What is Amazon S3?

Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance. Customers of all sizes and industries can use Amazon S3 to store and protect any amount of data for a range of use cases, such as data lakes, websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. Amazon S3 provides management features so that you can optimize, organize, and configure access to your data to meet your specific business, organizational, and compliance requirements.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Features of Amazon S3

Storage classes

Amazon S3 offers a range of storage classes designed for different use cases. For example, you can store mission-critical production data in S3 Standard or S3 Express One Zone for frequent access, save costs by storing infrequently accessed data in S3 Standard-IA or S3 One Zone-IA, and archive data at the lowest costs in S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive.

Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud object storage class available today, with data access speeds up to 10x faster and with request costs 50 percent lower than S3 Standard. S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed. Additionally, to further increase access speed and support hundreds of thousands of requests per second, data is stored in a new bucket type: an Amazon S3 directory bucket. For more information, see [S3 Express One Zone](#) and [Working with directory buckets](#).

You can store data with changing or unknown access patterns in S3 Intelligent-Tiering, which optimizes storage costs by automatically moving your data between four access tiers when your access patterns change. These four access tiers include two low-latency access tiers optimized for frequent and infrequent access, and two opt-in archive access tiers designed for asynchronous access for rarely accessed data.

For more information, see [Understanding and managing Amazon S3 storage classes](#).

Storage management

Amazon S3 has storage management features that you can use to manage costs, meet regulatory requirements, reduce latency, and save multiple distinct copies of your data for compliance requirements.

- [S3 Lifecycle](#) – Configure a lifecycle configuration to manage your objects and store them cost effectively throughout their lifecycle. You can transition objects to other S3 storage classes or expire objects that reach the end of their lifetimes.
- [S3 Object Lock](#) – Prevent Amazon S3 objects from being deleted or overwritten for a fixed amount of time or indefinitely. You can use Object Lock to help meet regulatory requirements that require *write-once-read-many (WORM)* storage or to simply add another layer of protection against object changes and deletions.
- [S3 Replication](#) – Replicate objects and their respective metadata and object tags to one or more destination buckets in the same or different AWS Regions for reduced latency, compliance, security, and other use cases.
- [S3 Batch Operations](#) – Manage billions of objects at scale with a single S3 API request or a few clicks in the Amazon S3 console. You can use Batch Operations to perform operations such as **Copy**, **Invoke AWS Lambda function**, and **Restore** on millions or billions of objects.

Access management and security

Amazon S3 provides features for auditing and managing access to your buckets and objects. By default, S3 buckets and the objects in them are private. You have access only to the S3 resources that you create. To grant granular resource permissions that support your specific use case or to audit the permissions of your Amazon S3 resources, you can use the following features.

- [**S3 Block Public Access**](#) – Block public access to S3 buckets and objects. By default, Block Public Access settings are turned on at the bucket level. We recommend that you keep all Block Public Access settings enabled unless you know that you need to turn off one or more of them for your specific use case. For more information, see [Configuring block public access settings for your S3 buckets](#).
- [**AWS Identity and Access Management \(IAM\)**](#) – IAM is a web service that helps you securely control access to AWS resources, including your Amazon S3 resources. With IAM, you can centrally manage permissions that control which AWS resources users can access. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- [**Bucket policies**](#) – Use IAM-based policy language to configure resource-based permissions for your S3 buckets and the objects in them.
- [**Amazon S3 access points**](#) – Configure named network endpoints with dedicated access policies to manage data access at scale for shared datasets in Amazon S3.
- [**Access control lists \(ACLs\)**](#) – Grant read and write permissions for individual buckets and objects to authorized users. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM user policies for access control instead of ACLs. Policies are a simplified and more flexible access control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources. For more information about the specific cases when you'd use ACLs instead of resource-based policies or IAM user policies, see [Managing access with ACLs](#).
- [**S3 Object Ownership**](#) – Take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable or enable ACLs. By default, ACLs are disabled. With ACLs disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively by using access-management policies.
- [**IAM Access Analyzer for S3**](#) – Evaluate and monitor your S3 bucket access policies, ensuring that the policies provide only the intended access to your S3 resources.

Data processing

To transform data and trigger workflows to automate a variety of other processing activities at scale, you can use the following features.

- [S3 Object Lambda](#) – Add your own code to S3 GET, HEAD, and LIST requests to modify and process data as it is returned to an application. Filter rows, dynamically resize images, redact confidential data, and much more.
- [Event notifications](#) – Trigger workflows that use Amazon Simple Notification Service (Amazon SNS), Amazon Simple Queue Service (Amazon SQS), and AWS Lambda when a change is made to your S3 resources.

Storage logging and monitoring

Amazon S3 provides logging and monitoring tools that you can use to monitor and control how your Amazon S3 resources are being used. For more information, see [Monitoring tools](#).

Automated monitoring tools

- [Amazon CloudWatch metrics for Amazon S3](#) – Track the operational health of your S3 resources and configure billing alerts when estimated charges reach a user-defined threshold.
- [AWS CloudTrail](#) – Record actions taken by a user, a role, or an AWS service in Amazon S3. CloudTrail logs provide you with detailed API tracking for S3 bucket-level and object-level operations.

Manual monitoring tools

- [Server access logging](#) – Get detailed records for the requests that are made to a bucket. You can use server access logs for many use cases, such as conducting security and access audits, learning about your customer base, and understanding your Amazon S3 bill.
- [AWS Trusted Advisor](#) – Evaluate your account by using AWS best practice checks to identify ways to optimize your AWS infrastructure, improve security and performance, reduce costs, and monitor service quotas. You can then follow the recommendations to optimize your services and resources.

Analytics and insights

Amazon S3 offers features to help you gain visibility into your storage usage, which empowers you to better understand, analyze, and optimize your storage at scale.

- [Amazon S3 Storage Lens](#) – Understand, analyze, and optimize your storage. S3 Storage Lens provides 60+ usage and activity metrics and interactive dashboards to aggregate data for your entire organization, specific accounts, AWS Regions, buckets, or prefixes.
- [Storage Class Analysis](#) – Analyze storage access patterns to decide when it's time to move data to a more cost-effective storage class.
- [S3 Inventory with Inventory reports](#) – Audit and report on objects and their corresponding metadata and configure other Amazon S3 features to take action in Inventory reports. For example, you can report on the replication and encryption status of your objects. For a list of all the metadata available for each object in Inventory reports, see [Amazon S3 Inventory list](#).

Strong consistency

Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your Amazon S3 bucket in all AWS Regions. This behavior applies to both writes of new objects as well as PUT requests that overwrite existing objects and DELETE requests. In addition, read operations on Amazon S3 Select, Amazon S3 access control lists (ACLs), Amazon S3 Object Tags, and object metadata (for example, the HEAD object) are strongly consistent. For more information, see [Amazon S3 data consistency model](#).

How Amazon S3 works

Amazon S3 is an object storage service that stores data as objects, hierarchical data, or tabular data within buckets. An *object* is a file and any metadata that describes the file. A *bucket* is a container for objects.

To store your data in Amazon S3, you first create a bucket and specify a bucket name and AWS Region. Then, you upload your data to that bucket as objects in Amazon S3. Each object has a *key* (or *key name*), which is the unique identifier for the object within the bucket.

S3 provides features that you can configure to support your specific use case. For example, you can use S3 Versioning to keep multiple versions of an object in the same bucket, which allows you to restore objects that are accidentally deleted or overwritten.

Buckets and the objects in them are private and can be accessed only if you explicitly grant access permissions. You can use bucket policies, AWS Identity and Access Management (IAM) policies, access control lists (ACLs), and S3 Access Points to manage access.

Buckets

Amazon S3 supports four types of buckets—general purpose buckets, directory buckets, table buckets, and vector buckets. Each type of bucket provides a unique set of features for different use cases.

General purpose buckets – General purpose buckets are recommended for most use cases and access patterns and are the original S3 bucket type. A general purpose bucket is a container for objects stored in Amazon S3, and you can store any number of objects in a bucket and across all storage classes (except for S3 Express One Zone), so you can redundantly store objects across multiple Availability Zones. For more information, see [Creating, configuring, and working with Amazon S3 general purpose buckets](#).

 **Note**

By default, all general purpose buckets are private. However, you can grant public access to general purpose buckets. You can control access to general purpose buckets at the bucket, prefix (folder), or object tag level. For more information, see [Access control in Amazon S3](#).

Directory buckets – Recommended for low-latency use cases and data-residency use cases. By default, you can create up to 100 directory buckets in your AWS account, with no limit on the number of objects that you can store in a directory bucket. Directory buckets organize objects into hierarchical directories (prefixes) instead of the flat storage structure of general purpose buckets. This bucket type has no prefix limits and individual directories can scale horizontally. For more information, see [Working with directory buckets](#).

- For low-latency use cases, you can create a directory bucket in a single AWS Availability Zone to store data. Directory buckets in Availability Zones support the S3 Express One Zone storage class. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. The S3 Express One Zone storage class is recommended if your application is performance sensitive and benefits from single-digit millisecond PUT and GET latencies. To learn more about creating directory buckets in Availability Zones, see [High performance workloads](#).
- For data-residency use cases, you can create a directory bucket in a single AWS Dedicated Local Zone (DLZ) to store data. In Dedicated Local Zones, you can create S3 directory buckets to store data in a specific data perimeter, which helps support your data residency and isolation use cases. Directory buckets in Local Zones support the S3 One Zone-Infrequent Access (S3 One Zone-IA; Z-IA) storage class. To learn more about creating directory buckets in Local Zones, see [Data residency workloads](#).

 **Note**

Directory buckets have all public access disabled by default. This behavior can't be changed. You can't grant access to objects stored in directory buckets. You can grant access only to your directory buckets. For more information, see [Authenticating and authorizing requests](#).

Table buckets – Recommended for storing tabular data, such as daily purchase transactions, streaming sensor data, or ad impressions. Tabular data represents data in columns and rows, like in a database table. Table buckets provide S3 storage that's optimized for analytics and machine learning workloads, with features designed to continuously improve query performance and reduce storage costs for tables. S3 Tables are purpose-built for storing tabular data in the Apache Iceberg format. You can query tabular data in S3 Tables with popular query engines, including Amazon Athena, Amazon Redshift, and Apache Spark. By default, you can create up to 10 table buckets per

AWS account per AWS Region and up to 10,000 tables per table bucket. For more information, see [Working with S3 Tables and table buckets](#).

 **Note**

All table buckets and tables are private and can't be made public. These resources can only be accessed by users who are explicitly granted access. To grant access, you can use IAM resource-based policies for table buckets and tables, and IAM identity-based policies for users and roles. For more information, see [Security for S3 Tables](#).

Vector buckets – S3 vector buckets are a type of Amazon S3 bucket that are purpose-built to store and query vectors. Vector buckets use dedicated API operations to write and query vector data efficiently. With S3 vector buckets, you can store vector embeddings for machine learning models, perform similarity searches, and integrate with services like Amazon Bedrock and Amazon OpenSearch.

S3 vector buckets organize data using vector indexes, which are resources within a bucket that store and organize vector data for efficient similarity search. Each vector index can be configured with specific dimensions, distance metrics (like cosine similarity), and metadata configurations to optimize for your specific use case. For more information, see [Working with S3 Vectors and vector buckets](#).

Additional information about all bucket types

When you create a bucket, you enter a bucket name and choose the AWS Region where the bucket will reside. After you create a bucket, you cannot change the name of the bucket or its Region. Bucket names must follow the following bucket naming rules:

- [General purpose bucket naming rules](#)
- [Directory bucket naming rules](#)
- [Table bucket naming rules](#)

Buckets also:

- Organize the Amazon S3 namespace at the highest level. For general purpose buckets, this namespace is S3. For directory buckets, this namespace is s3express. For table buckets, this namespace is s3tables.

- Identify the account responsible for storage and data transfer charges.
- Serve as the unit of aggregation for usage reporting.

Objects

Objects are the fundamental entities stored in Amazon S3. Objects consist of object data and metadata. The metadata is a set of name-value pairs that describe the object. These pairs include some default metadata, such as the date last modified, and standard HTTP metadata, such as Content-Type. You can also specify custom metadata at the time that the object is stored.

Every object is contained in a bucket. For example, if the object named photos/puppy.jpg is stored in the amzn-s3-demo-bucket general purpose bucket in the US West (Oregon) Region, then it is addressable by using the URL <https://amzn-s3-demo-bucket.s3.us-west-2.amazonaws.com/photos/puppy.jpg>. For more information, see [Accessing a Bucket](#).

An object is uniquely identified within a bucket by a [key \(name\)](#) and a [version ID](#) (if S3 Versioning is enabled on the bucket). For more information about objects, see [Amazon S3 objects overview](#).

Keys

An *object key* (or *key name*) is the unique identifier for an object within a bucket. Every object in a bucket has exactly one key. The combination of a bucket, object key, and optionally, version ID (if S3 Versioning is enabled for the bucket) uniquely identify each object. So you can think of Amazon S3 as a basic data map between "bucket + key + version" and the object itself.

Every object in Amazon S3 can be uniquely addressed through the combination of the web service endpoint, bucket name, key, and optionally, a version. For example, in the URL <https://amzn-s3-demo-bucket.s3.us-west-2.amazonaws.com/photos/puppy.jpg>, *amzn-s3-demo-bucket* is the name of the bucket and *photos/puppy.jpg* is the key.

For more information about object keys, see [Naming Amazon S3 objects](#).

S3 Versioning

You can use S3 Versioning to keep multiple variants of an object in the same bucket. With S3 Versioning, you can preserve, retrieve, and restore every version of every object stored in your buckets. You can easily recover from both unintended user actions and application failures.

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Version ID

When you enable S3 Versioning in a bucket, Amazon S3 generates a unique version ID for each object added to the bucket. Objects that already existed in the bucket at the time that you enable versioning have a version ID of null. If you modify these (or any other) objects with other operations, such as [CopyObject](#) and [PutObject](#), the new objects get a unique version ID.

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Bucket policy

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size.

Bucket policies use JSON-based access policy language that is standard across AWS. You can use bucket policies to add or deny permissions for the objects in a bucket. Bucket policies allow or deny requests based on the elements in the policy, including the requester, S3 actions, resources, and aspects or conditions of the request (for example, the IP address used to make the request). For example, you can create a bucket policy that grants cross-account permissions to upload objects to an S3 bucket while ensuring that the bucket owner has full control of the uploaded objects. For more information, see [Examples of Amazon S3 bucket policies](#).

In your bucket policy, you can use wildcard characters on Amazon Resource Names (ARNs) and other values to grant permissions to a subset of objects. For example, you can control access to groups of objects that begin with a common [prefix](#) or end with a given extension, such as .html.

S3 access points

Amazon S3 access points are named network endpoints with dedicated access policies that describe how data can be accessed using that endpoint. Access points are attached to an underlying data source, such as a general purpose bucket, directory bucket, or a FSx for OpenZFS volume, that you can use to perform S3 object operations, such as GetObject and PutObject. Access points simplify managing data access at scale for shared datasets in Amazon S3.

Each access point has its own access point policy. You can configure [Block Public Access](#) settings for each access point attached to a bucket. To restrict Amazon S3 data access to a private network, you can also configure any access point to accept requests only from a virtual private cloud (VPC).

For more information about access points for general purpose buckets, see [Managing access to shared datasets with access points](#). For more information about access points for directory buckets, see [Managing access to shared datasets in directory buckets with access points](#).

Access control lists (ACLs)

You can use ACLs to grant read and write permissions to authorized users for individual general purpose buckets and objects. Each general purpose bucket and object has an ACL attached to it as a subresource. The ACL defines which AWS accounts or groups are granted access and the type of access. ACLs are an access control mechanism that predates IAM. For more information about ACLs, see [Access control list \(ACL\) overview](#).

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Regions

You can choose the geographical AWS Region where Amazon S3 stores the buckets that you create. You might choose a Region to optimize latency, minimize costs, or address regulatory requirements. Objects stored in an AWS Region never leave the Region unless you explicitly transfer or replicate them to another Region. For example, objects stored in the Europe (Ireland) Region never leave it.

Note

You can access Amazon S3 and its features only in the AWS Regions that are enabled for your account. For more information about enabling a Region to create and manage AWS resources, see [Managing AWS Regions](#) in the *AWS General Reference*.

For a list of Amazon S3 Regions and endpoints, see [Regions and endpoints](#) in the *AWS General Reference*.

Amazon S3 data consistency model

Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your Amazon S3 bucket in all AWS Regions. This behavior applies to both writes to new objects as well as PUT requests that overwrite existing objects and DELETE requests. In addition, read operations on Amazon S3 Select, Amazon S3 access controls lists (ACLs), Amazon S3 Object Tags, and object metadata (for example, the HEAD object) are strongly consistent.

Updates to a single key are atomic. For example, if you make a PUT request to an existing key from one thread and perform a GET request on the same key from a second thread concurrently, you will get either the old data or the new data, but never partial or corrupt data.

Amazon S3 achieves high availability by replicating data across multiple servers within AWS data centers. If a PUT request is successful, your data is safely stored. Any read (GET or LIST request) that is initiated following the receipt of a successful PUT response will return the data written by the PUT request. Here are examples of this behavior:

- A process writes a new object to Amazon S3 and immediately lists keys within its bucket. The new object appears in the list.
- A process replaces an existing object and immediately tries to read it. Amazon S3 returns the new data.
- A process deletes an existing object and immediately tries to read it. Amazon S3 does not return any data because the object has been deleted.
- A process deletes an existing object and immediately lists keys within its bucket. The object does not appear in the listing.

Note

- Amazon S3 does not support object locking for concurrent writers. If two PUT requests are simultaneously made to the same key, the request with the latest timestamp wins. If this is an issue, you must build an object-locking mechanism into your application.

- Updates are key-based. There is no way to make atomic updates across keys. For example, you cannot make the update of one key dependent on the update of another key unless you design this functionality into your application.

Bucket configurations have an eventual consistency model. Specifically, this means that:

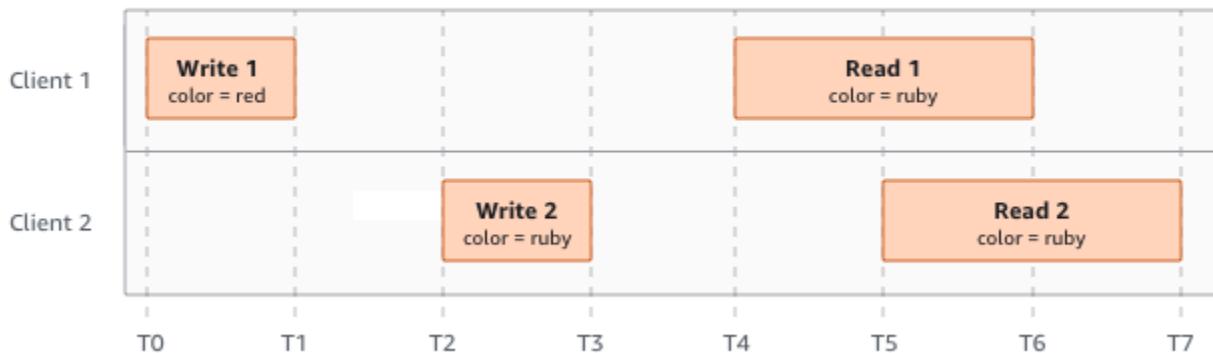

- If you delete a bucket and immediately list all buckets, the deleted bucket might still appear in the list.
- If you enable versioning on a bucket for the first time, it might take a short amount of time for the change to be fully propagated. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (PUT or DELETE requests) on objects in the bucket.

Concurrent applications

This section provides examples of behavior to be expected from Amazon S3 when multiple clients are writing to the same items.

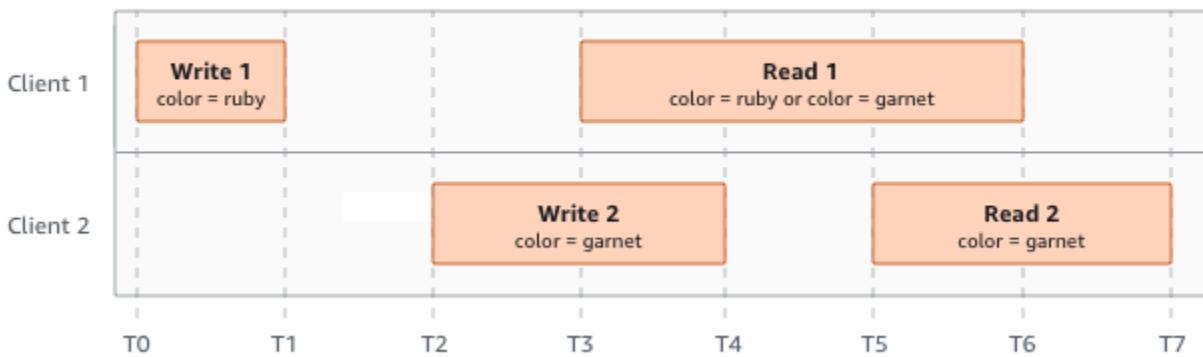

In this example, both W1 (write 1) and W2 (write 2) finish before the start of R1 (read 1) and R2 (read 2). Because S3 is strongly consistent, R1 and R2 both return `color = ruby`.

Domain = MyDomain, Item = StandardFez

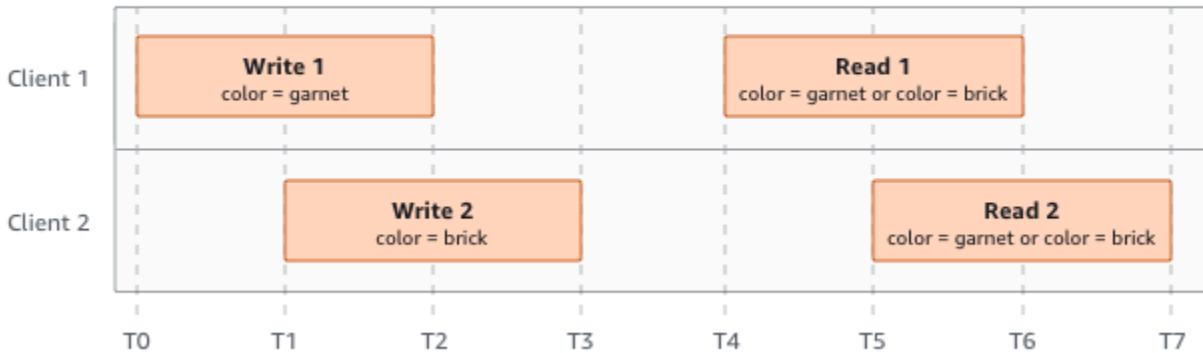

In the next example, W2 does not finish before the start of R1. Therefore, R1 might return `color = ruby` or `color = garnet`. However, because W1 and W2 finish before the start of R2, R2 returns `color = garnet`.

