch Replication job has the following settings:

Job run options

If you want the S3 Batch Replication job to run immediately, choose **Automatically run the job when it's ready**. If you want to run the job at a later time, choose **Wait to run the job when it's ready**.

Note

If you choose **Automatically run the job when it's ready**, you won't be able to create and save a Batch Operations manifest. To save the Batch Operations manifest, choose **Wait to run the job when it's ready**.

Batch Operations manifest

If you chose **Wait to run the job when it's ready**, the **Batch Operations manifest** section appears. The manifest is a list of all of the objects that you want to run the specified action on. You can choose to save the manifest. Similar to S3 Inventory files, the manifest will be saved as a CSV file and stored in a bucket. To learn more about Batch Operations manifests, see [Specifying a manifest](#).

Completion report

S3 Batch Operations executes one task for each object specified in the manifest.

Completion reports provide an easy way to view the results of your tasks in a consolidated format with no additional setup required. You can request a completion report for all tasks or only for failed tasks. To learn more about completion reports, see [Completion reports](#).

Permissions

One of the most common causes of replication failures is insufficient permissions in the provided AWS Identity and Access Management (IAM) role. For information about creating this role, see [Configuring an IAM role for S3 Batch Replication](#). Make sure that you create or choose an IAM role that has the required permissions for Batch Replication.

8. Choose **Save**.

Create a Batch Replication job for existing replication rules

In Amazon S3, live replication doesn't replicate any objects that already existed in your source bucket before you created a replication configuration. Live replication automatically replicates only new and updated objects that are written to the bucket after the replication configuration is created. To replicate already existing objects, you can use S3 Batch Replication to replicate these objects on demand.

You can configure S3 Batch Replication for an existing replication configuration by using the AWS SDKs, AWS Command Line Interface (AWS CLI), or the Amazon S3 console. For an overview of Batch Replication, see [Replicating existing objects with Batch Replication](#).

When the Batch Replication job finishes, you receive a completion report. For more information about how to use the report to examine the job, see [Tracking job status and completion reports](#).

Prerequisites

Before creating your Batch Replication job, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. Verify that the **AWS Region** section shows the Region where you want to create your job.
5. In the **Manifest** section, specify the manifest format that you want to use. The manifest is a list of all of the objects that you want to run the specified action on. To learn more about Batch Operations manifests, see [Specifying a manifest](#).
 - If you have a manifest prepared, choose **S3 inventory report (manifest.json)** or **CSV**. If your manifest is in a versioned bucket, you can specify the version ID for the manifest. If you don't specify a version ID, Batch Operations uses the current version of your manifest. For more information about creating a manifest, see [Specifying a manifest](#).

 **Note**

If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. For more information, see [Specifying a manifest](#).

- To create a manifest based on your replication configuration, choose **Create manifest using S3 Replication configuration**. Then choose the source bucket of your replication configuration.
6. (Optional) If you chose **Create manifest using S3 Replication configuration**, you can include additional filters, such as the object creation date and replication status. For examples of how to filter by replication status, see [Specifying a manifest for a Batch Replication job](#).
 7. (Optional) If you chose **Create manifest using S3 Replication configuration**, you can save the generated manifest. To save this manifest, select **Save Batch Operations manifest**. Then specify the destination bucket for the manifest and choose whether to encrypt the manifest.

Note

The generated manifest must be stored in the same AWS Region as the source bucket.

8. Choose **Next**.
9. On the **Operations** page, choose **Replicate**, then choose **Next**.
10. (Optional) Provide a **Description**.
11. Adjust the **Priority** of the job if needed. Higher numbers indicate higher priority. Amazon S3 attempts to run higher priority jobs before lower priority jobs. For more information about job priority, see [Assigning job priority](#).
12. (Optional) Generate a completion report. To generate this report, select **Generate completion report**.
If you choose to generate a completion report, you must choose either to report **Failed tasks only** or **All tasks**, and provide a destination bucket for the report.
13. In the **Permissions** section, make sure that you choose an IAM role that has the required permissions for Batch Replication. One of the most common causes of replication failures is insufficient permissions in the provided IAM role. For information about creating this role, see [Configuring an IAM role for S3 Batch Replication](#).
14. (Optional) Add job tags to the Batch Replication job.
15. Choose **Next**.
16. Review your job configuration, and then choose **Create job**.

Using the AWS CLI with an S3 manifest

The following example `create-job` command creates an S3 Batch Replication job by using an S3 generated manifest for the AWS account [111122223333](#). This example replicates existing objects and objects that previously failed to replicate. For information about filtering by replication status, see [Specifying a manifest for a Batch Replication job](#).

To use this command, replace the *user input placeholders* with your own information. Replace the IAM role `role/batch-Replication-IAM-policy` with the IAM role that you previously created. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

```
aws s3control create-job --account-id 111122223333 \
--operation '{"S3ReplicateObject":{}}' \
```

```
--report '{"Bucket":"arn:aws:s3:::amzn-s3-demo-completion-report-bucket",\ 
"Prefix":"batch-replication-report", \
"Format":"Report_CSV_20180820","Enabled":true,"ReportScope":"AllTasks"}' \
--manifest-generator '{"S3JobManifestGenerator": {"ExpectedBucketOwner": \
"111122223333", \
"SourceBucket": "arn:aws:s3:::amzn-s3-demo-source-bucket", \
"EnableManifestOutput": false, "Filter": {"EligibleForReplication": true, \
"ObjectReplicationStatuses": ["NONE","FAILED"]}}}' \
--priority 1 \
--role-arn arn:aws:iam::111122223333:role/batch-Replication-IAM-policy \
--no-confirmation-required \
--region source-bucket-region
```

Note

You must initiate the job from the same AWS Region as the replication source bucket.

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job by using the following `describe-job` command. To use this command, replace the *user input placeholders* with your own information.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Using the AWS CLI with a user-provided manifest

The following example creates an S3 Batch Replication job by using a user-defined manifest for AWS account **111122223333**. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID specified in the manifest will be replicated. For more information about creating a manifest, see [Specifying a manifest](#).

To use this command, replace the *user input placeholders* with your own information. Replace the IAM role `role/batch-Replication-IAM-policy` with the IAM role that you previously created. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

```
aws s3control create-job --account-id 111122223333 \
--operation '{"S3ReplicateObject":{}}' \
--report '{"Bucket":"arn:aws:s3:::amzn-s3-demo-completion-report-bucket",\ 
"Prefix":"batch-replication-report", \
```

```
"Format":"Report_CSV_20180820","Enabled":true,"ReportScope":"AllTasks"}' \
--manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820",\
"Fields":["Bucket","Key","VersionId"]}},\
"Location":{"ObjectArn":"arn:aws:s3:::amzn-s3-demo-manifest-bucket/manifest.csv",\
"ETag":"Manifest Etag"}' \
--priority 1 \
--role-arn arn:aws:iam::111122223333:role/batch-Replication-IAM-policy \
--no-confirmation-required \
--region source-bucket-region
```

Note

You must initiate the job from the same AWS Region as the replication source bucket.

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job by using the following describe-job command.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Troubleshooting replication

This section lists troubleshooting tips for Amazon S3 Replication and information about S3 Batch Replication errors.

Topics

- [Troubleshooting tips for S3 Replication](#)
- [Batch Replication errors](#)

Troubleshooting tips for S3 Replication

If object replicas don't appear in the destination bucket after you configure replication, use these troubleshooting tips to identify and fix issues.

- The majority of objects replicate within 15 minutes. The time that it takes Amazon S3 to replicate an object depends on several factors, including the source and destination Region pair, and the size of the object. For large objects, replication can take up to several hours. For visibility into replication times, you can use [S3 Replication Time Control \(S3 RTC\)](#).

If the object that is being replicated is large, wait a while before checking to see whether it appears in the destination. You can also check the replication status of the source object. If the object replication status is PENDING, Amazon S3 hasn't completed the replication. If the object replication status is FAILED, check the replication configuration that's set on the source bucket.

Additionally, to receive information about failures during replication, you can set up Amazon S3 Event Notifications replication to receive failure events. For more information, see [Receiving replication failure events with Amazon S3 Event Notifications](#).

- To check the replication status of an object, you can call the HeadObject API operation. The HeadObject API operation returns the PENDING, COMPLETED, or FAILED replication status of an object. In a response to a HeadObject API call, the replication status is returned in the x-amz-replication-status header.

Note

To run HeadObject, you must have read access to the object that you're requesting.

A HEAD request has the same options as a GET request, without performing a GET operation. For example, to run a HeadObject request by using the AWS Command Line Interface (AWS CLI), you can run the following command. Replace the *user input placeholders* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-source-bucket --key index.html
```

- If HeadObject returns objects with a FAILED replication status, you can use S3 Batch Replication to replicate those failed objects. For more information, see [the section called "Replicating existing objects"](#). Alternatively, you can re-upload the failed objects to the source bucket, which will initiate replication for the new objects.
- In the replication configuration on the source bucket, verify the following:
 - The Amazon Resource Name (ARN) of the destination bucket is correct.
 - The key name prefix is correct. For example, if you set the configuration to replicate objects with the prefix Tax, then only objects with key names such as Tax/document1 or Tax/document2 are replicated. An object with the key name document3 is not replicated.
 - The status of the replication rule is Enabled.
- Verify that versioning hasn't been suspended on any bucket in the replication configuration. Both the source and destination buckets must have versioning enabled.

- If a replication rule is set to **Change object ownership to the destination bucket owner**, then the AWS Identity and Access Management (IAM) role that's used for replication must have the `s3:ObjectOwnerOverrideToBucketOwner` permission. This permission is granted on the resource (in this case, the destination bucket). For example, the following Resource statement shows how to grant this permission on the destination bucket:

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:ObjectOwnerOverrideToBucketOwner"  
    ],  
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
}
```

- If the destination bucket is owned by another account, the owner of the destination bucket must also grant the `s3:ObjectOwnerOverrideToBucketOwner` permission to the source bucket owner through the destination bucket policy. To use the following example bucket policy, replace the *user input placeholders* with your own information:

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1644945280205",  
    "Statement": [  
        {  
            "Sid": "Stmt1644945277847",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"  
            },  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateTags",  
                "s3:ObjectOwnerOverrideToBucketOwner"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        }  
    ]  
}
```

Note

If the destination bucket's object ownership settings include **Bucket owner enforced**, then you don't need to update the setting to **Change object ownership to the destination bucket owner** in the replication rule. The object ownership change will occur by default. For more information about changing replica ownership, see [Changing the replica owner](#).

- If you're setting the replication configuration in a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, the destination buckets can't be configured as a Requester Pays bucket. For more information, see [Using Requester Pays general purpose buckets for storage transfers and usage](#).
- If a bucket's source objects are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), then the replication rule must be configured to include AWS KMS-encrypted objects. Make sure to select **Replicate objects encrypted with AWS KMS** under your **Encryption** settings in the Amazon S3 console. Then, select an AWS KMS key for encrypting the destination objects.

Note

If the destination bucket is in a different account, specify an AWS KMS customer managed key that is owned by the destination account. Don't use the default Amazon S3 managed key (aws/s3). Using the default key encrypts the objects with the Amazon S3 managed key that's owned by the source account, preventing the object from being shared with another account. As a result, the destination account won't be able to access the objects in the destination bucket.

To use an AWS KMS key that belongs to the destination account to encrypt the destination objects, the destination account must grant the `kms:GenerateDataKey` and `kms:Encrypt` permissions to the replication role in the KMS key policy. To use the following example statement in your KMS key policy, replace the `user input placeholders` with your own information:

```
{  
    "Sid": "AllowS3ReplicationSourceRoleToUseTheKey",  
    "Effect": "Allow",
```

```
"Principal": {  
    "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"  
},  
"Action": ["kms:GenerateDataKey", "kms:Encrypt"],  
"Resource": "*"  
}
```

If you use an asterisk (*) for the Resource statement in the AWS KMS key policy, the policy grants permission to use the KMS key to only the replication role. The policy doesn't allow the replication role to elevate its permissions.

By default, the KMS key policy grants the root user full permissions to the key. These permissions can be delegated to other users in the same account. Unless there are Deny statements in the source KMS key policy, using an IAM policy to grant the replication role permissions to the source KMS key is sufficient.

 **Note**

KMS key policies that restrict access to specific CIDR ranges, virtual private cloud (VPC) endpoints, or S3 access points can cause replication to fail.

If either the source or destination KMS keys grant permissions based on the encryption context, confirm that Amazon S3 Bucket Keys are turned on for the buckets. If the buckets have S3 Bucket Keys turned on, the encryption context must be the bucket-level resource, like this:

```
"kms:EncryptionContext:arn:aws:arn": [  
    "arn:aws:s3::::amzn-s3-demo-source-bucket"  
]  
"kms:EncryptionContext:arn:aws:arn": [  
    "arn:aws:s3::::amzn-s3-demo-destination-bucket"  
]
```

In addition to the permissions granted by the KMS key policy, the source account must add the following minimum permissions to the replication role's IAM policy:

```
{  
    "Effect": "Allow",  
    "Action": [
```

```
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": [
        "Source-KMS-Key-ARN"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey",
        "kms:Encrypt"
    ],
    "Resource": [
        "Destination-KMS-Key-ARN"
    ]
}
```

For more information about how to replicate objects that are encrypted with AWS KMS, see [Replicating encrypted objects](#).

- If the destination bucket is owned by another AWS account, verify that the bucket owner has a bucket policy on the destination bucket that allows the source bucket owner to replicate objects. For an example, see [Configuring replication for buckets in different accounts](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are s3:GetObjectRetention and s3:GetObjectLegalHold. If the role has an s3:Get* permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).
- If your objects still aren't replicating after you've validated the permissions, check for any explicit Deny statements in the following locations:
 - Deny statements in the source or destination bucket policies. Replication fails if the bucket policy denies access to the replication role for any of the following actions:

Source bucket:

```
"s3:GetReplicationConfiguration",
"s3>ListBucket",
"s3:GetObjectVersionForReplication",
"s3:GetObjectVersionAcl",
```

```
"s3:GetObjectVersionTagging"
```

Destination buckets:

```
"s3:ReplicateObject",
"s3:ReplicateDelete",
"s3:ReplicateTags"
```

- Deny statements or permissions boundaries attached to the IAM role can cause replication to fail.
- Deny statements in AWS Organizations service control policies (SCPs) that are attached to either the source or destination accounts can cause replication to fail.
- Deny statements in AWS Organizations resource control policies (RCPs) that are attached to either the source or destination buckets can cause replication to fail.
- If an object replica doesn't appear in the destination bucket, the following issues might have prevented replication:
 - Amazon S3 doesn't replicate an object in a source bucket that is a replica created by another replication configuration. For example, if you set a replication configuration from bucket A to bucket B to bucket C, Amazon S3 doesn't replicate object replicas in bucket B to bucket C.
 - A source bucket owner can grant other AWS accounts permission to upload objects. By default, the source bucket owner doesn't have permissions for the objects created by other accounts. The replication configuration replicates only the objects for which the source bucket owner has access permissions. To avoid this problem, the source bucket owner can grant other AWS accounts permissions to create objects conditionally, requiring explicit access permissions on those objects. For an example policy, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).
- Suppose that in the replication configuration, you add a rule to replicate a subset of objects that have a specific tag. In this case, you must assign the specific tag key and value at the time the object is created in order for Amazon S3 to replicate the object. If you first create an object and then add the tag to the existing object, Amazon S3 doesn't replicate the object.
- Use Amazon S3 Event Notifications to notify you of instances when objects don't replicate to their destination AWS Region. Amazon S3 Event Notifications are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [Receiving replication failure events with Amazon S3 Event Notifications](#).

You can also view replication failure reasons by using Amazon S3 Event Notifications. To review the list of failure reasons, see [Amazon S3 replication failure reasons](#).

Batch Replication errors

To troubleshoot objects that aren't replicating to the destination bucket, check the different types of permissions for your buckets, replication role, and IAM role that's used to create the Batch Replication job. Also, make sure to check the Block Public Access settings and S3 Object Ownership settings for your buckets.

For additional troubleshooting tips for working with Batch Operations, see [the section called "Troubleshooting S3 Batch Operations"](#).

If you've set up replication and objects aren't replicating, see [Why aren't my Amazon S3 objects replicating when I set up replication between my buckets?](#) in the AWS re:Post Knowledge Center.

While using Batch Replication, you might encounter one of these errors:

- Manifest generation found no keys matching the filter criteria.

This error occurs for one of the following reasons:

- When objects in the source bucket are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.

To use Batch Replication on these objects, first restore them to the S3 Standard storage class by using a **Restore** (`S3InitiateRestoreObjectOperation`) operation in a Batch Operations job. For more information, see [Restoring an archived object](#) and [Restore objects \(Batch Operations\)](#). After you've restored the objects, you can replicate them by using a Batch Replication job.

- When the provided filter criteria doesn't match any valid objects in the source bucket.

Verify and correct the filter criteria. For example, in the Batch Replication rule, the filter criteria is looking for all objects in the source bucket with the prefix Tax/. If the prefix name was entered inaccurately, with a slash in the beginning and the end /Tax/ instead of only at the end, then no S3 objects were found. To resolve the error, correct the prefix, in this case, from / Tax/ to Tax/ in the replication rule.

- Batch operation status is failed with reason: The job report could not be written to your report bucket.

This error occurs if the IAM role that's used for the Batch Operations job is unable to put the completion report into the location that was specified when you created the job. To resolve this error, check that the IAM role has the `s3:PutObject` permission for the bucket where you want to save the Batch Operations completion report. We recommend delivering the report to a bucket different from the source bucket.

- Batch operation is completed with failures and Total failed is not 0.

This error occurs if there are insufficient object permissions issues with the Batch Replication job that is running. If you're using a replication rule for your Batch Replication job, make sure that the IAM role that's used for replication has the proper permissions to access objects from either the source or destination bucket. You can also check the [Batch Replication completion report](#) to review the specific [Amazon S3 replication failure reason](#).

- Batch job ran successfully but the number of objects expected in destination bucket is not the same.

This error occurs when there's a mismatch between the objects listed in the manifest that's supplied in the Batch Replication job and the filters that you selected when you created the job. You might also receive this message when the objects in your source bucket don't match any replication rules and aren't included in the generated manifest.

Batch Operations failures occur after adding a new replication rule to an existing replication configuration

Batch Operations attempts to perform existing object replication for every rule in the source bucket's replication configuration. If there are problems with any of the existing replication rules, failures might occur.

The Batch Operations job's completion report explains the job failure reasons. For a list of common errors, see [Amazon S3 replication failure reasons](#).

Monitoring replication with metrics, event notifications, and statuses

You can monitor your live replication configurations and your S3 Batch Replication jobs through the following mechanisms:

- **S3 Replication metrics** – When you enable S3 Replication metrics, Amazon CloudWatch emits metrics that you can use to track bytes pending, operations pending, and replication latency at

the replication rule level. You can view S3 Replication metrics through the Amazon S3 console and the Amazon CloudWatch console. In the Amazon S3 console, you can view these metrics in the source bucket's **Metrics** tab. For more information about S3 Replication metrics, see [the section called "Using S3 Replication metrics"](#).

- **S3 Storage Lens metrics** – In addition to S3 Replication metrics, you can use the replication-related Data Protection metrics provided by S3 Storage Lens dashboards. For example, if you use the free metrics in S3 Storage Lens, you can see metrics such as the total number of bytes that are replicated from the source bucket or the count of replicated objects from the source bucket.

To audit your overall replication stance, you can enable advanced metrics in S3 Storage Lens. With advanced metrics in S3 Storage Lens, you can see how many replication rules you have of various types, including the count of replication rules with a replication destination that's not valid.

For more information about working with replication metrics in S3 Storage Lens, see [the section called "Viewing replication metrics in S3 Storage Lens dashboards"](#).

- **S3 Event Notifications** – S3 Event Notifications can notify you at the object level in instances when objects don't replicate to their destination AWS Region or when objects aren't replicated within certain thresholds. S3 Event Notifications provides the following replication event types: `s3:Replication:OperationFailedReplication`, `s3:Replication:OperationMissedThreshold`, `s3:Replication:OperationReplicatedAfterThreshold`, and `s3:Replication:OperationNotTracked`.

Amazon S3 events are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [the section called "Receiving replication failure events"](#).

- **Replication status values** – You can also retrieve the replication status of your objects. The replication status can help you determine the current state of an object that's being replicated. The replication status of a source object will return either PENDING, COMPLETED, or FAILED. The replication status of a replica will return REPLICA.

You can also use replication status values when you're creating S3 Batch Replication jobs. For example, you can use these status values to replicate objects that have either never been replicated or that have failed replication.

For more information about retrieving the replication status of your objects, see [the section called “Getting replication status”](#). For more information about using these values with Batch Replication, see [the section called “Filters for a Batch Replication job”](#).

Topics

- [Viewing replication metrics in S3 Storage Lens dashboards](#)
- [Receiving replication failure events with Amazon S3 Event Notifications](#)
- [Getting replication status information](#)

Using S3 Replication metrics

S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

Note

- S3 Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics. For more information, see [Amazon CloudWatch pricing](#).
- If you're using S3 Replication Time Control, Amazon CloudWatch begins reporting replication metrics 15 minutes after you enable S3 RTC on the respective replication rule.

S3 Replication metrics are turned on automatically when you enable S3 Replication Time Control (S3 RTC). You can also enable S3 Replication metrics independently of S3 RTC while [creating or editing a rule](#). S3 RTC includes other features, such as a service level agreement (SLA) and notifications for missed thresholds. For more information, see [Meeting compliance requirements with S3 Replication Time Control](#).

When S3 Replication metrics are enabled, Amazon S3 publishes the following metrics to Amazon CloudWatch. CloudWatch metrics are delivered on a best-effort basis.

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Bytes Pending Replication	The total number of bytes of objects that are pending replication for a given replication rule.	This metric applies only to new objects that are replicated with S3 Cross-Region Replication (S3 CRR) or S3 Same-Region Replication (S3 SRR).	This metric is published in the Region of the destination bucket.	No	Yes
Replication Latency	The maximum number of seconds by which the replication destination bucket is behind the source bucket for a given replication rule.	This metric applies only to new objects that are replicated with S3 CRR or S3 SRR.	This metric is published in the Region of the destination bucket.	No	Yes

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Operations Pending Replication	The number of operations that are pending replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, access control lists (ACLs), and S3 Object Lock.	This metric applies only to new objects that are replicated with S3 CRR or S3 SRR.	This metric is published in the Region of the destination bucket.	No	Yes

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Operations Failed Replication	The number of operations that failed replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, access control lists (ACLs), and Object Lock.	This metric applies both to new objects that are replicated with S3 CRR or S3 SRR and also to existing objects that are replicated with S3 Batch Replication.	This metric is published in the Region of the source bucket.	Yes	No

 **Note**

If an S3 Batch Replication job fails to run at all, metrics aren't sent

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
	<p>objects that have failed replication and their failure reasons, subscribe to the Operation FailedReplication event in Amazon S3 Event Notifications. For more information, see Receiving replication failure events with Amazon S3 Event Notifications.</p>	<p>to Amazon CloudWatch. For example, your job won't run if you don't have the necessary permissions to run an S3 Batch Replication job, or if the tags or prefix in your replicati</p>			

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
		on configuration don't match.			

For information about working with these metrics in CloudWatch, see [the section called "S3 Replication metrics in CloudWatch"](#).

Enabling S3 Replication metrics

You can start using S3 Replication metrics with a new or existing replication rule. For full instructions on creating replication rules, see [Configuring replication for buckets in the same account](#). You can choose to apply your replication rule to an entire S3 bucket, or to Amazon S3 objects with a specific prefix or tag.

This topic provides instructions for enabling S3 Replication metrics in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable replication metrics by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with Metrics enabled. In this example configuration, objects under the prefix **Tax** are replicated to the destination bucket **amzn-s3-demo-bucket**, and metrics are generated for those objects.