Domain = MyDomain, Item = StandardFez

In the last example, W2 begins before W1 has received an acknowledgment. Therefore, these writes are considered concurrent. Amazon S3 internally uses last-writer-wins semantics to determine which write takes precedence. However, the order in which Amazon S3 receives the requests and the order in which applications receive acknowledgments cannot be predicted because of various factors, such as network latency. For example, W2 might be initiated by an Amazon EC2 instance in the same Region, while W1 might be initiated by a host that is farther away. The best way to determine the final value is to perform a read after both writes have been acknowledged.

Domain = MyDomain, Item = StandardFez

Related services

After you load your data into Amazon S3, you can use it with other AWS services. The following are the services that you might use most frequently:

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) – Provides secure and scalable computing capacity in the AWS Cloud. Using Amazon EC2 eliminates your need to invest in hardware

upfront, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.

- **[Amazon EMR](#)** – Helps businesses, researchers, data analysts, and developers easily and cost-effectively process vast amounts of data. Amazon EMR uses a hosted Hadoop framework running on the web-scale infrastructure of Amazon EC2 and Amazon S3.
- **[AWS Snow Family](#)** – Helps customers that need to run operations in austere, non-data center environments, and in locations where there's a lack of consistent network connectivity. You can use AWS Snow Family devices to locally and cost-effectively access the storage and compute power of the AWS Cloud in places where an internet connection might not be an option.
- **[AWS Transfer Family](#)** – Provides fully managed support for file transfers directly into and out of Amazon S3 or Amazon Elastic File System (Amazon EFS) using Secure Shell (SSH) File Transfer Protocol (SFTP), File Transfer Protocol over SSL (FTPS), and File Transfer Protocol (FTP).

Accessing Amazon S3

You can work with Amazon S3 in any of the following ways:

AWS Management Console

The console is a web-based user interface for managing Amazon S3 and AWS resources. If you've signed up for an AWS account, you can access the Amazon S3 console by signing into the AWS Management Console and choosing **S3** from the AWS Management Console home page.

AWS Command Line Interface

You can use the AWS command line tools to issue commands or build scripts at your system's command line to perform AWS (including S3) tasks.

The [AWS Command Line Interface \(AWS CLI\)](#) provides commands for a broad set of AWS services. The AWS CLI is supported on Windows, macOS, and Linux. To get started, see the [AWS Command Line Interface User Guide](#). For more information about the commands for Amazon S3, see [s3api](#) and [s3control](#) in the [AWS CLI Command Reference](#).

AWS SDKs

AWS provides SDKs (software development kits) that consist of libraries and sample code for various programming languages and platforms (Java, Python, Ruby, .NET, iOS, Android, and so on).

The AWS SDKs provide a convenient way to create programmatic access to S3 and AWS. Amazon S3 is a REST service. You can send requests to Amazon S3 using the AWS SDK libraries, which wrap the underlying Amazon S3 REST API and simplify your programming tasks. For example, the SDKs take care of tasks such as calculating signatures, cryptographically signing requests, managing errors, and retrying requests automatically. For information about the AWS SDKs, including how to download and install them, see [Tools for AWS](#).

Every interaction with Amazon S3 is either authenticated or anonymous. If you are using the AWS SDKs, the libraries compute the signature for authentication from the keys that you provide. For more information about how to make requests to Amazon S3, see [Making requests](#).

Amazon S3 REST API

The architecture of Amazon S3 is designed to be programming language-neutral, using AWS-supported interfaces to store and retrieve objects. You can access S3 and AWS programmatically by using the Amazon S3 REST API. The REST API is an HTTP interface to Amazon S3. With the REST API, you use standard HTTP requests to create, fetch, and delete buckets and objects.

To use the REST API, you can use any toolkit that supports HTTP. You can even use a browser to fetch objects, as long as they are anonymously readable.

The REST API uses standard HTTP headers and status codes, so that standard browsers and toolkits work as expected. In some areas, we have added functionality to HTTP (for example, we added headers to support access control). In these cases, we have done our best to add the new functionality in a way that matches the style of standard HTTP usage.

If you make direct REST API calls in your application, you must write the code to compute the signature and add it to the request. For more information about how to make requests to Amazon S3, see [Making requests](#) in the *Amazon S3 API Reference*.

Note

SOAP API support over HTTP is deprecated, but it is still available over HTTPS. Newer Amazon S3 features are not supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.

Paying for Amazon S3

Pricing for Amazon S3 is designed so that you don't have to plan for the storage requirements of your application. Most storage providers require you to purchase a predetermined amount of storage and network transfer capacity. In this scenario, if you exceed that capacity, your service is shut off or you are charged high overage fees. If you do not exceed that capacity, you pay as though you used it all.

Amazon S3 charges you only for what you actually use, with no hidden fees and no overage charges. This model gives you a variable-cost service that can grow with your business while giving you the cost advantages of the AWS infrastructure. For more information, see [Amazon S3 Pricing](#).

When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon S3. However, you are charged only for the services that you use. If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see [AWS free tier](#).

To see your bill, go to the Billing and Cost Management Dashboard in the [AWS Billing and Cost Management console](#). To learn more about AWS account billing, see the [AWS Billing User Guide](#). If you have questions concerning AWS billing and AWS accounts, contact [AWS Support](#).

PCI DSS compliance

Amazon S3 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see [PCI DSS Level 1](#).

Amazon S3 Object Lambda availability change

After careful consideration, S3 Object Lambda as of November 7th, 2025 is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners. Existing customers of S3 Object Lambda, as well as customers using or deploying APN partner solutions, can continue to use the service as usual. AWS will prioritize security and availability improvements for S3 Object Lambda, but we do not plan to introduce new capabilities.

There are several alternative services and designs that allow you to modify and process data accessed from S3 to meet the needs of various client applications or users who are accessing the data. Those alternatives include the AWS Solution Dynamic Image Transformation for Amazon CloudFront, invoking AWS Lambda by other means (via CloudFront, API Gateway, or function URLs), or processing data in the client application. All of these alternatives continue to use Amazon S3 for the underlying storage, so no data migration is necessary.

In this post, we discuss how to choose the best option for your use case.

Dynamic Image Transformation for Amazon CloudFront

This AWS solution enables real-time image processing through the global content delivery network (CDN) of Amazon CloudFront using API Gateway and Lambda. It supports a variety of transformations such as format changes, dimensions, fit methods, rotations, and filters. If you are using S3 Object Lambda today for image transformation, this can be a good alternative. The [solution overview](#) has more details on capabilities and how to get started using it. Be sure to modify the Enable S3 Object Lambda template parameter to "No" when deploying the solution to your account.

For more information, see [Dynamic Image Transformation for Amazon CloudFront](#).

Data processing in AWS Lambda

You can continue to use AWS Lambda for your data processing, but invoke it directly or through other AWS services. Your data processing logic can remain the same, but your Lambda function will need to be updated based on how you choose to invoke it. This option is best for use cases such as sensitive data redaction, format changes, or situations where the application that invokes S3 Object Lambda relies on receiving processed data. This option also minimizes the changes required if you choose to migrate off S3 Object Lambda.

If you are using an S3 Object Lambda access point as the origin of a CloudFront distribution, you can create a new origin using either Lambda Function URLs or API Gateway. [This blog](#) details how you can setup a Lambda Function URL to act as an origin for your CloudFront distribution.

If you directly invoke S3 Object Lambda from your client code today, you can use Lambda Function URLs to directly invoke your Lambda function or you can use API Gateway. If you're not sure which is the best method for your use case, see [Select a method to invoke your Lambda function using an HTTP request](#) in the *AWS Lambda Developer Guide*. After you have decided which method for invoking Lambda is best for your use case and have setup your Lambda function accordingly, you will also need to update your calling application to invoke your Lambda function rather than calling S3 Object Lambda.

Data processing in the client application

You also have the option of moving your data processing logic from S3 Object Lambda into your client application. This works best if you are using S3 Object Lambda as part of an application that already performs further processing or analysis of the data returned by S3 Object Lambda. For example, if your S3 Object Lambda access point was responsible for redirecting to particular objects or object versions, that redirect logic can be moved into the calling application which would then directly access data in the S3 bucket.

Getting started with Amazon S3

You can get started with Amazon S3 by working with buckets and objects. A *bucket* is a container for objects. An *object* is a file and any metadata that describes that file.

To store an object in Amazon S3, you create a bucket and then upload the object to the bucket. When the object is in the bucket, you can open it, download it, and move it. When you no longer need an object or a bucket, you can clean up your resources.

With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see [Amazon S3](#). If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see [AWS Free Tier](#).

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Video: Getting started with Amazon S3

Prerequisites

Before you begin, confirm that you've completed the steps in [Setting up Amazon S3](#).

Setting up Amazon S3

When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon S3. You are charged only for the services that you use.

With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see [Amazon S3](#). If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see [AWS Free Tier](#).

To set up Amazon S3, use the steps in the following sections.

When you sign up for AWS and set up Amazon S3, you can optionally change the display language in the AWS Management Console. For more information, see [Changing the language of the AWS Management Console](#) in the *AWS Management Console Getting Started Guide*.

Topics

- [Sign up for an AWS account](#)
- [Create a user with administrative access](#)

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call or text message and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to a user, and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

Create a user with administrative access

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.
For help signing in by using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.
2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

Create a user with administrative access

1. Enable IAM Identity Center.

For instructions, see [Enabling AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to a user.

For a tutorial about using the IAM Identity Center directory as your identity source, see [Configure user access with the default IAM Identity Center directory](#) in the *AWS IAM Identity Center User Guide*.

Sign in as the user with administrative access

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

Assign access to additional users

1. In IAM Identity Center, create a permission set that follows the best practice of applying least-privilege permissions.

For instructions, see [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

2. Assign users to a group, and then assign single sign-on access to the group.

For instructions, see [Add groups](#) in the *AWS IAM Identity Center User Guide*.

Step 1: Create your first S3 bucket

After you sign up for AWS, you're ready to create a bucket in Amazon S3 using the AWS Management Console. Every object in Amazon S3 is stored in a *bucket*. Before you can store data in Amazon S3, you must create a bucket.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Note

You are not charged for creating a bucket. You are charged only for storing objects in the bucket and for transferring objects in and out of the bucket. The charges that you incur through following the examples in this guide are minimal (less than \$1). For more information about storage charges, see [Amazon S3 pricing](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

- After you create a bucket, you can't change its Region.
- To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket.

The bucket name must:

- Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (commercial Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions).
- Be between 3 and 63 characters long.
- Consist only of lowercase letters, numbers, periods (.), and hyphens (-). For best compatibility, we recommend that you avoid using periods (.) in bucket names, except for buckets that are used only for static website hosting.
- Begin and end with a letter or number.
- For a complete list of bucket-naming rules, see [General purpose bucket naming rules](#).

 **Important**

- After you create the bucket, you can't change its name.
- Don't include sensitive information in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

6. (Optional) Under **General configuration**, you can choose to copy an existing bucket's settings to your new bucket. If you don't want to copy the settings of an existing bucket, skip to the next step.

 **Note**

This option:

- Isn't available in the AWS CLI and is only available in the Amazon S3 console
- Doesn't copy the bucket policy from the existing bucket to the new bucket

To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you want to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window reopens.

Under **Copy settings from existing bucket**, you now see the name of the bucket that you selected. The settings of your new bucket now match the settings of the bucket that you selected. If you want to remove the copied settings, choose **Restore defaults**. Review the remaining bucket settings on the **Create bucket** page. If you don't want to make any changes, you can skip to the final step.

7. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the general purpose bucket. ACLs no longer affect access permissions to data in the S3 general purpose bucket. The bucket uses policies exclusively to define access control.

By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you must control access for each object individually. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can [add a bucket policy](#) that allows only object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Note

The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

- Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

 **Note**

To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

- (Optional) By default, **Bucket Versioning** is disabled. Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can recover more easily from both unintended user actions and application failures. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

To enable versioning on your bucket, choose **Enable**.

- (Optional) Under **Tags**, you can choose to add tags to your bucket. With AWS cost allocation, you can use bucket tags to annotate billing for your use of a bucket. A tag is a key-value pair that represents a label that you assign to a bucket. For more information, see [the section called "Using cost allocation tags"](#).

To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

- To configure **Default encryption**, under **Encryption type**, choose one of the following:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)**
- Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
- Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**

 **Important**

If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS.

For more information about AWS KMS quotas and how to request a quota increase, see [Quotas in the AWS Key Management Service Developer Guide](#).

Buckets and new objects are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption configuration. For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about SSE-S3, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

For more information about using server-side encryption to encrypt your data, see [the section called "Data encryption"](#).

12. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**, do the following:

a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys in the AWS Key Management Service Developer Guide](#).

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that isn't listed, you must enter your

KMS key ARN. If you want to use a KMS key that's owned by a different account, you must first have permission to use the key, and then you must enter the KMS key ARN. For more information about cross account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*. For more information about SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#). For more information about DSSE-KMS, see [the section called "Dual-layer server-side encryption \(DSSE-KMS\)"](#). When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

- b. When you configure your bucket to use default encryption with SSE-KMS, you can also use S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#). S3 Bucket Keys aren't supported for DSSE-KMS.

By default, S3 Bucket Keys are enabled in the Amazon S3 console. We recommend leaving S3 Bucket Keys enabled to lower your costs. To disable S3 Bucket Keys for your bucket, under **Bucket Key**, choose **Disable**.

13. (Optional) S3 Object Lock helps protect new objects from being deleted or overwritten. For more information, see [Locking objects with Object Lock](#). If you want to enable S3 Object Lock, do the following:

- a. Choose **Advanced settings**.

 **Important**

Enabling Object Lock automatically enables versioning for the bucket. After you've enabled and successfully created the bucket, you must also configure the Object Lock default retention and legal hold settings on the bucket's **Properties** tab.

- ol style="list-style-type: none;">- b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

Note

To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning`, and `s3:PutBucketObjectLockConfiguration`.

14. Choose **Create bucket.**

You've created a bucket in Amazon S3.

Next step

To add an object to your bucket, see [Step 2: Upload an object to your bucket](#).

Step 2: Upload an object to your bucket

After creating a bucket in Amazon S3, you're ready to upload an object to the bucket. An object can be any kind of file: a text file, a photo, a video, and so on.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

To upload an object to a bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to upload your object to.
3. On the **Objects** tab for your bucket, choose **Upload**.
4. Under **Files and folders**, choose **Add files**.
5. Choose a file to upload, and then choose **Open**.
6. Choose **Upload**.

You've successfully uploaded an object to your bucket.

Next step

To view your object, see [Step 3: Download an object](#).

Step 3: Download an object

After you upload an object to a bucket, you can view information about your object and download the object to your local computer.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Using the S3 console

This section explains how to use the Amazon S3 console to download an object from an S3 bucket.

 **Note**

- You can download only one object at a time.
- If you use the Amazon S3 console to download an object whose key name ends with a period (.), the period is removed from the key name of the downloaded object. To retain the period at the end of the name of the downloaded object, you must use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

To download an object from an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the buckets list, choose the name of the bucket that you want to download an object from.
4. You can download an object from an S3 bucket in any of the following ways:

- Select the check box next to the object, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.
- If you want to download a specific version of the object, turn on **Show versions** (located next to the search box). Select the check box next to the version of the object that you want, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.

You've successfully downloaded your object.

Next step

To copy and paste your object within Amazon S3, see [Step 4: Copy your object to a folder](#).

Step 4: Copy your object to a folder

You've already added an object to a bucket and downloaded the object. Now, you create a folder and copy the object and paste it into the folder.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

To copy an object to a folder

1. In the **Buckets** list, choose your bucket name.
2. Choose **Create folder** and configure a new folder:
 - a. Enter a folder name (for example, favorite-pics).
 - b. For the folder encryption setting, choose **Disable**.
 - c. Choose **Save**.
3. Navigate to the Amazon S3 bucket or folder that contains the objects that you want to copy.
4. Select the check box to the left of the names of the objects that you want to copy.
5. Choose **Actions** and choose **Copy** from the list of options that appears.

Alternatively, choose **Copy** from the options in the upper right.

6. Choose the destination folder:

- a. Choose **Browse S3**.
- b. Choose the option button to the left of the folder name.

To navigate into a folder and choose a subfolder as your destination, choose the folder name.

- c. Choose **Choose destination**.

The path to your destination folder appears in the **Destination** box. In **Destination**, you can alternately enter your destination path, for example, `s3://bucket-name/folder-name/`.

7. In the bottom right, choose **Copy**.

Amazon S3 copies your objects to the destination folder.

Next step

To delete an object and a bucket in Amazon S3, see [Step 5: Delete your objects and bucket](#).

Step 5: Delete your objects and bucket

When you no longer need an object or a bucket, we recommend that you delete them to prevent further charges. If you completed this getting started walkthrough as a learning exercise, and you don't plan to use your bucket or objects, we recommend that you delete your bucket and objects so that charges no longer accrue.

Before you delete your bucket, empty the bucket or delete the objects in the bucket. After you delete your objects and bucket, they are no longer available.

If you want to continue to use the same bucket name, we recommend that you delete the objects or empty the bucket, but don't delete the bucket. After you delete a bucket, the name becomes available to reuse. However, another AWS account might create a bucket with the same name before you have a chance to reuse it.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Topics

- [Deleting an object](#)
- [Emptying your bucket](#)
- [Deleting your bucket](#)

Deleting an object

If you want to choose which objects you delete without emptying all the objects from your bucket, you can delete an object.

1. In the **Buckets** list, choose the name of the bucket that you want to delete an object from.
2. Select the object that you want to delete.
3. Choose **Delete** from the options in the upper right.
4. On the **Delete objects** page, type **delete** to confirm deletion of your objects.
5. Choose **Delete objects**.

Emptying your bucket

If you plan to delete your bucket, you must first empty your bucket, which deletes all the objects in the bucket.

To empty a bucket

1. In the **Buckets** list, select the bucket that you want to empty, and then choose **Empty**.
2. To confirm that you want to empty the bucket and delete all the objects in it, in **Empty bucket**, type **permanently delete**.

 **Important**

Emptying the bucket cannot be undone. Objects added to the bucket while the empty bucket action is in progress will be deleted.

3. To empty the bucket and delete all the objects in it, and choose **Empty**.

An **Empty bucket: Status** page opens that you can use to review a summary of failed and successful object deletions.

4. To return to your bucket list, choose **Exit**.

Deleting your bucket

After you empty your bucket or delete all the objects from your bucket, you can delete your bucket.

1. To delete a bucket, in the **Buckets** list, select the bucket.
2. Choose **Delete**.
3. To confirm deletion, in **Delete bucket**, type the name of the bucket.

Important

Deleting a bucket cannot be undone. Bucket names are unique. If you delete your bucket, another AWS user can use the name. If you want to continue to use the same bucket name, don't delete your bucket. Instead, empty and keep the bucket.

4. To delete your bucket, choose **Delete bucket**.

Next steps

In the preceding examples, you learned how to perform some basic Amazon S3 tasks.

The following topics explain the learning paths that you can use to gain a deeper understanding of Amazon S3 so that you can implement it in your applications.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

- [Explore training and support](#)

Understand common use cases

You can use Amazon S3 to support your specific use case. The [AWS Solutions Library](#) and [AWS Blog](#) provide use-case specific information and tutorials. The following are some common use cases for Amazon S3:

- **Backup and storage** – Use Amazon S3 storage management features to manage costs, meet regulatory requirements, reduce latency, and save multiple distinct copies of your data for compliance requirements.
- **Application hosting** – Deploy, install, and manage web applications that are reliable, highly scalable, and low-cost. For example, you can configure your Amazon S3 bucket to host a static website. For more information, see [Hosting a static website using Amazon S3](#).
- **Media hosting** – Build a highly available infrastructure that hosts video, photo, or music uploads and downloads.
- **Software delivery** – Host your software applications for customers to download.

Control access to your buckets and objects

Amazon S3 provides a variety of security features and tools. For an overview, see [Access control in Amazon S3](#).

By default, S3 buckets and the objects in them are private. You have access only to the S3 resources that you create. You can use the following features to grant granular resource permissions that support your specific use case or to audit the permissions of your Amazon S3 resources.

- [S3 Block Public Access](#) – Block public access to S3 buckets and objects. By default, Block Public Access settings are turned on at the bucket level.
- [AWS Identity and Access Management \(IAM\) identities](#) – Use IAM or AWS IAM Identity Center to create IAM identities in your AWS account to manage access to your Amazon S3 resources. For example, you can use IAM with Amazon S3 to control the type of access that a user or group of users has to an Amazon S3 bucket that your AWS account owns. For more information about IAM identities and best practices, see [IAM identities \(users, user groups, and roles\)](#) in the *IAM User Guide*.

- [Bucket policies](#) – Use IAM-based policy language to configure resource-based permissions for your S3 buckets and the objects in them.
- [Access control lists \(ACLs\)](#) – Grant read and write permissions for individual buckets and objects to authorized users. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM user policies for access control instead of ACLs. Policies are a simplified and more flexible access-control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources. For more information about the specific cases when you'd use ACLs instead of resource-based policies or IAM user policies, see [Identity and Access Management for Amazon S3](#).
- [S3 Object Ownership](#) – Take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable or enable ACLs. By default, ACLs are disabled. With ACLs disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively by using access-management policies.
- [IAM Access Analyzer for S3](#) – Evaluate and monitor your S3 bucket access policies, ensuring that the policies provide only the intended access to your S3 resources.

Protect and monitor your storage

- [Protecting your storage](#) – After you create buckets and upload objects in Amazon S3, you can protect your object storage. For example, you can use S3 Versioning, S3 Replication, and Multi-Region Access Point failover controls for disaster recovery, AWS Backup to back up your data, and S3 Object Lock to set retention periods, prevent deletions and overwrites, and meet compliance requirements.
- [Monitoring your storage](#) – Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. You can monitor storage activity and costs. Also, we recommend that you collect monitoring data from all the parts of your AWS solution so that you can more easily debug a multipoint failure if one occurs.

You can also use analytics and insights in Amazon S3 to understand, analyze, and optimize your storage usage. For example, use [Amazon S3 Storage Lens](#) to understand, analyze, and optimize your storage. S3 Storage Lens provides 29+ usage and activity metrics and interactive dashboards to aggregate data for your entire organization, specific accounts, Regions, buckets, or prefixes. Use [Storage Class Analysis](#) to analyze storage access patterns to decide when it's time to move your data to a more cost-effective storage class. To manage your costs, you can use [S3 Lifecycle](#).

Develop with Amazon S3

Amazon S3 is a REST service. You can send requests to Amazon S3 using the REST API or the AWS SDK libraries, which wrap the underlying Amazon S3 REST API, simplifying your programming tasks. You can also use the AWS Command Line Interface (AWS CLI) to make Amazon S3 API calls. For more information, see [Making requests](#) in the *Amazon S3 API Reference*.

The Amazon S3 REST API is an HTTP interface to Amazon S3. With the REST API, you use standard HTTP requests to create, fetch, and delete buckets and objects. To use the REST API, you can use any toolkit that supports HTTP. You can even use a browser to fetch objects, as long as they are anonymously readable. For more information, see [Developing with Amazon S3](#) in the *Amazon S3 API Reference*.

To help you build applications using the language of your choice, we provide the following resources.