```
{
  "Rules": [
    {
      "Status": "Enabled",
      "Filter": {
        "Prefix": "Tax"
      }
    }
  ]
}
```

```
        },
        "Destination": {
            "Bucket": "arn:aws:s3:::amzn-s3-demo-bucket",
            "Metrics": {
                "Status": "Enabled"
            }
        },
        "Priority": 1
    }
],
"Role": "IAM-Role-ARN"
}
```

Viewing replication metrics

You can view S3 Replication metrics in the source general purpose bucket's **Metrics** tab in the Amazon S3 console. These Amazon CloudWatch metrics are also available in the Amazon CloudWatch console. When you enable S3 Replication metrics, Amazon CloudWatch emits metrics that you can use to track bytes pending, operations pending, and replication latency at the replication rule level.

S3 Replication metrics are turned on automatically when you enable replication with S3 Replication Time Control (S3 RTC) by using the Amazon S3 console or the Amazon S3 REST API. You can also enable S3 Replication metrics independently of S3 RTC while [creating or editing a rule](#).

If you're using S3 Replication Time Control, Amazon CloudWatch begins reporting replication metrics 15 minutes after you enable S3 RTC on the respective replication rule. For more information, see [Using S3 Replication metrics](#).

Replication metrics track the rule IDs of the replication configuration. A replication rule ID can be specific to a prefix, a tag, or a combination of both.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

Prerequisites

Create a replication rule that has S3 Replication metrics enabled. For more information, see [the section called "Enabling replication metrics"](#).

To view S3 Replication metrics through the source bucket's Metrics tab

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the source bucket that contains the objects that you want replication metrics for.
4. Choose the **Metrics** tab.
5. Under **Replication metrics**, choose the replication rules that you want to see metrics for.
6. Choose **Display charts**.

Amazon S3 displays **Replication latency**, **Bytes pending replication**, **Operations pending replication**, and **Operations failed replication** charts for the rules that you selected.

Viewing replication metrics in S3 Storage Lens dashboards

In addition to [S3 Replication metrics](#), you can use the replication-related Data Protection metrics provided by S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to protect your data](#).

S3 Storage Lens has two tiers of metrics: free metrics, and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

If you use the free metrics in S3 Storage Lens, you can see metrics such as the total number of bytes that are replicated from the source bucket or the count of replicated objects from the source bucket.

To audit your overall replication stance, you can enable advanced metrics in S3 Storage Lens. With advanced metrics in S3 Storage Lens, you can see how many replication rules you have of various types, including the count of replication rules with a replication destination that's not valid.

For a complete list of S3 Storage Lens metrics, including which replication metrics are in each tier, see the [S3 Storage Lens metrics glossary](#).

Prerequisites

Create a [live replication configuration](#) or an [S3 Batch Replication job](#).

To view replication metrics in Amazon S3 Storage Lens

1. Create an S3 Storage Lens dashboard. For step-by-step instructions, see [the section called “Using the S3 console”](#).
2. (Optional) During your dashboard setup, if you want to see all S3 Storage Lens replication metrics, select **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For a complete list of metrics, see the [S3 Storage Lens metrics glossary](#).

If you enable advanced metrics and recommendations, you can gain further insights into your replication configurations. For example, you can use S3 Storage Lens replication rule count metrics to get detailed information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions. For more information, see [the section called “Count the total number of replication rules for each bucket”](#).

3. After you've created your dashboard, open the dashboard, and choose the **Buckets** tab.
4. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
5. To filter the **Buckets** list to display only replication metrics, choose the preferences icon ).
6. Clear the toggles for all data-protection metrics until only the replication metrics remain selected.
7. (Optional) Under **Page size**, choose the number of buckets to display in the list.
8. Choose **Continue**.

Receiving replication failure events with Amazon S3 Event Notifications

If you've enabled S3 Replication metrics on your replication configuration, you can set up Amazon S3 Event Notifications to notify you when objects don't replicate to their destination AWS Region. If you've enabled S3 Replication Time Control (S3 RTC) on your replication configuration, you can also be notified when objects don't replicate within the 15-minute S3 RTC threshold for replication.

By using the following Replication event types, you can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For more information about S3 Replication metrics, see [Using S3 Replication metrics](#).

- The `s3:Replication:OperationFailedReplication` event type notifies you when an object that was eligible for replication failed to replicate.
- The `s3:Replication:OperationMissedThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC exceeds the 15-minute threshold for replication.
- The `s3:Replication:OperationReplicatedAfterThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC replicates after the 15-minute threshold.
- The `s3:Replication:OperationNotTracked` event type notifies you when an object that was eligible for live replication (either Same-Region Replication [SRR] or Cross-Region Replication [CRR]) is no longer being tracked by replication metrics.

For full descriptions of all the supported replication event types, see [the section called “Supported event types for SQS, SNS, and Lambda”](#).

For a list of the failure codes captured by S3 Event Notifications, see [Amazon S3 replication failure reasons](#).

You can receive S3 Event Notifications through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [the section called “Amazon S3 Event Notifications”](#).

For instructions on how to configure Amazon S3 Event Notifications, see [Enabling event notifications](#).

 **Note**

In addition to enabling event notifications, make sure that you also enable S3 Replication metrics. For more information, see [the section called “Enabling replication metrics”](#).

The following is an example of a message that Amazon S3 sends to publish an `s3:Replication:OperationFailedReplication` event. For more information, see [the section called “Event message structure”](#).

```
{  
  "Records": [  
    {
```

```
"eventVersion": "2.2",

}
}]
```

}

Amazon S3 replication failure reasons

The following table lists Amazon S3 Replication failure reasons. You can view these reasons by receiving the `s3:Replication:OperationFailedReplication` event with Amazon S3 Event Notifications and then looking at the `failureReason` value.

You can also view these failure reasons in an S3 Batch Replication completion report. For more information, see [Batch Replication completion report](#).

Replication failure reason	Description
AssumeRoleNotPermitted	Amazon S3 can't assume the AWS Identity and Access Management (IAM) role that's specified in the replication configuration or in the Batch Operations job.
DstBucketInvalidRegion	The destination bucket is not in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.
DstBucketNotFound	Amazon S3 is unable to find the destination bucket that's specified in the replication configuration.
DstBucketObjectLockConfigMissing	To replicate objects from a source bucket with Object Lock enabled, the destination bucket must also have Object Lock enabled. This error indicates that Object Lock might not be enabled in the destination bucket. For more information, see Object Lock considerations .
DstBucketUnversioned	Versioning is not enabled for the S3 destination bucket. To replicate objects with S3 Replication, enable versioning for the destination bucket.

Replication failure reason	Description
DstDelObjNotPermitted	Amazon S3 is unable to replicate delete markers to the destination bucket. The <code>s3:ReplicateDelete</code> permission might be missing for the destination bucket.
DstKmsKeyInvalidState	The AWS Key Management Service (AWS KMS) key for the destination bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i> .
DstKmsKeyNotFound	The AWS KMS key that's configured for the destination bucket in the replication configuration doesn't exist.
DstMultipartCompleteNotPermitted	Amazon S3 is unable to complete multipart uploads of objects in the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartInitNotPermitted	Amazon S3 is unable to initiate multipart uploads of objects to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartUploadNotPermitted	Amazon S3 is unable to upload multipart upload objects to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstObjectHardDeleted	S3 Batch Replication does not support re-replicating objects deleted with the version ID of the object from the destination bucket. This error is specific to Batch Replication.

Replication failure reason	Description
DstPutAclNotPermitted	Amazon S3 is unable to replicate object access control lists (ACLs) to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstPutLegalHoldNotPermitted	Amazon S3 is unable to put an Object Lock legal hold on the destination objects when it's replicating immutable objects. The <code>s3:PutObjectLegalHold</code> permission might be missing for the destination bucket. For more information, see Legal holds .
DstPutObjectNotPermitted	Amazon S3 is unable to replicate objects to the destination bucket. This can occur when required permissions (<code>s3:ReplicateObject</code> or <code>s3:ObjectOwnerOverrideToBucketOwner</code> permissions) are missing for the destination bucket or when the AWS KMS key policy doesn't allow the source bucket's replication role to use the AWS KMS key (<code>kms:Decrypt</code> and <code>kms:GenerateDataKey*</code> actions) at the destination bucket.
DstPutRetentionNotPermitted	Amazon S3 is unable to put a retention period on the destination objects when it's replicating immutable objects. The <code>s3:PutObjectRetention</code> permission might be missing for the destination bucket.
DstPutTaggingNotPermitted	Amazon S3 is unable to replicate object tags to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.

Replication failure reason	Description
DstVersionNotFound	Amazon S3 is unable to find the required object version in the destination bucket for which metadata needs to be replicated.
InitiateReplicationNotPermitted	Amazon S3 is unable to initiate replication on objects. The s3:InitiateReplication permission might be missing for the Batch Operations job. This error is specific to Batch Replication.
SrcBucketInvalidRegion	The source bucket isn't in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.
SrcBucketNotFound	Amazon S3 is unable to find the source bucket.
SrcBucketReplicationConfigMissing	Amazon S3 couldn't find a replication configuration for the source bucket.

Replication failure reason	Description
SrcGetAclNotPermitted	<p>Amazon S3 is unable to access the object in the source bucket for replication. The <code>s3:GetObjectVersionAcl</code> permission might be missing for the source bucket object.</p> <p>The objects in the source bucket must be owned by the bucket owner. If ACLs are enabled, then verify if Object Ownership is set to Bucket owner preferred or Object writer. If Object Ownership is set to Bucket owner preferred, then the source bucket objects must have the <code>bucket-owner-full-control</code> ACL for the bucket owner to become the object owner. The source account can take ownership of all objects in their bucket by setting Object Ownership to Bucket owner enforced and disabling ACLs.</p>
SrcGetLegalHoldNotPermitted	Amazon S3 is unable to access the S3 Object Lock legal hold information.
SrcGetObjectNotPermitted	Amazon S3 is unable to access the object in the source bucket for replication. The <code>s3:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcGetRetentionNotPermitted	Amazon S3 is unable to access the S3 Object Lock retention period information.
SrcGetTaggingNotPermitted	Amazon S3 is unable to access object tag information from the source bucket. The <code>s3:GetObjectVersionTagging</code> permission might be missing for the source bucket.

Replication failure reason	Description
SrcHeadObjectNotPermitted	Amazon S3 is unable to retrieve object metadata from the source bucket. The <code>s3:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcKeyNotFound	Amazon S3 is unable to find the source object key to replicate. Source object may have been deleted before replication was complete.
SrcKmsKeyInvalidState	The AWS KMS key for the source bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i> .
SrcObjectNotEligible	Some objects aren't eligible for replication. This may be due to the object's storage class or the object tags don't match the replication configuration.
SrcObjectNotFound	Source object does not exist.
SrcReplicationNotPending	Amazon S3 has already replicated this object. This object is no longer pending replication.
SrcVersionNotFound	Amazon S3 is unable to find the source object version to replicate. Source object version may have been deleted before replication was complete.

Getting replication status information

Replication status can help you determine the current state of an object being replicated. The replication status of a source object will return either PENDING, COMPLETED, or FAILED. The replication status of a replica will return REPLICA.

You can also use replication status values when you're creating S3 Batch Replication jobs. For example, you can use these status values to replicate objects that have either never been replicated or that have failed replication. For more information about using these values with Batch Replication, see [the section called "Using replication status information with Batch Replication jobs".](#)

Topics

- [Replication status overview](#)
- [Replication status if replicating to multiple destination buckets](#)
- [Replication status if Amazon S3 replica modification sync is enabled](#)
- [Using replication status information with Batch Replication jobs](#)
- [Finding replication status](#)

Replication status overview

In replication, you have a source bucket on which you configure replication and one or more destination buckets where Amazon S3 replicates objects. When you request an object (by using `GetObject`) or object metadata (by using `HeadObject`) from these buckets, Amazon S3 returns the `x-amz-replication-status` header in the response:

- When you request an object from the source bucket, Amazon S3 returns the `x-amz-replication-status` header if the object in your request is eligible for replication.

For example, suppose that you specify the object prefix `TaxDocs` in your replication configuration to tell Amazon S3 to replicate only objects with the key name prefix `TaxDocs`.

Any objects that you upload that have this key name prefix—for example, TaxDocs/document1.pdf—will be replicated. For object requests with this key name prefix, Amazon S3 returns the x-amz-replication-status header with one of the following values for the object's replication status: PENDING, COMPLETED, or FAILED.

 **Note**

If object replication fails after you upload an object, you can't retry replication. You must upload the object again, or you must use S3 Batch Replication to replicate any failed objects. For more information about using Batch Replication, see [the section called "Replicating existing objects".](#)

Objects transition to a FAILED state for issues such as missing replication role permissions, AWS Key Management Service (AWS KMS) permissions, or bucket permissions. For temporary failures, such as if a bucket or Region is unavailable, replication status doesn't transition to FAILED, but remains PENDING. After the resource is back online, Amazon S3 resumes replicating those objects.

- When you request an object from a destination bucket, if the object in your request is a replica that Amazon S3 created, Amazon S3 returns the x-amz-replication-status header with the value REPLICA.

 **Note**

Before deleting an object from a source bucket that has replication enabled, check the object's replication status to make sure that the object has been replicated.

If an S3 Lifecycle configuration is enabled on the source bucket, Amazon S3 suspends lifecycle actions until it marks the objects' status as either COMPLETED or FAILED.

Replication status if replicating to multiple destination buckets

When you replicate objects to multiple destination buckets, the x-amz-replication-status header acts differently. The header of the source object returns a value of COMPLETED only when replication is successful to all destinations. The header remains at the PENDING value until replication has completed for all destinations. If one or more destinations fail replication, the header returns FAILED.

Replication status if Amazon S3 replica modification sync is enabled

When your replication rules enable Amazon S3 replica modification sync, replicas can report statuses other than REPLICA. If metadata changes are in the process of replicating, the x-amz-replication-status header returns PENDING. If replica modification sync fails to replicate metadata, the header returns FAILED. If metadata is replicated correctly, the replicas return the header REPLICA.

Using replication status information with Batch Replication jobs

When creating a Batch Replication job, you can optionally specify additional filters, such as the object creation date and replication status, to reduce the scope of the job.

You can filter objects to replicate based on the ObjectReplicationStatuses value, by providing one or more of the following values:

- "NONE" – Indicates that Amazon S3 has never attempted to replicate the object before.
- "FAILED" – Indicates that Amazon S3 has attempted, but failed, to replicate the object before.
- "COMPLETED" – Indicates that Amazon S3 has successfully replicated the object before.
- "REPLICA" – Indicates that this is a replica object that Amazon S3 has replicated from another source.

For more information about using these replication status values with Batch Replication, see [the section called "Filters for a Batch Replication job".](#)

Finding replication status

To get the replication status of the objects in a bucket, you can use the Amazon S3 Inventory tool. Amazon S3 sends a CSV file to the destination bucket that you specify in the inventory configuration. You can also use Amazon Athena to query the replication status in the inventory report. For more information about Amazon S3 Inventory, see [Cataloging and analyzing your data with S3 Inventory](#).

You can also find the object replication status by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the AWS SDK.

Using the S3 console

In the Amazon S3 console, you can view the replication status for an object on the object's details page.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **General purpose buckets** list, choose the name of the replication source bucket.
4. In the **Objects** list, choose the object name. The object's details page appears.
5. On the **Properties** tab, scroll down to the **Object management overview** section. Under **Management configurations**, see the value under **Replication status**.

Using the AWS CLI

Use the AWS Command Line Interface (AWS CLI) head-object command to retrieve object metadata, as shown in the following example. Replace the *amzn-s3-demo-source-bucket1* with the name of your replication source bucket, and replace the other *user input placeholders* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-source-bucket1 --key object-key --version-id object-version-id
```

The command returns object metadata, including the **ReplicationStatus** as shown in the following example response.

```
{  
    "AcceptRanges": "bytes",  
    "ContentType": "image/jpeg",  
    "LastModified": "Mon, 23 Mar 2015 21:02:29 GMT",  
    "ContentLength": 3191,  
    "ReplicationStatus": "COMPLETED",  
    "VersionId": "jfnW.HIM0fYiD_9rGbSkmroXsFj3fqZ.",  
    "ETag": "\"6805f2cfc46c0f04559748bb039d69ae\"",  
    "Metadata": {}  
}
```

Using the AWS SDKs

The following code fragments get your replication status by using the AWS SDK for Java and AWS SDK for .NET, respectively.

Java

```
GetObjectMetadataRequest metadataRequest = new GetObjectMetadataRequest(bucketName,  
    key);  
ObjectMetadata metadata = s3Client.getObjectMetadata(metadataRequest);  
  
System.out.println("Replication Status : " +  
    metadata.getRawMetadataValue(Headers.OBJECT_REPLICATION_STATUS));
```

.NET

```
GetObjectMetadataRequest getmetadataRequest = new GetObjectMetadataRequest  
{  
    BucketName = sourceBucket,  
    Key        = objectKey  
};  
  
GetObjectMetadataResponse getmetadataResponse =  
    client.GetObjectMetadata(getmetadataRequest);  
Console.WriteLine("Object replication status: {0}",  
    getmetadataResponse.ReplicationStatus);
```

Managing multi-Region traffic with Multi-Region Access Points

Amazon S3 Multi-Region Access Points provides a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, Multi-Region Access Points provides built-in network resilience with acceleration of internet-based requests to Amazon S3. Application requests made to a Multi-Region Access Point global endpoint uses [AWS Global Accelerator](#) to automatically route over the AWS global network to the closest proximity S3 bucket with an active routing status.

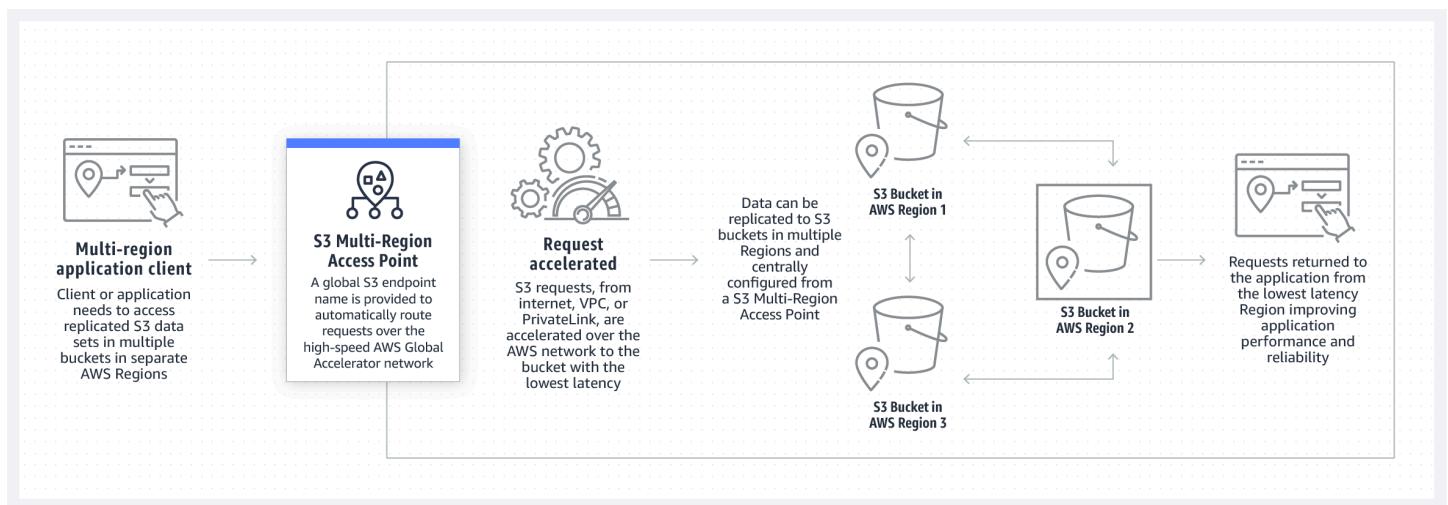

If a Regional traffic disruption occurs, you can use Multi-Region Access Points failover controls to shift the S3 data request traffic between AWS Regions and redirect S3 traffic away from the disruptions within minutes. You can also test the application resiliency against a disruption to conduct application failover and perform disaster recovery simulations. If you need to connect and accelerate requests to S3 from outside of a VPC, you can simplify applications and network architecture with Amazon S3 Multi-Region Access Points. Your Multi-Region Access Points requests

will be routed over the AWS global network and then back to S3 within the AWS Region, without having to traverse the public internet. As a result, you can build more highly available applications.

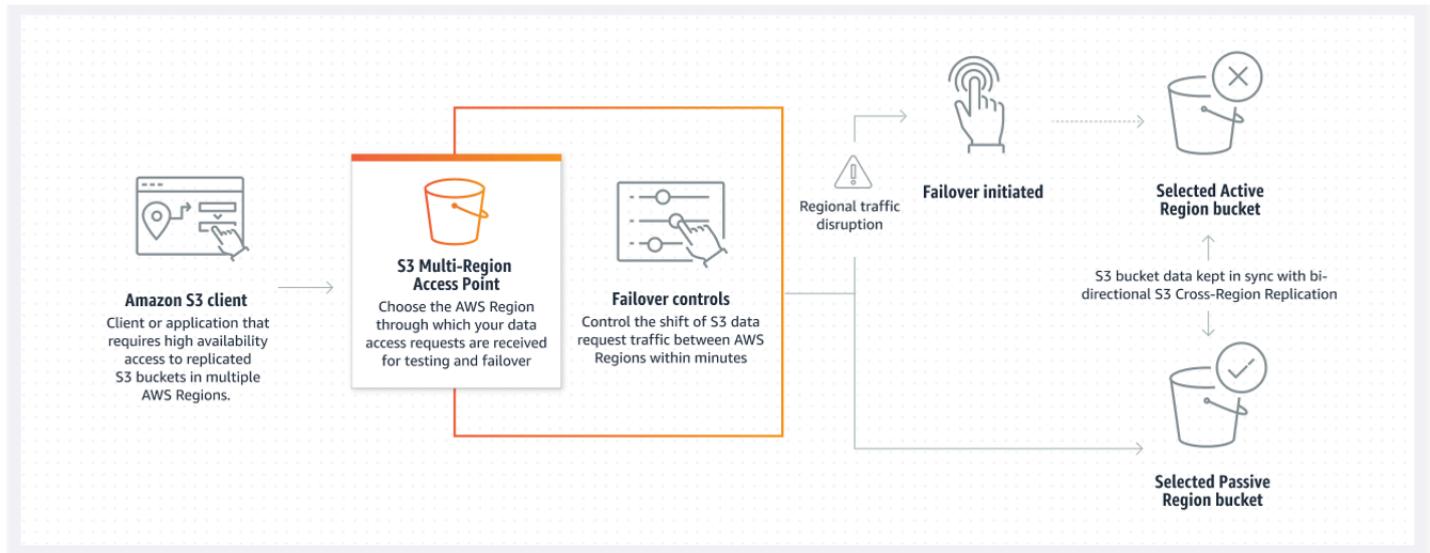

During your Multi-Region Access Points creation and setup, you'll specify a set of AWS Regions where you want to store data to be served through that Multi-Region Access Point. You can use the provided Multi-Region Access Points endpoint name to connect your clients. After you've established your client connections, you can select the existing or new buckets that you'd like to route the Multi-Region Access Points requests between. Then, use [S3 Cross-Region Replication \(CRR\)](#) rules to synchronize data among buckets in those Regions.

After you've set up your Multi-Region Access Point, you can then request or write data through the Multi-Region Access Points global endpoint. Amazon S3 automatically serves requests to the replicated data set from the closest available Region. Within the AWS Management Console, you're also able to view the underlying replication topology and replication metrics related to your Multi-Region Access Points requests. This gives you an even easier way to build, manage, and monitor storage for multi-Region applications. Alternatively, you can use Amazon CloudFront to automate the creation and configuration of S3 Multi-Region Access Points.

The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-active configuration. The graphic shows how Amazon S3 requests are automatically routed to buckets in the closest active AWS Region.

The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-passive configuration. The graphic shows how you can control Amazon S3 data-access traffic to fail over between active and passive AWS Regions.

Topics

- [Creating Multi-Region Access Points](#)
- [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#)
- [Making requests through a Multi-Region Access Point](#)

Creating Multi-Region Access Points

To create a Multi-Region Access Point in Amazon S3, you do the following:

- Specify the name for the Multi-Region Access Point.
- Choose one bucket in each AWS Region that you want to serve requests for the Multi-Region Access Point.
- Configure the Amazon S3 Block Public Access settings for the Multi-Region Access Point.

You provide all of this information in a create request, which Amazon S3 processes asynchronously. Amazon S3 provides a token that you can use to monitor the status of the asynchronous creation request.

Make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide actionable recommendations to help you author policies that

are functional and conform to security best practices. To learn more about validating policies using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

When you use the API, the request to create a Multi-Region Access Point is asynchronous. When you submit a request to create a Multi-Region Access Point, Amazon S3 synchronously authorizes the request. It then immediately returns a token that you can use to track the progress of the creation request. For more information about tracking asynchronous requests to create and manage Multi-Region Access Points, see [Using Multi-Region Access Points with supported API operations](#).

After you create the Multi-Region Access Point, you can create an access control policy for it. Each Multi-Region Access Point can have an associated policy. A Multi-Region Access Point policy is a resource-based policy that you can use to limit the use of the Multi-Region Access Point by resource, user, or other conditions.

Note

For an application or user to be able to access an object through a Multi-Region Access Point, both of the following policies must permit the request:

- The access policy for the Multi-Region Access Point
- The access policy for the underlying bucket that contains the object

When the two policies are different, the more restrictive policy takes precedence.

To simplify permissions management for Multi-Region Access Points, you can delegate access control from the bucket to the Multi-Region Access Point. For more information, see [the section called “Multi-Region Access Point policy examples”](#).

Using a bucket with a Multi-Region Access Point doesn't change the bucket's behavior when the bucket is accessed through the existing bucket name or an Amazon Resource Name (ARN). All existing operations against the bucket continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests that are made through the Multi-Region Access Point.

You can update the policy for a Multi-Region Access Point after creating it, but you can't delete the policy. However, you can update the Multi-Region Access Point policy to deny all permissions.

- [Deleting a Multi-Region Access Point](#)

Rules for naming Amazon S3 Multi-Region Access Points

When you create a Multi-Region Access Point, you give it a name, which is a string that you choose. You can't change the name of the Multi-Region Access Point after it is created. The name must be unique in your AWS account, and it must conform to the naming requirements listed in [Multi-Region Access Point restrictions and limitations](#). To help you identify the Multi-Region Access Point, use a name that is meaningful to you, to your organization, or that reflects the scenario.

You use this name when invoking Multi-Region Access Point management operations, such as `GetMultiRegionAccessPoint` and `PutMultiRegionAccessPointPolicy`. The name is not used to send requests to the Multi-Region Access Point, and it doesn't need to be exposed to clients who make requests by using the Multi-Region Access Point.

When Amazon S3 creates a Multi-Region Access Point, it automatically assigns an alias to it. This alias is a unique alphanumeric string that ends in `.mrap`. The alias is used to construct the hostname and the Amazon Resource Name (ARN) for a Multi-Region Access Point. The fully qualified name is also based on the alias for the Multi-Region Access Point.

You can't determine the name of a Multi-Region Access Point from its alias, so you can disclose an alias without risk of exposing the name, purpose, or owner of the Multi-Region Access Point. Amazon S3 selects the alias for each new Multi-Region Access Point, and the alias can't be changed. For more information about addressing a Multi-Region Access Point, see [Making requests through a Multi-Region Access Point](#).

Multi-Region Access Point aliases are unique throughout time and aren't based on the name or configuration of a Multi-Region Access Point. If you create a Multi-Region Access Point, and then

delete it and create another one with the same name and configuration, the second Multi-Region Access Point will have a different alias than the first. New Multi-Region Access Points can never have the same alias as a previous Multi-Region Access Point.

Rules for choosing buckets for Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point is associated with the Regions where you want to fulfill requests. The Multi-Region Access Point must be associated with exactly one bucket in each of those Regions. You specify the name of each bucket in the request to create the Multi-Region Access Point. Buckets that support the Multi-Region Access Point can either be in the same AWS account that owns the Multi-Region Access Point, or they can be in other AWS accounts.

A single bucket can be used by multiple Multi-Region Access Points.

Important

- You can specify the buckets that are associated with a Multi-Region Access Point only at the time that you create it. After it is created, you can't add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one.
- You can't delete a bucket that is part of a Multi-Region Access Point. If you want to delete a bucket that's attached to a Multi-Region Access Point, delete the Multi-Region Access Point first.
- If you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see [Multi-Region Access Point policy examples](#).
- Not all Regions support Multi-Region Access Points. To see the list of supported Regions, see [Multi-Region Access Point restrictions and limitations](#).

You can create replication rules to synchronize data between buckets. These rules enable you to automatically copy data from source buckets to destination buckets. Having buckets connected to a Multi-Region Access Point does not affect how replication works. Configuring replication with Multi-Region Access Points is described in a later section.

⚠ Important

When you make a request to a Multi-Region Access Point, the Multi-Region Access Point isn't aware of the data contents of the buckets in the Multi-Region Access Point. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, we recommend that you configure S3 Cross-Region Replication (CRR). For more information, see [Configuring replication for use with Multi-Region Access Points](#).

Create an Amazon S3 Multi-Region Access Point

The following example demonstrates how to create a Multi-Region Access Point by using the Amazon S3 console.

Using the S3 console

To create a Multi-Region Access Point

ℹ Note

Multi-Region Access Point opt-in Regions aren't currently supported in the Amazon S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose **Create Multi-Region Access Points** to begin creating your Multi-Region Access Point.
4. On the **Multi-Region Access Point** page, supply a name for the Multi-Region Access Point in the **Multi-Region Access Point name** field.
5. Select the buckets that will be associated with this Multi-Region Access Point. You can choose buckets that are in your account, or you can choose buckets from other accounts.

ℹ Note

You must add at least one bucket from either your account or other accounts. Also, be aware that Multi-Region Access Points support only one bucket per AWS Region.

Therefore, you can't add two buckets from the same Region. [AWS Regions that are disabled by default](#) are not supported.

- To add a bucket that is in your account, choose **Add buckets**. A list of all the buckets in your account displays. You can search for your bucket by name, or sort the bucket names in alphabetical order.
- To add a bucket from another account, choose **Add bucket from other accounts**. Make sure that you know the exact bucket name and AWS account ID because you can't search or browse for buckets in other accounts.

 **Note**

You must enter a valid AWS account ID and bucket name. The bucket must also be in a supported Region, or you will encounter an error when you try to create your Multi-Region Access Point. For the list of Regions that support Multi-Region Access Points, see [Multi-Region Access Points restrictions and limitations](#).

6. (Optional) If you need to remove a bucket that you added, choose **Remove**.

 **Note**

You can't add or remove buckets to this Multi-Region Access Point after you've finished creating it.

7. Under **Block Public Access settings for this Multi-Region Access Point**, select the Block Public Access settings that you want to apply to the Multi-Region Access Point. By default, all Block Public Access settings are enabled for new Multi-Region Access Points. We recommend that you leave all settings enabled unless you know that you have a specific need to disable any of them.

 **Note**

You can't change the Block Public Access settings for a Multi-Region Access Point after the Multi-Region Access Point has been created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

8. Choose **Create Multi-Region Access Point**.

⚠ Important

When you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see [Multi-Region Access Point policy examples](#).

Using the AWS CLI

You can use the AWS CLI to create a Multi-Region Access Point. When you create the Multi-Region Access Point, you must provide all the buckets that it will support. You can't add buckets to the Multi-Region Access Point after it has been created.

The following example creates a Multi-Region Access Point with two buckets by using the AWS CLI. To use this example command, replace the *user input placeholders* with your own information.

ℹ Note

To create a Multi-Region Access Point using buckets in an opt-in Region, make sure to [enable all opt-in Regions](#) first. Otherwise, you'll get a `403 InvalidRegion` error when you try to create a Multi-Region Access Point using buckets for an opt-in Region that you haven't actually opted in to.

```
aws s3control create-multi-region-access-point --account-id 111122223333 --details '{  
    "Name": "simple-multiregionaccesspoint-with-two-regions",  
    "PublicAccessBlock": {  
        "BlockPublicAcls": true,  
        "IgnorePublicAcls": true,  
        "BlockPublicPolicy": true,  
        "RestrictPublicBuckets": true  
    },  
    "Regions": [  
        { "Bucket": "amzn-s3-demo-bucket1" }]
```

```
{ "Bucket": "amzn-s3-demo-bucket2" }  
]  
}' --region us-west-2
```

Blocking public access with Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point has distinct settings for Amazon S3 Block Public Access. These settings operate in conjunction with the Block Public Access settings for the AWS account that owns the Multi-Region Access Point and the underlying buckets.

When Amazon S3 authorizes a request, it applies the most restrictive combination of these settings. If the Block Public Access settings for any of these resources (the Multi-Region Access Point owner account, the underlying bucket, or the bucket owner account) block access for the requested action or resource, Amazon S3 rejects the request.

We recommend that you enable all Block Public Access settings unless you have a specific need to disable any of them. By default, all Block Public Access settings are enabled for a Multi-Region Access Point. If Block Public Access is enabled, the Multi-Region Access Point can't accept internet-based requests.

Important

You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

For more information about Amazon S3 Block Public Access, see [Blocking public access to your Amazon S3 storage](#).

Viewing Amazon S3 Multi-Region Access Points configuration details

The following example demonstrates how to view Multi-Region Access Point configuration details by using the Amazon S3 console.

Using the S3 console

To create a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.

3. Choose the name of the Multi-Region Access Point for which you want to view the configuration details.
 - The **Properties** tab lists all of the buckets that are associated with your Multi-Region Access Point, the creation date, the Amazon Resource Name (ARN), and the alias. The AWS account ID column also lists any buckets owned by external accounts that are associated with your Multi-Region Access Point.
 - The **Permissions** tab lists the Block Public Access settings that are applied to the buckets associated with this Multi-Region Access Point. You can also view the Multi-Region Access Point policy for your Multi-Region Access Point, if you've created one. The **Info** alert on the **Permissions** page also lists all the buckets (in your account and other accounts) for this Multi-Region Access Point that have the **Public Access is blocked** setting enabled.
 - The **Replication and failover** tab provides a map view of the buckets that are associated with your Multi-Region Access Point and the Regions that the buckets reside in. If there are buckets from another account that you don't have permission to pull data from, the Region will be marked in red on the **Replication summary** map, indicating that it is an **AWS Region with errors getting replication status**.

 **Note**

To retrieve replication status information from a bucket in an external account, the bucket owner must grant you the `s3:GetBucketReplication` permission in their bucket policy.

This tab also provides the replication metrics, replication rules, and failover statuses for the Regions that are used with your Multi-Region Access Point.

Using the AWS CLI

You can use the AWS CLI to view the configuration details for a Multi-Region Access Point.

The following AWS CLI example gets your current Multi-Region Access Point configuration. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point --account-id 111122223333 --name amzn-s3-demo-bucket
```

Deleting a Multi-Region Access Point

The following procedure explains how to delete a Multi-Region Access Point by using the Amazon S3 console. Be aware that deleting a Multi-Region Access Point doesn't delete the buckets associated with the Multi-Region Access Point. Instead, it only deletes the Multi-Region Access Point itself.

Note

S3 Multi-Region Access Points using buckets in AWS opt-in Regions is currently only supported through AWS SDKs and the AWS CLI. To delete a Multi-Region Access Point using buckets in an opt-in Region, make sure to specify which AWS opt-in Regions your account can use first. Otherwise, if you try to delete a Multi-Region Access Point that uses buckets in disabled AWS opt-in Regions, you'll receive an error.

Using the S3 console

To delete a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Select the option button next to the name of your Multi-Region Access Point.
4. Choose **Delete**.
5. In the **Delete Multi-Region Access Point** dialog box, enter the name of the AWS bucket that you want to delete.

Note

Make sure to enter a valid bucket name. Otherwise, the **Delete** button will be disabled.

6. Choose **Delete** to confirm deletion of your Multi-Region Access Point.

Using the AWS CLI

You can use the AWS CLI to delete a Multi-Region Access Point. This action does not delete the buckets associated with the Multi-Region Access Point, only the Multi-Region Access Point itself. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-multi-region-access-point --account-id 123456789012 --details  
Name=example-multi-region-access-point-name
```

Configuring a Multi-Region Access Point for use with AWS PrivateLink

You can use Multi-Region Access Points to route Amazon S3 request traffic between AWS Regions. Each Multi-Region Access Point global endpoint routes Amazon S3 data request traffic from multiple sources without your having to build complex networking configurations with separate endpoints. These data-request traffic sources include:

- Traffic originating in a virtual private cloud (VPC)
- Traffic from on-premises data centers traveling over AWS PrivateLink
- Traffic from the public internet

If you establish an AWS PrivateLink connection to an S3 Multi-Region Access Point, you can route S3 requests into AWS, or across multiple AWS Regions, over a private connection by using a simple network architecture and configuration. When you use AWS PrivateLink, you don't need to configure a VPC peering connection.

Topics

- [Configuring Multi-Region Access Point opt-in Regions](#)
- [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#)
- [Removing access to a Multi-Region Access Point from a VPC endpoint](#)

Configuring Multi-Region Access Point opt-in Regions

An AWS opt-in Region is a Region that isn't enabled by default in your AWS account. In contrast, Regions that are enabled by default are known as AWS Regions or commercial Regions.

To start using Multi-Region Access Points in AWS opt-in Regions, you must manually enable the opt-in Region for your AWS account before creating your Multi-Region Access Point. After you

enable the opt-in Region, you can create Multi-Region Access Points with buckets in the selected opt-in Region. For instructions on how to enable or disable an opt-in Region for your AWS account or AWS Organization, see [Enable or disable a Region for standalone accounts](#) or [Enable or disable a Region in your organization](#).

 **Note**

Multi-Region Access Point opt-in Regions are currently only supported through AWS SDKs and AWS CLI.

S3 Multi-Region Access Points supports the following AWS opt-in Regions:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Asia Pacific (Hyderabad)
- Canada West (Calgary)
- Europe (Zurich)
- Europe (Milan)
- Europe (Spain)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- Middle East (UAE)

 **Note**

There are no additional costs for enabling an opt-in Region. However, creating or using a resource in a Multi-Region Access Point results in billing charges.

Using a Multi-Region Access Point in an AWS opt-in Region

To perform a [data plane operation](#) on your Multi-Region Access Point, all associated AWS accounts must enable the opt-in Regions that are part of the Multi-Region Access Point. This requirement applies to the requester account, the Multi-Region Access Point owner, S3 bucket owners, and the VPC endpoint owner. If any of these accounts don't enable AWS opt-in Regions, the Multi-Region Access Point requests fail. For more information about the `InvalidToken` or `AllAccessDisabled` errors, see [List of error codes](#).

Note

[Control plane operations](#) such as updating your Multi-Region Access Point policy or updating your failover configuration aren't impacted by the opt-in Region status of any Region that is part of your Multi-Region Access Point. You also don't need to disable any active opt-in Regions before deleting a Multi-Region Access Point.

Disabling an active AWS opt-in Region

If you disable opt-in Region that is part of your Multi-Region Access Point, requests routed to this Region result in a `403 AllAccessDisabled` error. To safely disable an opt-in Region, we recommend that you first identify an alternate Region in your Multi-Region Access Point configuration to route the traffic to. You can then use Multi-Region Access Point failover controls to mark the alternate Region as active, and mark the Region to be disabled as passive. After changing the failover controls, you can disable the Region you want to opt out of.

Enabling a previously disabled AWS opt-in Region

To enable an opt-in AWS Region that was previously disabled for your Multi-Region Access Point, make sure to update your AWS account settings. After you re-enable the opt-in Region, run the [PutMultiRegionAccessPointPolicy](#) API operation to apply the Multi-Region Access Points policy to the opt-in Region.

If your Multi-Region Access Point is accessed through a VPC endpoint, we recommend that you update your VPCE policy and use the [ModifyVpcEndpoint](#) API operation to apply the updated VPC endpoint policy to the re-enabled opt-in Region.

Multi-Region Access Points policy and multiple AWS accounts

If your Multi-Region Access Points policy grants access to multiple AWS accounts, all requester accounts must also enable the same opt-in Regions in their account settings. If the requester account submits a Multi-Region Access Point request without enabling the opt-in Regions that are part of the Multi-Region Access Point, it'll result in a `400 InvalidToken` error.

AWS opt-in Region considerations

When you access a Multi-Region Access Point from an opt-in Region, be aware of the following:

- When you enable an opt-in Region, it allows you to create a Multi-Region Access Point using the buckets from the opt-in Region. When you disable an opt-in Region, the Multi-Region Access Point is no longer supported in the opt-in Region. If you no longer want an opt-in Region enabled for your Multi-Region Access Point, make sure to [disable the Region for your account](#) first. Then, create a new Multi-Region Access Point with your preferred list of opt-in Regions.
- If you attempt to create your Multi-Region Access Point with a disabled opt-in Region, you'll receive a `403 InvalidRegion` error. After you enable the opt-in Region, try creating the Multi-Region Access Point again.
- The maximum number of supported Regions for a Multi-Region Access Point is 17 Regions. This includes both opt-in Regions and commercial Regions. For more information, see [Multi-Region Access Points restrictions and limitations](#).
- Control plane requests for Multi-Region Access Points will work, even if you haven't opted in to any Regions.
- When you're trying to create a Multi-Region Access Point for the first time, you must opt into all Regions that are part of the Multi-Region Access Point.
- Any AWS accounts that are granted access to an S3 Multi-Region Access Point through the Multi-Region Access Point policy must also enable the same opt-in Regions that are part of the Multi-Region Access Point.

Configuring a Multi-Region Access Point for use with AWS PrivateLink

AWS PrivateLink provides you with private connectivity to Amazon S3 using private IP addresses in your virtual private cloud (VPC). You can provision one or more interface endpoints inside your VPC to connect to Amazon S3 Multi-Region Access Points.

You can create `com.amazonaws.s3-global.accesspoint` endpoints for Multi-Region Access Points through the AWS Management Console, AWS CLI, or AWS SDKs. To learn more about how to

configure an interface endpoint for Multi-Region Access Point, see [Interface VPC endpoints](#) in the *VPC User Guide*.

To make requests to a Multi-Region Access Point via interface endpoints, follow these steps to configure the VPC and the Multi-Region Access Point.

To configure a Multi-Region Access Point to use with AWS PrivateLink

1. Create or have an appropriate VPC endpoint that can connect to Multi-Region Access Points. For more information about creating VPC endpoints, see [Interface VPC endpoints](#) in the *VPC User Guide*.

 **Important**

Make sure to create a **com.amazonaws.s3-global.accesspoint** endpoint. Other endpoint types cannot access Multi-Region Access Points.

After this VPC endpoint is created, all Multi-Region Access Point requests in the VPC route through this endpoint if you have private DNS enabled for the endpoint. This is enabled by default.

2. If the Multi-Region Access Point policy does not support connections from VPC endpoints, you will need to update it.
3. Verify that the individual bucket policies will allow access to the users of the Multi-Region Access Point.

Remember that Multi-Region Access Points work by routing requests to buckets, not by fulfilling requests themselves. This is important to remember because the originator of the request must have permissions to the Multi-Region Access Point and be allowed to access the individual buckets in the Multi-Region Access Point. Otherwise, the request might be routed to a bucket where the originator doesn't have permissions to fulfill the request. A Multi-Region Access Point and the buckets associated can be owned by the same or another AWS account. However, VPCs from different accounts can use a Multi-Region Access Point if the permissions are configured correctly.

Because of this, the VPC endpoint policy must allow access both to the Multi-Region Access Point and to each underlying bucket that you want to be able to fulfill requests. For example, suppose that you have a Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`. It is backed by buckets `amzn-s3-demo-bucket1` and `amzn-s3-demo-bucket2`, all owned by AWS account

123456789012. In this case, the following VPC endpoint policy would allow GetObject requests from the VPC made to `mfzwi23gnjvgw.mrap` to be fulfilled by either backing bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Read-buckets-and-MRAP-VPCE-policy",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
                "arn:aws:s3:::amzn-s3-demo-bucket2/*",  
                "arn:aws:s3:::111122223333:accesspoint/mfzwi23gnjvgw.mrap/object/*"  
            ]  
        }  
    ]  
}
```

As mentioned previously, you also must make sure that the Multi-Region Access Point policy is configured to support access through a VPC endpoint. You don't need to specify the VPC endpoint that is requesting access. The following sample policy would grant access to any requester trying to use the Multi-Region Access Point for the GetObject requests.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Open-read-MRAP-policy",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": "  
                arn:aws:s3:::111122223333:accesspoint/mfzwi23gnjvgw.mrap/object/*"  
        }  
    ]  
}
```

```
        "Resource": "arn:aws:s3:::111122223333:accesspoint/mfzwi23gnjvgw.mrap/  
object/*"  
    }]  
}
```