AWS CLI

You can access the features of Amazon S3 using the AWS CLI. To download and configure the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the *Amazon S3 API Reference*.

The AWS CLI provides two tiers of commands for accessing Amazon S3: High-level ([s3](#)) commands and API-level ([s3api](#)) and [s3control](#) commands. The high-level S3 commands simplify performing common tasks, such as creating, manipulating, and deleting objects and buckets. The [s3api](#) and [s3control](#) commands expose direct access to all Amazon S3 API operations, which you can use to carry out advanced operations that might not be possible with the high-level commands alone.

For a list of Amazon S3 AWS CLI commands, see [s3](#), [s3api](#), and [s3control](#).

AWS SDKs and Explorers

You can use the AWS SDKs when developing applications with Amazon S3. The AWS SDKs simplify your programming tasks by wrapping the underlying REST API. The AWS Mobile SDKs and the Amplify JavaScript library are also available for building connected mobile and web applications using AWS.

In addition to the AWS SDKs, AWS Explorers are available for Visual Studio and Eclipse for Java IDE. In this case, the SDKs and the explorers are bundled together as AWS Toolkits.

For more information, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Sample Code and Libraries

The [AWS Developer Center](#) and [AWS Code Sample Catalog](#) have sample code and libraries written especially for Amazon S3. You can use these code samples to understand how to implement the Amazon S3 API. You can also view the [Amazon Simple Storage Service API Reference](#) to understand the Amazon S3 API operations in detail.

Learn from tutorials

You can get started with step-by-step tutorials to learn more about Amazon S3. These tutorials are intended for a lab-type environment, and they use fictitious company names, user names, and so on. Their purpose is to provide general guidance. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

Getting started with Amazon S3 using the AWS CLI

You can get started with Amazon S3 by using the AWS Command Line Interface (AWS CLI) to work with general purpose buckets and objects. A bucket is a container for objects. An object is a file and any metadata that describes that file.

To store an object in Amazon S3, you create a bucket and then upload the object to the bucket. When the object is in the bucket, you can open it, download it, and move it. When you no longer need an object or a bucket, you can clean up your resources.

With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see [Amazon S3](#). If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see [AWS Free Tier](#).

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [Tutorial: Getting started with S3 Express One Zone](#) and [Working with directory buckets](#).

Setting up

Before you begin using the AWS CLI with Amazon S3, make sure that you have:

- Signed up for an AWS account. For instructions, see [Setting up Amazon S3](#).
- Created a user with `s3:*` permissions. For instructions, see [Setting up Amazon S3](#).
- Installed and configured the AWS CLI. For instructions, see [Installing or updating the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To verify that the AWS CLI is properly configured, run the following command:

```
aws sts get-caller-identity
```

For more information, see [get-caller-identity](#) in the *AWS CLI Command Reference*.

This command displays a list of available Amazon S3 commands if the AWS CLI is properly installed and configured.

Step 1: Create your first Amazon S3 bucket

After you set up the AWS CLI, you're ready to create a bucket in Amazon S3. Every object in Amazon S3 is stored in a bucket. Before you can store data in Amazon S3, you must create a bucket.

Note

You are not charged for creating a bucket. You are charged only for storing objects in the bucket and for transferring objects in and out of the bucket. The charges that you incur through following the examples in this guide are minimal (less than \$1). For more information about storage charges, see [Amazon S3 pricing](#).

To create a bucket

1. Create a bucket using the `s3api create-bucket` command. Replace `amzn-s3-demo-bucket` with a unique bucket name and `us-east-1` with your desired Region:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket --region us-east-1
```

For Regions other than `us-east-1`, you need to specify the location constraint:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket --region us-west-2 --create-bucket-configuration LocationConstraint=us-west-2
```

Note

- After you create a bucket, you can't change its Region.
- To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.
- The bucket name must:
 - Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (commercial Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US) Regions).

- Be between 3 and 63 characters long.
- Consist only of lowercase letters, numbers, periods (.), and hyphens (-). For best compatibility, we recommend that you avoid using periods (.) in bucket names, except for buckets that are used only for static website hosting.
- Begin and end with a letter or number.
- After you create the bucket, you can't change its name.
- Don't include sensitive information in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

2. Verify that your bucket was created by listing all buckets:

```
aws s3 ls
```

3. For [Object Ownership](#), you can disable or enable ACLs and control ownership of objects uploaded to your bucket.

ACLs disabled

To set **Bucket owner enforced** (default) – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the general purpose bucket:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-controls="Rules=[{ObjectOwnership=BucketOwnerEnforced}]"
```

Note

By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you must control access for each object individually. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

ACLs enabled

- To set **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-controls="Rules=[{ObjectOwnership=BucketOwnerPreferred}]"
```

If you apply the **Bucket owner preferred** setting and want to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can [Requiring the bucket-owner-full-control canned ACL for Amazon S3 PUT operations \(bucket owner preferred\)](#) that allows only object uploads that use this ACL.

- To set **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-controls="Rules=[{ObjectOwnership=ObjectWriter}]"
```

 **Note**

The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

To check the current Object Ownership setting for your bucket:

```
aws s3api get-bucket-ownership-controls --bucket amzn-s3-demo-bucket
```

4. To verify that **Block Public Access** is enabled (it's enabled by default for new buckets):

```
aws s3api get-public-access-block --bucket amzn-s3-demo-bucket
```

By default, all four **Block Public Access** settings are enabled for new buckets. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

If you need to enable **Block Public Access**, use the following command:

```
aws s3api put-public-access-block --bucket amzn-s3-demo-bucket --public-access-block-configuration  
"BlockPublicAcls=true,IgnorePublicAcls=true,BlockPublicPolicy=true,RestrictPublicBuckets=true"
```

Note

To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

5. To enable versioning for your bucket:

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket --versioning-configuration Status=Enabled
```

By default, Bucket Versioning is disabled. Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can recover more easily from both unintended user actions and application failures. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

6. Amazon S3 Object Lock helps protect new objects from being deleted or overwritten. For more information, see [Locking objects with Object Lock](#). To enable [Locking objects with Object Lock](#) (requires bucket versioning):

For a new bucket:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket --region us-east-1 --object-lock-enabled-for-bucket
```

For an existing bucket:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket --object-lock-configuration '{"ObjectLockEnabled": "Enabled"}'
```

If you want to set a default [Locking objects with Object Lock](#) along with enabling Object Lock, you can use:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket --object-lock-configuration '{"ObjectLockEnabled": "Enabled", "Rule": {"DefaultRetention": {"Mode": "COMPLIANCE", "Days": 30}}}'
```

You can replace "COMPLIANCE" with "GOVERNANCE" for a less restrictive mode, and adjust the number of days as needed.

 **Note**

To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning`, and `s3:PutBucketObjectLockConfiguration`.

7. You can add tags to your bucket. With AWS cost allocation, you can use bucket tags to annotate billing for your use of a bucket. A tag is a key-value pair that represents a label that you assign to a bucket. For more information, see [Using cost allocation S3 bucket tags](#).

To add tags to your bucket:

```
aws s3api put-bucket-tagging --bucket amzn-s3-demo-bucket --tagging  
'TagSet=[{Key=Purpose,Value=Testing},{Key=Environment,Value=Development}]'
```

8. Buckets and new objects are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption configuration. To verify the default encryption of your bucket, use the following command:

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket
```

You can also configure server-side encryption with AWS KMS keys (SSE-KMS) and dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) for your bucket. Both the AWS managed key (`aws/s3`) and your customer managed keys can be used as your AWS KMS key for SSE-KMS and DSSE-KMS encryption configuration. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*. For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

⚠️ Important

The AWS KMS key must be in the same AWS Region as your Amazon S3 bucket. Cross-region KMS keys aren't supported for Amazon S3 bucket encryption.

When you configure your bucket to use default encryption with SSE-KMS, you can also use Amazon S3 Bucket Keys. Amazon S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#). Amazon S3 Bucket Keys aren't supported for DSSE-KMS. In the AWS CLI, Amazon S3 Bucket Keys are NOT enabled by default when creating a new bucket. This is different from the console behavior where they are enabled by default.

To configure SSE-KMS and enable Amazon S3 Bucket Keys:

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-  
encryption-configuration "{\"Rules\": [{\"ApplyServerSideEncryptionByDefault\":  
\"SSEAlgorithm\":\"aws:kms\", \"KMSMasterKeyID\":\"YOUR-KMS-KEY-ARN\"},  
\"BucketKeyEnabled\":true}]}"
```

To check whether Amazon S3 Bucket Keys are enabled for a bucket:

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket
```

The output will include a BucketKeyEnabled field set to either true or false.

To configure DSSE-KMS, use the following command:

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-  
encryption-configuration '["Rules": [{"ApplyServerSideEncryptionByDefault":  
{"SSEAlgorithm":"aws:kms:dsse", "KMSMasterKeyID":"YOUR-KMS-KEY-ARN"}}]}'
```

For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about SSE-S3, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

⚠️ Important

If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. You can reduce KMS API calls by enabling Amazon S3 Bucket Keys, which decreases the number of requests sent to AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

You've created a bucket in Amazon S3. Next step is to upload an object to your bucket.

Step 2: Upload an object to your bucket

After creating a bucket in Amazon S3, you're ready to upload an object to the bucket. An object can be any kind of file: a text file, a photo, a video, and so on.

To upload an object to a bucket

1. Create a simple text file to upload. You can use any text editor or run the following command:

```
echo 'Hello, Amazon S3!' > example.txt
```

2. Upload the file to your bucket using the s3 cp command:

```
aws s3 cp example.txt s3://amzn-s3-demo-bucket/
```

If the upload is successful, you'll see output similar to:

```
upload: ./example.txt to s3://amzn-s3-demo-bucket/example.txt
```

3. Verify that the object was uploaded by listing the contents of your bucket:

```
aws s3 ls s3://amzn-s3-demo-bucket/
```

You've successfully uploaded an object to your bucket. Next step is to download an object.

Step 3: Download an object

After you upload an object to a bucket, you can view information about your object and download the object to your local computer.

To download an object from an Amazon S3 bucket

1. To get information about your object:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key example.txt
```

This command returns metadata about the object, including its content type, content length, and last modified date.

2. Download the object to your local computer:

```
aws s3 cp s3://amzn-s3-demo-bucket/example.txt downloaded-example.txt
```

If the download is successful, you'll see output similar to:

```
download: s3://amzn-s3-demo-bucket/example.txt to ./downloaded-example.txt
```

3. Verify the contents of the downloaded file:

```
cat downloaded-example.txt
```

Note

- Unlike the console, the AWS CLI can download multiple objects at once using wildcards or the `--recursive` flag.
- When downloading objects with the AWS CLI, periods (.) at the end of object key names are preserved, unlike in the console where they are removed. This is important if your object keys end with periods.

Example of downloading multiple objects:

To download multiple objects from an Amazon S3 bucket with specific file extensions, use the recursive copy command with `exclude` and `include` filters as shown in the example.

```
aws s3 cp s3://amzn-s3-demo-bucket/ . --recursive --exclude "*" --include "*.txt"
```

You've successfully downloaded your object. Next step is to copy your object to a folder.

Step 4: Copy your object to a folder

You've already added an object to a bucket and downloaded the object. Now, you create a folder and copy the object to the folder.

To copy an object to a folder

1. In Amazon S3, folders are represented by prefixes in object keys. Create a "folder" by copying an object with a prefix:

```
aws s3 cp s3://amzn-s3-demo-source-bucket/example.txt s3://amzn-s3-demo-destination-bucket/favorite-files/example.txt
```

If the copy is successful, you'll see output similar to:

```
copy: s3://amzn-s3-demo-source-bucket/example.txt to s3://amzn-s3-demo-destination-bucket/favorite-files/example.txt
```

2. Verify that the object was copied by listing the contents of the folder:

```
aws s3 ls s3://amzn-s3-demo-destination-bucket/favorite-files/
```

You've successfully copied your object to a folder. Next step is to delete your objects and bucket.

Step 5: Delete your objects and bucket

When you no longer need an object or a bucket, we recommend that you delete them to prevent further charges. If you completed this getting started walkthrough as a learning exercise, and you don't plan to use your bucket or objects, we recommend that you delete your bucket and objects so that charges no longer accrue.

Before you delete your bucket, empty the bucket or delete the objects in the bucket. After you delete your objects and bucket, they are no longer available.

If you want to continue to use the same bucket name, we recommend that you delete the objects or empty the bucket, but don't delete the bucket. After you delete a bucket, the name becomes available to reuse. However, another AWS account might create a bucket with the same name before you have a chance to reuse it.

Deleting an object

If you want to choose which objects you delete without emptying all the objects from your bucket, you can delete an object.

Delete a specific object:

```
aws s3 rm s3://amzn-s3-demo-bucket/example.txt
```

If the deletion is successful, you'll see output similar to:

```
delete: s3://amzn-s3-demo-bucket/example.txt
```

Emptying your bucket

If you plan to delete your bucket, you must first empty your bucket, which deletes all the objects, versions, and delete markers in the bucket.

To empty a bucket

Important

Emptying the bucket cannot be undone. Objects added to the bucket while the empty bucket action is in progress will be deleted.

1. **Option 1:** For smaller buckets, use the `rm` command with the `--recursive` flag to delete all objects in the bucket:

```
aws s3 rm s3://amzn-s3-demo-bucket --recursive
```

This command deletes all objects in the bucket, including objects in folders.

 **Note**

If your bucket contains many objects or large objects, this command might time out. For buckets with large amounts of data, use the Amazon S3 Lifecycle rule to expire objects in the buckets.

Option 2: Use Amazon S3 Lifecycle rules (recommended for large buckets)

For buckets with many objects or large objects, use an Amazon S3 Lifecycle rule to automatically expire and delete all objects. Wait for the lifecycle rule to process (this may take up to 24 hours). For more information about using lifecycle rules to empty buckets, see [How do I empty an Amazon S3 bucket using a lifecycle configuration rule?](#)

2. Verify that the bucket is empty:

```
aws s3 ls s3://amzn-s3-demo-bucket
```

3. If your bucket has versioning enabled, use the following commands to delete versioned objects and delete markers.

Remove versioned objects:

```
aws s3api delete-objects --bucket amzn-s3-demo-bucket --delete "$(aws s3api list-object-versions --bucket amzn-s3-demo-bucket --output json --query='{Objects: Versions[].[Key:Key,VersionId:VersionId]}')"
```

Remove delete markers:

```
aws s3api delete-objects --bucket amzn-s3-demo-bucket --delete "$(aws s3api list-object-versions --bucket amzn-s3-demo-bucket --output json --query='{Objects: DeleteMarkers[].[Key:Key,VersionId:VersionId]}')"
```

4. Verify that the bucket is empty of all object versions and delete markers:

```
aws s3api list-object-versions --bucket amzn-s3-demo-bucket
```

The output should show no versions or delete markers remaining.

Deleting your bucket

After you empty your bucket or delete all the objects from your bucket, you can delete your bucket.

Important

Deleting a bucket can't be undone. Bucket names are unique. If you delete your bucket, another AWS user can use the name. If you want to continue to use the same bucket name, don't delete your bucket. Instead, empty and keep the bucket.

To delete your bucket

1. Delete your bucket:

```
aws s3api delete-bucket --bucket amzn-s3-demo-bucket
```

2. Verify that the bucket was deleted by listing all your buckets:

```
aws s3 ls
```

Next steps

In the preceding examples, you learned how to perform some basic Amazon S3 tasks using the AWS CLI.

The following list shows common AWS CLI commands for Amazon S3:

- [cp](#) – Copies files or objects between your local file system and Amazon S3, or between Amazon S3 locations
- [ls](#) – Lists Amazon S3 objects and common prefixes under a specified bucket and prefix
- [mb](#) – Creates an Amazon S3 bucket
- [mv](#) – Moves files or objects between your local file system and Amazon S3, or between Amazon S3 locations
- [presign](#) – Generates a pre-signed URL for an Amazon S3 object that allows temporary access without AWS credentials
- [rb](#) – Removes an empty Amazon S3 bucket. You can use the --force flag to automatically empty and delete a bucket with contents in a single command. This action can't be undone.
- [rm](#) – Deletes objects from Amazon S3
- [sync](#) – Syncs directories and Amazon S3 prefixes by recursively copying new and updated files from the source directory to the destination.
- [website](#) – Configures a bucket as a static website

Creating, configuring, and working with Amazon S3 general purpose buckets

To store your data in Amazon S3, you work with resources known as buckets and objects. A *bucket* is a container for objects. An *object* is a file and any metadata that describes that file.

To store an object in Amazon S3, you create a bucket and then upload the object to a bucket. When the object is in the bucket, you can open it, download it, and move it. When you no longer need an object or a bucket, you can clean up your resources.

The topics in this section provide an overview of working with general purpose buckets in Amazon S3. They include information about naming, creating, accessing, and deleting general purpose buckets. For more information about viewing or listing objects in a bucket, see [Organizing, listing, and working with your objects](#).

There are several types of Amazon S3 buckets. Before creating a bucket, make sure that you choose the bucket type that best fits your application and performance requirements. For more information about the various bucket types and the appropriate use cases for each, see [Buckets](#).

General purpose buckets overview

To upload your data (photos, videos, documents, etc.) to Amazon S3, you must first create an S3 bucket in one of the AWS Regions.

There are several types of Amazon S3 buckets. Before creating a bucket, make sure that you choose the bucket type that best fits your application and performance requirements. For more information about the various bucket types and the appropriate use cases for each, see [Buckets](#).

General purpose buckets overview

Every object is contained in a bucket. For example, if the object named photos/puppy.jpg is stored in the amzn-s3-demo-bucket general purpose bucket in the US West (Oregon) Region, then it is addressable by using the URL <https://amzn-s3-demo-bucket.s3.us-west-2.amazonaws.com/photos/puppy.jpg>. For more information, see [Accessing a Bucket](#).

- General purpose bucket quotas for commercial Regions can only be viewed and managed from US East (N. Virginia).
- General purpose bucket quotas for AWS GovCloud (US) can only be viewed and managed from AWS GovCloud (US-West).

In terms of implementation, buckets and objects are AWS resources, and Amazon S3 provides APIs for you to manage them. For example, you can create a bucket and upload objects using the Amazon S3 API. You can also use the Amazon S3 console to perform these operations. The console uses the Amazon S3 APIs to send requests to Amazon S3.

This section describes how to work with general purpose buckets. For information about working with objects, see [Amazon S3 objects overview](#).

Amazon S3 supports global general purpose buckets, which means that each bucket name must be unique across all AWS accounts in all the AWS Regions within a partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (Standard Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US)).

After a general purpose bucket is created, the name of that bucket cannot be used by another AWS account in the same partition until the bucket is deleted. You should not depend on specific bucket naming conventions for availability or security verification purposes. For bucket naming guidelines, see [General purpose bucket naming rules](#).

Amazon S3 creates buckets in a Region that you specify. To reduce latency, minimize costs, or address regulatory requirements, choose any AWS Region that is geographically close to you. For example, if you reside in Europe, you might find it advantageous to create buckets in the Europe (Ireland) or Europe (Frankfurt) Regions. For a list of Amazon S3 Regions, see [Regions and Endpoints in the AWS General Reference](#).

Note

Objects that belong to a bucket that you create in a specific AWS Region never leave that Region, unless you explicitly transfer them to another Region. For example, objects that are stored in the Europe (Ireland) Region never leave it.

Common general purpose bucket patterns

When you build applications on Amazon S3, you can use unique general purpose buckets to separate different datasets or workloads. Depending on your use case, there are different design patterns and best practices for using general purpose buckets. For more information, see [Common general purpose bucket patterns for building applications on Amazon S3](#).

Permissions

You can use your AWS account root user credentials to create a general purpose bucket and perform any other Amazon S3 operation. However, we recommend that you do not use the root user credentials of your AWS account to make requests, such as to create a bucket. Instead, create an AWS Identity and Access Management (IAM) user, and grant that user full access (users by default have no permissions).

These users are referred to as *administrators*. You can use the administrator user credentials, instead of the root user credentials of your account, to interact with AWS and perform tasks, such as create a bucket, create users, and grant them permissions.

For more information, see [AWS account root user credentials and IAM user credentials](#) in the *AWS General Reference* and [Security best practices in IAM](#) in the *IAM User Guide*.

The AWS account that creates a resource owns that resource. For example, if you create an IAM user in your AWS account and grant the user permission to create a bucket, the user can create a bucket. But the user does not own the bucket; the AWS account that the user belongs to owns the bucket. The user needs additional permission from the resource owner to perform any other bucket operations. For more information about managing permissions for your Amazon S3 resources, see [Identity and Access Management for Amazon S3](#).

Managing public access to general purpose buckets

Public access is granted to general purpose buckets and objects through bucket policies, access control lists (ACLs), or both. To help you manage public access to Amazon S3 resources, Amazon S3 provides settings to block public access. Amazon S3 Block Public Access settings can override ACLs and bucket policies so that you can enforce uniform limits on public access to these resources. You can apply Block Public Access settings to individual buckets or to all buckets in your account.

To ensure that all of your Amazon S3 general purpose buckets and objects have their public access blocked, all four settings for Block Public Access are enabled by default when you create a new bucket. We recommend that you turn on all four settings for Block Public Access for your account too. These settings block all public access for all current and future buckets.

Before applying these settings, verify that your applications will work correctly without public access. If you require some level of public access to your buckets or objects—for example, to host a static website, as described at [Hosting a static website using Amazon S3](#)—you can customize the individual settings to suit your storage use cases. For more information, see [Blocking public access to your Amazon S3 storage](#).

However, we highly recommend keeping Block Public Access enabled. If you want to keep all four Block Public Access settings enabled and host a static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Amazon S3 static websites support only HTTP endpoints. Amazon CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks.

For more information, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

Note

If you see an Error when you list your general purpose buckets and their public access settings, you might not have the required permissions. Make sure that you have the following permissions added to your user or role policy:

```
s3:GetAccountPublicAccessBlock  
s3:GetBucketPublicAccessBlock  
s3:GetBucketPolicyStatus  
s3:GetBucketLocation
```

s3:GetBucketAcl
s3>ListAccessPoints
s3>ListAllMyBuckets

In some rare cases, requests can also fail because of an AWS Region outage.

Managing public access to general purpose buckets

You can add tags to your Amazon S3 buckets to categorize and track your AWS costs or for access control. You can use tags as cost allocation tags to track storage costs in AWS Billing and Cost Management. You can also use tags for attribute-based access control (ABAC), to scale access permissions and grant access to S3 buckets based on their tags.

For more information, see [Using tags with S3 general purpose buckets](#)

General purpose buckets configuration options

Amazon S3 supports various options for you to configure your general purpose bucket. For example, you can configure your bucket for website hosting, add a configuration to manage the lifecycle of objects in the bucket, and configure the bucket to log all access to the bucket. Amazon S3 supports subresources for you to store and manage the bucket configuration information. You can use the Amazon S3 API to create and manage these subresources. However, you can also use the console or the AWS SDKs.

Note

There are also object-level configurations. For example, you can configure object-level permissions by configuring an access control list (ACL) specific to that object.

These are referred to as subresources because they exist in the context of a specific bucket or object. The following table lists subresources that enable you to manage bucket-specific configurations.

Subresource	Description
<code>cors</code> (cross-origin resource sharing)	You can configure your bucket to allow cross-origin requests.

Subresource	Description
	For more information, see Using cross-origin resource sharing (CORS) .
<i>event notification</i>	<p>You can enable your bucket to send you notifications of specified bucket events.</p> <p>For more information, see Amazon S3 Event Notifications.</p>
<i>lifecycle</i>	<p>You can define lifecycle rules for objects in your bucket that have a well-defined lifecycle. For example, you can define a rule to archive objects one year after creation, or delete an object 10 years after creation.</p> <p>For more information, see Managing the lifecycle of objects.</p>
<i>location</i>	<p>When you create a bucket, you specify the AWS Region where you want Amazon S3 to create the bucket. Amazon S3 stores this information in the location subresource and provides an API for you to retrieve this information.</p>
<i>logging</i>	<p>Logging enables you to track requests for access to your bucket. Each access log record provides details about a single access request, such as the requester, bucket name, request time, request action, response status, and error code, if any. Access log information can be useful in security and access audits. It can also help you learn about your customer base and understand your Amazon S3 bill.</p> <p>For more information, see Logging requests with server access logging.</p>
<i>object locking</i>	<p>To use S3 Object Lock, you must enable it for a bucket. You can also optionally configure a default retention mode and period that applies to new objects that are placed in the bucket.</p> <p>For more information, see Locking objects with Object Lock.</p>

Subresource	Description
<i>policy</i> and <i>ACL</i> (access control list)	<p>All your resources (such as buckets and objects) are private by default. Amazon S3 supports both bucket policy and access control list (ACL) options for you to grant and manage bucket-level permissions. Amazon S3 stores the permission information in the <i>policy</i> and <i>acl</i> subresources.</p> <p>For more information, see Identity and Access Management for Amazon S3.</p>
<i>replication</i>	<p>Replication is the automatic, asynchronous copying of objects across buckets in different or the same AWS Regions. For more information, see Replicating objects within and across Regions.</p>
<i>requestPayment</i>	<p>By default, the AWS account that creates the bucket (the bucket owner) pays for downloads from the bucket. Using this subresource, the bucket owner can specify that the person requesting the download will be charged for the download. Amazon S3 provides an API for you to manage this subresource.</p> <p>For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.</p>
<i>tagging</i>	<p>You can add tags to your Amazon S3 buckets to categorize and track your AWS costs or for access control. You can use tags as cost allocation tags to track storage costs in AWS Billing and Cost Management. You can also use tags for attribute-based access control (ABAC), to scale access permissions and grant access to S3 buckets based on their tags.</p> <p>For more information, see Using tags with S3 general purpose buckets.</p>
<i>transfer acceleration</i>	<p>Transfer Acceleration enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration takes advantage of the globally distributed edge locations of Amazon CloudFront.</p> <p>For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.</p>

Subresource	Description
<i>versioning</i>	<p>Versioning helps you recover accidental overwrites and deletes.</p> <p>We recommend versioning as a best practice to recover objects from being deleted or overwritten by mistake.</p> <p>For more information, see Retaining multiple versions of objects with S3 Versioning.</p>
<i>website</i>	<p>You can configure your bucket for static website hosting. Amazon S3 stores this configuration by creating a <i>website</i> subresource.</p> <p>For more information, see Hosting a static website using Amazon S3.</p>

General purpose buckets operations

The high availability engineering of Amazon S3 is focused on *get*, *put*, *list*, and *delete* operations. Because general purpose bucket operations work against a centralized, global resource space, we recommend that you don't create, delete, or configure buckets on the high availability code path of your application. It's better to create, delete, or configure buckets in a separate initialization or setup routine that you run less often.

General purpose buckets performance monitoring

When you have critical applications and business processes that rely on AWS resources, it's important to monitor and get alerts for your system. [Monitoring your data](#) can help maintain the reliability, availability, and performance of Amazon S3 and your AWS solutions. There are several AWS services that you can use to collect and aggregate metrics and logs for your S3 buckets.

Depending on your use case, you can choose which AWS service best suits your organization's needs to debug issues, monitor your data, optimize storage costs, or troubleshoot multi-point issues. For example:

- **To improve the performance of applications that use S3:** [Set up CloudWatch alarms](#) to monitor your storage data, replication metrics, or request metrics.
- **To plan for storage usage, optimize storage costs, or to find out how much storage you have across your entire organization:** [Use Amazon S3 Storage Lens](#). Alternatively, you can [use S3](#)

[Storage Lens to improve your data performance](#) by enabling advanced metrics and using the detailed status-code metrics to get counts for successful or failed requests.

- **For a unified view of your operational health:** [Publish S3 Storage Lens usage and activity metrics](#) to a [Amazon CloudWatch dashboard](#).

 **Note**

The Amazon CloudWatch publishing option is available for S3 Storage Lens dashboards upgraded to **Advanced metrics and recommendations**. You can enable the CloudWatch publishing option for a new or existing dashboard configuration in S3 Storage Lens.

- **To obtain a record of actions taken by a user, role, or an AWS service:** Set up [AWS CloudTrail logs](#). You can also use AWS CloudTrail logs to review API calls for Amazon S3 as events.
- **To receive notifications about when a certain event happens in your S3 bucket:** [Set up Amazon S3 event notifications](#).
- **To obtain detailed records for the requests that are made to an S3 bucket:** [Set up S3 access logs](#).

For a list of all the different AWS services that you can use to monitor your data, see [Logging and monitoring in Amazon S3](#).

Common general purpose bucket patterns for building applications on Amazon S3

When you build applications on Amazon S3, you can use unique general purpose buckets to separate different datasets or workloads. When you build applications that serve end users or different user groups, use our best practices design patterns to build applications that can best take advantage of Amazon S3 features and scalability.

 **Important**

We recommend that you create general purpose bucket names that are not predictable. Do not write code assuming your chosen bucket name is available unless you have already created the bucket. One method for creating bucket names that are not predictable is to append a Globally Unique Identifier (GUID) to your bucket name, for example, amzn-s3-

demo-bucket-a1b2c3d4-5678-90ab-cdef-EXAMPLE11111. For more information about general purpose bucket naming rules, see [General purpose bucket naming rules](#).

Topics

- [Multi-tenant general purpose bucket pattern](#)
- [Bucket-per-use pattern](#)

Multi-tenant general purpose bucket pattern

With multi-tenant buckets, you create a single general purpose bucket for a team or workload. You use [unique S3 prefixes](#) to organize the objects that you store in the bucket. A prefix is a string of characters at the beginning of the object key name. A prefix can be any length, subject to the maximum length of the object key name (1,024 bytes). You can think of prefixes as a way to organize your data in a similar way to directories. However, prefixes are not directories.

For example, to store information about cities, you might organize it by continent, then by country, then by province or state. Because these names don't usually contain punctuation, you might use slash (/) as the delimiter. The following examples shows prefixes being used to organize city names by continent, country, and then province or state, using a slash (/) delimiter.

- Europe/France/NouvelleA-Aquitaine/Bordeaux
- North America/Canada/Quebec/Montreal
- North America/USA/Washington/Bellevue
- North America/USA/Washington/Seattle

This pattern scales well when you have hundreds of unique datasets within a general purpose bucket. With prefixes, you can easily organize and group these datasets.

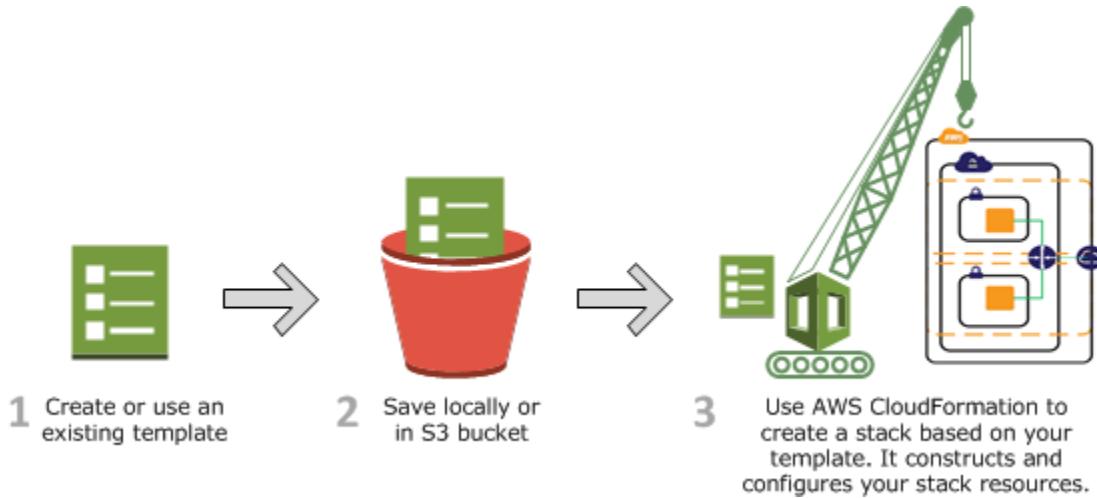

However, one potential drawback to the multi-tenant general purpose bucket pattern is that many S3 bucket-level features like [default bucket encryption](#), [S3 Versioning](#), and [S3 Requester Pays](#) are set at the bucket-level and not the prefix-level. If the different datasets within the multi-tenant bucket have unique requirements, the fact that you can't configure many S3 bucket-level features at the prefix-level can make it difficult for you to specify the correct settings for each dataset. Additionally, in a multi-tenant bucket, [cost allocation](#) can become complex as you work to understand the storage, requests, and data transfer associated with specific prefixes.

Bucket-per-use pattern

With the bucket-per-use pattern, you create a general purpose bucket for each distinct dataset, end user, or team. Because you can configure S3 bucket-level features for each of these buckets, you can use this pattern to configure unique bucket-level settings. For example, you can configure features like [default bucket encryption](#), [S3 Versioning](#), and [S3 Requester Pays](#) in a way that is customized to the dataset in each bucket. Using one bucket for each distinct dataset, end user, or team can also help you simplify both your access management and cost allocation strategies.

A potential drawback to this strategy is that you will need to manage potentially thousands of buckets. All AWS accounts have a default quota of 10,000 general purpose buckets. You can increase the bucket quota for an account by submitting a quota increase request. To request an increase for general purpose buckets, visit the [Service Quotas console](#).

To manage your bucket-per-use pattern and simplify your infrastructure management, you can use [AWS CloudFormation](#). You can create a custom CloudFormation template for your pattern that already defines all of your desired settings for your S3 general purpose buckets so that you can easily deploy and track any changes to your infrastructure. For more information, see [AWS::S3::Bucket](#) in the *AWS CloudFormation User Guide*.

General purpose bucket naming rules

When you create a general purpose bucket, make sure that you consider the length, valid characters, formatting, and uniqueness of bucket names. The following sections provide information about general purpose bucket naming, including naming rules, best practices, and an example for creating a general purpose bucket with a name that includes a globally unique identifier (GUID).

For information about object key names, see [Creating object key names](#).

To create a general purpose bucket, see [the section called “Creating a general purpose bucket”](#).

Topics

- [General purpose buckets naming rules](#)
- [Example general purpose bucket names](#)
- [Best practices](#)
- [Creating a bucket that uses a GUID in the bucket name](#)

General purpose buckets naming rules

The following naming rules apply for general purpose buckets.

- Bucket names must be between 3 (min) and 63 (max) characters long.
- Bucket names can consist only of lowercase letters, numbers, periods (.), and hyphens (-).
- Bucket names must begin and end with a letter or number.
- Bucket names must not contain two adjacent periods.
- Bucket names must not be formatted as an IP address (for example, 192.168.5.4).
- Bucket names must not start with the prefix xn--.
- Bucket names must not start with the prefix sthree-.
- Bucket names must not start with the prefix amzn-s3-demo-.
- Bucket names must not end with the suffix -s3alias. This suffix is reserved for access point alias names. For more information, see [Access point aliases](#).
- Bucket names must not end with the suffix --ol-s3. This suffix is reserved for Object Lambda Access Point alias names. For more information, see [How to use a bucket-style alias for your S3 bucket Object Lambda Access Point](#).
- Bucket names must not end with the suffix .mrap. This suffix is reserved for Multi-Region Access Point names. For more information, see [Rules for naming Amazon S3 Multi-Region Access Points](#).
- Bucket names must not end with the suffix --x-s3. This suffix is reserved for directory buckets. For more information, see [Directory bucket naming rules](#).
- Bucket names must not end with the suffix --table-s3. This suffix is reserved for S3 Tables buckets. For more information, see [Amazon S3 table bucket, table, and namespace naming rules](#).

- Buckets used with Amazon S3 Transfer Acceleration can't have periods (.) in their names. For more information about Transfer Acceleration, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

Important

- Bucket names **must** be unique across all AWS accounts in all of the AWS Regions within a partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (commercial Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions).
- A bucket name can't be used by another AWS account in the same partition until the bucket is deleted. **After you delete a bucket, be aware that another AWS account in the same partition can use the same bucket name for a new bucket and can therefore potentially receive requests intended for the deleted bucket.** If you want to prevent this, or if you want to continue to use the same bucket name, don't delete the bucket. We recommend that you empty the bucket and keep it, and instead, block any bucket requests as needed. For buckets no longer in active use, we recommend emptying the bucket of all objects to minimize costs while retaining the bucket itself.
- When you create a general purpose bucket, you choose its name and the AWS Region to create it in. After you create a general purpose bucket, you can't change its name or Region.
- Don't include sensitive information in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

Note

Before March 1, 2018, buckets created in the US East (N. Virginia) Region could have names that were up to 255 characters long and included uppercase letters and underscores. Beginning March 1, 2018, new buckets in US East (N. Virginia) must conform to the same rules applied in all other Regions.

Example general purpose bucket names

The following bucket names show examples of which characters are allowed in general purpose bucket names: a-z, 0-9, and hyphens (-). The amzn-s3-demo- reserved prefix is used here only for illustration. Because it's a reserved prefix, you can't create bucket names that start with amzn-s3-demo-.

- amzn-s3-demo-bucket1-a1b2c3d4-5678-90ab-cdef-example11111
- amzn-s3-demo-bucket

The following example bucket names are valid but not recommended for uses other than static website hosting because they contain periods (.):

- example.com
- www.example.com
- my.example.s3.bucket

The following example bucket names are *not* valid:

- amzn_s3_demo_bucket (contains underscores)
- AmznS3DemoBucket (contains uppercase letters)
- amzn-s3-demo-bucket- (starts with amzn-s3-demo- prefix and ends with a hyphen)
- example..com (contains two periods in a row)
- 192.168.5.4 (matches format of an IP address)

Best practices

When naming your general purpose buckets, consider the following bucket naming best practices.

Choose a bucket naming scheme that's unlikely to cause naming conflicts

If your application automatically creates buckets, choose a bucket naming scheme that's unlikely to cause naming conflicts. Ensure that your application logic will choose a different bucket name if a bucket name is already taken.

Append globally unique identifiers (GUIDs) to bucket names

We recommend that you create bucket names that aren't predictable. Don't write code assuming your chosen bucket name is available unless you have already created the bucket. One method for creating bucket names that aren't predictable is to append a Globally Unique Identifier (GUID) to your bucket name, for example, amzn-s3-demo-bucket-a1b2c3d4-5678-90ab-cdef-example11111. For more information, see [the section called "Creating a bucket that uses a GUID in the bucket name"](#).

Avoid using periods (.) in bucket names

For best compatibility, we recommend that you avoid using periods (.) in bucket names, except for buckets that are used only for static website hosting. If you include periods in a bucket's name, you can't use virtual-host-style addressing over HTTPS, unless you perform your own certificate validation. The security certificates used for virtual hosting of buckets don't work for buckets with periods in their names.

This limitation doesn't affect buckets used for static website hosting, because static website hosting is available only over HTTP. For more information about virtual-host-style addressing, see [Virtual hosting of general purpose buckets](#). For more information about static website hosting, see [Hosting a static website using Amazon S3](#).

Choose a relevant name

When you name a bucket, we recommend that you choose a name that's relevant to you or your business. Avoid using names associated with others. For example, avoid using AWS or Amazon in your bucket name.

Don't delete buckets so that you can reuse bucket names

If a bucket is empty, you can delete it. After a bucket is deleted, the name becomes available for reuse. However, you aren't guaranteed to be able to reuse the name right away, or at all. After you delete a bucket, some time might pass before you can reuse the name. In addition, another AWS account might create a bucket with the same name before you can reuse the name.

After you delete a general purpose bucket, be aware that another AWS account in the same partition can use the same bucket name for a new bucket and can therefore potentially receive requests intended for the deleted general purpose bucket. If you want to prevent this, or if you want to continue to use the same general purpose bucket name, don't delete the general purpose bucket. We recommend that you empty the bucket and keep it, and instead, block any bucket requests as needed.

Creating a bucket that uses a GUID in the bucket name

The following examples show you how to create a general purpose bucket that uses a GUID at the end of the bucket name.

Using the AWS CLI

The following AWS CLI example creates a general purpose bucket in the US West (N. California) Region (us-west-1) Region with an example bucket name that uses a globally unique identifier (GUID). To use this example command, replace the *user input placeholders* with your own information.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-bucket1$(uuidgen | tr -d - | tr '[:upper:]' '[:lower:]' ) \
--region us-west-1 \
--create-bucket-configuration LocationConstraint=us-west-1
```

Using the AWS SDK for Java

The following example shows you how to create a with a GUID at the end of the bucket name in US East (N. Virginia) Region (us-east-1) by using the AWS SDK for Java. To use this example, replace the *user input placeholders* with your own information. For information about other AWS SDKs, see [Tools to Build on AWS](#).

```
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.Bucket;
import com.amazonaws.services.s3.model.CreateBucketRequest;

import java.util.List;
import java.util.UUID;

public class CreateBucketWithUUID {
    public static void main(String[] args) {
        final AmazonS3 s3 =
        AmazonS3ClientBuilder.standard().withRegion(Regions.US_EAST_1).build();
        String bucketName = "amzn-s3-demo-bucket" +
        UUID.randomUUID().toString().replace("-", "");
        CreateBucketRequest createRequest = new CreateBucketRequest(bucketName);
```

```
        System.out.println(bucketName);
        s3.createBucket(createRequest);
    }
}
```

General purpose bucket quotas, limitations, and restrictions

An Amazon S3 general purpose bucket is owned by the AWS account that created it. Bucket ownership is not transferable to another account.

Bucket quotas

By default, you can create up to 10,000 general purpose buckets per AWS account. To request a quota increase for general purpose buckets, visit the [Service Quotas console](#).

Important

We strongly recommend using only paginated `ListBuckets` requests. Unpaginated `ListBuckets` requests are only supported for AWS accounts set to the default general purpose bucket quota of 10,000. If you have an approved general purpose bucket quota above 10,000, you must send paginated `ListBuckets` requests to list your account's buckets. All unpaginated `ListBuckets` requests will be rejected for AWS accounts with a general purpose bucket quota greater than 10,000.

Note

You must use the following AWS Regions to view your quota, bucket utilization, or request an increase for your general purpose buckets in your AWS account.

- General purpose bucket quotas for commercial Regions can only be viewed and managed from US East (N. Virginia).
- General purpose bucket quotas for AWS GovCloud (US) can only be viewed and managed from AWS GovCloud (US-West).

For information about service quotas, see [AWS service quotas](#) in the *Amazon Web Services General Reference*.

Objects and bucket limitations

There is no max bucket size or limit to the number of objects that you can store in a bucket. You can store all of your objects in a single bucket, or you can organize them across several buckets. However, you can't create a bucket from within another bucket.

Bucket naming rules

When you create a bucket, you choose its name and the AWS Region to create it in. After you create a bucket, you can't change its name or Region. For more information about bucket naming, see [General purpose bucket naming rules](#).

Accessing an Amazon S3 general purpose bucket

You can access your Amazon S3 general purpose buckets by using the Amazon S3 console, AWS Command Line Interface, AWS SDKs, or the Amazon S3 REST API. Each method of accessing an S3 general purpose bucket supports specific use cases. For more information, see the following sections.

Topics

- [Use cases](#)
- [Amazon S3 console](#)
- [AWS CLI](#)
- [AWS SDKs](#)
- [Amazon S3 REST API](#)
- [Virtual hosting of general purpose buckets](#)

Use cases

Depending on the use case for your Amazon S3 general purpose bucket, there are different recommended methods to access the underlying data in your buckets. The following list includes common use cases for accessing your data.

- **Static websites** – You can use Amazon S3 to host a static website. In this use case, you can configure your S3 general purpose bucket to function like a website. For an example that walks

you through the steps of hosting a website on Amazon S3, see [Tutorial: Configuring a static website on Amazon S3](#).

To host a static website with security settings like Block Public Access enabled, we recommend using Amazon CloudFront with Origin Access Control (OAC) and implementing additional security headers, such as HTTPS. For more information, see [Getting started with a secure static website](#).

 **Note**

Amazon S3 supports both [virtual-hosted-style](#) and [path-style URLs](#) for static website access. Because buckets can be accessed using path-style and virtual-hosted-style URLs, we recommend that you create buckets with DNS-compliant bucket names. For more information, see [General purpose bucket quotas, limitations, and restrictions](#).

- **Shared datasets** – As you scale on Amazon S3, it's common to adopt a multi-tenant model, where you assign different end customers or business units to unique prefixes within a shared general purpose bucket. By using [Amazon S3 access points](#), you can divide one large bucket policy into separate, discrete access point policies for each application that needs to access the shared dataset. This approach makes it simpler to focus on building the right access policy for an application without disrupting what any other application is doing within the shared dataset. For more information, see [Managing access to shared datasets with access points](#).
- **High-throughput workloads** – Mountpoint for Amazon S3 is a high-throughput open source file client for mounting an Amazon S3 general purpose bucket as a local file system. With Mountpoint, your applications can access objects stored in Amazon S3 through file-system operations, such as open and read. Mountpoint automatically translates these operations into S3 object API calls, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface. For more information, see [Mount an Amazon S3 bucket as a local file system](#).
- **Multi-Region applications** – Amazon S3 Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from S3 general purpose buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the public internet, Multi-Region Access Points provide built-in network resilience with acceleration of internet-based requests to Amazon S3. For more information, see [Managing multi-Region traffic with Multi-Region Access Points](#).
- **Secure Shell (SSH) File Transfer Protocol (SFTP)** – If you're trying to securely transfer sensitive data over the internet, you can use an SFTP-enabled server with your Amazon S3

general purpose bucket. AWS SFTP is a network protocol that supports the full security and authentication functionality of SSH. With this protocol, you have fine-grained control over user identity, permissions, and keys or you can use IAM policies to manage access. To associate an SFTP enabled server with your Amazon S3 bucket, make sure to create your SFTP-enabled server first. Then, you set up user accounts, and associate the server with an Amazon S3 general purpose bucket. For a walkthrough of this process, see [AWS Transfer for SFTP – Fully Managed SFTP Service for Amazon S3](#) in *AWS Blogs*.

Amazon S3 console

The console is a web-based user interface for managing Amazon S3 and AWS resources. With the Amazon S3 console, you can easily access a bucket and modify the bucket's properties. You can also perform most bucket operations by using the console UI, without having to write any code.

If you've signed up for an AWS account, you can access the Amazon S3 console by signing into the Amazon S3 console and choosing **S3** from the Amazon S3 console home page. You can also use this link to directly access the <https://console.aws.amazon.com/s3/>.

AWS CLI

You can use the AWS CLI to issue commands or build scripts at your system's command line to perform AWS (including S3) tasks. For example, if you need to access multiple buckets, you can save time by using the AWS CLI to automate common and repetitive tasks. Scriptability and repeatability for common actions are frequent considerations as organizations scale.

The [AWS CLI](#) provides commands for a broad set of AWS services. The AWS CLI is supported on Windows, macOS, and Linux. To get started, see the [AWS Command Line Interface User Guide](#). For more information about the commands for Amazon S3, see [s3api](#) and [s3control](#) in the [AWS CLI Command Reference](#).

AWS SDKs

AWS provides SDKs (software development kits) that consist of libraries and sample code for various programming languages and platforms (Java, Python, Ruby, .NET, iOS, Android, and so on). The AWS SDKs provide a convenient way to create programmatic access to S3 and AWS. Amazon S3 is a REST service. You can send requests to Amazon S3 using the AWS SDK libraries, which wrap the underlying Amazon S3 REST API and simplify your programming tasks. For example, the SDKs take care of tasks such as calculating signatures, cryptographically signing requests, managing

errors, and retrying requests automatically. For information about the AWS SDKs, including how to download and install them, see [Tools for AWS](#).

Every interaction with Amazon S3 is either authenticated or anonymous. If you are using the AWS SDKs, the libraries compute the signature for authentication from the keys that you provide. For more information about how to make requests to Amazon S3, see [Making requests](#).

Amazon S3 REST API

The architecture of Amazon S3 is designed to be programming language-neutral, using AWS-supported interfaces to store and retrieve objects. You can access S3 and AWS programmatically by using the Amazon S3 REST API. The REST API is an HTTP interface to Amazon S3. With the REST API, you use standard HTTP requests to create, fetch, and delete buckets and objects.

To use the REST API, you can use any toolkit that supports HTTP. You can even use a browser to fetch objects, as long as they are anonymously readable.

The REST API uses standard HTTP headers and status codes, so that standard browsers and toolkits work as expected. In some areas, we have added functionality to HTTP (for example, we added headers to support access control). In these cases, we have done our best to add the new functionality in a way that matches the style of standard HTTP usage.

If you make direct REST API calls in your application, you must write the code to compute the signature and add it to the request. For more information about how to make requests to Amazon S3, see [Making requests](#) in the *Amazon S3 API Reference*.

Virtual hosting of general purpose buckets

Virtual hosting is the practice of serving multiple websites from a single web server. One way to differentiate sites in your Amazon S3 REST API requests is by using the apparent hostname of the Request-URI instead of just the path name part of the URI. An ordinary Amazon S3 REST request specifies a bucket by using the first slash-delimited component of the Request-URI path. Instead, you can use Amazon S3 virtual hosting to address a general purpose bucket in a REST API call by using the HTTP Host header. In practice, Amazon S3 interprets Host as meaning that most buckets are automatically accessible for limited types of requests at `https://bucket-name.s3.region-code.amazonaws.com`. For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

Virtual hosting also has other benefits. By naming your bucket after your registered domain name and by making that name a DNS alias for Amazon S3, you can completely customize the

URL of your Amazon S3 resources, for example, `http://my.bucket-name.com/`. You can also publish to the "root directory" of your bucket's virtual server. This ability can be important because many existing applications search for files in this standard location. For example, `favicon.ico`, `robots.txt`, and `crossdomain.xml` are all expected to be found at the root.

Important

When you're using virtual-hosted-style general purpose buckets with SSL, the SSL wildcard certificate matches only buckets that do not contain dots (.). To work around this limitation, use HTTP or write your own certificate-verification logic. For more information, see [Amazon S3 Path Deprecation Plan](#) on the [AWS News Blog](#).

Path-style requests

Currently, Amazon S3 supports both virtual-hosted-style and path-style URL access in all AWS Regions. However, path-style URLs will be discontinued in the future. For more information, see the following **Important** note.

In Amazon S3, path-style URLs use the following format:

```
https://s3.region-code.amazonaws.com/bucket-name/key-name
```

For example, if you create a bucket named `amzn-s3-demo-bucket1` in the US West (Oregon) Region, and you want to access the `puppy.jpg` object in that bucket, you can use the following path-style URL:

<https://s3.us-west-2.amazonaws.com/amzn-s3-demo-bucket1/puppy.jpg>

Important

Update (September 23, 2020) – To make sure that customers have the time that they need to transition to virtual-hosted-style URLs, we have decided to delay the deprecation of path-style URLs. For more information, see [Amazon S3 Path Deprecation Plan – The Rest of the Story](#) in the *AWS News Blog*.

Warning

When hosting website content that will be accessed from a web browser, avoid using path-style URLs, which might interfere with the browser same origin security model. To host website content, we recommend that you use either S3 website endpoints or a CloudFront distribution. For more information, see [Website endpoints](#) and [Deploy a React-based single-page application to Amazon S3 and CloudFront](#) in the *AWS Perspective Guidance Patterns*.

Virtual-hosted-style requests

In a virtual-hosted-style URI, the bucket name is part of the domain name in the URL.

Amazon S3 virtual-hosted-style URLs use the following format:

[https://*bucket-name*.s3.*region-code*.amazonaws.com/*key-name*](https://bucket-name.s3.region-code.amazonaws.com/key-name)

In this example, amzn-s3-demo-bucket1 is the bucket name, US West (Oregon) is the Region, and puppy.png is the key name:

<https://amzn-s3-demo-bucket1.s3.us-west-2.amazonaws.com/puppy.png>

HTTP Host header bucket specification

As long as your GET request does not use the SSL endpoint, you can specify the bucket for the request by using the HTTP Host header. The Host header in a REST request is interpreted as follows:

- If the Host header is omitted or its value is `s3.region-code.amazonaws.com`, the bucket for the request will be the first slash-delimited component of the Request-URI, and the key for the request will be the rest of the Request-URI. This is the ordinary method, as illustrated by the first and second examples in this section. Omitting the Host header is valid only for HTTP 1.0 requests.
- Otherwise, if the value of the Host header ends in `.s3.region-code.amazonaws.com`, the bucket name is the leading component of the Host header's value up to `.s3.region-code.amazonaws.com`. The key for the request is the Request-URI. This interpretation exposes buckets as subdomains of `.s3.region-code.amazonaws.com`, as illustrated by the third and fourth examples in this section.
- Otherwise, the bucket for the request is the lowercase value of the Host header, and the key for the request is the Request-URI. This interpretation is useful when you have registered the same DNS name as your bucket name and have configured that name to be a canonical name (CNAME) alias for Amazon S3. The procedure for registering domain names and configuring CNAME DNS records is beyond the scope of this guide, but the result is illustrated by the final example in this section.

Examples

This section provides example URLs and requests.

Example – Path-style URLs and requests

This example uses the following:

- Bucket Name - `example.com`
- Region - US East (N. Virginia)
- Key Name - `homepage.html`

The URL is as follows:

```
http://s3.us-east-1.amazonaws.com/example.com/homepage.html
```

The request is as follows:

```
GET /example.com/homepage.html HTTP/1.1
```

```
Host: s3.us-east-1.amazonaws.com
```

The request with HTTP 1.0 and omitting the Host header is as follows:

```
GET /example.com/homepage.html HTTP/1.0
```

For information about DNS-compatible names, see [Limitations](#). For more information about keys, see [Keys](#).

Example – Virtual-hosted-style URLs and requests

This example uses the following:

- **Bucket name** - amzn-s3-demo-bucket1
- **Region** - Europe (Ireland)
- **Key name** - homepage.html

The URL is as follows:

```
http://amzn-s3-demo-bucket1.s3.eu-west-1.amazonaws.com/homepage.html
```

The request is as follows:

```
GET /homepage.html HTTP/1.1  
Host: amzn-s3-demo-bucket1.s3.eu-west-1.amazonaws.com
```

Example – CNAME alias method

To use this method, you must configure your DNS name as a CNAME alias for *bucket-name*.s3.us-east-1.amazonaws.com. For more information, see [Customizing Amazon S3 URLs with CNAME records](#).

This example uses the following:

- Bucket Name - example.com
- Key name - homepage.html

The URL is as follows:

```
http://www.example.com/homepage.html
```

The example is as follows:

```
GET /homepage.html HTTP/1.1  
Host: www.example.com
```

Customizing Amazon S3 URLs with CNAME records

Depending on your needs, you might not want s3.*region-code*.amazonaws.com to appear on your website or service. For example, if you're hosting website images on Amazon S3, you might prefer http://images.example.com/ instead of http://images.example.com.s3.us-east-1.amazonaws.com/. Any bucket with a DNS-compatible name can be referenced as follows: http://*BucketName*.s3.*Region*.amazonaws.com/[*Filename*], for example, http://images.example.com.s3.us-east-1.amazonaws.com/mydog.jpg. By using CNAME, you can map images.example.com to an Amazon S3 hostname so that the previous URL could become http://images.example.com/mydog.jpg.

Your bucket name must be the same as the CNAME. For example, if you create a CNAME to map images.example.com to images.example.com.s3.us-east-1.amazonaws.com, both http://images.example.com/filename and http://images.example.com.s3.us-east-1.amazonaws.com/filename will be the same.

The CNAME DNS record should alias your domain name to the appropriate virtual hosted-style hostname. For example, if your bucket name and domain name are images.example.com and your bucket is in the US East (N. Virginia) Region, the CNAME record should alias to images.example.com.s3.us-east-1.amazonaws.com.

```
images.example.com CNAME      images.example.com.s3.us-east-1.amazonaws.com.
```

Amazon S3 uses the hostname to determine the bucket name. So the CNAME and the bucket name must be the same. For example, suppose that you have configured www.example.com as a CNAME for www.example.com.s3.us-east-1.amazonaws.com. When you access http://www.example.com, Amazon S3 receives a request similar to the following:

Example

```
GET / HTTP/1.1  
Host: www.example.com
```

Date: *date*

Authorization: *signatureValue*

Amazon S3 sees only the original hostname `www.example.com` and is unaware of the CNAME mapping used to resolve the request.

You can use any Amazon S3 endpoint in a CNAME alias. For example, `s3.ap-southeast-1.amazonaws.com` can be used in CNAME aliases. For more information about endpoints, see [Request endpoints](#) in the *Amazon S3 API Reference*. To create a static website by using a custom domain, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Important

When using custom URLs with CNAMEs, you will need to ensure a matching bucket exists for any CNAME or alias record you configure. For example, if you create DNS entries for `www.example.com` and `login.example.com` to publish web content using S3, you will need to create both buckets `www.example.com` and `login.example.com`.

When a CNAME or alias records is configured pointing to an S3 endpoint without a matching bucket, any AWS user can create that bucket and publish content under the configured alias, even if ownership is not the same.

For the same reason, we recommend that you change or remove the corresponding CNAME or alias when deleting a bucket.

How to associate a hostname with an Amazon S3 bucket

To associate a hostname with an Amazon S3 bucket by using a CNAME alias

1. Select a hostname that belongs to a domain that you control.

This example uses the `images` subdomain of the `example.com` domain.

2. Create a bucket that matches the hostname.

In this example, the host and bucket names are `images.example.com`. The bucket name must *exactly* match the hostname.

3. Create a CNAME DNS record that defines the hostname as an alias for the Amazon S3 bucket.

For example:

images.example.com CNAME images.example.com.s3.us-west-2.amazonaws.com

⚠️ Important

For request-routing reasons, the CNAME DNS record must be defined exactly as shown in the preceding example. Otherwise, it might appear to operate correctly, but it will eventually result in unpredictable behavior.

The procedure for configuring CNAME DNS records depends on your DNS server or DNS provider. For specific information, see your server documentation or contact your provider.

Limitations

SOAP APIs for Amazon S3 are not available for new customers, and are approaching End of Life (EOL) on August 31, 2025. We recommend that you use either the REST API or the AWS SDKs.

Backward compatibility

The following sections cover various aspects of Amazon S3 backward compatibility that relate to path-style and virtual-hosted-style URL requests.

Legacy endpoints

Some Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, review the following information. For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

⚠️ Important

Although you might see legacy endpoints in your logs, we recommend that you always use the standard endpoint syntax to access your buckets.

Amazon S3 virtual-hosted-style URLs use the following format:

`https://bucket-name.s3.region-code.amazonaws.com/key-name`

In Amazon S3, path-style URLs use the following format:

`https://s3.region-code.amazonaws.com/bucket-name/key-name`

s3-Region

Some older Amazon S3 Regions support endpoints that contain a dash (-) between s3 and the Region code (for example, s3-us-west-2), instead of a dot (for example, s3.us-west-2). If your bucket is in one of these Regions, you might see the following endpoint format in your server access logs or CloudTrail logs:

`https://bucket-name.s3-region-code.amazonaws.com`

In this example, the bucket name is amzn-s3-demo-bucket1 and the Region is US West (Oregon):

`https://amzn-s3-demo-bucket1.s3-us-west-2.amazonaws.com`

Legacy global endpoint

For some Regions, you can use the legacy global endpoint to construct requests that do not specify a Region-specific endpoint. The legacy global endpoint point is as follows:

`bucket-name.s3.amazonaws.com`

In your server access logs or CloudTrail logs, you might see requests that use the legacy global endpoint. In this example, the bucket name is amzn-s3-demo-bucket1 and the legacy global endpoint is:

`https://amzn-s3-demo-bucket1.s3.amazonaws.com`

Virtual-hosted-style requests for US East (N. Virginia)

Requests made with the legacy global endpoint go to the US East (N. Virginia) Region by default. Therefore, the legacy global endpoint is sometimes used in place of the Regional endpoint for US East (N. Virginia). If you create a bucket in US East (N. Virginia) and use the global endpoint, Amazon S3 routes your request to this Region by default.

Virtual-hosted-style requests for other Regions

The legacy global endpoint is also used for virtual-hosted-style requests in other supported Regions. If you create a bucket in a Region that was launched before March 20, 2019, and use the legacy global endpoint, Amazon S3 updates the DNS record to reroute the request to the correct location, which might take time. In the meantime, the default rule applies, and your virtual-hosted-style request goes to the US East (N. Virginia) Region. Amazon S3 then redirects it with an HTTP 307 Temporary Redirect to the correct Region.

For S3 buckets in Regions launched after March 20, 2019, the DNS server doesn't route your request directly to the AWS Region where your bucket resides. It returns an HTTP 400 Bad Request error instead. For more information, see [Making requests](#) in the *Amazon S3 API Reference*.

Path-style requests

For the US East (N. Virginia) Region, you can use the legacy global endpoint for path-style requests.

For all other Regions, the path-style syntax requires that you use the Region-specific endpoint when attempting to access a bucket. If you try to access a bucket with the legacy global endpoint or another endpoint that is different than the one for the Region where the bucket resides, you receive an HTTP response code 301 Permanent Redirect error and a message that indicates the correct URI for your resource. For example, if you use `https://s3.amazonaws.com/bucket-name` for a bucket that was created in the US West (Oregon) Region, you will receive an HTTP 301 Permanent Redirect error.

Creating a general purpose bucket

To upload your data to Amazon S3, you must first create an Amazon S3 general purpose bucket in one of the AWS Regions. The AWS account that creates the bucket owns it. When you create a bucket, you must choose a bucket name and Region. During the creation process, you can optionally choose other storage management options for the bucket.

Important

After you create a bucket, you can't change the bucket name, the bucket owner, or the Region. For more information about bucket naming, see [the section called "Naming rules"](#).

By default, you can create up to 10,000 general purpose buckets per AWS account. To request a quota increase for general purpose buckets, visit the [Service Quotas console](#).

You can store any number of objects in a bucket. For a list of restriction and limitations related to Amazon S3 general purpose buckets, see [General purpose bucket quotas, limitations, and restrictions](#).

General purpose bucket settings

When you're creating a general purpose bucket, you can use the following settings to control various aspects of your bucket's behavior:

- **S3 Object Ownership** – S3 Object Ownership is an Amazon S3 bucket-level setting that you can use both to control ownership of objects that are uploaded to your bucket and to disable or enable access control lists (ACLs). By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using policies. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).
- **S3 Object Lock** – S3 Object Lock can help prevent Amazon S3 objects from being deleted or overwritten for a fixed amount of time or indefinitely. Object Lock uses a *write-once-read-many* (WORM) model to store objects. You can use Object Lock to help meet regulatory requirements that require WORM storage, or to add another layer of protection against object changes or deletion. For more information, see [the section called "Locking objects"](#).
- **Tags** – An AWS tag is a key-value pair that holds metadata. You attach the tags to your Amazon S3 resources, such as buckets. You can tag resources when you create them or manage tags on existing resources. You can use tags for cost allocation to track storage costs by bucket tag in AWS Billing and Cost Management. You can also use tags for attribute-based access control (ABAC), to scale access permissions and grant access to S3 resources based on their tags. For more information, see [Using tags with S3 general purpose buckets](#).

After you create a general purpose bucket, or when you're creating a general purpose bucket by using the Amazon S3 console, you can also use the following settings to control other aspects of your bucket's behavior:

- **S3 Block Public Access** – The S3 Block Public Access feature provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, or object permissions to allow public access. S3 Block Public Access settings override these policies and permissions so that you can limit public access to these resources. For more information, see [the section called "Blocking public access"](#).

- **S3 Versioning** – Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can easily recover from both unintended user actions and application failures. By default, versioning is disabled for buckets. For more information, see [the section called “Retaining multiple versions of objects”](#).
- **Default encryption** – You can set the default encryption type for all objects in your bucket. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the base level of encryption configuration for every bucket in Amazon S3. All new objects uploaded to an S3 bucket are automatically encrypted with SSE-S3 as the base level of encryption. If you want to use a different type of default encryption, you can specify server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C) to encrypt your data. For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

You can use the Amazon S3 console, Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs to create a general purpose bucket. For more information about the permissions required to create a general purpose bucket, see [CreateBucket](#) in the *Amazon Simple Storage Service API Reference*.

If you're having trouble creating an Amazon S3 bucket, see [How do I troubleshoot errors when creating an Amazon S3 bucket?](#) on AWS re:Post.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

- After you create a bucket, you can't change its Region.
- To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly

transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket.

The bucket name must:

- Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (commercial Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions).
- Be between 3 and 63 characters long.
- Consist only of lowercase letters, numbers, periods (.), and hyphens (-). For best compatibility, we recommend that you avoid using periods (.) in bucket names, except for buckets that are used only for static website hosting.
- Begin and end with a letter or number.
- For a complete list of bucket-naming rules, see [General purpose bucket naming rules](#).

Important

- After you create the bucket, you can't change its name.
- Don't include sensitive information in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

6. (Optional) Under **General configuration**, you can choose to copy an existing bucket's settings to your new bucket. If you don't want to copy the settings of an existing bucket, skip to the next step.

Note

This option:

- Isn't available in the AWS CLI and is only available in the Amazon S3 console
- Doesn't copy the bucket policy from the existing bucket to the new bucket

To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you want to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window reopens.

Under **Copy settings from existing bucket**, you now see the name of the bucket that you selected. The settings of your new bucket now match the settings of the bucket that you selected. If you want to remove the copied settings, choose **Restore defaults**. Review the remaining bucket settings on the **Create bucket** page. If you don't want to make any changes, you can skip to the final step.

7. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the general purpose bucket. ACLs no longer affect access permissions to data in the S3 general purpose bucket. The bucket uses policies exclusively to define access control.

By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you must control access for each object individually. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can [add a bucket policy](#) that allows only object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Note

The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

8. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

Note

To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

9. (Optional) By default, **Bucket Versioning** is disabled. Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can recover more easily from both unintended user actions and application failures. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

To enable versioning on your bucket, choose **Enable**.

10. (Optional) Under **Tags**, you can choose to add tags to your bucket. With AWS cost allocation, you can use bucket tags to annotate billing for your use of a bucket. A tag is a key-value pair that represents a label that you assign to a bucket. For more information, see [the section called “Using cost allocation tags”](#).

To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

11. To configure **Default encryption**, under **Encryption type**, choose one of the following:

- **Server-side encryption with Amazon S3 managed keys (SSE-S3)**

- **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
- **Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**

⚠ Important

If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas in the AWS Key Management Service Developer Guide](#).

Buckets and new objects are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption configuration. For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about SSE-S3, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

For more information about using server-side encryption to encrypt your data, see [the section called “Data encryption”](#).

12. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**, do the following:
 - a. Under **AWS KMS key**, specify your KMS key in one of the following ways:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys in the AWS Key Management Service Developer Guide](#).

 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

⚠️ Important

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that isn't listed, you must enter your KMS key ARN. If you want to use a KMS key that's owned by a different account, you must first have permission to use the key, and then you must enter the KMS key ARN. For more information about cross account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*. For more information about SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#). For more information about DSSE-KMS, see [the section called "Dual-layer server-side encryption \(DSSE-KMS\)"](#). When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

- b. When you configure your bucket to use default encryption with SSE-KMS, you can also use S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#). S3 Bucket Keys aren't supported for DSSE-KMS.

By default, S3 Bucket Keys are enabled in the Amazon S3 console. We recommend leaving S3 Bucket Keys enabled to lower your costs. To disable S3 Bucket Keys for your bucket, under **Bucket Key**, choose **Disable**.

13. (Optional) S3 Object Lock helps protect new objects from being deleted or overwritten. For more information, see [Locking objects with Object Lock](#). If you want to enable S3 Object Lock, do the following:

- a. Choose **Advanced settings**.

⚠ Important

Enabling Object Lock automatically enables versioning for the bucket. After you've enabled and successfully created the bucket, you must also configure the Object Lock default retention and legal hold settings on the bucket's **Properties** tab.

- b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

ⓘ Note

To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning`, and `s3:PutBucketObjectLockConfiguration`.

14. Choose **Create bucket**.

Using the AWS SDKs

When you use the AWS SDKs to create a general purpose bucket, you must create a client and then use the client to send a request to create a bucket. As a best practice, you should create your client and bucket in the same AWS Region. If you don't specify a Region when you create a client or a bucket, Amazon S3 uses the default Region, US East (N. Virginia). If you want to constrain the bucket creation to a specific AWS Region, use the [LocationConstraint](#) condition key.

To create a client to access a dual-stack endpoint, you must specify an AWS Region. For more information, see [Using Amazon S3 dual-stack endpoints](#) in the *Amazon S3 API Reference*. For a list of available AWS Regions, see [Amazon Simple Storage Service endpoints and quotas](#) in the *AWS General Reference*.

When you create a client, the Region maps to the Region-specific endpoint. The client uses this endpoint to communicate with Amazon S3: `s3.region.amazonaws.com`. If your Region launched after March 20, 2019, your client and bucket must be in the same Region. However, you can use a client in the US East (N. Virginia) Region to create a bucket in any Region that launched before March 20, 2019. For more information, see [Legacy endpoints](#).

These AWS SDK code examples perform the following tasks:

- **Create a client by explicitly specifying an AWS Region** – In the example, the client uses the `s3.us-west-2.amazonaws.com` endpoint to communicate with Amazon S3. You can specify any AWS Region. For a list of AWS Regions, see [Regions and endpoints](#) in the *AWS General Reference*.
- **Send a create bucket request by specifying only a bucket name** – The client sends a request to Amazon S3 to create the bucket in the Region where you created a client.
- **Retrieve information about the location of the bucket** – Amazon S3 stores bucket location information in the *location* subresource that's associated with the bucket.

For additional AWS SDK examples and examples in other languages, see [Use CreateBucket with an AWS SDK or CLI](#) in the *Amazon Simple Storage Service API Reference*.

Java

For examples of how to create a bucket with the AWS SDK for Java, see [Create a bucket](#) in the *Amazon S3 API Reference*.

When using the AWS SDK for Java v2, you can create a general purpose bucket with a globally unique identifier (GUID) appended to the bucket name to ensure uniqueness. Use `UUID.randomUUID().toString().replace("-", "")` to generate a GUID and concatenate it with your base bucket name. This approach helps avoid bucket naming conflicts across all AWS accounts.

.NET

For information about how to create and test a working sample, see the [AWS SDK for .NET Version 3 API Reference](#).

Example

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using Amazon.S3.Util;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CreateBucketTest
    {
```

```
private const string bucketName = "**** bucket name ****";
// Specify your bucket region (an example region is shown).
private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
private static IAmazonS3 s3Client;
public static void Main()
{
    s3Client = new AmazonS3Client(bucketRegion);
    CreateBucketAsync().Wait();
}

static async Task CreateBucketAsync()
{
    try
    {
        if (!(await AmazonS3Util.DoesS3BucketExistAsync(s3Client,
bucketName)))
        {
            var putBucketRequest = new PutBucketRequest
            {
                BucketName = bucketName,
                UseClientRegion = true
            };

            PutBucketResponse putBucketResponse = await
s3Client.PutBucketAsync(putBucketRequest);
        }
        // Retrieve the bucket location.
        string bucketLocation = await FindBucketLocationAsync(s3Client);
    }
    catch (AmazonS3Exception e)
    {
        Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
    catch (Exception e)
    {
        Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
}
static async Task<string> FindBucketLocationAsync(IAmazonS3 client)
{
    string bucketLocation;
```

```
        var request = new GetBucketLocationRequest()
    {
        BucketName = bucketName
    };
    GetBucketLocationResponse response = await
client.GetBucketLocationAsync(request);
    bucketLocation = response.Location.ToString();
    return bucketLocation;
}
}
```

Ruby

For information about how to create and test a working sample, see the [AWS SDK for Ruby - Version 3](#).