And of course, the individual buckets would each need a policy to support access from requests submitted through VPC endpoint. The following example policy grants read access to any anonymous users, which would include requests made through the VPC endpoint.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Public-read",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": "s3:GetObject",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket1",  
                "arn:aws:s3:::amzn-s3-demo-bucket2/*"]  
        }]  
}
```

For more information about editing a VPC endpoint policy, see [Control access to services with VPC endpoints](#) in the *VPC User Guide*.

Removing access to a Multi-Region Access Point from a VPC endpoint

If you own a Multi-Region Access Point and want to remove access to it from an interface endpoint, you must supply a new access policy for the Multi-Region Access Point that prevents access for requests coming through VPC endpoints. However, if the buckets in your Multi-Region Access Point support requests through VPC endpoints, they will continue to support these requests. If you want to prevent that support, you must also update the policies for the buckets. Supplying a new access policy to the Multi-Region Access Point prevents access only to the Multi-Region Access Point, not to the underlying buckets.

Note

You can't delete an access policy for a Multi-Region Access Point. To remove access to a Multi-Region Access Point, you must provide a new access policy with the modified access that you want.

Instead of updating the access policy for the Multi-Region Access Point, you can update the bucket policies to prevent requests through VPC endpoints. In this case, users can still access the Multi-Region Access Point through the VPC endpoint. However, if the Multi-Region Access Point request is routed to a bucket where the bucket policy prevents access, the request will generate an error message.

Making requests through a Multi-Region Access Point

Like other resources, Amazon S3 Multi-Region Access Points have Amazon Resource Names (ARNs). You can use these ARNs to direct requests to Multi-Region Access Points by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 API. You can also use these ARNs to identify Multi-Region Access Points in access control policies. A Multi-Region Access Point ARN doesn't include or disclose the name of the Multi-Region Access Point. For more information about ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

Note

The Multi-Region Access Point alias and ARN cannot be used interchangeably.

Multi-Region Access Point ARNs use the following format:

`arn:aws:s3:::account-id:accesspoint/MultiRegionAccessPoint_alias`

The following are a few examples of Multi-Region Access Point ARNs:

- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap` represents the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, which is owned by AWS account 123456789012.
- `arn:aws:s3:::123456789012:accesspoint/*` represents all Multi-Region Access Points under the account 123456789012. This ARN matches all Multi-Region Access Points for account 123456789012, but doesn't match any Regional Amazon S3 Access Points

because the ARN doesn't include an AWS Region. In contrast, the ARN `arn:aws:s3:us-west-2:123456789012:accesspoint/*` matches all Regional Amazon S3 Access Points in the Region us-west-2 for the account 123456789012, but doesn't match any Multi-Region Access Points.

ARNs for objects that are accessed through a Multi-Region Access Point use the following format:

`arn:aws:s3:::account_id:accesspoint/MultiRegionAccessPoint_alias//key`

As with Multi-Region Access Point ARNs, the ARNs for objects that are accessed through Multi-Region Access Points don't include an AWS Region. Here are some examples.

- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01` represents the -01, which is accessed through the Multi-Region Access Point with the alias mfzwi23gnjvgw.mrap, which is owned by account 123456789012.
- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap//*` represents all objects that can be accessed through the Multi-Region Access Point with the alias mfzwi23gnjvgw.mrap, in account 123456789012.
- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01/finance/*` represents all objects that can be accessed under the -01/finance/ for the Multi-Region Access Point with the alias mfzwi23gnjvgw.mrap, in account 123456789012.

Multi-Region Access Point hostnames

You can access data in Amazon S3 through a Multi-Region Access Point by using the hostname of the Multi-Region Access Point. Requests can be directed to this hostname from the public internet. If you have configured one or more internet gateways for the Multi-Region Access Point, requests can also be directed to this hostname from a virtual private cloud (VPC). For more information about creating VPC interface endpoints to use with Multi-Region Access Points, see [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#).

To make requests through a Multi-Region Access Point from a VPC by using a VPC endpoint, you can use AWS PrivateLink. When you're making requests to a Multi-Region Access Point by using AWS PrivateLink, you cannot directly use an endpoint-specific Regional DOMAIN NAME SYSTEM (DNS) name that ends with `region.vpce.amazonaws.com`. This hostname will not have a certificate associated with it, so it cannot be used directly. You can still use the public DOMAIN NAME SYSTEM (DNS) name of the VPC endpoint as a CNAME or ALIAS target. Alternatively, you can

enable private DOMAIN NAME SYSTEM (DNS) on the endpoint and use the standard Multi-Region Access Point *MultiRegionAccessPoint_alias.accesspoint.s3-global.amazonaws.com* DOMAIN NAME SYSTEM (DNS) name, as described in this section.

When you make requests to the API for Amazon S3 data operations (for example, `GetObject`) through a Multi-Region Access Point, the hostname for the request is as follows:

MultiRegionAccessPoint_alias.accesspoint.s3-global.amazonaws.com

For example, to make a `GetObject` request through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, make a request to the hostname `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. The `s3-global` portion of the hostname indicates that this hostname is not for a specific Region.

Making requests through a Multi-Region Access Point is similar to making requests through a single-Region access point. However, it's important to be aware of the following differences:

- Multi-Region Access Point ARNs don't include an AWS Region. They follow the format `arn:aws:s3:::account-id:accesspoint/MultiRegionAccessPoint_alias`.
- For requests made through API operations (these requests don't require the use of an ARN), Multi-Region Access Points use a different endpoint scheme. The scheme is *MultiRegionAccessPoint_alias.accesspoint.s3-global.amazonaws.com*—for example, `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. Note the differences compared to a single-Region access point:
 - Multi-Region Access Point hostnames use their alias, not the Multi-Region Access Point name.
 - Multi-Region Access Point hostnames don't include the owner's AWS account ID.
 - Multi-Region Access Point hostnames don't include an AWS Region.
 - Multi-Region Access Point hostnames include `s3-global.amazonaws.com` instead of `s3.amazonaws.com`.
- Multi-Region Access Point requests must be signed by using Signature Version 4A (SigV4A). When you use the AWS SDKs, the SDK automatically converts a SigV4 to SigV4A. Therefore, make sure that your [AWS SDK supports](#) SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about SigV4A, see [Signing AWS API requests](#) in the [AWS General Reference](#).

Multi-Region Access Points and Amazon S3 Transfer Acceleration

Amazon S3 Transfer Acceleration is a feature that enables fast transfer of data to buckets. Transfer Acceleration is configured on the individual bucket level. For more information about Transfer Acceleration, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

Multi-Region Access Points use a similar accelerated transfer mechanism as Transfer Acceleration for sending large objects over the AWS network. Because of this, you don't need to use Transfer Acceleration when sending requests through a Multi-Region Access Point. This increased transfer performance is automatically incorporated into the Multi-Region Access Point.

Topics

- [Permissions](#)
- [Multi-Region Access Point restrictions and limitations](#)
- [Multi-Region Access Point request routing](#)
- [Amazon S3 Multi-Region Access Points failover controls](#)
- [Configuring replication for use with Multi-Region Access Points](#)
- [Using Multi-Region Access Points with supported API operations](#)
- [Monitoring and logging requests made through a Multi-Region Access Point to underlying resources](#)

Permissions

Amazon S3 Multi-Region Access Points can simplify data access for Amazon S3 buckets in multiple AWS Regions. Multi-Region Access Points are named global endpoints that you can use to perform Amazon S3 data-access object operations, such as `GetObject` and `PutObject`. Each Multi-Region Access Point can have distinct permissions and network controls for any request that is made through the global endpoint.

Each Multi-Region Access Point can also enforce a customized access policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For a cross-account request to succeed, the following policies must permit the operation:

- The Multi-Region Access Point policy
- The underlying AWS Identity and Access Management (IAM) policy
- The underlying bucket policy (where the request is routed to)

Note

For same account requests, only the underlying IAM policy, which grants the appropriate access, is required.

You can configure any Multi-Region Access Point policy to accept requests only from specific IAM users or groups. For an example of how to do this, see Example 2 in [the section called “Multi-Region Access Point policy examples”](#). To restrict Amazon S3 data access to a private network, you can configure the Multi-Region Access Point policy to accept requests only from a virtual private cloud (VPC).

For example, suppose that you make a `GetObject` request through a Multi-Region Access Point by using a user called `AppDataReader` in your AWS account. To help ensure that the request won't be denied, the `AppDataReader` user must be granted the `s3:GetObject` permission by the Multi-Region Access Point and by each bucket underlying the Multi-Region Access Point. `AppDataReader` won't be able to retrieve data from any bucket that doesn't grant this permission.

Important

Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

Managing public access to a Multi-Region Access Point

Multi-Region Access Points support independent Block Public Access settings for each Multi-Region Access Point. When you create a Multi-Region Access Point, you can specify the Block Public Access settings that apply to that Multi-Region Access Point.

Note

Any Block Public Access settings that are enabled under **Block Public Access settings for this account** (in your own account) or **Block Public Settings for external buckets** still apply

even if the independent Block Public Access settings for your Multi-Region Access Point are disabled.

For any request that is made through a Multi-Region Access Point, Amazon S3 evaluates the Block Public Access settings for:

- The Multi-Region Access Point
- The underlying buckets (including external buckets)
- The account that owns the Multi-Region Access Point
- The account that owns the underlying buckets (including external accounts)

If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request.

For more information about the Amazon S3 Block Public Access feature, see [Blocking public access to your Amazon S3 storage](#).

Important

By default, all Block Public Access settings are enabled for Multi-Region Access Points. You must explicitly turn off any settings that you don't want to apply to a Multi-Region Access Point.

You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

Viewing Block Public Access settings for a Multi-Region Access Point

To view the Block Public Access settings for a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to review.
4. Choose the **Permissions** tab.
5. Under **Block Public Access settings for this Multi-Region Access Point**, review the Block Public Access settings for your Multi-Region Access Point.

Note

You can't edit the Block Public Access settings after the Multi-Region Access Point is created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

Using a Multi-Region Access Point policy

The following example Multi-Region Access Point policy grants an IAM user access to list and download files from your Multi-Region Access Point. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/JohnDoe"
            },
            "Action": [
                "s3>ListBucket",
                "s3GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias",
                "arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias/*
            ]
        }
    ]
}
```

To associate your Multi-Region Access Point policy with the specified Multi-Region Access Point by using the AWS Command Line Interface (AWS CLI), use the following `put-multi-region-`

access-point-policy command. To use this example command, replace the *user input placeholders* with your own information. Each Multi-Region Access Point can have only one policy, so a request made to the put-multi-region-access-point-policy action replaces any existing policy that is associated with the specified Multi-Region Access Point.

AWS CLI

```
aws s3control put-multi-region-access-point-policy
--account-id 111122223333
--details { "Name": "amzn-s3-demo-bucket-MultiRegionAccessPoint", "Policy": "{ \"Version\": \"2012-10-17\", \"Statement\": { \"Effect\": \"Allow\", \"Principal\": { \"AWS\": \"arn:aws:iam::111122223333:root\" }, \"Action\": [\"s3>ListBucket\", \"s3:GetObject\"], \"Resource\": [ \"arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias\", \"arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias/object/*\" ] } } }
```

To query your results for the previous operation, use the following command:

AWS CLI

```
aws s3control describe-multi-region-access-point-operation
--account-id 111122223333
--request-token-arn requestArn
```

To retrieve your Multi-Region Access Point policy, use the following command:

AWS CLI

```
aws s3control get-multi-region-access-point-policy
--account-id 111122223333
--name=amzn-s3-demo-bucket-MultiRegionAccessPoint
```

Editing the Multi-Region Access Point policy

The Multi-Region Access Point policy (written in JSON) provides storage access to the Amazon S3 buckets that are used with this Multi-Region Access Point. You can allow or deny specific principals to perform various actions on your Multi-Region Access Point. When a request is routed to a bucket

through the Multi-Region Access Point, both the access policies for the Multi-Region Access Point and the bucket apply. The more restrictive access policy always takes precedence.

Note

If a bucket contains objects that are owned by other accounts, the Multi-Region Access Point policy doesn't apply to the objects that are owned by other AWS accounts.

After you apply a Multi-Region Access Point policy, the policy cannot be deleted. You can either edit the policy or create a new policy that overwrites the existing one.

To edit the Multi-Region Access Point policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to edit the policy for.
4. Choose the **Permissions** tab.
5. Scroll down to the **Multi-Region Access Point policy** section. Choose **Edit** to update the policy (in JSON).
6. The **Edit Multi-Region Access Point policy** page appears. You can either enter the policy directly into the text field, or you can choose **Add statement** to select policy elements from a dropdown list.

Note

The console automatically displays the Multi-Region Access Point Amazon Resource Name (ARN), which you can use in the policy. For example Multi-Region Access Point policies, see [the section called "Multi-Region Access Point policy examples"](#).

Multi-Region Access Point policy examples

Amazon S3 Multi-Region Access Points support AWS Identity and Access Management (IAM) resource policies. You can use these policies to control the use of the Multi-Region Access Point by

resource, user, or other conditions. For an application or user to be able to access objects through a Multi-Region Access Point, both the Multi-Region Access Point and the underlying bucket must allow the same access.

To allow the same access to both the Multi-Region Access Point and the underlying bucket, do one of the following:

- **(Recommended)** To simplify access controls when using an Amazon S3 Multi-Region Access Point, delegate access control for the Amazon S3 bucket to the Multi-Region Access Point. For an example of how to do this, see Example 1 in this section.
- Add the same permissions contained in the Multi-Region Access Point policy to the underlying bucket policy.

Important

Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

Example 1 – Delegating access to specific Multi-Region Access Points in your bucket policy (for the same account or cross-account)

The following example bucket policy grants full bucket access to a specific Multi-Region Access Point. This means that all access to this bucket is controlled by the policies that are attached to the Multi-Region Access Point. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket. You can use this bucket policy structure for Multi-Region Access Points in either the same account or in another account.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Effect": "Allow",
```

```
    "Principal" : { "AWS": "*" },
    "Action" : "*",
    "Resource" : [ "arn:aws:s3:::amzn-s3-demo-bucket", "arn:aws:s3:::amzn-s3-
demo-bucket/*"],
    "Condition": {
        "StringEquals" : { "s3:DataAccessPointArn" :
"arn:aws:s3:::1112222333:accesspoint/example-multi-region-access-point" }
    }
}
```

 **Note**

If there are multiple Multi-Region Access Points that you're granting access to, make sure to list each Multi-Region Access Point.

Example 2 – Granting an account access to a Multi-Region Access Point in your Multi-Region Access Point policy

The following Multi-Region Access Point policy allows account **123456789012** permission to list and read the objects contained in the Multi-Region Access Point defined by the *MultiRegionAccessPoint_ARN*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::1112222333:user/JohnDoe"
            },
            "Action": [
                "s3>ListBucket",
                "s3GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::1112222333:accesspoint/MultiRegionAccessPoint_alias",
                "arn:aws:s3:::1112222333:accesspoint/MultiRegionAccessPoint_alias/*"
            ]
        }
    ]
}
```

```
"arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias/object/*"
```

Example 3 – Multi-Region Access Point policy that allows bucket listing

The following Multi-Region Access Point policy allows account *123456789012* permission to list the objects contained in the Multi-Region Access Point defined by the *MultiRegionAccessPoint_ARN*.

Multi-Region Access Point restrictions and limitations

Multi-Region Access Points in Amazon S3 have the following restrictions and limitations.

Names and aliases

Multi-Region Access Point names must meet the following requirements:

- Must be unique within a single AWS account.
- Must begin with a number or lowercase letter.
- Must be between 3 and 50 characters long.
- Can't begin or end with a hyphen (-).
- Can't contain underscores (_), uppercase letters, or periods (.).
- Can't be edited after they are created.

Multi-Region Access Point aliases (which are different from a Multi-Region Access Point name), are automatically generated by Amazon S3 and can't be edited or reused. For more information about the difference between Multi-Region Access Point aliases and Multi-Region Access Point names and their respective naming rules, see [Rules for naming Amazon S3 Multi-Region Access Points](#).

Accessing a Multi-Region Access Point

You can't access data through a Multi-Region Access Point by using gateway endpoints. However, you can access data through a Multi-Region Access Point by using interface endpoints. To use AWS

PrivateLink, you must create VPC endpoints. For more information, see [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#). However, be aware that IPv6 isn't supported.

To use Multi-Region Access Points with Amazon CloudFront, you must configure the Multi-Region Access Point as a Custom Origin distribution type. For more information about various origin types, see [Using various origins with CloudFront distributions](#). For more information about using Multi-Region Access Points with Amazon CloudFront, see [Building an active-active, proximity-based application across multiple Regions](#) on the [AWS Storage Blog](#).

 **Note**

S3 on Outposts buckets aren't supported.

Signing AWS API requests

To sign an AWS API request, your Multi-Region Access Point must meet the following minimum requirements:

 **Note**

Multi-Region Access Points don't support anonymous requests.

- Support for Transport Layer Security (TLS) version 1.2.
- Support for Signature Version 4 (SigV4A)—This version of SigV4 allows requests to be signed for multiple AWS Regions. This feature is useful in API operations that might result in data access from one of several Regions. When using an AWS SDK, you supply your credentials, and the requests to Multi-Region Access Points will use Signature Version 4A without additional configuration. Make sure to check your [AWS SDK compatibility](#) with the SigV4A algorithm. For more information about SigV4A, see [Signing AWS API requests](#) in the [AWS General Reference](#).

 **Note**

To use SigV4A with temporary security credentials—for example, when using AWS Identity and Access Management (IAM) roles—you can request the temporary credentials from a Regional AWS Security Token Service (AWS STS) endpoint. If you request temporary credentials from the global AWS STS endpoint (`sts.amazonaws.com`), then

you must first set the Region compatibility of session tokens for the global endpoint to be valid in all AWS Regions. For more information, see [Managing AWS STS in an AWS Region](#) in the *IAM User Guide*.

Amazon S3 API operations

- CopyObject is supported as a destination only when using the Multi-Region Access Point ARN.
- The S3 Batch Operations feature isn't supported.

AWS SDKs

Certain AWS SDKs aren't supported. To confirm which AWS SDKs are supported for Multi-Region Access Points, see [Compatibility with AWS SDKs](#).

Service quotas

Be aware of the following service quota limitations:

- There is a maximum of 100 Multi-Region Access Points per account.
- There is a limit of 17 Regions for a single Multi-Region Access Point.

Creating, deleting, or modifying a Multi-Region Access Point

When you create, delete, or modify an Multi-Region Access Point, be aware of the following rules and restrictions:

- After you create a Multi-Region Access Point, you can't add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one. If a cross-account bucket in your Multi-Region Access Point is deleted, the only way to reconnect this bucket is to recreate the bucket, using the same name and Region in that account.
- Underlying buckets (in the same account) that are used in a Multi-Region Access Point can be deleted only after a Multi-Region Access Point is deleted.

Region support

Control plane requests

All control plane requests to create or maintain Multi-Region Access Points must be routed to the US West (Oregon) Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified.

For the Multi-Region Access Point failover control plane, requests must be routed to one of these five supported Regions:

- US East (N. Virginia)
- US West (Oregon)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Ireland)

Regions enabled by default

Your Multi-Region Access Point supports buckets in the following default AWS Regions (which are enabled by default in your AWS account):

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)

- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)

AWS opt-in Regions

Your Multi-Region Access Point also supports buckets in the following opt-in AWS Regions (which are [disabled by default](#) in your AWS account):

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Asia Pacific (Hyderabad)
- Canada West (Calgary)
- Europe (Zurich)
- Europe (Milan)
- Europe (Spain)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- Middle East (UAE)

 **Note**

There are no additional costs for enabling an opt-in Region. However, creating or using a resource in a Multi-Region Access Point results in billing charges.

An opt-in Region must be manually enabled when configuring or creating your Multi-Region Access Point. For more information about opt-in Region behaviors for Multi-Region Access Points, see [Configuring Multi-Region Access Point opt-in Regions](#). For information about how to enable an opt-in Region in your AWS account, see [Enable or disable a Region for standalone accounts](#) in the [AWS Account Management Reference Guide](#).

Multi-Region Access Point request routing

When you make a request through a Multi-Region Access Point, Amazon S3 determines which of the buckets that are associated with the Multi-Region Access Point is closest to you. Amazon S3 then directs the request to that bucket, regardless of the AWS Region it is located in.

After the Multi-Region Access Point routes the request to the closest-proximity bucket, Amazon S3 processes the request as if you made it directly to that bucket. Multi-Region Access Points aren't aware of the data contents of an Amazon S3 bucket. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, you can configure S3 Cross-Region Replication (CRR). Then any bucket can fulfill the request successfully.

Amazon S3 directs Multi-Region Access Point requests according to the following rules:

- Amazon S3 optimizes requests to be fulfilled according to proximity. It looks at the buckets supported by the Multi-Region Access Point and relays the request to the bucket that has the closest proximity.
- If the request specifies an existing resource (for example, `GetObject`), Amazon S3 does *not* consider the name of the object when fulfilling the request. This means that even if an object exists in one bucket in the Multi-Region Access Point, your request can be routed to a bucket that doesn't contain the object. This situation will result in a 404 error message being returned to the client.

To avoid 404 errors, we recommend that you configure S3 Cross-Region Replication (CRR) for your buckets. Replication helps resolve the potential issue when the object that you want is in a bucket in the Multi-Region Access Point, but it's not located in the specific bucket that your request was routed to. For more information about configuring replication, see [Configuring replication for use with Multi-Region Access Points](#).

To ensure that your requests are fulfilled by using the specific objects that you want, we also recommend that you turn on bucket versioning and include version IDs in your requests. This approach helps ensure that you have the correct version of the object that you are looking for. Versioning-enabled buckets can also help you recover objects from accidental overwrite. For more information, see [Using S3 Versioning in S3 buckets](#).

- If the request is to create a resource (for example, `PutObject` or `CreateMultipartUpload`), Amazon S3 fulfills the request by using the closest-proximity bucket. For example, consider a video company that wants to support video uploads from anywhere in the world. When a user

makes a PUT request to the Multi-Region Access Point, the object is put into the bucket with the closest proximity. To then make that uploaded video available to others around the world for download with the lowest latency, you can use CRR with bidirectional (two-way) replication. Using CRR with two-way replication keeps the contents of all the buckets that are associated with the Multi-Region Access Point synchronized. For more information about using replication with Multi-Region Access Points, see [Configuring replication for use with Multi-Region Access Points](#).

Amazon S3 Multi-Region Access Points failover controls

With Amazon S3 Multi-Region Access Point failover controls, you can maintain business continuity during Regional traffic disruptions, while also giving your applications a multi-Region architecture to fulfill compliance and redundancy needs. If your Regional traffic gets disrupted, you can use Multi-Region Access Point failover controls to select which AWS Regions behind an Amazon S3 Multi-Region Access Point will process data-access and storage requests.

To support failover, you can set up your Multi-Region Access Point in an active-passive configuration, with traffic flowing to the active Region during normal conditions, and a passive Region on standby for failover.

For example, to perform failover to an AWS Region of your choice, you shift traffic from your primary (active) Region to your secondary (passive) Region. In an active-passive configuration like this, one bucket is active and accepting traffic, while the other bucket is passive and not accepting traffic. The passive bucket is used for disaster recovery. When you initiate failover, all traffic (such as GET or PUT requests) is directed to the bucket in the active state (in one Region) and away from the bucket in the passive state (in another Region).

If you have S3 Cross-Region Replication (CRR) enabled with two-way replication rules, you can keep your buckets synchronized during a failover. In addition, if you have CRR enabled in an active-active configuration, Amazon S3 Multi-Region Access Points can also fetch data from the bucket location of closest proximity, which improves application performance.

AWS Region support

With Amazon S3 Multi-Region Access Points failover controls, your S3 buckets can be in any of the [17 Regions](#) where Multi-Region Access Points are supported. You can initiate failover across any two Regions at one time.

Note

Although failover is initiated between only two Regions at one time, you can separately update the routing statuses for multiple Regions at the same time in your Multi-Region Access Point.

The following topics demonstrate how to use and manage Amazon S3 Multi-Region Access Point failover controls.

Topics

- [Amazon S3 Multi-Region Access Points routing states](#)
- [Using Amazon S3 Multi-Region Access Point failover controls](#)
- [Amazon S3 Multi-Region Access Point failover controls errors](#)

Amazon S3 Multi-Region Access Points routing states

Your Amazon S3 Multi-Region Access Points failover configuration determines the routing status of the AWS Regions that are used with the Multi-Region Access Point. You can configure your Amazon S3 Multi-Region Access Point to be in an active-active state or active-passive state.

- **Active-active** – In an active-active configuration, all requests are automatically sent to the closest proximity AWS Region in your Multi-Region Access Point. After the Multi-Region Access Point has been configured to be in an active-active state, all Regions can receive traffic. If traffic disruption occurs in an active-active configuration, network traffic will automatically be redirected to one of the active Regions.
- **Active-passive** – In an active-passive configuration, the active Regions in your Multi-Region Access Point receive traffic and the passive ones do not. If you intend to use S3 failover controls to initiate failover in a disaster situation, set up your Multi-Region Access Points in an active-passive configuration while you're testing and performing disaster-recovery planning.

Using Amazon S3 Multi-Region Access Point failover controls

This section explains how to manage and use your Amazon S3 Multi-Region Access Points failover controls by using the AWS Management Console.

There are two failover controls in the **Failover configuration** section on your Multi-Region Access Point details page in the AWS Management Console: **Edit routing status** and **Failover**. You can use these controls as follows:

- **Edit routing status** – You can manually edit the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status**. You can use **Edit routing status** for the following purposes:
 - To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point
 - To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
 - To manually fail over your Regions
 - To manually switch traffic between Regions
- **Failover** – When you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

Editing the routing status of the Regions in your Multi-Region Access Point

You can manually update the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status** in the **Failover configuration** section on your Multi-Region Access Point details page. However, when you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

You can use **Edit routing status** (as described in the following procedure) for the following purposes:

- To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point
- To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
- To manually fail over your Regions
- To manually switch traffic between Regions

Using the S3 console

To update the routing status of the Regions in your Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to update.
5. Choose the **Replication and failover** tab.
6. Select one or more Regions that you want to edit the routing status of.

 **Note**

To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.

7. Choose **Edit routing status**.
8. In the dialog box that appears, select **Active** or **Passive** for the **Routing status** for each Region.

An active state allows traffic to be routed to the Region. A passive state stops any traffic from being directed to the Region.

If you are creating a failover configuration for your Multi-Region Access Point or initiating failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.