Example

```
require 'aws-sdk-s3'

# Wraps Amazon S3 bucket actions.
class BucketCreateWrapper
  attr_reader :bucket

  # @param bucket [Aws::S3::Bucket] An Amazon S3 bucket initialized with a name.
  This is a client-side object until
  #                               create is called.
  def initialize(bucket)
    @bucket = bucket
  end

  # Creates an Amazon S3 bucket in the specified AWS Region.
  #
  # @param region [String] The Region where the bucket is created.
  # @return [Boolean] True when the bucket is created; otherwise, false.
  def create?(region)
    @bucket.create(create_bucket_configuration: { location_constraint: region })
    true
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't create bucket. Here's why: #{e.message}"
    false
  end
}
```

```
# Gets the Region where the bucket is located.  
#  
# @return [String] The location of the bucket.  
def location  
  if @bucket.nil?  
    'None. You must create a bucket before you can get its location!'  
  else  
    @bucket.client.get_bucket_location(bucket: @bucket.name).location_constraint  
  end  
rescue Aws::Errors::ServiceError => e  
  "Couldn't get the location of #{@bucket.name}. Here's why: #{e.message}"  
end  
end  
  
# Example usage:  
def run_demo  
  region = "us-west-2"  
  wrapper = BucketCreateWrapper.new(Aws::S3::Bucket.new("amzn-s3-demo-bucket-  
#{Random.uuid}"))  
  return unless wrapper.create?(region)  
  
  puts "Created bucket #{wrapper.bucket.name}."  
  puts "Your bucket's region is: #{wrapper.location}"  
end  
  
run_demo if $PROGRAM_NAME == __FILE__
```

Using the AWS CLI

The following AWS CLI example creates a general purpose bucket in the US West (N. California) Region (us-west-1) Region with an example bucket name that uses a globally unique identifier (GUID). To use this example command, replace the *user input placeholders* with your own information.

```
aws s3api create-bucket \  
  --bucket amzn-s3-demo-bucket1$({uuidgen | tr -d - | tr '[:upper:]' '[:lower:]'}) \  
  --region us-west-1 \  
  --create-bucket-configuration LocationConstraint=us-west-1
```

For more information and additional examples, see [create-bucket](#) in the *AWS CLI Command Reference*.

Viewing the properties for an S3 general purpose bucket

You can view properties for any Amazon S3 bucket you own. These settings include the following:

- **Bucket Versioning** – Keep multiple versions of an object in one general purpose bucket by using versioning. By default, versioning is disabled for a new bucket. For information about enabling versioning, see [Enabling versioning on buckets](#).
- **Tags** – An AWS tag is a key-value pair that holds metadata. You attach the tags to your Amazon S3 resources, such as buckets. You can tag resources when you create them or manage tags on existing resources. You can use tags for cost allocation to track storage costs by bucket tag in AWS Billing and Cost Management. You can also use tags for attribute-based access control (ABAC), to scale access permissions and grant access to S3 resources based on their tags. For more information, see [Using tags with S3 general purpose buckets](#).
- **Default encryption** – Enabling default encryption provides you with automatic server-side encryption. Amazon S3 encrypts an object before saving it to a disk and decrypts the object when you download it. For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).
- **Server access logging** – Get detailed records for the requests that are made to your general purpose bucket with server access logging. By default, Amazon S3 doesn't collect server access logs. For information about enabling server access logging, see [Enabling Amazon S3 server access logging](#).
- **AWS CloudTrail data events** – Use CloudTrail to log data events. By default, trails don't log data events. Additional charges apply for data events. For more information, see [Logging Data Events for Trails](#) in the *AWS CloudTrail User Guide*.
- **Event notifications** – Enable certain Amazon S3 general purpose bucket events to send notification messages to a destination whenever the events occur. For more information, see [Enabling and configuring event notifications using the Amazon S3 console](#).
- **Transfer acceleration** – Enable fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. For information about enabling transfer acceleration, see [Enabling and using S3 Transfer Acceleration](#).
- **Object Lock** – Use S3 Object Lock to prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. For more information, see [Locking objects with Object Lock](#).
- **Requester Pays** – Enable Requester Pays if you want the requester (instead of the general purpose bucket owner) to pay for requests and data transfers. For more information, see [Using Requester Pays general purpose buckets for storage transfers and usage](#).

- **Static website hosting** – You can host a static website on Amazon S3. For more information, see [Hosting a static website using Amazon S3](#).

You can view bucket properties using the AWS Management Console, AWS CLI, or AWS SDKs

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to view the properties for.
4. Choose the **Properties** tab.
5. On the **Properties** page, you can configure the above properties for the bucket.

Using the AWS CLI

View bucket properties with the AWS CLI

The following commands show how you can use the AWS CLI to list different general purpose bucket properties.

The following returns the tag set associated with the bucket `amzn-s3-demo-bucket1`. For more information about bucket tags see, [Using cost allocation S3 bucket tags](#).

```
aws s3api get-bucket-tagging --bucket amzn-s3-demo-bucket1
```

For more information and examples, see [get-bucket-tagging](#) in the *AWS CLI Command Reference*.

The following returns the versioning state of the bucket `amzn-s3-demo-bucket1`. For information about the bucket versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

```
aws s3api get-bucket-versioning --bucket amzn-s3-demo-bucket1
```

For more information and examples, see [get-bucket-versioning](#) in the *AWS CLI Command Reference*.

The following returns the default encryption configuration for the bucket `amzn-s3-demo-bucket1`. By default, all buckets have a default encryption configuration that uses server-side

encryption with Amazon S3 managed keys (SSE-S3). For information about the bucket default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
```

For more information and examples, see [get-bucket-encryption](#) in the *AWS CLI Command Reference*.

The following returns the notification configuration of the bucket *amzn-s3-demo-bucket1*. For information about the bucket event notifications, see [Amazon S3 Event Notifications](#).

```
aws s3api get-bucket-notification-configuration --bucket amzn-s3-demo-bucket1
```

For more information and examples, see [get-bucket-notification-configuration](#) in the *AWS CLI Command Reference*.

The following returns the logging status for the bucket *amzn-s3-demo-bucket1*. For information about the bucket logging, see [Logging requests with server access logging](#).

```
aws s3api get-bucket-logging --bucket amzn-s3-demo-bucket1
```

For more information and examples, see [get-bucket-logging](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

For examples of how to return general purpose bucket properties with the AWS SDKs, such as versioning, tags, and more, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Listing Amazon S3 general purpose buckets

To return a list of general purpose buckets that you own, you can use [ListBuckets](#). You can list your buckets by using the Amazon S3 console, the AWS Command Line Interface, or the AWS SDKs. For ListBuckets requests using the AWS CLI, AWS SDKs, and Amazon S3 REST API, AWS accounts that use the default service quota for buckets (10,000 buckets), support both paginated and unpaginated requests. Regardless of how many buckets you have in your account, you can create page sizes between 1 and 10,000 buckets to list all of your buckets. For paginated requests, ListBuckets requests return both the bucket names and the corresponding AWS Regions for

each bucket. The following AWS Command Line Interface and AWS SDK examples show you how to use pagination in your `ListBuckets` request. Note that some AWS SDKs assist with pagination.

Permissions

To list all of your general purpose buckets, you must have the `s3:ListAllMyBuckets` permission. If you're encountering an HTTP Access Denied (403 Forbidden) error, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#).

Important

We strongly recommend using only paginated `ListBuckets` requests. Unpaginated `ListBuckets` requests are only supported for AWS accounts set to the default general purpose bucket quota of 10,000. If you have an approved general purpose bucket quota above 10,000, you must send paginated `ListBuckets` requests to list your account's buckets. All unpaginated `ListBuckets` requests will be rejected for AWS accounts with a general purpose bucket quota greater than 10,000.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. On the **General purpose buckets** tab, you can see a list of your general purpose buckets.
4. To find buckets by name, enter a bucket name in the **Find buckets by name** field.

Using the AWS CLI

To use the AWS CLI to generate a listing of general purpose buckets, you can use the `ls` or `list-buckets` commands. The following examples show you how to create a paginated `list-buckets` request and an unpaginated `ls` request. To use these examples, replace the *user input placeholders*.

Example – List all the buckets in your account by using `ls` (unpaginated)

The following example command lists all the general purpose buckets in your account in a single non-paginated call. This call returns a list of all buckets in your account (up to 10,000 results):

```
$ aws s3 ls
```

For more information and examples, see [List bucket and objects](#).

Example – List all the buckets in your account by using `ls` (paginated)

The following example command makes one or more paginated calls to list all the general purpose buckets in your account, returning 100 buckets per page:

```
$ aws s3 ls --page-size 100
```

For more information and examples, see [List bucket and objects](#).

Example – List all the buckets in your account (paginated)

The following example provides a paginated `list-buckets` command to list all the general purpose buckets in your account. The `--max-items` and `--page-size` options limit the number of buckets listed to 100 per page.

```
$ aws s3api list-buckets /  
  --max-items 100 /  
  --page-size 100
```

If the number of items output (`--max-items`) is fewer than the total number of items returned by the underlying API calls, the output includes a continuation token, specified by the `starting-token` argument, that you can pass to a subsequent command to retrieve the next set of items. The following example shows how to use the `starting-token` value returned by the previous example. You can specify the `starting-code` to retrieve the next 100 buckets.

```
$ aws s3api list-buckets /  
  --max-items 100 /  
  --page-size 100 /  
  --starting-token eyJNYXJrZXIi0iBudWxsLCAiYm90b190cnVuY2F0ZV9hbW91bnQi0iAxfQ==
```

Example – List all the buckets in an AWS Region (paginated)

The following example command uses the `--bucket-region` parameter to list up to 100 buckets in an account that are in the `us-east-2` Region. Requests made to a Regional endpoint that is

different from the value specified in the `--bucket-region` parameter are not supported. For example, if you want to limit the response to your buckets in us-east-2, you must make your request to an endpoint in us-east-2.

```
$ aws s3api list-buckets /  
  --region us-east-2 /  
  --max-items 100 /  
  --page-size 100 /  
  --bucket-region us-east-2
```

Example – List all the buckets that begin with a specific bucket name prefix (paginated)

The following example command lists up to 100 buckets that have a name starting with the `amzn-s3-demo-bucket` prefix.

```
$ aws s3api list-buckets /  
  --max-items 100 /  
  --page-size 100 /  
  --prefix amzn-s3-demo-bucket
```

Using the AWS SDKs

The following examples show you how to list your general purpose buckets by using the AWS SDKs for Python

Example – ListBuckets request (paginated)

```
import boto3  
  
s3 = boto3.client('s3')  
response = s3.list_buckets(MaxBuckets=100)
```

Example – ListBuckets response (paginated)

```
import boto3  
  
s3 = boto3.client('s3')  
response =  
s3.list_buckets(MaxBuckets=1,ContinuationToken="eyJNYXJrZXIiOiBudWxsLCAiYm90b190cnVuY2F0ZV9
```

SDK for Java

For examples of how to list buckets with the AWS SDK for Java, see [List buckets](#) in the *Amazon S3 API Reference*.

SDK for Go

```
package main
import (
    "context"
    "fmt"
    "log"
    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
)
func main() {
    cfg, err := config.LoadDefaultConfig(context.TODO(), config.WithRegion("us-east-2"))
    if err != nil {
        log.Fatal(err)
    }
    client := s3.NewFromConfig(cfg)
    maxBuckets := 1000
    resp, err := client.ListBuckets(context.TODO(), management
portals3.ListBucketsInput{MaxBuckets: aws.Int32(int32(maxBuckets))})
    if err != nil {
        log.Fatal(err)
    }
    fmt.Println("S3 Buckets:")
    for _, bucket := range resp.Buckets {
        fmt.Println("- Name:", *bucket.Name)
        fmt.Println("-BucketRegion", *bucket.BucketRegion)
    }
    fmt.Println(resp.ContinuationToken == nil)
    fmt.Println(resp.Prefix == nil)
}
```

Emptying a general purpose bucket

You can empty a general purpose bucket's contents using the Amazon S3 console, AWS SDKs, or AWS Command Line Interface (AWS CLI). When you empty a general purpose bucket, you delete

all the objects, but you keep the bucket. After you empty a bucket, it cannot be undone. Objects added to the bucket while the empty bucket action is in progress might be deleted. All objects (including all object versions and delete markers) in the bucket must be deleted before the bucket itself can be deleted.

When you empty a general purpose bucket that has S3 Versioning enabled or suspended, all versions of all the objects in the bucket are deleted. For more information, see [Working with objects in a versioning-enabled bucket](#).

While emptying your bucket, we recommend that you also remove all incomplete multipart uploads. You can use multipart uploads to upload very large objects (up to 50 TB) as a set of parts for improved throughput and quicker recovery from network issues. In cases where the multipart upload process doesn't finish, the incomplete parts remain in the bucket (in an unusable state). These incomplete parts incur storage costs until the upload process is finished, or until the incomplete parts are removed. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).

As a best practice, we recommend configuring lifecycle rules to expire objects and incomplete multipart uploads that are older than a specific number of days. When you create your lifecycle rule to expire incomplete multipart uploads, we recommend 7 days as a good starting point. For more information, see [Setting an S3 Lifecycle configuration on a bucket](#).

Lifecycle expiration is an asynchronous process, so the rule might take some days to run before your bucket is empty. After the first time that Amazon S3 runs the rule, all objects that are eligible for expiration are marked for deletion. You're no longer charged for those objects that are marked for deletion. For more information, see [How do I empty an Amazon S3 bucket using a lifecycle configuration rule?](#).

Using the S3 console

You can use the Amazon S3 console to empty a general purpose bucket, which deletes all of the objects in the bucket without deleting the bucket.

To empty an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.

3. In the bucket list, select the option next to the name of the bucket that you want to empty, and then choose **Empty**.
4. On the **Empty bucket** page, confirm that you want to empty the bucket by entering the bucket name into the text field, and then choose **Empty**.
5. Monitor the progress of the bucket emptying process on the **Empty bucket: Status** page.

Using the AWS CLI

You can empty a general purpose bucket using the AWS CLI only if the bucket does not have Bucket Versioning enabled. If versioning is not enabled, you can use the `rm` (remove) AWS CLI command with the `--recursive` parameter to empty the bucket (or remove a subset of objects with a specific key name prefix).

The following `rm` command removes objects that have the key name prefix `doc`, for example, `doc/doc1` and `doc/doc2`.

```
$ aws s3 rm s3://bucket-name/doc --recursive
```

Use the following command to remove all objects without specifying a prefix.

```
$ aws s3 rm s3://bucket-name --recursive
```

For more information, see [Using high-level S3 commands with the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Note

You can't remove objects from a bucket that has versioning enabled. Amazon S3 adds a delete marker when you delete an object, which is what this command does. For more information about S3 Bucket Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

Using the AWS SDKs

You can use the AWS SDKs to empty a general purpose bucket or remove a subset of objects that have a specific key name prefix.

For an example of how to empty a bucket using AWS SDK for Java, see [Deleting a general purpose bucket](#). The code deletes all objects, regardless of whether the bucket has versioning enabled, and then it deletes the bucket. To just empty the bucket, make sure that you remove the statement that deletes the bucket.

For more information about using other AWS SDKs, see [Tools for Amazon Web Services](#).

Using a lifecycle configuration

To empty a large general purpose bucket, we recommend that you use an S3 Lifecycle configuration rule. Lifecycle expiration is an asynchronous process, so the rule might take some days to run before the bucket is empty. After the first time that Amazon S3 runs the rule, all objects that are eligible for expiration are marked for deletion. You're no longer charged for those objects that are marked for deletion. For more information, see [How do I empty an Amazon S3 bucket using a lifecycle configuration rule?](#)

If you use a lifecycle configuration to empty your bucket, the configuration should include [current versions](#), [non-current versions](#), [delete markers](#), and [incomplete multipart uploads](#).

You can add lifecycle configuration rules to expire all objects or a subset of objects that have a specific key name prefix. For example, to remove all objects in a bucket, you can set a lifecycle rule to expire objects one day after creation.

Amazon S3 supports a bucket lifecycle rule that you can use to stop multipart uploads that don't complete within a specified number of days after being initiated. We recommend that you configure this lifecycle rule to minimize your storage costs. For more information, see [Configuring a bucket lifecycle configuration to delete incomplete multipart uploads](#).

For more information about using a lifecycle configuration to empty a bucket, see [Setting an S3 Lifecycle configuration on a bucket](#) and [Expiring objects](#).

Emptying a general purpose bucket with AWS CloudTrail configured

AWS CloudTrail tracks object-level data events in an Amazon S3 general purpose bucket, such as deleting objects. If you use a general purpose bucket as a destination to log your CloudTrail events and are deleting objects from that same bucket you may be creating new objects while emptying your bucket. To prevent this, stop your AWS CloudTrail trails. For more information about stopping your CloudTrail trails from logging events, see [Turning off logging for a trail](#) in the *AWS CloudTrail User Guide*.

Another alternative to stopping CloudTrail trails from being added to the bucket is to add a deny s3:PutObject statement to your bucket policy. If you want to store new objects in the bucket at a later time you will need to remove this deny s3:PutObject statement. For more information, see [Object operations](#) and [IAM JSON policy elements: Effect](#) in the *IAM User Guide*.

Deleting a general purpose bucket

You can delete an empty Amazon S3 general purpose bucket. For information about emptying a general purpose bucket, see [the section called “Emptying a general purpose bucket”](#).

You can delete a bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

Important

Before deleting a general purpose bucket, consider the following:

- **If a bucket is deleted, it can't be restored by AWS.** Before deleting a bucket, make sure that you have backed up or replicated your data.
- General purpose bucket names are unique within a global namespace. **If you delete a bucket, be aware that another AWS account can use the same general purpose bucket name for a new bucket and can therefore potentially receive requests intended for the deleted bucket.** If you want to prevent this, or if you want to continue to use the same bucket name, don't delete the bucket. We recommend that you empty the bucket and keep it, and instead, block any bucket requests as needed. For buckets no longer in active use, we recommend emptying the bucket of all objects to minimize costs while retaining the bucket itself.
- When you delete a general purpose bucket, the bucket might not be instantly removed. Instead, Amazon S3 queues the bucket for deletion. Because Amazon S3 is distributed across AWS Regions, the deletion process takes time to fully propagate and achieve consistency throughout the system.
- If the bucket hosts a static website, and you created and configured an Amazon Route 53 hosted zone as described in [Tutorial: Configuring a static website using a custom domain registered with Route 53](#), you must clean up the Route 53 hosted zone settings that are related to the bucket. For more information, see [Step 2: Delete the Route 53 hosted zone](#).

- If the bucket receives log data from Elastic Load Balancing (ELB), we recommend that you stop the delivery of ELB logs to the bucket before deleting it. After you delete the bucket, if another user creates a bucket using the same name, your log data could potentially be delivered to that bucket. For information about ELB access logs, see [Access logs for your Classic Load Balancer](#) in the *User Guide for Classic Load Balancers* and [Access logs for your Application Load Balancer](#) in the *User Guide for Application Load Balancers*.

Troubleshooting

If you are unable to delete an Amazon S3 general purpose bucket, consider the following:

- **Make sure that the bucket is empty** – You can delete buckets only if they don't have any objects in them. Make sure that the bucket is empty. For information about emptying a bucket, see [the section called "Emptying a general purpose bucket"](#).
- **Make sure that there aren't any access points attached** – You can delete buckets only if they don't have any S3 Access Points or Multi-Region Access Points attached within the same account. Before deleting the bucket, delete any same-account access points that are attached to the bucket.
- **Make sure that you have the s3:DeleteBucket permission** – If you can't delete a bucket, work with your IAM administrator to confirm that you have the s3:DeleteBucket permission. For information about how to view or update IAM permissions, see [Changing permissions for an IAM user](#) in the *IAM User Guide*. For troubleshooting information, see [the section called "Troubleshoot access denied \(403 Forbidden\) errors"](#).
- **Check for s3:DeleteBucket Deny statements in AWS Organizations service control policies (SCPs) and resource control policies (RCPs)** – SCPs and RCPs can deny the delete permission on a bucket. For more information, see [service control policies](#) and [resource control policies](#) in the *AWS Organizations User Guide*.
- **Check for s3:DeleteBucket Deny statements in your bucket policy** – If you have s3:DeleteBucket permissions in your IAM user or role policy and you can't delete a bucket, the bucket policy might include a Deny statement for s3:DeleteBucket. Buckets created by AWS Elastic Beanstalk have a policy containing this statement by default. Before you can delete the bucket, you must delete this statement or the bucket policy.

Prerequisites

Before you can delete a general purpose bucket, you must empty it. For information about emptying a bucket, see [the section called “Emptying a general purpose bucket”](#).

Using the S3 console

To delete an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, select the option button next to the name of the bucket that you want to delete, and then choose **Delete** at the top of the page.
4. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

 **Note**

If the bucket contains any objects, empty the bucket before deleting it by choosing the **Empty bucket** button in the **This bucket is not empty** error alert and following the instructions on the **Empty bucket** page. Then return to the **Delete bucket** page and delete the bucket.

5. To verify that you've deleted the bucket, open the **General purpose buckets** list and enter the name of the bucket that you deleted. If the bucket can't be found, your deletion was successful.

Using the AWS SDK for Java

To empty and delete a general purpose bucket using the AWS SDK for Java, you must first delete all objects in the general purpose bucket, and then delete the bucket.

For examples in other languages, see [Use DeleteBucket with an AWS SDK or CLI](#) in the *Amazon Simple Storage Service API Reference*. For information about using other AWS SDKs, see [Tools for Amazon Web Services](#).

Java

To delete a bucket that contains objects using the AWS SDK for Java, you must delete all objects first, and then delete the bucket. This approach works for buckets with or without versioning enabled.

 **Note**

For buckets without versioning enabled, you can delete all objects directly and then delete the bucket. For buckets with versioning enabled, you must delete all object versions before deleting the bucket.

For examples of how to delete a bucket with the AWS SDK for Java, see [Delete a bucket](#) in the *Amazon S3 API Reference*.

Using the AWS CLI

You can delete a general purpose bucket that contains objects with the AWS CLI if the bucket doesn't have versioning enabled. When you delete a bucket that contains objects, all the objects in the bucket are permanently deleted, including objects that have been transitioned to the S3 Glacier Flexible Retrieval storage class.

If your bucket doesn't have versioning enabled, you can use the `rb` (remove bucket) AWS CLI command with the `--force` parameter to delete the bucket and all the objects in it. This command deletes all the objects first and then deletes the bucket.

If versioning is enabled, using the `rb` command with the `--force` parameter doesn't delete versioned objects, so the bucket deletion fails because the bucket isn't empty. For more information about deleting versioned objects, see [Deleting object versions](#).

To use the following command, replace `amzn-s3-demo-bucket` with the name of the bucket that you want to delete:

```
$ aws s3 rb s3://amzn-s3-demo-bucket --force
```

For more information, see [Using High-Level S3 Commands with the AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.

Mount an Amazon S3 bucket as a local file system

Mountpoint for Amazon S3 is a high-throughput open source file client for mounting an Amazon S3 bucket as a local file system. With Mountpoint, your applications can access objects stored in Amazon S3 through file system operations, such as open and read. Mountpoint automatically translates these operations into S3 object API calls, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface.

Mountpoint for Amazon S3 is [available for production use on your large-scale read-heavy applications](#): data lakes, machine learning training, image rendering, autonomous vehicle simulation, extract, transform, and load (ETL), and more.

Mountpoint supports basic file system operations, and can read files up to 50 TB in size. It can list and read existing files, and it can create new ones. It cannot modify existing files or delete directories, and it does not support symbolic links or file locking. Mountpoint is ideal for applications that do not need all of the features of a shared file system and POSIX-style permissions but require Amazon S3's elastic throughput to read and write large S3 datasets. For details, see [Mountpoint file system behavior](#) on GitHub. For workloads that require full POSIX support, we recommend [Amazon FSx for Lustre](#) and its [support for linking Amazon S3 buckets](#).

Mountpoint for Amazon S3 is available only for Linux operating systems. You can use Mountpoint to access S3 objects in all storage classes except S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, S3 Intelligent-Tiering Archive Access Tier, and S3 Intelligent-Tiering Deep Archive Access Tier.

Amazon Linux 2023 (AL2023)

Mountpoint is available directly in the Amazon Linux 2023 repository since AL2023 version 2023.9.20251110.

1. Install it by entering the following command:

```
sudo dnf install mount-s3
```

2. Verify that Mountpoint for Amazon S3 is successfully installed:

```
mount-s3 --version
```

You should see output similar to the following:

```
mount-s3 1.21.0+1.amzn2023
```

Other RPM-based distributions (Amazon Linux 2, Fedora, CentOS, RHEL)

1. Copy the following download URL for your architecture.

x86_64:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86\_64/mount-s3.rpm
```

ARM64 (Graviton):

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.rpm
```

2. Download the Mountpoint for Amazon S3 package. Replace *download-link* with the appropriate download URL from the preceding step.

```
wget download-link
```

3. (Optional) Verify the authenticity and integrity of the downloaded file. First, copy the appropriate signature URL for your architecture.

x86_64:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86\_64/mount-s3.rpm.asc
```

ARM64 (Graviton):

```

```

Next, see [Verifying the signature of the Mountpoint for Amazon S3 package](#).

4. Install the package by using the following command:

```
sudo yum install ./mount-s3.rpm
```

5. Verify that Mountpoint is successfully installed by entering the following command:

```
mount-s3 --version
```

You should see output similar to the following:

```
mount-s3 1.21.0
```

DEB-based distributions (Debian, Ubuntu)

1. Copy the download URL for your architecture.

```

ARM64 (Graviton):

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.deb.asc
```

Next, see [Verifying the signature of the Mountpoint for Amazon S3 package](#).

4. Install the package by using the following command:

```
sudo apt-get install ./mount-s3.deb
```

5. Verify that Mountpoint for Amazon S3 is successfully installed by running the following command:

```
mount-s3 --version
```

You should see output similar to the following:

```
mount-s3 1.21.0
```

Other Linux distributions

1. Consult your operating system documentation to install the FUSE and libfuse2 packages, which are required.

2. Copy the download URL for your architecture.

x86_64:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.tar.gz
```

ARM64 (*Graviton*):

```

```

3. Download the Mountpoint for Amazon S3 package. Replace *download-link* with the appropriate download URL from the preceding step.

```
wget download-link
```

4. (Optional) Verify the authenticity and integrity of the downloaded file. First, copy the signature URL for your architecture.

x86_64:

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.tar.gz.asc
```

ARM64 (*Graviton*):

```
https://s3.amazonaws.com/mountpoint-s3-release/latest/arm64/mount-s3.tar.gz.asc
```

Next, see [Verifying the signature of the Mountpoint for Amazon S3 package](#).

5. Install the package by using the following command:

```
sudo mkdir -p /opt/aws/mountpoint-s3 && sudo tar -C /opt/aws/mountpoint-s3 -xzf ./mount-s3.tar.gz
```

6. Add the mount-s3 binary to your PATH environment variable. In your \$HOME/.profile file, append the following line:

```
export PATH=$PATH:/opt/aws/mountpoint-s3/bin
```

Save the .profile file, and run the following command:

```
source $HOME/.profile
```

7. Verify that Mountpoint for Amazon S3 is successfully installed by running the following command:

```
mount-s3 --version
```

You should see output similar to the following:

```
mount-s3 1.21.0
```

Verifying the signature of the Mountpoint for Amazon S3 package

1. Install GnuPG (the gpg command). It is required to verify the authenticity and integrity of a downloaded Mountpoint for Amazon S3 package. GnuPG is installed by default on Amazon Linux Amazon Machine Images (AMIs). After you install GnuPG, proceed to step 2.
2. Download the Mountpoint public key by running the following command:

```
wget https://s3.amazonaws.com/mountpoint-s3-release/public_keys/KEYS
```

3. Import the Mountpoint public key into your keyring by running the following command:

```
gpg --import KEYS
```

4. Verify the fingerprint of the Mountpoint public key by running the following command:

```
gpg --fingerprint mountpoint-s3@amazon.com
```

Confirm that the displayed fingerprint string matches the following:

```
673F E406 1506 BB46 9A0E F857 BE39 7A52 B086 DA5A
```

If the fingerprint string doesn't match, do not finish installing Mountpoint, and contact [AWS Support](#).

5. Download the package signature file. Replace *signature-link* with the appropriate signature link from the preceding sections.

```
wget signature-link
```

- Verify the signature of the downloaded package by running the following command. Replace *signature-filename* with the file name from the previous step.

```
gpg --verify signature-filename
```

For example, on RPM-based distributions, including Amazon Linux, enter the following command:

```
gpg --verify mount-s3.rpm.asc
```

- The output should include the phrase Good signature. If the output includes the phrase BAD signature, redownload the Mountpoint package file and repeat these steps. If the issue persists, do not finish installing Mountpoint, and contact [AWS Support](#).

The output may include a warning about a trusted signature. This does not indicate a problem. It only means that you have not independently verified the Mountpoint public key.

Configuring and using Mountpoint

To use Mountpoint for Amazon S3, your host needs valid AWS credentials with access to the Amazon S3 bucket or buckets that you would like to mount. For different ways to authenticate, see Mountpoint [AWS Credentials](#) on GitHub.

For example, you can create a new AWS Identity and Access Management (IAM) user and role for this purpose. Make sure that this role has access to the bucket or buckets that you would like to mount. You can [pass the IAM role](#) to your Amazon EC2 instance with an instance profile.

Using Mountpoint for Amazon S3

Use Mountpoint for Amazon S3 to do the following:

1. Mount your Amazon S3 buckets.

- You can mount Amazon S3 buckets manually by using the `mount-s3` command.

In the following example, replace `amzn-s3-demo-bucket` with the name of your S3 bucket, and replace `~/mnt` with the directory on your host where you want your S3 bucket to be mounted.

```
mkdir ~/mnt  
mount-s3 amzn-s3-demo-bucket ~/mnt
```

Because the Mountpoint client runs in the background by default, the `~/mnt` directory now gives you access to the objects in your Amazon S3 bucket.

- Alternatively, since Mountpoint v1.18, you can configure automatic mounting of Amazon S3 buckets when an instance starts up or reboots.

For existing or running Amazon EC2 instances, find the `fstab` file in the `/etc/fstab` directory of your Linux system. Then, add a line to your `fstab` file. For example, to mount `amzn-s3-demo-bucket` using the prefix `example-prefix/` to your system path `/mnt/mountpoint`, see the following. To use the following example, replace the *user input placeholders* with your own information.

```
s3://amzn-s3-demo-bucket/example-prefix/ /mnt/mountpoint mount-s3  
_netdev,nosuid,nodev,nofail,rw 0 0
```

See the following table for an explanation of the options used in the example.

Option	Description
<code>_netdev</code>	Specifies that the filesystem requires networking to mount.
<code>nosuid</code>	Specifies that the filesystem cannot contain set user ID files.
<code>nodev</code>	Specifies that the filesystem cannot contain special devices.

Option	Description
nofail	Specifies that failure to mount the filesystem should still allow the system to boot.
rw	Specifies that the mount point is created with read and write permissions. Alternatively, use ro for read only.

For new Amazon EC2 instances, you can modify user data on an Amazon EC2 template and set up the fstab file as follows. To use the following example, replace the *user input placeholders* with your own information.

```
#!/bin/bash -e
MP_RPM=$(mktemp --suffix=.rpm)
curl https://s3.amazonaws.com/mountpoint-s3-release/latest/x86_64/mount-s3.rpm
> $MP_RPM
yum install -y $MP_RPM
rm $MP_RPM

MNT_PATH=/mnt/mountpoint
echo "s3://amzn-s3-demo-bucket/${MNT_PATH} mount-s3
    _netdev,nosuid,nodev,rw,allow-other,nofail" >> /etc/fstab
mkdir ${MNT_PATH}

systemctl daemon-reload
mount -a
```

2. Access the objects in your Amazon S3 bucket through Mountpoint.

After you mount your bucket locally, you can use common Linux commands, such as cat or ls, to work with your S3 objects. Mountpoint for Amazon S3 interprets keys in your Amazon S3 bucket as file system paths by splitting them on the forward slash (/) character. For example, if you have the object key Data/2023-01-01.csv in your bucket, you will have a directory named Data in your Mountpoint file system, with a file named 2023-01-01.csv inside it.

Mountpoint for Amazon S3 intentionally does not implement the full [POSIX](#) standard specification for file systems. Mountpoint is optimized for workloads that need high-

throughput read and write access to data stored in Amazon S3 through a file system interface, but that otherwise do not rely on file system features. For more information, see Mountpoint for Amazon S3 [file system behavior](#) on GitHub. Customers that need richer file system semantics should consider other AWS file services, such as [Amazon Elastic File System \(Amazon EFS\)](#) or [Amazon FSx](#).

3. Unmount your Amazon S3 bucket by using the `umount` command. This command unmounts your S3 bucket and exits Mountpoint.

To use the following example command, replace `~/mnt` with the directory on your host where your S3 bucket is mounted.

```
umount ~/mnt
```

 **Note**

To get a list of options for this command, run `umount --help`.

For additional Mountpoint configuration details, see [Amazon S3 bucket configuration](#), and [file system configuration](#) on GitHub.

Configuring caching in Mountpoint

Mountpoint for Amazon S3 supports different types of data caching. To accelerate repeated read requests, you can opt in to the following:

- **Local cache** – You can use a local cache in your Amazon EC2 instance storage or an Amazon Elastic Block Store volume. If you repeatedly read the same data from the same compute instance and if you have unused space in your local instance storage for the repeatedly read dataset, you should opt in to a local cache.
- **Shared cache** – You can use a shared cache on S3 Express One Zone. If you repeatedly read small objects from multiple compute instances or if you do not know the size of your repeatedly read dataset and want to benefit from elasticity of cache size, you should opt in to the shared cache. Once you opt in, Mountpoint retains objects with sizes up to one megabyte in a directory bucket that uses S3 Express One Zone.
- **Combined local and shared cache** – If you have unused space in your local cache but also want a shared cache across multiple instances, you can opt in to both a local cache and shared cache.

Caching in Mountpoint is ideal for use cases where you repeatedly read the same data that doesn't change during the multiple reads. For example, you can use caching with machine learning training jobs that need to read a training dataset multiple times to improve model accuracy.

For more information about how to configure caching in Mountpoint, see the following examples.

Topics

- [Local cache](#)
- [Shared cache](#)
- [Combined local and shared cache](#)

Local cache

You can opt in to a local cache with the `--cache` *CACHE_PATH* flag. In the following example, replace *CACHE_PATH* with the filepath to the directory that you want to cache your data in. Replace *amzn-s3-demo-bucket* with the name of your Amazon S3 bucket, and replace *~/mnt* with the directory on your host where you want your S3 bucket to be mounted.

```
mkdir ~/mnt
mount-s3 --cache CACHE_PATH amzn-s3-demo-bucket ~/mnt
```

When you opt in to local caching while mounting an Amazon S3 bucket, Mountpoint creates an empty sub-directory at the configured cache location, if that sub-directory doesn't already exist. When you first mount a bucket and when you unmount, Mountpoint deletes the contents of the local cache.

Important

If you enable local caching, Mountpoint will persist unencrypted object content from your mounted Amazon S3 bucket at the local cache location provided at mount. In order to protect your data, you should restrict access to the data cache location by using file system access control mechanisms.

Shared cache

If you repeatedly read small objects (up to 1 MB) from multiple compute instances or the size of the dataset that you repeatedly read often exceeds the size of your local cache, you should use

a shared cache in [S3 Express One Zone](#). When you read the same data repeatedly from multiple instances, this improves latency by avoiding redundant requests to your mounted Amazon S3 bucket.

Once you opt in to the shared cache, you pay for the data cached in your directory bucket in S3 Express One Zone. You also pay for requests made against your data in the directory bucket in S3 Express One Zone. For more information, see [Amazon S3 pricing](#). Mountpoint never deletes cached objects from directory buckets. To manage your storage costs, you should set up a [Lifecycle policy on your directory bucket](#) so that Amazon S3 expires the cached data in S3 Express One Zone after a period of time that you specify. For more information, see [Mountpoint for Amazon S3 caching configuration](#) on GitHub.

To opt in to caching in S3 Express One Zone when you mount an Amazon S3 bucket to your compute instance, use the `--cache-xz` flag and specify a directory bucket as your cache location. In the following example, replace the *user input placeholders*.

```
mount-s3 amzn-s3-demo-bucket ~/mnt --cache-xz amzn-s3-demo-bucket--usw2-az1--x-s3
```

Combined local and shared cache

If you have unused space on your instance but you also want to use a shared cache across multiple instances, you can opt in to both a local cache and shared cache. With this caching configuration, you can avoid redundant read requests from the same instance to the shared cache in directory bucket when the required data is cached in local storage. This can reduce request costs and improve performance.

To opt in to both a local cache and shared cache when you mount an Amazon S3 bucket, you specify both cache locations by using the `--cache` and `--cache-xz` flags. To use the following example to opt into both a local and shared cache, replace the *user input placeholders*.

```
mount -s3 amzn-s3-demo-bucket ~/mnt --cache /path/to/mountpoint/cache --cache -xz amzn-s3-demo-bucket--usw2-az1--x-s3
```

For more information, [Mountpoint for Amazon S3 caching configuration](#) on GitHub.

Important

If you enable shared caching, Mountpoint will copy object content from your mounted Amazon S3 bucket into the S3 directory bucket that you provide as your shared cache

location, making it accessible to any caller with access to the S3 directory bucket. To protect your cached data, you should follow the [Security best practices for Amazon S3](#) to ensure that your buckets use the correct policies and are not publicly accessible. You should use a directory bucket dedicated to Mountpoint shared caching and grant access only to Mountpoint clients.

Troubleshooting Mountpoint

Mountpoint for Amazon S3 is backed by Support. If you need assistance, contact the [AWS Support Center](#).

You can also review and submit Mountpoint [Issues](#) on GitHub.

If you discover a potential security issue in this project, we ask that you notify AWS Security through our [vulnerability reporting page](#). Do not create a public GitHub issue.

If your application behaves unexpectedly with Mountpoint, you can inspect your log information to diagnose the problem.

Logging

By default, Mountpoint emits high-severity log information to [syslog](#).

To view logs on most modern Linux distributions, including Amazon Linux, run the following `journald` command:

```
journalctl -e SYSLOG_IDENTIFIER=mount-s3
```

On other Linux systems, `syslog` entries are likely written to a file such as `/var/log/syslog`.

You can use these logs to troubleshoot your application. For example, if your application tries to overwrite an existing file, the operation fails, and you will see a line similar to the following in the log:

```
[WARN] open{req=12 ino=2}: mountpoint_s3::fuse: open failed: inode error: inode 2 (full key "README.md") is not writable
```

For more information, see Mountpoint for Amazon S3 [Logging](#) on GitHub.

Working with Storage Browser for Amazon S3

[Storage Browser for S3](#) is an open source component that you can add to your web application to provide your end users with a simple graphical interface for data stored in Amazon S3. With Storage Browser for S3, you can provide authorized end users access to browse, download, upload, copy, and delete data in S3 directly from your own applications.

Storage Browser for S3 supports the following operations for files: LIST, GET, PUT, COPY, UPLOAD, and DELETE. To deliver high throughput data transfer, Storage Browser for S3 only displays the data that your end users are authorized to access and optimizes upload requests. Storage Browser also optimizes performance for faster load times, calculates checksums of the data that your end users upload, and accepts objects after confirming that your data integrity was maintained (in transit) over the public internet. You can control access to your data based on your end user's identity using AWS security and identity services, or your own managed services. You can also customize Storage Browser to match your existing application's design and branding.

Storage Browser for S3 is only available for web and intranet applications on the React framework. You can use Storage Browser to access Amazon S3 objects in all storage classes except S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, S3 Intelligent-Tiering Archive Access tier, and S3 Intelligent-Tiering Deep Archive Access tier.

Storage Browser for S3 is available to use with your web applications in the [AWS Amplify React](#) library. For more information about Storage Browser, see [Storage Browser for S3](#).

Using Storage Browser for S3

In Storage Browser for S3, a *location* is an S3 general purpose bucket or prefix, that you grant end users access to using [S3 Access Grants](#), IAM policies, or your own managed authorization service. After you've authorized your end users to access a specific location, they can work with any data within that location.

The Storage Browser for S3 user interface has four main views:

- **Home page:** The home page lists the S3 locations that your users can access, as well as your permissions for each. This is the initial view for users that shows the root level S3 resources that your end users have access to and the permissions (READ/WRITE/READWRITE) for each S3 location.
- **Location details:** This view allows users to browse files and folders in S3, and upload or download files. (Note that in Storage Browser for S3, *objects* are known as files, and *prefixes* and *buckets* are known as folders.)
- **Location action:** After a user chooses an action (such as **Upload**) in Storage Browser, it opens up another view of the file location.
- **Vertical ellipsis:** The vertical ellipsis icon opens the drop-down list of actions.

When using Storage Browser for S3, be aware of the following limitations:

- Folders starting or ending with dots (.) aren't supported.
- S3 Access Grants with WRITE only permission isn't supported.
- Storage Browser for S3 supports the PUT operation for files up to 160 GB in size.
- Storage Browser for S3 only supports the COPY operation for files smaller than 5 GB. If the file size exceeds 5 GB, Storage Browser fails the request.

Installing Storage Browser for S3

The fastest way to get started with Storage Browser is to clone one of the sample projects on GitHub. These sample projects can help you deploy production ready web apps for Storage Browser with preset integrations of AWS services for AWS Identity and Access Management so you can quickly connect authorized end users to data in S3.

For more information, see [Quick start](#) in the *Amplify Dev Center*.

Installing Storage Browser for S3 from GitHub

Alternatively, you can install Storage Browser for S3 from the latest version of `aws-amplify/ui-react-storage` and `aws-amplify` packages in the [aws-amplify](#) GitHub repository to start integrating Storage Browser into your existing application. When installing Storage Browser for S3, make sure to add the following dependencies to your package.json file:

```
"dependencies": {  
    "aws-amplify/ui-react-storage": "latest",  
    "aws-amplify": "latest",  
}
```

Alternatively, you can add the dependencies using Node Package Manager (NPM):

```
npm i --save @aws-amplify/ui-react-storage aws-amplify
```

Setting up Storage Browser for S3

To connect end users with Amazon S3 *locations*, you must first set up an authentication and authorization method. There are three methods to set up an authentication and authorization method with Storage Browser:

- [Method 1: Managing data access for your customers and third party partners](#)
- [Method 2: Managing data access for your IAM principals for your AWS account](#)
- [Method 3: Managing data access at scale](#)

Method 1: Managing data access for your customers and third party partners

With this method, you can use [AWS Amplify Auth](#) to manage access control and security for files. This method is ideal when you want to connect your customers or third party partners with data in S3. With this option, your customers can authenticate using social or enterprise identity providers.