9. Choose **Save routing status**. It takes about 2 minutes for traffic to be redirected.

After you submit the routing status of the AWS Regions for your Multi-Region Access Point, you can verify your routing status changes. To verify these changes, go to Amazon CloudWatch at <https://console.aws.amazon.com/cloudwatch/> to monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

Using the AWS CLI

Note

You can run Multi-Region Access Point AWS CLI routing commands against any of these five Regions:

- ap-southeast-2
- ap-northeast-1
- us-east-1
- us-west-2
- eu-west-1

The following example command updates your current Multi-Region Access Point route configuration. To update the active or passive status of a bucket, set the TrafficDialPercentage value to 100 for active and to 0 for passive. In this example, `amzn-s3-demo-bucket1` is set to active, and `amzn-s3-demo-bucket2` is set to passive. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control submit-multi-region-access-point-routes
--region ap-southeast-2
--account-id 123456789012
--mrapi MultiRegionAccessPoint_ARN
--route-updates Bucket=amzn-s3-demo-bucket1,TrafficDialPercentage=100
          Bucket=amzn-s3-demo-bucket2
          ,TrafficDialPercentage=0
```

The following example command gets your updated Multi-Region Access Point routing configuration. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 123456789012
--mrapi MultiRegionAccessPoint_ARN
```

Initiating failover

When you initiate failover by choosing **Failover** in the **Failover configuration** section on your Multi-Region Access Point details page, Amazon S3 request traffic automatically gets shifted to an alternate AWS Region. The failover process is completed within 2 minutes.

You can initiate a failover across any two AWS Regions at one time (of the [17 Regions](#) where Multi-Region Access Points are supported). Failover events are then logged in AWS CloudTrail. Upon failover completion, you can monitor Amazon S3 traffic and any traffic routing updates to the new active Region in Amazon CloudWatch.

Important

To keep all metadata and objects in sync across buckets during data replication, we recommend that you create two-way replication rules and enable replica modification sync before configuring your failover controls.

Two-way replication rules help ensure that when data is written to the Amazon S3 bucket that traffic fails over to, that data is then replicated back to the source bucket. Replica modification sync helps ensure that object metadata is also synchronized between buckets during two-way replication.

For more information about configuring replication to support failover, see [the section called “Bucket replication”](#).

To initiate failover between replicated buckets

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to use to initiate failover.
5. Choose the **Replication and failover** tab.
6. Scroll down to the **Failover configuration** section and select two AWS Regions.

Note

To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point. An active

state allows traffic to be directed to a Region. A passive state stops any traffic from being directed to the Region.

7. Choose **Failover**.
8. In the dialog box, choose **Failover** again to initiate the failover process. During this process, the routing statuses of the two Regions are automatically switched. All new traffic is directed to the Region that becomes active, and traffic stops being directed to the Region that becomes passive. It takes about 2 minutes for traffic to be redirected.

After you initiate the failover process, you can verify your traffic changes. To verify these changes, go to Amazon CloudWatch at <https://console.aws.amazon.com/cloudwatch/> to monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

Viewing your Amazon S3 Multi-Region Access Point routing controls

Using the S3 console

To view the routing controls for your Amazon S3 Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to review.
5. Choose the **Replication and failover** tab. This page displays the routing configuration details and summary for your Multi-Region Access Point, associated replication rules, and replication metrics. You can see the routing status of your Regions in the **Failover configuration** section.

Using the AWS CLI

The following example AWS CLI command gets your current Multi-Region Access Point route configuration for the specified Region. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
```

```
--region eu-west-1  
--account-id 123456789012  
--mrap MultiRegionAccessPoint_ARN
```

Note

This command can only be executed against these five Regions:

- ap-southeast-2
- ap-northeast-1
- us-east-1
- us-west-2
- eu-west-1

Amazon S3 Multi-Region Access Point failover controls errors

When you update the failover configuration for your Multi-Region Access Point, you might encounter one of these errors:

- HTTP 400 Bad Request: This error can occur if you enter an invalid Multi-Region Access Point ARN while updating your failover configuration. You can confirm your Multi-Region Access Point ARN by reviewing your Multi-Region Access Point policy. To review or update your Multi-Region Access Point policy, see [Editing the Multi-Region Access Point policy](#). This error can also occur if you use an empty string or a random string while updating your Amazon S3 Multi-Region Access Point failover controls. Make sure to use the Multi-Region Access Point ARN format:

`arn:aws:s3:::account-id:accesspoint/MultiRegionAccessPoint_alias`

- HTTP 503 Slow Down: This error occurs if you send too many requests in a short period of time. Rejected requests will result in an error.
- HTTP 409 Conflict: This error occurs when two or more concurrent route configuration update requests are targeting a single Multi-Region Access Point. The first request succeeds, but any other requests fail with an error.
- HTTP 405 Method Not Allowed: This error occurs when you've selected a Multi-Region Access Point with only one AWS Region when initiating failover. You must select two Regions before you can initiate failover. Otherwise, an error is returned.

Configuring replication for use with Multi-Region Access Points

When you make a request to a Multi-Region Access Point endpoint, Amazon S3 automatically routes the request to the bucket that is closest to you. Amazon S3 doesn't consider the contents of the request when making this decision. If you make a request to GET an object, your request might be routed to a bucket that doesn't have a copy of this object. If that happens, you receive an HTTP status code 404 (Not Found) error. For more information about Multi-Region Access Point request routing, see [the section called "Request routing"](#).

If you want the Multi-Region Access Point to be able to retrieve the object regardless of which bucket receives the request, you must configure Amazon S3 Cross-Region Replication (CRR).

For example, consider a Multi-Region Access Point with three buckets:

- A bucket named *amzn-s3-demo-bucket1* in the Region US West (Oregon) that contains the object `my-image.jpg`
- A bucket named *amzn-s3-demo-bucket2* in the Region Asia Pacific (Mumbai) that contains the object `my-image.jpg`
- A bucket named *amzn-s3-demo-bucket* in the Region Europe (Frankfurt) that doesn't contain the object `my-image.jpg`

In this situation, if you make a `GetObject` request for the object `my-image.jpg`, the success of that request depends upon which bucket receives your request. Because Amazon S3 doesn't consider the contents of the request, it might route your `GetObject` request to the *amzn-s3-demo-bucket* bucket if that bucket responds of closest proximity. Even though your object is in a bucket in the Multi-Region Access Point, you will get an HTTP 404 Not Found error because the individual bucket that received your request didn't have the object.

Enabling Cross-Region Replication (CRR) helps avoid this result. With appropriate replication rules, the `my-image.jpg` object is copied over to the *amzn-s3-demo-bucket* bucket. Therefore, if Amazon S3 routes your request to that bucket, you can now retrieve the object.

Replication works as normal with buckets that are assigned to a Multi-Region Access Point. Amazon S3 doesn't perform any special replication handling with buckets that are in Multi-Region Access Points. For more information about configuring replication in your buckets, see [Setting up live replication overview](#).

Recommendations for using replication with Multi-Region Access Points

For the best replication performance when working with Multi-Region Access Points, we recommend the following:

- Configure S3 Replication Time Control (S3 RTC). To replicate your data across different Regions within a predictable time frame, you can use S3 RTC. S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called “Using S3 Replication Time Control”](#). There are additional charges for S3 RTC. For information, see [Amazon S3 pricing](#).
- Use two-way (bidirectional) replication to support keeping buckets synchronized when buckets are updated through the Multi-Region Access Point. For more information, see [the section called “Create two-way replication rules for your Multi-Region Access Point”](#).
- Create cross-account Multi-Region Access Points to replicate data to buckets in separate AWS accounts. This approach provides account-level separation, so that data can be accessed from and replicated across different accounts in different Regions other than the source bucket. Setting up cross-account Multi-Region Access Points comes at no additional cost. If you're a bucket owner but don't own the Multi-Region Access Point, you pay only for data transfer and request costs. Multi-Region Access Point owners pay for data routing and internet-acceleration costs. For more information, see [Amazon S3 pricing](#).
- Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see [Enabling replica modification sync](#).
- Enable Amazon CloudWatch metrics to [monitor replication events](#). CloudWatch metrics fees apply. For more information, see [Amazon CloudWatch pricing](#).

Topics

- [Create one-way replication rules for your Multi-Region Access Point](#)
- [Create two-way replication rules for your Multi-Region Access Point](#)
- [View the replication rules for your Multi-Region Access Point](#)

Create one-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A one-way replication rule helps ensure that data is fully replicated from a source bucket in one AWS Region to a destination bucket in another Region. When one-way replication is set up, a replication rule from the source bucket (*amzn-s3-demo-bucket*) to the destination bucket (*amzn-s3-demo-*

bucket) is created. Like all replication rules, you can apply the one-way replication rule to the entire Amazon S3 bucket or to a subset of objects that are filtered by a prefix or object tags.

Important

We recommend using one-way replication if your users will only be consuming the objects in your destination buckets. If your users will be uploading or modifying the objects in your destination buckets, use two-way replication to keep all of your buckets in sync. We also recommend two-way replication if you plan to use your Multi-Region Access Point for failover. To set up two-way replication, see [the section called “Create two-way replication rules for your Multi-Region Access Point”](#).

To create a one-way replication rule for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**. Make sure that you have sufficient permissions to create the replication rule, or versioning will be disabled.

Note

You can create replication rules only for buckets in your own account. To create replication rules for external buckets, the bucket owners must create the replication rules for those buckets.

6. On the **Create replication rules** page, choose the **Replicate objects from one or more source buckets to one or more destination buckets** template.

Important

When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.

To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, SDKs, or REST API. For more information, see [Replication configuration file elements](#).

7. In the **Source and destination** section, under **Source buckets**, select one or more buckets that you want to replicate objects from. All buckets (source and destination) that are chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see [Using versioning in Amazon S3 buckets](#).

Under **Destination buckets**, select one or more buckets that you want to replicate objects to.

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

 **Note**

You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

- To replicate the whole bucket, choose **Apply to all objects in the bucket**.
- To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

You can filter your objects by using a prefix, object tags, or a combination of both.

- To limit replication to all objects that have names that begin with the same string (for example pictures), enter a prefix in the **Prefix** box.

If you enter a prefix that is the name of a folder, you must use a delimiter such as a / (forward slash) to indicate its level of hierarchy (for example, pictures/). For more information about prefixes, see [Organizing objects using prefixes](#).

- To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see [Categorizing your objects using tags](#).

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

 **Note**

We recommend that you apply the following options:

- **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called "Using S3 Replication Time Control"](#).
- **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.
- **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see [Replicating delete markers between buckets](#).

There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see [Amazon S3 Pricing](#) and [Amazon CloudWatch pricing](#).

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.
12. Choose **Create replication rules** to create and save your new one-way replication rule.

Create two-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A two-way replication rule (also known as a bidirectional replication rule) ensures that data is fully synchronized between two or more buckets in different AWS Regions. When two-way replication is set up, a replication rule from the source bucket (DOC-EXAMPLE-BUCKET-1) to the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) is created. Then, a second replication rule from the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) to the source bucket (DOC-EXAMPLE-BUCKET-1) is created.

Like all replication rules, you can apply the two-way replication rule to the entire Amazon S3 bucket or to a subset of objects filtered by a prefix or object tags. You can also keep metadata changes to your objects in sync by [enabling replica modification sync](#) for each replication rule. You can enable replica modification sync through the Amazon S3 console, the AWS CLI, the AWS SDKs, the Amazon S3 REST API, or AWS CloudFormation.

To monitor the replication progress of objects and object metadata in Amazon CloudWatch, enable S3 Replication metrics and notifications. For more information, see [Monitoring progress with replication metrics and Amazon S3 event notifications](#).

To create a two-way replication rule for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to update.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**.
6. On the **Create replication rules** page, choose the **Replicate objects among all specified buckets** template. The **Replicate objects among all specified buckets** template sets up two-way replication (with failover capabilities) for your buckets.

Important

When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.

To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see [Replication configuration file elements](#).

7. In the **Buckets** section, select at least two buckets that you want to replicate objects from. All buckets chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see [Using versioning in Amazon S3 buckets](#).

Note

Make sure that you have the required read and replicate permissions to establish replication, or you will encounter errors. For more information, see [Creating an IAM role](#).

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

Note

You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

- To replicate the whole bucket, choose **Apply to all objects in the bucket**.
- To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

You can filter your objects by using a prefix, object tags, or a combination of both.

- To limit replication to all objects that have names that begin with the same string (for example pictures), enter a prefix in the **Prefix** box.

If you enter a prefix that is the name of a folder, you must use a / (forward slash) as the last character (for example, pictures/).

- To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see [Categorizing your objects using tags](#).

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

Note

We recommend that you apply the following options, especially if you intend to configure your Multi-Region Access Point to support failover:

- **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called “Using S3 Replication Time Control”](#).
- **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.
- **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see [Replicating delete markers between buckets](#).
- **Replica modification sync** – Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see [Enabling replica modification sync](#).

There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see [Amazon S3 Pricing](#) and [Amazon CloudWatch pricing](#).

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.
12. Choose **Create replication rules** to create and save your new two-way replication rules.

View the replication rules for your Multi-Region Access Point

With Multi-Region Access Points, you can either set up one-way replication rules or two-way (bidirectional) replication rules. For information about how to manage your replication rules, see [Managing replication rules by using the Amazon S3 console](#).

To view the replication rules for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.

4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section. This section lists all of the replication rules that have been created for your Multi-Region Access Point.

 **Note**

If you've added a bucket from another account to this Multi-Region Access Point, you must have the `s3:GetBucketReplication` permission from the bucket owner to view the replication rules for that bucket.

Using Multi-Region Access Points with supported API operations

Amazon S3 provides a set of operations to manage Multi-Region Access Points. Amazon S3 processes some of these operations synchronously and some asynchronously. When you invoke an asynchronous operation, Amazon S3 first synchronously authorizes the requested operation. If authorization is successful, Amazon S3 returns a token that you can use to track the progress and results of the requested operation.

 **Note**

Requests that are made through the Amazon S3 console are always synchronous. The console waits until the request is completed before allowing you to submit another request.

You can view the current status and results of asynchronous operations by using the console, or you can use `DescribeMultiRegionAccessPointOperation` in the AWS CLI, AWS SDKs, or REST API. Amazon S3 provides a tracking token in the response to an asynchronous operation. You include that tracking token as an argument to `DescribeMultiRegionAccessPointOperation`. When you include the tracking token, Amazon S3 then returns the current status and results of the specified operation, including any errors or relevant resource information. Amazon S3 performs `DescribeMultiRegionAccessPointOperation` operations synchronously.

All control plane requests to create or maintain Multi-Region Access Points must be routed to the US West (Oregon) Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified. For the Multi-Region Access Point failover control plane, the request must be

routed to one of the five supported Regions. For more information about Multi-Region Access Point supported Regions, see [Multi-Region Access Point restrictions and limitations](#).

In addition, you must grant the `s3>ListAllMyBuckets` permission to the user, role, or other AWS Identity and Access Management (IAM) entity that makes a request to manage a Multi-Region Access Point.

The following examples demonstrate how to use Multi-Region Access Points with compatible operations in Amazon S3.

Topics

- [Multi-Region Access Point compatibility with AWS services and AWS SDKs](#)
- [Multi-Region Access Point compatibility with S3 operations](#)
- [View your Multi-Region Access Point routing configuration](#)
- [Update your underlying Amazon S3 bucket policy](#)
- [Update a Multi-Region Access Point route configuration](#)
- [Add an object to a bucket in your Multi-Region Access Point](#)
- [Retrieve objects from your Multi-Region Access Point](#)
- [List objects that are stored in a bucket underlying your Multi-Region Access Point](#)
- [Use a presigned URL with Multi-Region Access Points](#)
- [Use a bucket that's configured with Requester Pays with Multi-Region Access Points](#)

Multi-Region Access Point compatibility with AWS services and AWS SDKs

To use a Multi-Region Access Point with applications that require an Amazon S3 bucket name, use the Amazon Resource Name (ARN) of the Multi-Region Access Point when making requests by using an AWS SDK. To check which AWS SDKs are compatible with Multi-Region Access Points, see [Compatibility with AWS SDKs](#).

Multi-Region Access Point compatibility with S3 operations

You can use the following Amazon S3 data plane API operations to perform actions on objects in buckets that are associated with your Multi-Region Access Point. The following S3 operations can accept Multi-Region Access Point ARNs:

- [AbortMultipartUpload](#)

- [CompleteMultipartUpload](#)
- [CreateMultipartUpload](#)
- [DeleteObject](#)
- [DeleteObjectTagging](#)
- [GetObject](#)
- [GetObjectAcl](#)
- [GetObjectLegalHold](#)
- [GetObjectRetention](#)
- [GetObjectTagging](#)
- [HeadObject](#)
- [ListMultipartUploads](#)
- [ListObjectsV2](#)
- [ListParts](#)
- [PutObject](#)
- [PutObjectAcl](#)
- [PutObjectLegalHold](#)
- [PutObjectRetention](#)
- [PutObjectTagging](#)
- [RestoreObject](#)
- [UploadPart](#)

 **Note**

Multi-Region Access Points supports copy operations using Multi-Region Access Points only as a destination when using the Multi-Region Access Point ARN.

You can use the following Amazon S3 control plane operations to create and manage your Multi-Region Access Points:

- [CreateMultiRegionAccessPoint](#)

- [DescribeMultiRegionAccessPointOperation](#)
- [GetMultiRegionAccessPoint](#)
- [GetMultiRegionAccessPointPolicy](#)
- [GetMultiRegionAccessPointPolicyStatus](#)
- [GetMultiRegionAccessPointRoutes](#)
- [ListMultiRegionAccessPoints](#)
- [PutMultiRegionAccessPointPolicy](#)
- [SubmitMultiRegionAccessPointRoutes](#)

View your Multi-Region Access Point routing configuration

AWS CLI

The following example command retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 111122223333
--mrapi arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap
```

SDK for Java

The following SDK for Java code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_EAST_1)
    .credentialsProvider(credentialsProvider)
    .build();

GetMultiRegionAccessPointRoutesRequest request =
    GetMultiRegionAccessPointRoutesRequest.builder()
        .accountId("111122223333")
        .mrapi("arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap")
```

```
.build();  
  
GetMultiRegionAccessPointRoutesResponse response =  
    s3ControlClient.getMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'us-east-1'  
  
const s3ControlClient = new S3ControlClient({  
    region: REGION  
})  
  
export const run = async () => {  
    try {  
        const data = await s3ControlClient.send(  
            new GetMultiRegionAccessPointRoutesCommand({  
                AccountId: '111122223333',  
                Mrap: 'arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap',  
            })  
        )  
        console.log('Success', data)  
        return data  
    } catch (err) {  
        console.log('Error', err)  
    }  
}  
  
run()
```

SDK for Python

The following SDK for Python code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.get_multi_region_access_point_routes(  
    AccountId='111122223333',
```

```
Mrap=arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap)['Routes']
```

Update your underlying Amazon S3 bucket policy

To grant proper access, you must also update the underlying Amazon S3 bucket policy. The following examples delegate access control to the Multi-Region Access Point policy. After you delegate access control to the Multi-Region Access Point policy, the bucket policy is no longer used for access control when requests are made through the Multi-Region Access Point.

Here's an example bucket policy that delegates access control to the Multi-Region Access Point policy. To use this example bucket policy, replace the *user input placeholders* with your own information. To apply this policy through the AWS CLI `put-bucket-policy` command, as shown in the next example, save the policy in a file, for example, `policy.json`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::444455556666:root"
            },
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject",
                "s3>ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ],
            "Condition": {
                "StringEquals": {
                    "s3:DataAccessPointAccount": "444455556666"
                }
            }
        }
    ]
}
```

{}

The following put-bucket-policy example command associates the updated S3 bucket policy with your S3 bucket:

```
aws s3api put-bucket-policy  
--bucket amzn-s3-demo-bucket  
--policy file:///tmp/policy.json
```

Update a Multi-Region Access Point route configuration

The following example command updates the Multi-Region Access Point route configuration. Multi-Region Access Point route commands can be run against the following five Regions:

- ap-southeast-2
- ap-northeast-1
- us-east-1
- us-west-2
- eu-west-1

In a Multi-Region Access Point routing configuration, you can set buckets to an active or passive routing status. Active buckets receive traffic, whereas passive buckets do not. You can set a bucket's routing status by setting the `TrafficDialPercentage` value for the bucket to 100 for active or 0 for passive.

AWS CLI

The following example command updates your Multi-Region Access Point routing configuration. In this example, *amzn-s3-demo-bucket1* is set to active status and *amzn-s3-demo-bucket2* is set to passive. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control submit-multi-region-access-point-routes  
--region ap-southeast-2  
--account-id 111122223333  
--mrapi arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrapi  
--route-updates Bucket=amzn-s3-demo-bucket1,TrafficDialPercentage=100
```

Bucket=**amzn-s3-demo-bucket2**, TrafficDialPercentage=0

SDK for Java

The following SDK for Java code updates your Multi-Region Access Point routing configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.ap-southeast-2)
    .credentialsProvider(credentialsProvider)
    .build();

SubmitMultiRegionAccessPointRoutesRequest request =
    SubmitMultiRegionAccessPointRoutesRequest.builder()
        .accountId("111122223333")
        .mrap("arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap")
        .routeUpdates(
            MultiRegionAccessPointRoute.builder()
                .region("eu-west-1")
                .trafficDialPercentage(100)
                .build(),
            MultiRegionAccessPointRoute.builder()
                .region("ca-central-1")
                .bucket("111122223333")
                .trafficDialPercentage(0)
                .build()
        )
    .build();

SubmitMultiRegionAccessPointRoutesResponse response =
    s3ControlClient.submitMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'ap-southeast-2'

const s3ControlClient = new S3ControlClient({
    region: REGION
```

```
})

export const run = async () => {
  try {
    const data = await s3ControlClient.send(
      new SubmitMultiRegionAccessPointRoutesCommand({
        AccountId: '111122223333',
        Mrap: 'arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap',
        RouteUpdates: [
          {
            Region: 'eu-west-1',
            TrafficDialPercentage: 100,
          },
          {
            Region: 'ca-central-1',
            Bucket: 'amzn-s3-demo-bucket1',
            TrafficDialPercentage: 0,
          },
        ],
      })
    )
    console.log('Success', data)
    return data
  } catch (err) {
    console.log('Error', err)
  }
}

run()
```

SDK for Python

The following SDK for Python code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.submit_multi_region_access_point_routes(
  AccountId=111122223333,
  Mrap=arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap,
  RouteUpdates= [
    {'Bucket': amzn-s3-demo-bucket,
     'Region': ap-southeast-2,
     'TrafficDialPercentage': 10}
```

```
 }])
```

Add an object to a bucket in your Multi-Region Access Point

To add an object to the bucket that's associated with the Multi-Region Access Point, you can use the [PutObject](#) operation. To keep all buckets in the Multi-Region Access Point in sync, enable [Cross-Region Replication](#).

Note

To use this operation, you must have the `s3:PutObject` permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permission requirements, see [Permissions](#).

AWS CLI

The following example data plane request uploads `example.txt` to the specified Multi-Region Access Point. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api put-object --bucket
    arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap --key example.txt --
    body example.txt
```

SDK for Java

```
S3Client s3Client = S3Client.builder()
    .build();

PutObjectRequest objectRequest = PutObjectRequest.builder()
    .bucket("arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap")
    .key("example.txt")
    .build();

s3Client.putObject(objectRequest, RequestBody.fromString("Hello S3!));
```

SDK for JavaScript

```
const client = new S3Client({});
```

```
async function putObjectExample() {
    const command = new PutObjectCommand({
        Bucket: "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap",
        Key: "example.txt",
        Body: "Hello S3!",
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.put_object(
    Bucket='arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap',
    Key='example.txt',
    Body='Hello S3!'
)
```

Retrieve objects from your Multi-Region Access Point

To retrieve objects from the Multi-Region Access Point, you can use the [GetObject](#) operation.

Note

To use this API operation, you must have the `s3:GetObject` permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permissions requirements, see [Permissions](#).

AWS CLI

The following example data plane request retrieves *example.txt* from the specified Multi-Region Access Point and downloads it as *downloaded_example.txt*. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket  
arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap --  
key example.txt downloaded_example.txt
```

SDK for Java

```
S3Client s3 = S3Client.  
.builder()  
.build();  
  
GetObjectRequest getObjectRequest = GetObjectRequest.builder()  
.bucket("arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap")  
.key("example.txt")  
.build();  
  
s3Client.getObject(getObjectRequest);
```

SDK for JavaScript

```
const client = new S3Client({})  
  
async function getObjectExample() {  
    const command = new GetObjectCommand({  
        Bucket: "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap",  
        Key: "example.txt"  
    });  
  
    try {  
        const response = await client.send(command);  
        console.log(response);  
    } catch (err) {  
        console.error(err);  
    }  
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.get_object(
    Bucket='arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap',
    Key='example.txt'
)
```

List objects that are stored in a bucket underlying your Multi-Region Access Point

To return a list of objects that are stored in a bucket underlying your Multi-Region Access Point, use the [ListObjectsV2](#) operation. In the following example command, all objects for the specified Multi-Region Access Point are listed by using the ARN for the Multi-Region Access Point. In this case, the Multi-Region Access Point ARN is:

arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap

Note

To use this API operation, you must have the `s3:ListBucket` permission for the Multi-Region Access Point and the underlying bucket. For more information about Multi-Region Access Point permissions requirements, see [Permissions](#).

AWS CLI

The following example data plane request lists the objects in the bucket that underlies the Multi-Region Access Point that's specified by the ARN. To use this example, replace the `user input placeholders` with your own information.

```
aws s3api list-objects-v2 --bucket
    arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap
```

SDK for Java

```
S3Client s3Client = S3Client.builder()
    .build();
```

```
String bucketName = "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap";  
  
ListObjectsV2Request listObjectsRequest = ListObjectsV2Request  
.builder()  
.bucket(bucketName)  
.build();  
  
s3Client.listObjectsV2(listObjectsRequest);
```

SDK for JavaScript

```
const client = new S3Client({});  
  
async function listObjectsExample() {  
    const command = new ListObjectsV2Command({  
        Bucket: "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap",  
    });  
  
    try {  
        const response = await client.send(command);  
        console.log(response);  
    } catch (err) {  
        console.error(err);  
    }  
}
```

SDK for Python

```
import boto3  
  
client = boto3.client('s3')  
client.list_objects_v2(  
    Bucket='arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap'  
)
```

Use a presigned URL with Multi-Region Access Points

You can use a presigned URL to generate a URL that allows others to access your Amazon S3 buckets through an Amazon S3 Multi-Region Access Point. When you create a presigned URL, you associate it with a specific object action, such as an S3 upload (`PutObject`) or an S3 download

(GetObject). You can share the presigned URL, and anyone with access to it can perform the action embedded in the URL as if they were the original signing user.

Presigned URLs have an expiration date. When the expiration time is reached, the URL will no longer work.

Before you use S3 Multi-Region Access Points with presigned URLs, check the [AWS SDK compatibility](#) with the SigV4A algorithm. Verify that your SDK version supports SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about using presigned URLs with Amazon S3, see [Sharing objects by using presigned URLs](#).

The following examples show how you can use Multi-Region Access Points with presigned URLs. To use these examples, replace the *user input placeholders* with your own information.

AWS CLI

```
aws s3 presign
arn:aws:s3:::123456789012:accesspoint/MultiRegionAccessPoint_alias/example-file.txt
```

SDK for Python

```
import logging
import boto3
from botocore.exceptions import ClientError

s3_client = boto3.client('s3', aws_access_key_id='xxx', aws_secret_access_key='xxx')
s3_client.generate_presigned_url(HttpMethod='PUT', ClientMethod="put_object",
    Params={'Bucket': 'arn:aws:s3:::123456789012:accesspoint/
    abcdef0123456.mrap', 'Key': 'example-file'})
```

SDK for Java

```
S3Presigner s3Presigner = S3Presigner.builder()
    .credentialsProvider(StsAssumeRoleCredentialsProvider.builder()
        .refreshRequest(assumeRole)
        .stsClient(stsClient)
        .build())
    .build();

GetObjectRequest getObjectRequest = GetObjectRequest.builder()
    .bucket("arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap")
```

```
.key("example-file")
.build();

GetObjectPresignRequest preSignedReq = GetObjectPresignRequest.builder()
.getGetObjectRequest(getObjectRequest)
.signatureDuration(Duration.ofMinutes(10))
.build();

PresignedGetObjectRequest presignedGetObjectRequest =
s3Presigner.presignGetObject(preSignedReq);
```

Note

To use SigV4A with temporary security credentials—for example, when using IAM roles—make sure that you request the temporary credentials from a Regional endpoint in AWS Security Token Service (AWS STS), instead of a global endpoint. If you use the global endpoint for AWS STS (`sts.amazonaws.com`), AWS STS will generate temporary credentials from a global endpoint, which isn't supported by Sig4A. As a result, you'll get an error. To resolve this issue, use any of the listed [Regional endpoints for AWS STS](#).

Use a bucket that's configured with Requester Pays with Multi-Region Access Points

If an S3 bucket that is associated with your Multi-Region Access Points is [configured to use Requester Pays](#), the requester will pay for the bucket request, the download, and any Multi-Region Access Points related costs. For more information, see [Amazon S3 pricing](#).

Here's an example of a data plane request to a Multi-Region Access Point that is connected to a Requester Pays bucket.

AWS CLI

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify `--request-payer requester` as part of your [get-object](#) request. You must also specify the name of the file in the bucket and the location where the downloaded file should be stored.

```
aws s3api get-object --bucket MultiRegionAccessPoint_ARN --request-payer requester
--key example-file-in-bucket.txt example-location-of-downloaded-file.txt
```

SDK for Java

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify the `RequestPayer.REQUESTER` as part of your `GetObject` request. You must also specify the name of the file in the bucket, as well as the location where it should be stored.

```
GetObjectResponse getObjectContext = s3Client.getObject(GetObjectRequest.builder()
    .key("example-file.txt")
    .bucket("arn:aws:s3:::
123456789012:accesspoint/abcdef0123456.mrap")
    .requestPayer(RequestPayer.REQUESTER)
    .build()
).response();
```

Monitoring and logging requests made through a Multi-Region Access Point to underlying resources

Amazon S3 logs requests made through Multi-Region Access Points and requests made to the API operations that manage them, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. Requests made to Amazon S3 through a Multi-Region Access Point appear in your Amazon S3 server access logs and AWS CloudTrail logs with the Multi-Region Access Point hostname. An access point's hostname takes the form `MRAP_alias.accesspoint.s3-global.amazonaws.com`. For example, suppose that you have the following bucket and Multi-Region Access Point configuration:

- A bucket named `my-bucket-usw2` in the Region `us-west-2` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-aps1` in the Region `ap-south-1` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-euc1` in the Region `eu-central-1` that doesn't contain an object named `my-image.jpg`.
- A Multi-Region Access Point named `my-mrap` with the alias `mfzwi23gnjvgw.mrap` that is configured to fulfill requests from all three buckets.
- Your AWS account ID is `123456789012`.

A request made to retrieve `my-image.jpg` directly through any of the buckets appears in your logs with a hostname of `bucket_name.s3.Region.amazonaws.com`.

If you make the request through the Multi-Region Access Point instead, Amazon S3 first determines which of the buckets in the different Regions is closest. After Amazon S3 determines which bucket to use to fulfill the request, it sends the request to that bucket and logs the operation by using the Multi-Region Access Point hostname. In this example, if Amazon S3 relays the request to `my-bucket-aps1`, your logs will reflect a successful GET request for `my-image.jpg` from `my-bucket-aps1`, using a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

Important

Multi-Region Access Points aren't aware of the data contents of the underlying buckets. Therefore, the bucket that gets the request might not contain the requested data. For example, if Amazon S3 determines that the `my-bucket-euc1` bucket is the closest, your logs will reflect a failed GET request for `my-image.jpg` from `my-bucket-euc1`, using a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. If the request was routed to `my-bucket-usw2` instead, your logs would indicate a successful GET request.

For more information about Amazon S3 server access logs, see [Logging requests with server access logging](#). For more information about AWS CloudTrail, see [What is AWS CloudTrail?](#) in the [AWS CloudTrail User Guide](#).

Monitoring and logging requests made to Multi-Region Access Point management API operations

Amazon S3 provides several API operations to manage Multi-Region Access Points, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. When you make requests to these API operations by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, Amazon S3 processes these requests asynchronously. Provided that you have the appropriate permissions for the request, Amazon S3 returns a token for these requests. You can use this token with `DescribeAsyncOperation` to help you to view the status of ongoing asynchronous operations. Amazon S3 processes `DescribeAsyncOperation` requests synchronously. To view the status of asynchronous requests, you can use the Amazon S3 console, AWS CLI, SDKs, or REST API.

Note

The console displays only the status of asynchronous requests that were made within the previous 14 days. To view the status of older requests, use the AWS CLI, SDKs, or REST API.

Asynchronous management operations can be in one of several states:

NEW

Amazon S3 has received the request and is preparing to perform the operation.

IN_PROGRESS

Amazon S3 is currently performing the operation.

SUCCESS

The operation succeeded. The response includes relevant information, such as the Multi-Region Access Point alias for a `CreateMultiRegionAccessPoint` request.

FAILED

The operation failed. The response includes an error message that indicates the reason for the request failure.

Using AWS CloudTrail with Multi-Region Access Points

You can use AWS CloudTrail to view, search, download, archive, analyze, and respond to account activity across your AWS infrastructure. With Multi-Region Access Points and CloudTrail logging, you can identify the following:

- Who or what took which action
- Which resources were acted upon
- When the event occurred
- Other details regarding the event

You can use this logging information to help you analyze and respond to activity that occurred through your Multi-Region Access Points.

How to set up AWS CloudTrail for Multi-Region Access Points

To enable CloudTrail logging for any operations related to creating or maintaining Multi-Region Access Points, you must configure CloudTrail logging to record the events in the US West (Oregon) Region. You must set up your logging configuration this way regardless of which Region you are in when making the request, or which Regions the Multi-Region Access Point supports. All requests to create or maintain a Multi-Region Access Point are routed through the US West (Oregon) Region. We recommend that you either add this Region to an existing trail or create a new trail that contains this Region and all the Regions associated with the Multi-Region Access Point.

Amazon S3 logs all requests made through a Multi-Region Access Point and requests made to the API operations that manage access points, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. When you log these requests through a Multi-Region Access Point, they appear in your AWS CloudTrail logs with the hostname of the Multi-Region Access Point. For example, if you make requests to a bucket through a Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, the entries in the CloudTrail log will have a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

Multi-Region Access Points route requests to the closest bucket. Because of this behavior, when you are looking at the CloudTrail logs for a Multi-Region Access Point, you will see requests being made to the underlying buckets. Some of those requests might be direct requests to the bucket that are not routed through the Multi-Region Access Point. Keep this fact in mind when reviewing traffic. When a bucket is in a Multi-Region Access Point, requests can still be made to that bucket directly without going through the Multi-Region Access Point.

There are asynchronous events involved with creating and managing Multi-Region Access Points. Asynchronous requests don't have completion events in the CloudTrail log. For more information about asynchronous requests, see [Monitoring and logging requests made to Multi-Region Access Point management API operations](#).

For more information about AWS CloudTrail, see [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

Retaining multiple versions of objects with S3 Versioning

Versioning in Amazon S3 is a means of keeping multiple variants of an object in the same bucket. You can use the S3 Versioning feature to preserve, retrieve, and restore every version of every object stored in your buckets. With versioning you can recover more easily from both unintended

user actions and application failures. After versioning is enabled for a bucket, if Amazon S3 receives multiple write requests for the same object simultaneously, it stores all of those objects.

Versioning-enabled buckets can help you recover objects from accidental deletion or overwrite. For example, if you delete an object, Amazon S3 inserts a delete marker instead of removing the object permanently. The delete marker becomes the current object version. If you overwrite an object, it results in a new object version in the bucket. You can always restore the previous version. For more information, see [Deleting object versions from a versioning-enabled bucket](#).

By default, S3 Versioning is disabled on buckets, and you must explicitly enable it. For more information, see [Enabling versioning on buckets](#).

 **Note**

- The SOAP API does not support S3 Versioning. SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features are not supported for SOAP.
- Normal Amazon S3 rates apply for every version of an object stored and transferred. Each version of an object is the entire object; it is not just a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Unversioned, versioning-enabled, and versioning-suspended buckets

Buckets can be in one of three states:

- Unversioned (the default)
- Versioning-enabled
- Versioning-suspended

You enable and suspend versioning at the bucket level. After you version-enable a bucket, it can never return to an unversioned state. But you can *suspend* versioning on that bucket.

The versioning state applies to all (never some) of the objects in that bucket. When you enable versioning in a bucket, all new objects are versioned and given a unique version ID. Objects that already existed in the bucket at the time versioning was enabled will thereafter *always* be versioned and given a unique version ID when they are modified by future requests. Note the following:

- Objects that are stored in your bucket before you set the versioning state have a version ID of null. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests. For more information, see [Working with objects in a versioning-enabled bucket](#).
- The bucket owner (or any user with appropriate permissions) can suspend versioning to stop accruing object versions. When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. For more information, see [Working with objects in a versioning-suspended bucket](#).

Using S3 Versioning with S3 Lifecycle

To customize your data retention approach and control storage costs, use object versioning with S3 Lifecycle. For more information, see [Managing the lifecycle of objects](#). For information about creating S3 Lifecycle configurations using the AWS Management Console, AWS CLI, AWS SDKs, or the REST API, see [Setting an S3 Lifecycle configuration on a bucket](#).

Important

If you have an object expiration lifecycle configuration in your unversioned bucket and you want to maintain the same permanent delete behavior when you enable versioning, you must add a noncurrent expiration configuration. The noncurrent expiration lifecycle configuration manages the deletes of the noncurrent object versions in the versioning-enabled bucket. (A versioning-enabled bucket maintains one current, and zero or more noncurrent, object versions.) For more information, see [Setting an S3 Lifecycle configuration on a bucket](#).

For information about working with S3 Versioning, see the following topics.

Topics

- [How S3 Versioning works](#)
- [Enabling versioning on buckets](#)
- [Configuring MFA delete](#)
- [Working with objects in a versioning-enabled bucket](#)
- [Working with objects in a versioning-suspended bucket](#)

- [Troubleshooting versioning](#)

How S3 Versioning works

You can use S3 Versioning to keep multiple versions of an object in one bucket so that you can restore objects that are accidentally deleted or overwritten. For example, if you apply S3 Versioning to a bucket, the following changes occur:

- If you delete an object, instead of removing the object permanently, Amazon S3 inserts a delete marker, which becomes the current object version. You can then restore the previous version. For more information, see [Deleting object versions from a versioning-enabled bucket](#).
- If you overwrite an object, Amazon S3 adds a new object version in the bucket. The previous version remains in the bucket and becomes a noncurrent version. You can restore the previous version.

 **Note**

Normal Amazon S3 rates apply for every version of an object that is stored and transferred. Each version of an object is the entire object; it is not a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see [General purpose buckets configuration options](#).) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes an Enabled status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to Suspended.

Note

When you enable versioning on a bucket for the first time, it might take a short amount of time for the change to be fully propagated. While this change is propagating, you may encounter intermittent HTTP 404 NoSuchKey errors for requests to objects created or updated after enabling versioning. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (PUT or DELETE) on objects in the bucket.

The bucket owner and all authorized AWS Identity and Access Management (IAM) users can enable versioning. The bucket owner is the AWS account that created the bucket. For more information about permissions, see [Identity and Access Management for Amazon S3](#).

For more information about enabling and disabling S3 Versioning by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or REST API, see [the section called “Enabling versioning on buckets”](#).

Topics

- [Version IDs](#)
- [Versioning workflows](#)

Version IDs

If you enable versioning for a bucket, Amazon S3 automatically generates a unique version ID for the object that is being stored. For example, in one bucket you can have two objects with the same key (object name) but different version IDs, such as photo.gif (version 111111) and photo.gif (version 121212).

Diagram depicting a versioning-enabled bucket that has two objects with the same key but different version IDs.

Each object has a version ID, whether or not S3 Versioning is enabled. If S3 Versioning is not enabled, Amazon S3 sets the value of the version ID to null. If you enable S3 Versioning, Amazon S3 assigns a version ID value for the object. This value distinguishes that object from other versions of the same key.

When you enable S3 Versioning on an existing bucket, objects that are already stored in the bucket are unchanged. Their version IDs (null), contents, and permissions remain the same. After you

enable S3 Versioning, each object that is added to the bucket gets a version ID, which distinguishes it from other versions of the same key.

Only Amazon S3 generates version IDs, and they cannot be edited. Version IDs are Unicode, UTF-8 encoded, URL-ready, opaque strings that are no more than 1,024 bytes long. The following is an example:

```
3sL4kqtJlcpXroDTDmJ+rmSpXd3dIbrHY+MTRCx3v+jVBH40Nr8X8gdRQBpUMLUo
```

 **Note**

For simplicity, the other examples in this topic use much shorter IDs.

Versioning workflows

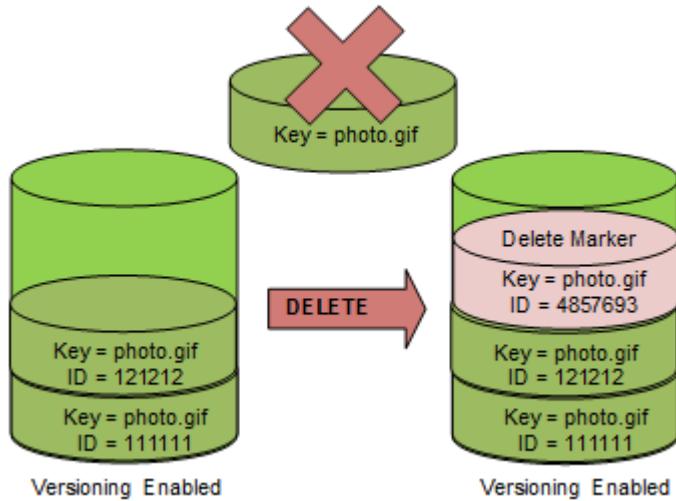

When you PUT an object in a versioning-enabled bucket, the noncurrent version is not overwritten. As shown in the following figure, when a new version of photo.gif is PUT into a bucket that already contains an object with the same name, the following behavior occurs:

- The original object (ID = 111111) remains in the bucket.
- Amazon S3 generates a new version ID (121212), and adds this newer version of the object to the bucket.

Diagram depicting how S3 Versioning works when you PUT an object in a versioning-enabled bucket.

With this functionality, you can retrieve a previous version of an object if an object has been accidentally overwritten or deleted.

When you DELETE an object, all versions remain in the bucket, and Amazon S3 inserts a delete marker, as shown in the following figure.

The delete marker becomes the current version of the object. By default, GET requests retrieve the most recently stored version. Performing a GET Object request when the current version is a delete marker returns a 404 Not Found error, as shown in the following figure.

Illustration that shows a GetObject call for a delete marker returning a 404 (Not Found) error.

However, you can GET a noncurrent version of an object by specifying its version ID. In the following figure, you GET a specific object version, 111111. Amazon S3 returns that object version even though it's not the current version.

For more information, see [Retrieving object versions from a versioning-enabled bucket](#).

Diagram depicting how S3 Versioning works when you GET a noncurrent version in a versioning-enabled bucket.

You can permanently delete an object by specifying the version that you want to delete. Only the owner of an Amazon S3 bucket or an authorized IAM user can permanently delete a version. If your DELETE operation specifies the `versionId`, that object version is permanently deleted, and Amazon S3 doesn't insert a delete marker.

Diagram that shows how `DELETE versionId` permanently deletes a specific object version.

You can add more security by configuring a bucket to enable multi-factor authentication (MFA) delete. When you enable MFA delete for a bucket, the bucket owner must include two forms of authentication in any request to delete a version or change the versioning state of the bucket. For more information, see [Configuring MFA delete](#).

When are new versions created for an object?

New versions of objects are created only when you PUT a new object. Be aware that certain actions, such as `CopyObject`, work by implementing a PUT operation.

Some actions that modify the current object don't create a new version because they don't PUT a new object. This includes actions such as changing the tags on an object.

Important

If you notice a significant increase in the number of HTTP 503 (Service Unavailable) responses received for Amazon S3 PUT or DELETE object requests to a bucket that has S3 Versioning enabled, you might have one or more objects in the bucket for which there are millions of versions. For more information, see the S3 Versioning section of [Troubleshooting versioning](#).

Enabling versioning on buckets

You can use S3 Versioning to keep multiple versions of an object in one bucket. This section provides examples of how to enable versioning on a bucket using the console, REST API, AWS SDKs, and AWS Command Line Interface (AWS CLI).

Note

After enabling versioning on a bucket for the first time, it may take up to 15 minutes for the change to fully propagate across the S3 system. During this time, GET requests for objects created or updated after enabling versioning may result in HTTP 404 NoSuchKey errors. We recommend waiting 15 minutes after enabling versioning before performing any write operations (PUT or DELETE) on objects in the bucket. This waiting period helps avoid potential issues with object visibility and version tracking.

For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#). For information about working with objects that are in versioning-enabled buckets, see [Working with objects in a versioning-enabled bucket](#).

To learn more about how to use S3 Versioning to protect data, see [Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication](#).

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see [General purpose buckets configuration options](#).) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes a status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to Suspended.

The bucket owner and all authorized users can enable versioning. The bucket owner is the AWS account that created the bucket (the root account). For more information about permissions, see [Identity and Access Management for Amazon S3](#).

The following sections provide more detail about enabling S3 Versioning using the console, AWS CLI, and the AWS SDKs.

Using the S3 console

Follow these steps to use the AWS Management Console to enable versioning on an S3 bucket.

To enable or disable versioning on an S3 general purpose bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable versioning for.
4. Choose **Properties**.
5. Under **Bucket Versioning**, choose **Edit**.
6. Choose **Suspend** or **Enable**, and then choose **Save changes**.

Note

You can use AWS multi-factor authentication (MFA) with versioning. When you use MFA with versioning, you must provide your AWS account's access keys and a valid code from

the account's MFA device to permanently delete an object version or suspend or reactivate versioning.

To use MFA with versioning, you enable MFA Delete. However, you can't enable MFA Delete using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API. For more information, see [Configuring MFA delete](#).

Using the AWS CLI

The following example enables versioning on an S3 general purpose bucket.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a physical MFA device. For physical MFA devices, in the --mfa parameter, pass a concatenation of the MFA device serial number, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled,MFADelete=Enabled --mfa "SerialNumber 123456"
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a virtual MFA device. For virtual MFA devices, in the --mfa parameter, pass a concatenation of the MFA device ARN, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled,MFADelete=Enabled --mfa "arn:aws:iam::account-id:mfa/root-account-mfa-device 123789"
```

Note

Using MFA delete requires an approved physical or virtual authentication device. For more information about using MFA delete in Amazon S3, see [Configuring MFA delete](#).

For more information about enabling versioning using the AWS CLI, see [put-bucket-versioning](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

The following examples enable versioning on a bucket and then retrieve versioning status using the AWS SDK for Java and the AWS SDK for .NET. For information about using other AWS SDKs, see the [AWS Developer Center](#).

.NET

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using System;
using Amazon.S3;
using Amazon.S3.Model;

namespace s3.amazonaws.com.docsamples
{
    class BucketVersioningConfiguration
    {
        static string bucketName = "*** bucket name ***";

        public static void Main(string[] args)
        {
            using (var client = new AmazonS3Client(Amazon.RegionEndpoint.USEast1))
            {
                try
                {
                    EnableVersioningOnBucket(client);
                    string bucketVersioningStatus =
                    RetrieveBucketVersioningConfiguration(client);
                }
                catch (AmazonS3Exception amazonS3Exception)
                {
                    if (amazonS3Exception.ErrorCode != null &&
                        (amazonS3Exception.ErrorCode.Equals("InvalidAccessKeyId") ||
                        amazonS3Exception.ErrorCode.Equals("InvalidSecurity")))
                    {
                        Console.WriteLine("Check the provided AWS Credentials.");
                        Console.WriteLine(

        }
    }
}
```

Python

The following Python code example creates an Amazon S3 bucket, enables it for versioning, and configures a lifecycle that expires noncurrent object versions after 7 days.

```
def create_versioned_bucket(bucket_name, prefix):
    """
    Creates an Amazon S3 bucket, enables it for versioning, and configures a
    lifecycle
    that expires noncurrent object versions after 7 days.

    Adding a lifecycle configuration to a versioned bucket is a best practice.
    It helps prevent objects in the bucket from accumulating a large number of
    noncurrent versions, which can slow down request performance.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket_name: The name of the bucket to create.
    :param prefix: Identifies which objects are automatically expired under the
                   configured lifecycle rules.
    :return: The newly created bucket.
    """
    try:
        bucket = s3.create_bucket(
            Bucket=bucket_name,
            CreateBucketConfiguration={
                "LocationConstraint": s3.meta.client.meta.region_name
            },
        )
        logger.info("Created bucket %s.", bucket.name)
    except ClientError as error:
        if error.response["Error"]["Code"] == "BucketAlreadyOwnedByYou":
            logger.warning("Bucket %s already exists! Using it.", bucket_name)
```

```
        bucket = s3.Bucket(bucket_name)
    else:
        logger.exception("Couldn't create bucket %s.", bucket_name)
        raise

    try:
        bucket.Versioning().enable()
        logger.info("Enabled versioning on bucket %s.", bucket.name)
    except ClientError:
        logger.exception("Couldn't enable versioning on bucket %s.", bucket.name)
        raise

    try:
        expiration = 7
        bucket.LifecycleConfiguration().put(
            LifecycleConfiguration={
                "Rules": [
                    {
                        "Status": "Enabled",
                        "Prefix": prefix,
                        "NoncurrentVersionExpiration": {"NoncurrentDays":
                expiration},
                    }
                ]
            }
        )
        logger.info(
            "Configured lifecycle to expire noncurrent versions after %s days "
            "on bucket %s.",
            expiration,
            bucket.name,
        )
    except ClientError as error:
        logger.warning(
            "Couldn't configure lifecycle on bucket %s because %s. "
            "Continuing anyway.",
            bucket.name,
            error,
        )

    return bucket
```

Configuring MFA delete

When working with S3 Versioning in Amazon S3 buckets, you can optionally add another layer of security by configuring a bucket to enable *MFA (multi-factor authentication) delete*. When you do this, the bucket owner must include two forms of authentication in any request to delete a version or change the versioning state of the bucket.

MFA delete requires additional authentication for either of the following operations:

- Changing the versioning state of your bucket
- Permanently deleting an object version

MFA delete requires two forms of authentication together:

- Your security credentials
- The concatenation of a valid serial number, a space, and the six-digit code displayed on an approved authentication device

MFA delete thus provides added security if, for example, your security credentials are compromised. MFA delete can help prevent accidental bucket deletions by requiring the user who initiates the delete action to prove physical possession of an MFA device with an MFA code and adding an extra layer of friction and security to the delete action.

To identify buckets that have MFA delete enabled, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

The bucket owner, the AWS account that created the bucket (root account), and all authorized users can enable versioning. However, only the bucket owner (root account) can enable MFA delete. For more information, see [Securing Access to AWS Using MFA](#) on the AWS Security Blog.

Note

To use MFA delete with versioning, you enable MFA Delete. However, you cannot enable MFA Delete using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API.

For examples of using MFA delete with versioning, see the examples section in the topic [Enabling versioning on buckets](#).

You cannot use MFA delete with lifecycle configurations. For more information about lifecycle configurations and how they interact with other configurations, see [How S3 Lifecycle interacts with other bucket configurations](#).

To enable or disable MFA delete, you use the same API that you use to configure versioning on a bucket. Amazon S3 stores the MFA delete configuration in the same *versioning* subresource that stores the bucket's versioning status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>VersioningState</Status>
  <MfaDelete>MfaDeleteState</MfaDelete>
</VersioningConfiguration>
```

To use MFA delete, you can use either a hardware or virtual MFA device to generate an authentication code. The following example shows a generated authentication code displayed on a hardware device.

MFA delete and MFA-protected API access are features intended to provide protection for different scenarios. You configure MFA delete on a bucket to help ensure that the data in your bucket cannot be accidentally deleted. MFA-protected API access is used to enforce another authentication factor (MFA code) when accessing sensitive Amazon S3 resources. You can require any operations against these Amazon S3 resources to be done with temporary credentials created using MFA. For an example, see [Requiring MFA](#).

For more information about how to purchase and activate an authentication device, see [Multi-factor authentication](#).

To enable S3 Versioning and configure MFA delete

Using the AWS CLI

The serial number is the number that uniquely identifies the MFA device. For physical MFA devices, this is the unique serial number that's provided with the device. For virtual MFA devices, the

serial number is the device ARN. To use the following commands, replace the *user input placeholders* with your own information.

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a physical MFA device. For physical MFA devices, in the `--mfa` parameter, pass a concatenation of the MFA device serial number, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled,MFADelete=Enabled --mfa "SerialNumber 123456"
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a virtual MFA device. For virtual MFA devices, in the `--mfa` parameter, pass a concatenation of the MFA device ARN, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled,MFADelete=Enabled --mfa "arn:aws:iam::account-id:mfa/root-account-mfa-device 123789"
```

For more information, see the AWS rePost article [How do I turn on MFA delete for my Amazon S3 bucket?](#).

Using the REST API

For more information about specifying MFA delete using the Amazon S3 REST API, see [PutBucketVersioning](#) *Amazon Simple Storage Service API Reference*.

Working with objects in a versioning-enabled bucket

Objects that are stored in an Amazon S3 bucket before you set the versioning state have a version ID of null. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests.

Transitioning object versions

You can define lifecycle configuration rules for objects that have a well-defined lifecycle to transition object versions to the S3 Glacier Flexible Retrieval storage class at a specific time in the object's lifetime. For more information, see [Managing the lifecycle of objects](#).

The topics in this section explain various object operations in a versioning-enabled bucket. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

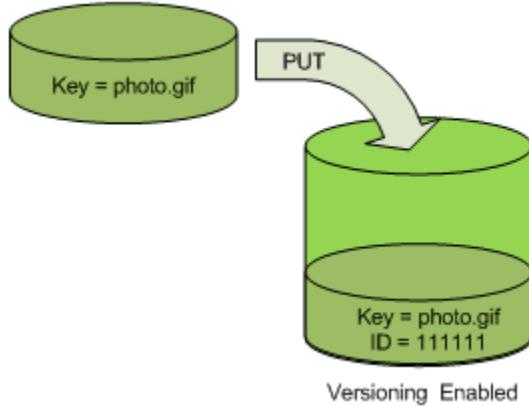

Topics

- [Adding objects to versioning-enabled buckets](#)
- [Listing objects in a versioning-enabled bucket](#)
- [Retrieving object versions from a versioning-enabled bucket](#)
- [Deleting object versions from a versioning-enabled bucket](#)
- [Configuring versioned object permissions](#)

Adding objects to versioning-enabled buckets

After you enable versioning on a bucket, Amazon S3 automatically adds a unique version ID to every object stored (using PUT, POST, or CopyObject) in the bucket.

The following figure shows that Amazon S3 adds a unique version ID to an object when it is added to a versioning-enabled bucket.

i Note

The version ID values that Amazon S3 assigns are URL safe (can be included as part of a URI).

For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#). You can add object versions to a versioning-enabled bucket using the console, AWS SDKs, and REST API.

Using the console

For instructions, see [Uploading objects](#).

Using the AWS SDKs

For examples of uploading objects using the AWS SDKs for Java, .NET, and PHP, see [Uploading objects](#). The examples for uploading objects in nonversioned and versioning-enabled buckets are the same, although in the case of versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Using the REST API

To add objects to versioning-enabled buckets

1. Enable versioning on a bucket using a PutBucketVersioning request.

For more information, see [PutBucketVersioning](#) in the *Amazon Simple Storage Service API Reference*.

2. Send a PUT, POST, or CopyObject request to store an object in the bucket.

When you add an object to a versioning-enabled bucket, Amazon S3 returns the version ID of the object in the `x-amz-version-id` response header, as shown in the following example.

```
x-amz-version-id: 3/L4kqtJlcpXroDTDmJ+rmSpXd3dIbrHY
```

Listing objects in a versioning-enabled bucket

This section provides examples of listing object versions from a versioning-enabled bucket. Amazon S3 stores object version information in the `versions` subresource that is associated with the bucket. For more information, see [General purpose buckets configuration options](#). In order to list the objects in a versioning-enabled bucket, you need the `ListBucketVersions` permission.

Using the S3 console

Follow these steps to use the Amazon S3 console to see the different versions of an object.

To see multiple versions of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. To see a list of the versions of the objects in the bucket, choose the **Show versions** switch.

For each object version, the console shows a unique version ID, the date and time the object version was created, and other properties. (Objects stored in your bucket before you set the versioning state have a version ID of **null**.)

To list the objects without the versions, choose the **List versions** switch.

You also can view, download, and delete object versions in the object overview pane on the console. For more information, see [Viewing object properties in the Amazon S3 console](#).

Note

To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Using the AWS SDKs

The examples in this section show how to retrieve an object listing from a versioning-enabled bucket. Each request returns up to 1,000 versions, unless you specify a lower number. If the bucket contains more versions than this limit, you send a series of requests to retrieve the list of all versions. This process of returning results in "pages" is called *pagination*.

To show how pagination works, the examples limit each response to two object versions. After retrieving the first page of results, each example checks to determine whether the version list was truncated. If it was, the example continues retrieving pages until all versions have been retrieved.

Note

The following examples also work with a bucket that isn't versioning-enabled, or for objects that don't have individual versions. In those cases, Amazon S3 returns the object listing with a version ID of null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Java

For instructions on creating and testing a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;

import com.amazonaws.services.s3.model.S3VersionSummary;
import com.amazonaws.services.s3.model.VersionListing;

public class ListKeysVersioningEnabledBucket {

    public static void main(String[] args) {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(clientRegion)
                .build();

            // Retrieve the list of versions. If the bucket contains more versions
        }
    }
}
```

```
// than the specified maximum number of results, Amazon S3 returns
// one page of results per request.
ListVersionsRequest request = new ListVersionsRequest()
    .withBucketName(bucketName)
    .withMaxResults(2);
VersionListing versionListing = s3Client.listVersions(request);
int numVersions = 0, numPages = 0;
while (true) {
    numPages++;
    for (S3VersionSummary objectSummary :
versionListing.getVersionSummaries()) {
        System.out.printf("Retrieved object %s, version %s\n",
            objectSummary.getKey(),
            objectSummary.getVersionId());
        numVersions++;
    }
    // Check whether there are more pages of versions to retrieve. If
    // there are, retrieve them. Otherwise, exit the loop.
    if (versionListing.isTruncated()) {
        versionListing =
s3Client.listNextBatchOfVersions(versionListing);
    } else {
        break;
    }
}
System.out.println(numVersions + " object versions retrieved in " +
numPages + " pages");
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

.NET

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ListObjectsVersioningEnabledBucketTest
    {
        static string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main(string[] args)
        {
            s3Client = new AmazonS3Client(bucketRegion);
            GetObjectListWithAllVersionsAsync().Wait();
        }

{
    Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
}
}
}
}
```

Using the REST API

Example — Listing all object versions in a bucket

To list all the versions of all the objects in a bucket, you use the `versions` subresource in a GET Bucket request. Amazon S3 can retrieve a maximum of 1,000 objects, and each object version counts fully as an object. Therefore, if a bucket contains two keys (for example, `photo.gif` and `picture.jpg`), and the first key has 990 versions and the second key has 400 versions, a single request would retrieve all 990 versions of `photo.gif` and only the most recent 10 versions of `picture.jpg`.

Amazon S3 returns object versions in the order in which they were stored, with the most recently stored returned first.

In a GET Bucket request, include the `versions` subresource.

```
GET /?versions HTTP/1.1
Host: bucketName.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 +0000
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Example — Retrieving all versions of a key

To retrieve a subset of object versions, you use the request parameters for GET Bucket. For more information, see [GET Bucket](#).

1. Set the `prefix` parameter to the key of the object that you want to retrieve.
2. Send a GET Bucket request using the `versions` subresource and `prefix`.

```
GET /?versions&prefix=objectName HTTP/1.1
```

Example — Retrieving objects using a prefix

The following example retrieves objects whose key is or begins with `myObject`.

```
GET /?versions&prefix=myObject HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can use the other request parameters to retrieve a subset of all versions of the object. For more information, see [GET Bucket](#) in the *Amazon Simple Storage Service API Reference*.

Example — Retrieving a listing of additional objects if the response is truncated

If the number of objects that could be returned in a GET request exceeds the value of `max-keys`, the response contains `<iTruncated>true</iTruncated>`, and includes the first key (in `NextKeyMarker`) and the first version ID (in `NextVersionIdMarker`) that satisfy the request, but were not returned. You use those returned values as the starting position in a subsequent request to retrieve the additional objects that satisfy the GET request.

Use the following process to retrieve additional objects that satisfy the original GET Bucket versions request from a bucket. For more information about key-marker, version-id-marker, NextKeyMarker, and NextVersionIdMarker, see [GET Bucket](#) in the *Amazon Simple Storage Service API Reference*.

The following are additional responses that satisfy the original GET request:

- Set the value of key-marker to the key returned in NextKeyMarker in the previous response.
- Set the value of version-id-marker to the version ID returned in NextVersionIdMarker in the previous response.
- Send a GET Bucket versions request using key-marker and version-id-marker.

Example — Retrieving objects starting with a specified key and version ID

```
GET /?versions&key-marker=myObject&version-id-marker=298459348571 HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Using the AWS CLI

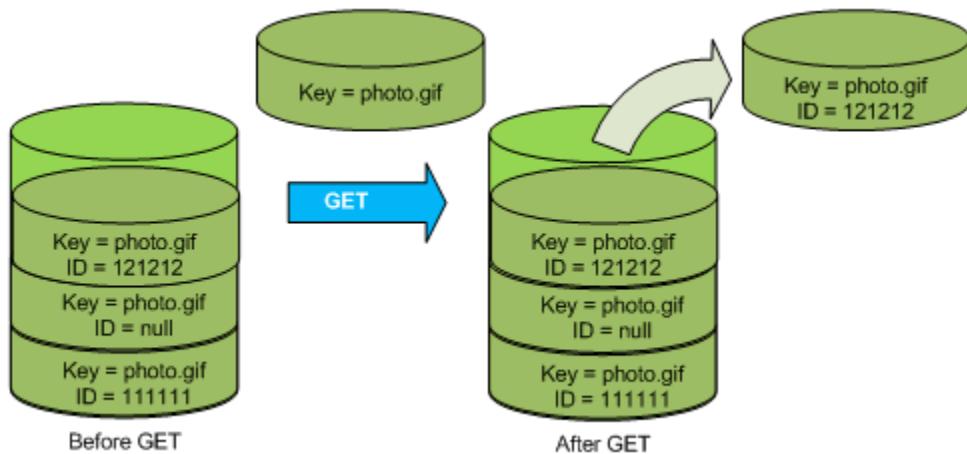

The following command returns metadata about all versions of the objects in a bucket.

```
aws s3api list-object-versions --bucket amzn-s3-demo-bucket1
```

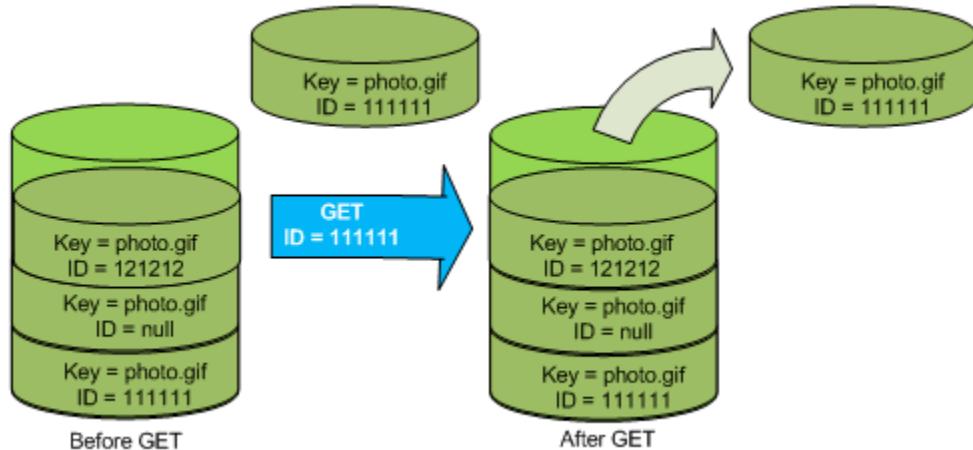

For more information about list-object-versions see [list-object-versions](#) in the *AWS CLI Command Reference*.

Retrieving object versions from a versioning-enabled bucket

Versioning in Amazon S3 is a way of keeping multiple variants of an object in the same bucket. A simple GET request retrieves the current version of an object. The following figure shows how GET returns the current version of the object, photo.gif.

To retrieve a specific version, you have to specify its version ID. The following figure shows that a `GET versionId` request retrieves the specified version of the object (not necessarily the current one).

You can retrieve object versions in Amazon S3 using the console, AWS SDKs, or REST API.

Note

To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see [Viewing object properties in the Amazon S3 console](#).

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Using the AWS SDKs

The examples for uploading objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For examples of downloading objects using AWS SDKs for Java, .NET, and PHP, see [Downloading objects](#).

For examples of listing the version of objects using AWS SDKs for .NET and Rust, see [List the version of objects in an Amazon S3 bucket](#).

Using the REST API

To retrieve a specific object version

1. Set `versionId` to the ID of the version of the object that you want to retrieve.
2. Send a `GET Object versionId` request.

Example — Retrieving a versioned object

The following request retrieves version L4kqtJlcpXroDTDmpUMLUo of my-image.jpg.

```
GET /my-image.jpg?versionId=L4kqtJlcpXroDTDmpUMLUo HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can retrieve just the metadata of an object (not the content). For information, see [the section called “Retrieving version metadata”](#).

For information about restoring a previous object version, see [the section called “Restoring previous versions”](#).

Retrieving the metadata of an object version

If you only want to retrieve the metadata of an object (and not its content), you use the HEAD operation. By default, you get the metadata of the most recent version. To retrieve the metadata of a specific object version, you specify its version ID.

To retrieve the metadata of an object version

1. Set `versionId` to the ID of the version of the object whose metadata you want to retrieve.
2. Send a `HEAD Object versionId` request.

Example — Retrieving the metadata of a versioned object

The following request retrieves the metadata of version 3HL4kqCxf3vjVBH40NrjfkD of my-image.jpg.

```
HEAD /my-image.jpg?versionId=3HL4kqCxf3vjVBH40NrjfkD HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

The following shows a sample response.

```
HTTP/1.1 200 OK
```

```
x-amz-id-2: ef8yU9AS1ed40pIszj7UDNEHGran
x-amz-request-id: 318BC8BC143432E5
x-amz-version-id: 3HL4kqtJlcpXroDTDmjVBH40Nrjfkd
Date: Wed, 28 Oct 2009 22:32:00 GMT
Last-Modified: Sun, 1 Jan 2006 12:00:00 GMT
ETag: "fba9dede5f27731c9771645a39863328"
Content-Length: 434234
Content-Type: text/plain
Connection: close
Server: AmazonS3
```

Restoring previous versions

You can use versioning to retrieve previous versions of an object. There are two approaches to doing so:

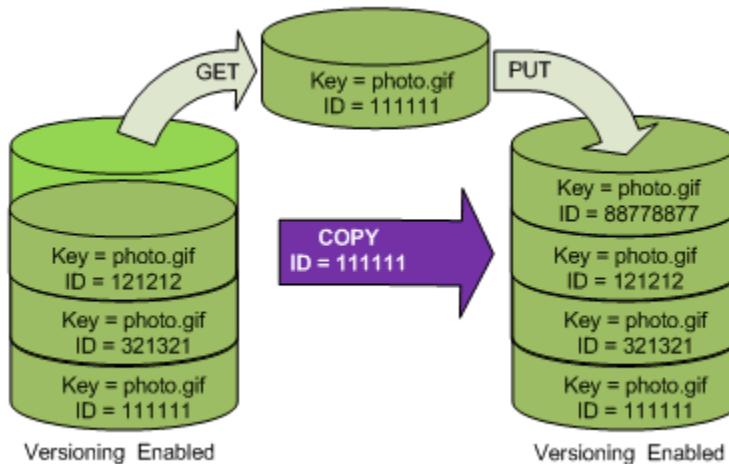

- Copy a previous version of the object into the same bucket.

The copied object becomes the current version of that object and all object versions are preserved.

- Permanently delete the current version of the object.

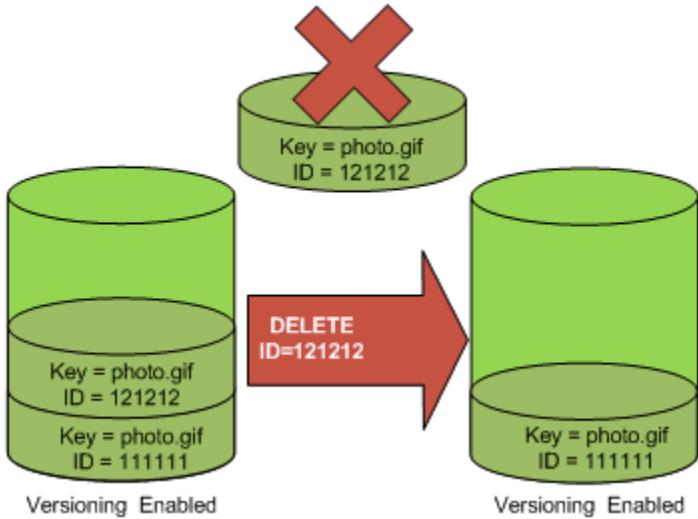

When you delete the current object version, you, in effect, turn the previous version into the current version of that object.

Because all object versions are preserved, you can make any earlier version the current version by copying a specific version of the object into the same bucket. In the following figure, the source object (ID = 111111) is copied into the same bucket. Amazon S3 supplies a new ID (88778877) and it becomes the current version of the object. So, the bucket has both the original object version (111111) and its copy (88778877). For more information about getting a previous version and then uploading it to make it the current version, see [Retrieving object versions from a versioning-enabled bucket](#) and [Uploading objects](#).

A subsequent GET retrieves version 88778877.

The following figure shows how deleting the current version (121212) of an object leaves the previous version (111111) as the current object. For more information about deleting an object, see [Deleting a single object](#).

A subsequent GET retrieves version 111111.

Note

To restore object versions in batches, you can [use the CopyObject operation](#). The CopyObject operation copies each object that is specified in the manifest. However, be aware that objects aren't necessarily copied in the same order as they appear in the manifest. For versioned buckets, if preserving current/non-current version order

is important, you should copy all non-current versions first. Then, after the first job is complete, copy the current versions in a subsequent job.

To restore previous object versions

For more guidance on restoring deleted objects, see [How can I retrieve an Amazon S3 object that was deleted in a versioning-enabled bucket?](#) in the AWS re:Post Knowledge Center.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see [Viewing object properties in the Amazon S3 console](#).

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Using the AWS SDKs

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Python

The following Python code example restores a versioned object's previous version by deleting all versions that occurred after the specified rollback version.

```
def rollback_object(bucket, object_key, version_id):
    """
    Rolls back an object to an earlier version by deleting all versions that
    occurred after the specified rollback version.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket: The bucket that holds the object to roll back.
    :param object_key: The object to roll back.
    :param version_id: The version ID to roll back to.
    """
    # Versions must be sorted by last_modified date because delete markers are
    # at the end of the list even when they are interspersed in time.
    versions = sorted(
        bucket.object_versions.filter(Prefix=object_key),
        key=attrgetter("last_modified"),
        reverse=True,
    )

    logger.debug(
        "Got versions:\n%s",
        "\n".join(
            [
                f"\t{version.version_id}, last modified {version.last_modified}"
                for version in versions
            ]
        ),
    )

    if version_id in [ver.version_id for ver in versions]:
        print(f"Rolling back to version {version_id}")
        for version in versions:
            if version.version_id != version_id:
                version.delete()
                print(f"Deleted version {version.version_id}")
            else:
                break

        print(f"Active version is now {bucket.Object(object_key).version_id}")
    else:
        raise KeyError()
```

```
f"{version_id} was not found in the list of versions for "
f"{object_key}."
)
```

Deleting object versions from a versioning-enabled bucket

You can delete object versions from Amazon S3 buckets whenever you want. You can also define lifecycle configuration rules for objects that have a well-defined lifecycle to request Amazon S3 to expire current object versions or permanently remove noncurrent object versions. When your bucket has versioning enabled or the versioning is suspended, the lifecycle configuration actions work as follows:

- The `Expiration` action applies to the current object version. Instead of deleting the current object version, Amazon S3 retains the current version as a noncurrent version by adding a *delete marker*, which then becomes the current version.
- The `NoncurrentVersionExpiration` action applies to noncurrent object versions, and Amazon S3 permanently removes these object versions. You cannot recover permanently removed objects.

For more information about S3 Lifecycle, see [Managing the lifecycle of objects](#) and [Examples of S3 Lifecycle configurations](#).

To see how many current and noncurrent object versions that your buckets have, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to optimize your storage costs](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

Note

Normal Amazon S3 rates apply for every version of an object that is stored and transferred, including noncurrent object versions. For more information, see [Amazon S3 pricing](#).

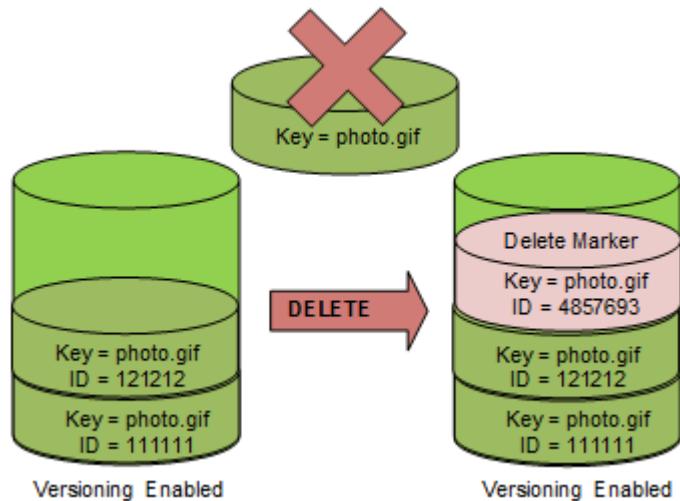

Delete request use cases

A DELETE request has the following use cases:

- When versioning is enabled, a simple DELETE cannot permanently delete an object. (A simple DELETE request is a request that doesn't specify a version ID.) Instead, Amazon S3 inserts a delete marker in the bucket, and that marker becomes the current version of the object with a new ID.

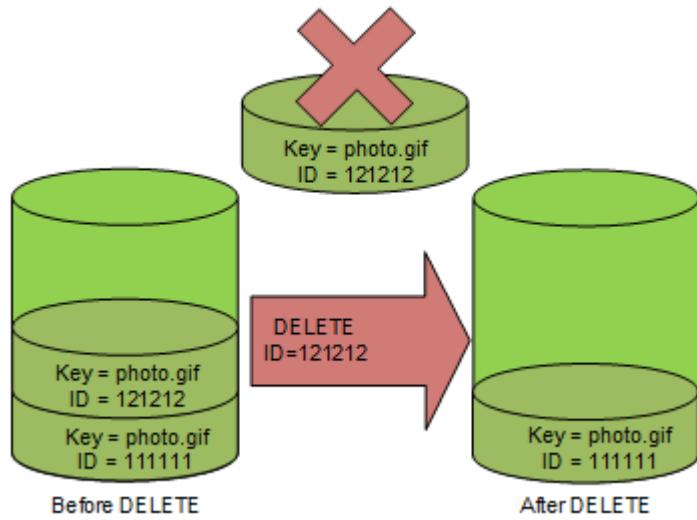

When you try to GET an object whose current version is a delete marker, Amazon S3 behaves as though the object has been deleted (even though it has not been erased) and returns a 404 error. For more information, see [Working with delete markers](#).

The following figure shows that a simple DELETE does not actually remove the specified object. Instead, Amazon S3 inserts a delete marker.

- To delete versioned objects permanently, you must use `DELETE Object versionId`.

The following figure shows that deleting a specified object version permanently removes that object.

To delete object versions

You can delete object versions in Amazon S3 using the console, AWS SDKs, the REST API, or the AWS Command Line Interface.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to permanently delete.
6. Choose **Delete**.
7. In **Permanently delete objects?**, enter **permanently delete**.

⚠ Warning

When you permanently delete an object version, the action cannot be undone.

8. Choose **Delete objects**.

Amazon S3 deletes the object version.

Using the AWS SDKs

For examples of deleting objects using the AWS SDKs for Java, .NET, and PHP, see [Deleting Amazon S3 objects](#). The examples for deleting objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Python

The following Python code example permanently deletes a versioned object by deleting all of its versions.

```
def permanently_delete_object(bucket, object_key):
    """
    Permanently deletes a versioned object by deleting all of its versions.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket: The bucket that contains the object.
    :param object_key: The object to delete.
    """
    try:
        bucket.object_versions.filter(Prefix=object_key).delete()
        logger.info("Permanently deleted all versions of object %s.", object_key)
    except ClientError:
        logger.exception("Couldn't delete all versions of %s.", object_key)
        raise
```

Using the REST API

To delete a specific version of an object

- In a DELETE, specify a version ID.

Example — Deleting a specific version

The following example deletes version UIORUnfnd89493jJFJ of photo.gif.

```
DELETE /photo.gif?versionId=UIORUnfnd89493jJFJ HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:xQE0diMbLRepdf3YB+FIEXAMPLE=
Content-Type: text/plain
Content-Length: 0
```

Using the AWS CLI

The following command deletes an object named test.txt from a bucket named *amzn-s3-demo-bucket1*. To remove a specific version of an object, you must be the bucket owner and you must use the version Id subresource.

```
aws s3api delete-object --bucket amzn-s3-demo-bucket1 --key test.txt --version-id versionID
```

For more information about `delete-object` see [delete-object](#) in the *AWS CLI Command Reference*.

For more information about deleting object versions, see the following topics:

- [Working with delete markers](#)
- [Removing delete markers to make an older version current](#)
- [Deleting an object from an MFA delete-enabled bucket](#)

Working with delete markers

A *delete marker* in Amazon S3 is a placeholder (or marker) for a versioned object that was specified in a simple DELETE request. A simple DELETE request is a request that doesn't specify a version ID. Because the object is in a versioning-enabled bucket, the object is not deleted. But the delete marker makes Amazon S3 behave as if the object is deleted. You can use an Amazon S3 API DELETE call on a delete marker. To do this, you must make the DELETE request by using an AWS Identity and Access Management (IAM) user or role with the appropriate permissions.

A delete marker has a *key name* (or *key*) and version ID like any other object. However, a delete marker differs from other objects in the following ways:

- A delete marker doesn't have data associated with it.
- A delete marker isn't associated with an access control list (ACL) value.
- If you issue a GET request for a delete marker, the GET request doesn't retrieve anything because a delete marker has no data. Specifically, when your GET request doesn't specify a `versionId`, you get a 404 (Not Found) error.

Delete markers accrue a minimal charge for storage in Amazon S3. The storage size of a delete marker is equal to the size of the key name of the delete marker. A key name is a sequence of Unicode characters. The UTF-8 encoding for the key name adds 1-4 bytes of storage to your bucket for each character in the name. Delete markers are stored in the S3 Standard storage class.

If you want to find out how many delete markers you have and what storage class they're stored in, you can use Amazon S3 Storage Lens. For more information, see [Monitoring your storage activity and usage with Amazon S3 Storage Lens](#) and [Amazon S3 Storage Lens metrics glossary](#).

For more information about key names, see [Naming Amazon S3 objects](#). For information about deleting a delete marker, see [Managing delete markers](#).

Only Amazon S3 can create a delete marker, and it does so whenever you send a `DeleteObject` request on an object in a versioning-enabled or suspended bucket. The object specified in the `DELETE` request is not actually deleted. Instead, the delete marker becomes the current version of the object. The object's key name (or key) becomes the key of the delete marker.

When you get an object without specifying a `versionId` in your request, if its current version is a delete marker, Amazon S3 responds with the following:

- A 404 (Not Found) error
- A response header, `x-amz-delete-marker: true`

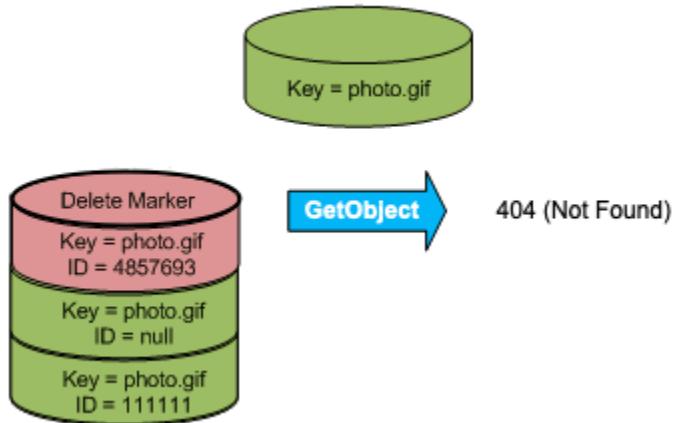

When you get an object by specifying a `versionId` in your request, if the specified version is a delete marker, Amazon S3 responds with the following:

- A 405 (Method Not Allowed) error
- A response header, `x-amz-delete-marker: true`
- A response header, `Last-Modified: timestamp` (only when using the [HeadObject](#) or [GetObject](#) API operations)

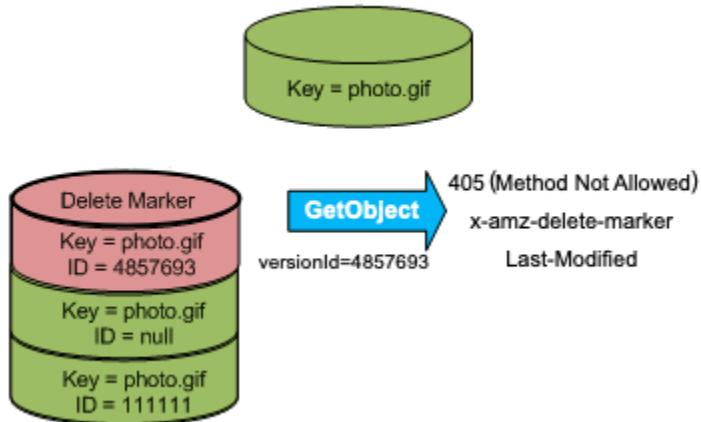

The `x-amz-delete-marker: true` response header tells you that the object accessed was a delete marker. This response header never returns false, because when the value is false, the current or specified version of the object is not a delete marker.

The `Last-Modified` response header provides the creation time of the delete markers.

The following figure shows how a `GetObject` API call on an object whose current version is a delete marker responds with a 404 (Not Found) error and the response header includes `x-amz-delete-marker: true`.

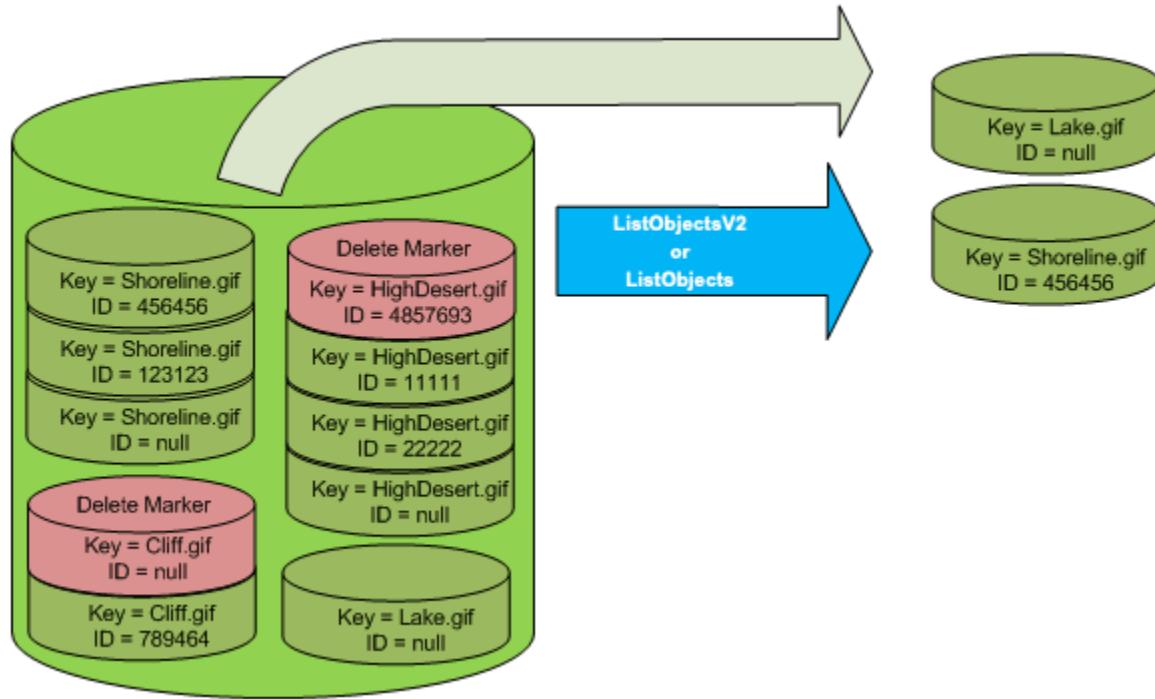

If you make a `GetObject` call on an object by specifying a `versionId` in your request, and if the specified version is a delete marker, Amazon S3 responds with a 405 (Method Not Allowed) error and the response headers include `x-amz-delete-marker: true` and `Last-Modified: timestamp`.

Even if overwritten, delete markers remain in your object versions. The only way to list delete markers (and other versions of an object) is by using a [ListObjectVersions](#) request. You can make this request in the AWS Management Console by listing your objects in an general purpose bucket

and selecting **Show versions**. For more information, see [Listing objects in a versioning-enabled bucket](#).

The following figure shows that a [ListObjectsV2](#) or [ListObjects](#) request doesn't return objects whose current version is a delete marker.

Managing delete markers

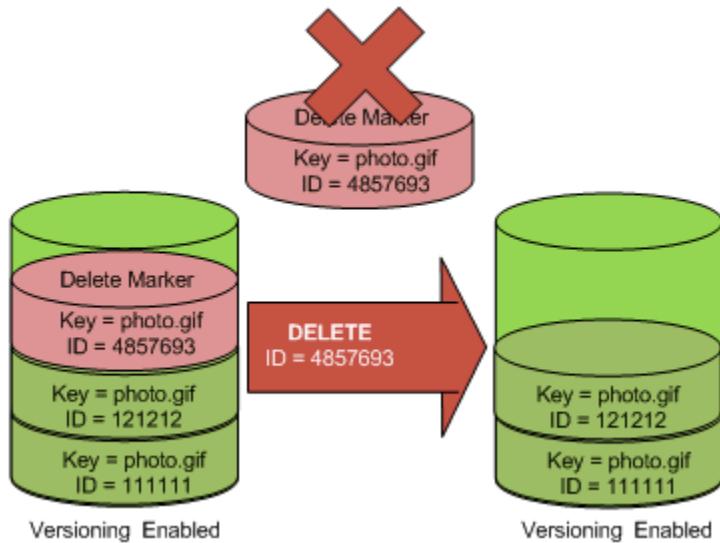

Configuring lifecycle to clean up expired delete markers automatically

An expired object delete marker is one where all object versions are deleted and only a single delete marker remains. If the lifecycle configuration is set to delete current versions, or the `ExpiredObjectDeleteMarker` action is explicitly set, Amazon S3 removes the expired object's delete marker. For an example, see [Removing expired object delete markers in a versioning-enabled bucket](#).

Removing delete markers to make an older version current

When you delete an object in a versioning-enabled bucket, all versions remain in the bucket, and Amazon S3 creates a delete marker for the object. To undelete the object, you must delete this delete marker. For more information about versioning and delete markers, see [Retaining multiple versions of objects with S3 Versioning](#).

To delete a delete marker permanently, you must include its version ID in a `DeleteObject` `versionId` request. The following figure shows how a `DeleteObject` `versionId` request permanently removes a delete marker.

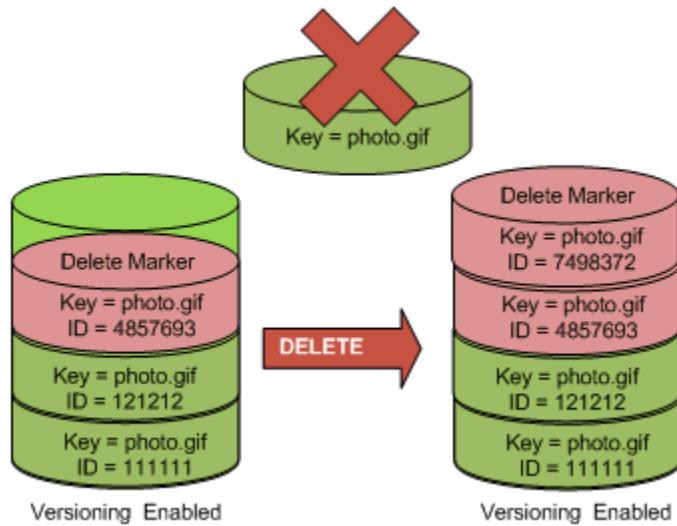

The effect of removing the delete marker is that a simple GET request will now retrieve the current version ID (121212) of the object.

Note

If you use a `DeleteObject` request where the current version is a delete marker (without specifying the version ID of the delete marker), Amazon S3 does not delete the delete marker, but instead PUTs another delete marker.

To delete a delete marker with a NULL version ID, you must pass the NULL as the version ID in the `DeleteObject` request. The following figure shows how a simple `DeleteObject` request made without a version ID where the current version is a delete marker, removes nothing, but instead adds an additional delete marker with a unique version ID (7498372).

Using the S3 console

Use the following steps to recover deleted objects that are not folders from your S3 bucket, including objects that are within those folders.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. To see a list of the **versions** of the objects in the bucket, choose the **List versions** switch. You'll be able to see the delete markers for deleted objects.
4. To undelete an object, you must delete the delete marker. Select the check box next to the **delete marker** of the object to recover, and then choose **Delete**.
5. Confirm the deletion on the **Delete objects** page.
 - a. For **Permanently delete objects?** enter **permanently delete**.
 - b. Choose **Delete objects**.

Note

You can't use the Amazon S3 console to undelete folders. You must use the AWS CLI or SDK. For examples, see [How can I retrieve an Amazon S3 object that was deleted in a versioning-enabled bucket?](#) in the AWS Knowledge Center.

Using the REST API

To permanently remove a delete marker

1. Set `versionId` to the ID of the version to the delete marker you want to remove.
2. Send a `DELETE Object versionId` request.

Example — Removing a delete marker

The following example removes the delete marker for `photo.gif` version 4857693.

```
DELETE /photo.gif?versionId=4857693 HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

When you delete a delete marker, Amazon S3 includes the following in the response.

```
204 NoContent
x-amz-version-id: versionID
x-amz-delete-marker: true
```

Using the AWS SDKs

For information about using other AWS SDKs, see the [AWSDeveloper Center](#).

Python

The following Python code example demonstrates how to remove a delete marker from an object and thus makes the most recent non-current version, the current version of the object.

```
def revive_object(bucket, object_key):
    """
    Revives a versioned object that was deleted by removing the object's active
    delete marker.

    A versioned object presents as deleted when its latest version is a delete
    marker.

    By removing the delete marker, we make the previous version the latest version
    and the object then presents as *not* deleted.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

```

```
:param bucket: The bucket that contains the object.
:param object_key: The object to revive.
"""
# Get the latest version for the object.
response = s3.meta.client.list_object_versions(
    Bucket=bucket.name, Prefix=object_key, MaxKeys=1
)

if "DeleteMarkers" in response:
    latest_version = response["DeleteMarkers"][0]
    if latest_version["IsLatest"]:
        logger.info(
            "Object %s was indeed deleted on %s. Let's revive it.",
            object_key,
            latest_version["LastModified"],
        )
        obj = bucket.Object(object_key)
        obj.Version(latest_version["VersionId"]).delete()
        logger.info(
            "Revived %s, active version is now %s with body '%s'",
            object_key,
            obj.version_id,
            obj.get()["Body"].read(),
        )
    else:
        logger.warning(
            "Delete marker is not the latest version for %s!", object_key
        )
elif "Versions" in response:
    logger.warning("Got an active version for %s, nothing to do.", object_key)
else:
    logger.error("Couldn't get any version info for %s.", object_key)
```

Deleting an object from an MFA delete-enabled bucket

When you configure MFA delete, only the root user can permanently delete object versions or change the versioning configuration on your S3 bucket. You must use an MFA device to authenticate the root user to perform the delete action.

If a bucket's versioning configuration is MFA delete enabled, the bucket owner must include the `x-amz-mfa` request header in requests to permanently delete an object version or change the versioning state of the bucket. Requests that include `x-amz-mfa` must use HTTPS.

The header's value is the concatenation of your authentication device's serial number, a space, and the authentication code displayed on it. If you don't include this request header, the request fails.

When using the AWS CLI include the same information as the value of the `mfa` parameter.

For more information about authentication devices, see [Multi-factor Authentication](#).

For more information about enabling MFA delete, see [Configuring MFA delete](#).

Note

Deleting an object in a versioning-enabled bucket that is MFA delete enabled is not available through the AWS Management Console.

Using the AWS CLI

To delete an object in a versioning-enabled bucket that is MFA delete enabled, use the following command. When you use the following example command, replace the *user input placeholders* with your own information.

```
aws s3api delete-object --bucket amzn-s3-demo-bucket --key OBJECT-KEY --version-id "VERSION ID" --mfa "MFA_DEVICE_SERIAL_NUMBER MFA_DEVICE_CODE"
```

Using the REST API

The following example deletes `my-image.jpg` (with the specified version), which is in a bucket configured with MFA delete enabled.

For more information, see [DeleteObject](#) in the Amazon Simple Storage Service API Reference

```
DELETE /my-image.jpg?versionId=3HL4kqCxf3vjVBH40Nrjfkd HTTPS/1.1
Host: bucketName.s3.amazonaws.com
x-amz-mfa: 20899872 301749
Date: Wed, 28 Oct 2009 22:32:00 GMT
```

Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=

Configuring versioned object permissions

Permissions for objects in Amazon S3 are set at the version level. Each version has its own object owner. The AWS account that creates the object version is the owner. So, you can set different permissions for different versions of the same object. To do so, you must specify the version ID of the object whose permissions you want to set in a `PUT Object versionId acl` request. For a detailed description and instructions on using ACLs, see [Identity and Access Management for Amazon S3](#).