You provide IAM credentials to your end users and third party partners using AWS Amplify Auth with an S3 bucket that's configured to use Amplify Storage. AWS Amplify Auth is built on [Amazon Cognito](#), a fully managed customer identity and access management service where you can authenticate and authorize users from a built-in user directory or enterprise directory, or from consumer identity providers. The Amplify authorization model defines which prefixes the current authenticated user can access. For more information about how to set up authorization for AWS Amplify, see [Set up storage](#).

To initialize the component with the Amplify authentication and storage methods, add the following code snippet to your web application:

```
import {  
    createAmplifyAuthAdapter,  
    createStorageBrowser,
```

```
} from '@aws-amplify/ui-react-storage/browser';
import "@aws-amplify/ui-react-storage/styles.css";

import config from './amplify_outputs.json';

Amplify.configure(config);

export const { StorageBrowser } = createStorageBrowser({
  config: createAmplifyAuthAdapter(),
});
```

Method 2: Managing data access for your IAM principals for your AWS account

If you want to manage access for your IAM principals or your AWS account directly, you can create an IAM role that has permissions to invoke the [GetDataAdapter](#) S3 API operation. To set this up, you must create an S3 Access Grants instance to map out permissions for S3 general purpose buckets and prefixes to the specified IAM identities. The Storage Browser component (which must be called on the client side after obtaining the IAM credentials) will then invoke the [ListCallerAccessGrants](#) S3 API operation to fetch the available grants to the identity requester and populate the locations in the component. After you obtain the s3:GetDataAccess permission, those credentials are then used by the Storage Browser component to request data access to S3.

```
import {
  createManagedAuthAdapter,
  createStorageBrowser,
} from '@aws-amplify/ui-react-storage/browser';
import "@aws-amplify/ui-react-storage/styles.css";

export const { StorageBrowser } = createStorageBrowser({
  config: createManagedAuthAdapter({
    credentialsProvider: async (options?: { forceRefresh?: boolean }) => {
      // return your credentials object
      return {
        credentials: {
          accessKeyId: 'my-access-key-id',
          secretAccessKey: 'my-secret-access-key',
          sessionToken: 'my-session-token',
          expiration: new Date()
        },
      }
    },
    // AWS `region` and `accountId`
  })
});
```

```
region: '',
accountId: '',
// call `onAuthStateChange` when end user auth state changes
// to clear sensitive data from the `StorageBrowser` state
registerAuthListener: (onAuthStateChange) => {},
})
});
```

Method 3: Managing data access at scale

If you want to associate an [S3 Access Grants](#) instance to your IAM Identity Center for a more scalable solution (such as providing data access to your whole company), you can request data from Amazon S3 on behalf of the current authenticated user. For example, you can grant user groups in your corporate directory access to your data in S3. This approach allows you to centrally manage S3 Access Grants permissions for your users and groups, including the ones hosted on external providers such as Microsoft Entra, Okta, and others.

When using this method, the [Integration with the IAM Identity Center](#) allows you to use existing user directories. Another benefit of an IAM Identity Center trusted identity propagation is that each [AWS CloudTrail data event for Amazon S3](#) contains a direct reference to the end user identity that accessed the S3 data.

If you have an application that supports OAuth 2.0 and your users need access from these applications to AWS services, we recommend that you use trusted identity propagation. With trusted identity propagation, a user can sign in to an application, and that application can pass the user's identity in any requests that access data in AWS services. This application interacts with IAM Identity Center on behalf of any authenticated users. For more information, see [Using trusted identity propagation with customer managed applications](#).

[Trusted identity propagation](#) is an AWS IAM Identity Center feature that administrators of connected AWS services can use to grant and audit access to service data. Access to this data is based on user attributes such as group associations. Setting up trusted identity propagation requires collaboration between the administrators of connected AWS services and the IAM Identity Center administrators. For more information, see [Prerequisites and considerations](#).

Setup

To set up Storage Browser authentication in the AWS Management Console using [S3 Access Grants](#) and [IAM Identity Center trusted identity propagation](#), your applications must request data from Amazon S3 on behalf of the current authenticated user. With this approach, you can give users or

groups of users from your corporate directory direct access to your S3 buckets, prefixes, or objects. This means that your application won't need to map any users to an IAM principal.

The following workflow outlines the steps for setting up Storage Browser for S3, using IAM Identity Center and S3 Access Grants:

Steps	Description
1	Enable IAM Identity Center for your AWS Organizations
2	Configure AWS Identity and Access Management Identity Center federation
3	Add a trusted token issuer in the AWS Identity and Access Management Identity Center console The trusted token issuer represents your external identity provider (IdP) within IAM Identity Center, enabling it to recognize identity tokens for your application's authenticated users.
4	Create an IAM role for the bootstrap application and identity bearer
5	Create and configure your application in IAM Identity Center This application interacts with IAM Identity Center on behalf of authenticated users.
6	Add S3 Access Grants as a trusted application for identity propagation This step connects your application to S3 Access Grants, so that it can make requests to S3 Access Grants on behalf of authenticated users.
7	Create a grant to a user or group This step syncs users from AWS Identity and Access Management Identity Center with the System for Cross-dom

Steps	Description
	ain Identity Management (SCIM). SCIM keeps your IAM Identity Center identities in sync with identities from your identity provider (IdP).
8	Create your Storage Browser for S3 component

Enable IAM Identity Center for your AWS Organizations

To enable IAM Identity Center for your AWS Organizations, perform the following steps:

1. Sign in to the AWS Management Console, using one of these methods:
 1. **New to AWS (root user)** – Sign in as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.
 2. **Already using AWS (IAM credentials)** – Sign in using your IAM credentials with administrative permissions.
2. Open the [IAM Identity Center console](#).
3. Under **Enable IAM Identity Center**, choose **Enable**.

 **Note**

IAM Identity Center requires the setup of AWS Organizations. If you haven't set up an organization, you can choose to have AWS create one for you. Choose **Create AWS organization** to complete this process.

4. Choose **Enable with AWS Organizations**.
5. Choose **Continue**.
6. (Optional) Add any tags that you want to associate with this organization instance.
7. (Optional) Configure the delegated administration.

 **Note**

If you're using a multi-account environment, we recommend that you configure delegated administration. With delegated administration, you can limit the number

of people who require access to the management account in AWS Organizations. For more information, see [Delegated administration](#).

8. Choose **Save**.

AWS Organizations automatically sends a verification email to the address that is associated with your management account. There might be a delay before you receive the verification email. Make sure to verify your email address within 24 hours, before your verification email expires.

Configure AWS Identity and Access Management Identity Center federation

To use Storage Browser for S3 with corporate directory users, you must configure IAM Identity Center to use an external identity provider (IdP). You can use the preferred identity provider of your choice. However, be aware that each identity provider uses different configuration settings. For tutorials on using different external identity providers, see [IAM Identity Center source tutorials](#).

Note

Make sure to record the issuer URL and the audience attributes of the identity provider that you've configured because you will need to refer to it in later steps. If you don't have the required access or permissions to configure an IdP, you might need to contact the administrator of the external IdP to obtain them.

Add a trusted token issuer in the AWS Identity and Access Management Identity Center console

The trusted token issuer represents your external identity provider in the AWS Identity and Access Management Identity Center, and recognizes tokens for your application's authenticated users. The account owner of the IAM Identity Center instance in your AWS Organizations must perform these steps. These steps can be done either in the IAM Identity Center console, or programmatically.

To add a trusted token issuer in the AWS Identity and Access Management Identity Center console, perform the following steps:

1. Open the [IAM Identity Center console](#).
2. Choose **Settings**.
3. Choose the **Authentication** tab.
4. Navigate to the **Trusted token issuers** section, and fill out the following details:

1. Under **Issuer URL**, enter the URL of the external IdP that serves as the trusted token issuer. You might need to contact the administrator of the external IdP to obtain this information. For more information, see [Using applications with a trusted token issuer](#).
2. Under **Trusted token issuer name**, enter a name for the trusted token issuer. This name will appear in the list of trusted token issuers that you can select in *Step 8*, when an application resource is configured for identity propagation.
5. Update your **Map attributes** to your preferred application attribute, where each identity provider attribute is mapped to an IAM Identity Center attribute. For example, you might want to [map the application attribute](#) `email` to the IAM Identity Center user attribute `email`. To see the list of allowed user attributes in IAM Identity Center, see the table in [Attribute mappings for AWS Managed Microsoft AD directory](#).
6. (Optional) If you want to add a resource tag, enter the key and value pair. To add multiple resource tags, choose **Add new tag** to generate a new entry and enter the key and value pairs.
7. Choose **Create trusted token issuer**.
8. After you finish creating the trusted token issuer, contact the application administrator to let them know the name of the trusted token issuer, so that they can confirm that the trusted token issuer is visible in the applicable console.
9. Make sure the application administrator selects this trusted token issuer in the applicable console to enable user access to the application from applications that are configured for trusted identity propagation.

Create an IAM role for the bootstrap application and identity bearer

To ensure that the bootstrap application and identity bearer users can properly work with each other, make sure to [create two IAM roles](#). One IAM role is required for the bootstrap application and the other IAM role must be used for the identity bearer, or end users who are accessing the web application that requests access through S3 Access Grants. The bootstrap application receives the token issued by the identity provider and invokes the `CreateTokenWithIAM` API, exchanging this token with the one issued by the Identity Center.

Create an IAM role, such as `bootstrap-role`, with permissions such as the following. The following example IAM policy gives permissions to the `bootstrap-role` to perform the token exchange:

{

```
"Version": "2012-10-17",
"Statement": [
    "Action": [
        "sso-oauth>CreateTokenWithIAM",
    ],
    "Resource": "arn:${Partition}:sso::${AccountId}:application/${InstanceId}/
${ApplicationId}",
    "Effect": "Allow"
},
{
    "Action": [
        "sts:AssumeRole",
        "sts:SetContext"
    ],
    "Resource": "arn:aws:iam::${AccountId}:role/identity-bearer-role",
    "Effect": "Allow"
}
]
```

Then, create a second IAM role (such as `identity-bearer-role`), which the identity broker uses to generate the IAM credentials. The IAM credentials returned from the identity broker to the web application are used by the Storage Browser for S3 component to allow access to S3 data:

```
{
    "Action": [
        "s3:GetDataAccess",
        "s3>ListCallerAccessGrants",
    ],
    "Resource": "arn:${Partition}:s3:${Region}:${Account}:access-grants/default",
    "Effect": "Allow"
}
```

This IAM role (`identity-bearer-role`) must use a trust policy with the following statement:

```
{
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:${Partition}:iam::${AccountId}:role/${RoleNameWithPath}"
    },
    "Action": [
        "sts:AssumeRole",
        "sts:SetContext"
    ]
}
```

```
]  
}
```

Create and configure your application in IAM Identity Center

Note

Before you begin, make sure that you've created the required IAM roles from the previous step. You'll need to specify one of these IAM roles in this step.

To create and configure a customer managed application in AWS IAM Identity Center, perform the following steps:

1. Open the [IAM Identity Center console](#).
2. Choose **Applications**.
3. Choose the **Customer managed** tab.
4. Choose **Add application**.
5. On the **Select application type** page, under **Setup preference**, choose **I have an application I want to set up**.
6. Under **Application type**, choose **OAuth 2.0**.
7. Choose **Next**. The **Specify application** page is displayed.
8. Under the **Application name and description** section, enter a **Display name** for the application, such as **storage-browser-oauth**.
9. Enter a **Description**. The application description appears in the IAM Identity Center console and API requests, but not in the AWS access portal.
10. Under **User and group assignment method**, choose **Do not require assignments**. This option allows all authorized IAM Identity Center users and groups access to this application.
11. Under **AWS access portal**, enter an application URL where users can access the application.
12. (Optional) If you want to add a resource tag, enter the key and value pair. To add multiple resource tags, choose **Add new tag** to generate a new entry and enter the key and value pairs.
13. Choose **Next**. The **Specify authentication** page displays.
14. Under **Authentication with trusted token issuer**, use the checkbox to select the trusted token issuer that you previously created.

15. Under **Configure selected trusted token issuers**, enter the [aud claim](#). The **aud claim** identifies the audience of the JSON Web Token (JWT), and it is the name by which the trusted token issuer identifies this application.

 **Note**

You might need to contact the administrator of the external IdP to obtain this information.

16. Choose **Next**. The **Specify authentication credentials** page displays.
17. Under **Configuration method**, choose **Enter one or more IAM roles**.
18. Under **Enter IAM roles**, add the [IAM role](#) or Amazon Resource Name (ARN) for the identity bearer token. You must enter the IAM role that you created from the previous step for the identity broker application (for example, **bootstrap-role**).
19. Choose **Next**.
20. On the **Review and configure** page, review the details of your application configuration. If you need to modify any of the settings, choose **Edit** for the section that you want to edit and make your changes to.
21. Choose **Submit**. The details page of the application that you just added is displayed.

After you've set up your applications, your users can access your applications from within their AWS access portal based on the [permission sets that you've created](#) and the [user access that you've assigned](#).

Add S3 Access Grants as a trusted application for identity propagation

After you set up your customer managed application, you must specify S3 Access Grants for identity propagation. S3 Access Grants vends credentials for users to access Amazon S3 data. When you sign in to your customer managed application, S3 Access Grants will pass your user identity to the trusted application.

Prerequisite: Make sure that you've set up S3 Access Grants (such as [creating an S3 Access Grants instance](#) and [registering a location](#)) before following these steps. For more information, see [Getting started with S3 Access Grants](#).

To add S3 Access Grants for identity propagation to your customer managed application, perform the following steps:

1. Open the [IAM Identity Center console](#).
2. Choose **Applications**.
3. Choose the **Customer managed** tab.
4. In the **Customer managed applications** list, select the OAuth 2.0 application for which you want to initiate access requests. This is the application that your users will sign in to.
5. On the **Details** page, under **Trusted applications for identity propagation**, choose **Specify trusted applications**.
6. Under **Setup type**, select **Individual applications** and specify access, and then choose **Next**.
7. On the **Select service** page, choose **S3 Access Grants**. S3 Access Grants has applications that you can use to define your own web application for trusted identity propagation.
8. Choose **Next**. You'll select your applications in the next step.
9. On the **Select applications** page, choose **Individual applications**, select the checkbox for each application that can receive requests for access, and then choose **Next**.
10. On the **Configure access** page, under **Configuration method**, choose either of the following:
 - **Select access per application** – Select this option to configure different access levels for each application. Choose the application for which you want to configure the access level, and then choose **Edit access**. In **Level of access to apply**, change the access levels as needed, and then choose **Save changes**.
 - **Apply same level of access to all applications** – Select this option if you don't need to configure access levels on a per-application basis.
11. Choose **Next**.
12. On the **Review configuration** page, review the choices that you made.

 **Note**

You'll want to make sure the `s3:access_grants:read_write` permission is granted for your users. This permission allows your users to retrieve credentials to access Amazon S3. Make sure to use either the IAM policy you created previously, or S3 Access Grants, to limit access to write operations.

13. To make changes, choose **Edit** for the configuration section that you want to make changes to. Then, make the required changes and choose **Save changes**.
14. Choose **Trust applications** to add the trusted application for identity propagation.

Create a grant to a user or group

In this step, you use IAM Identity Center to provision your users. You can use SCIM for [automated or manual provisioning of users and groups](#). SCIM keeps your IAM Identity Center identities in sync with identities from your identity provider (IdP). This includes any provisioning, updates, and deprovisioning of users between your IdP and IAM Identity Center.

Note

This step is required because when S3 Access Grants is used with IAM Identity Center, local IAM Identity Center users aren't used. Instead, users must be synchronized from the identity provider with IAM Identity Center.

To synchronize users from your identity provider with IAM Identity Center, perform the following steps:

1. [Enable automatic provisioning](#).
2. [Generate an access token](#).

For examples of how to set up the identity provider with IAM Identity Center for your specific use case, see [IAM Identity Center Identity source tutorials](#).

Create your Storage Browser for S3 component

After you've set up your IAM Identity Center instance and created grants in S3 Access Grants, open your React application. In the React application, use `createManagedAuthAdapter` to set up the authorization rules. You must provide a credentials provider to return the credentials you acquired from IAM Identity Center. You can then call `createStorageBrowser` to initialize the Storage Browser for S3 component:

```
import {  
  createManagedAuthAdapter,  
  createStorageBrowser,  
} from '@aws-amplify/ui-react-storage/browser';  
import '@aws-amplify/ui-react-storage/styles.css';  
  
export const { StorageBrowser } = createStorageBrowser({  
  config: createManagedAuthAdapter({  
    credentialsProvider: async (options?: { forceRefresh?: boolean }) => {  
      // Your logic here  
    },  
  }),  
});
```

```
// return your credentials object
return {
  credentials: {
    accessKeyId: 'my-access-key-id',
    secretAccessKey: 'my-secret-access-key',
    sessionToken: 'my-session-token',
    expiration: new Date(),
  },
},
},
// AWS `region` and `accountId` of the S3 Access Grants Instance.
region: '',
accountId: '',
// call `onAuthStateChange` when end user auth state changes
// to clear sensitive data from the `StorageBrowser` state
registerAuthListener: (onAuthStateChange) => {},
})
});
```

Then, create a mechanism to exchange the JSON web tokens (JWTs) from your web application with the IAM credentials from IAM Identity Center. For more information about how to exchange the JWT, see the following resources:

- [How to develop a user-facing data application with IAM Identity Center and S3 Access Grants](#) post in *AWS Storage Blog*
- [Scaling data access with S3 Access Grants](#) post in *AWS Storage Blog*
- [S3 Access Grants workshop](#) on *AWS workshop studio*
- [S3 Access Grants workshop](#) on *GitHub*

Then, set up an API endpoint to handle requests for fetching credentials. To validate the JSON web token (JWT) exchange, perform the following steps:

1. Retrieve the JSON web token from the authorization header for incoming requests.
2. Validate the token using the public keys from the specified JSON web key set (JWKS) URL.
3. Verify the token's expiration, issuer, subject, and audience claims.

To exchange the identity provider's JSON web token with AWS IAM credentials, perform the following steps:

Tip

Make sure to avoid logging any sensitive information. We recommend that you use error handling controls for missing authorization, expired tokens, and other exceptions. For more information, see the [Implementing AWS Lambda error handling patterns](#) post in AWS Compute Blog.

1. Verify that the required **Permission** and **Scope** parameters are provided in the request.
2. Use the [CreateTokenWithIAM](#) API to exchange the JSON web token for an IAM Identity Center token.

Note

After the IdP JSON web token is used, it can't be used again. A new token must be used to exchange with IAM Identity Center.

3. Use the [AssumeRole](#) API operation to assume a transient role using the IAM Identity Center token. Make sure to use the identity bearer role, also known as the role that carries the identity context (for example, **identity-bearer-role**) to request the credentials.
4. Return the IAM credentials to the web application.

Note

Make sure that you've set up a proper logging mechanism. Responses are returned in a standardized JSON format with an appropriate HTTP status code.

Configuring Storage Browser for S3

To allow Storage Browser for S3 access to S3 buckets, the Storage Browser component makes the REST API calls to Amazon S3. By default, [cross-origin resource sharing \(CORS\)](#) isn't enabled on S3 buckets. As a result, you must enable CORS for each S3 bucket that Storage Browser is accessing data from.

For example, to enable CORS on your S3 bucket, you can update your CORS policy like this:

[

```
{  
    "ID": "S3CORSRuleId1",  
    "AllowedHeaders": [  
        "*"  
    ],  
    "AllowedMethods": [  
        "GET",  
        "HEAD",  
        "PUT",  
        "POST",  
        "DELETE"  
    ],  
    "AllowedOrigins": [  
        "*"  
    ],  
    "ExposeHeaders": [  
        "last-modified",  
        "content-type",  
        "content-length",  
        "etag",  
        "x-amz-version-id",  
        "x-amz-request-id",  
        "x-amz-id-2",  
        "x-amz-cf-id",  
        "x-amz-storage-class",  
        "date",  
        "access-control-expose-headers"  
    ],  
    "MaxAgeSeconds": 3000  
}  
]  
]
```

Troubleshooting Storage Browser for S3

If you're experiencing issues with Storage Browser for S3, make sure to review the following troubleshooting tips:

- Avoid trying to use the same token (`idToken` or `accessToken`) for multiple requests. Tokens can't be reused. This will result in a request failure.
- Make sure that the IAM credentials that you provide to the Storage Browser component includes permissions to invoke the `s3:GetDataAccess` operation. Otherwise, your end users won't be able to access your data.

Alternatively, you can check the following resources:

- Storage Browser for S3 is backed by AWS Support. If you need assistance, contact the [AWS Support Center](#).
- If you're having trouble with Storage Browser for S3 or would like to submit feedback, visit the [Amplify GitHub page](#).
- If you discover a potential security issue in this project, you can notify AWS Security through the [AWS Vulnerability Reporting](#) page.

Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration

Amazon S3 Transfer Acceleration is a bucket-level feature that enables fast, easy, and secure transfers of files over long distances between your client and an S3 general purpose bucket. Transfer Acceleration is designed to optimize transfer speeds from across the world into S3 general purpose buckets. Transfer Acceleration takes advantage of the globally distributed edge locations in Amazon CloudFront. As the data arrives at an edge location, the data is routed to Amazon S3 over an optimized network path.

When you use Transfer Acceleration, additional data transfer charges might apply. For more information about pricing, see [Amazon S3 pricing](#).

Why use Transfer Acceleration?

You might want to use Transfer Acceleration on a general purpose bucket for various reasons:

- Your customers upload to a centralized general purpose bucket from all over the world.
- You transfer gigabytes to terabytes of data on a regular basis across continents.
- You can't use all of your available bandwidth over the internet when uploading to Amazon S3.

For more information about when to use Transfer Acceleration, see [Amazon S3 FAQs](#).

Requirements for using Transfer Acceleration

The following are required when you are using Transfer Acceleration on an S3 bucket:

- Transfer Acceleration is only supported on virtual-hosted style requests. For more information about virtual-hosted style requests, see [Making requests using the REST API](#) in the *Amazon S3 API Reference*.
- The name of the bucket used for Transfer Acceleration must be DNS-compliant and must not contain periods (".").
- Transfer Acceleration must be enabled on the bucket. For more information, see [Enabling and using S3 Transfer Acceleration](#).

After you enable Transfer Acceleration on a bucket, it might take up to 20 minutes before the data transfer speed to the bucket increases.

Note

Transfer Acceleration is currently supported for buckets located in the following Regions:

- Asia Pacific (Tokyo) (ap-northeast-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Canada (Central) (ca-central-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)
- Europe (London) (eu-west-2)
- Europe (Paris) (eu-west-3)
- South America (São Paulo) (sa-east-1)
- US East (N. Virginia) (us-east-1)
- US East (Ohio) (us-east-2)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)

- To access the bucket that is enabled for Transfer Acceleration, you must use the endpoint ***bucket-name*.s3-accelerate.amazonaws.com**. Or, use the dual-stack endpoint ***bucket-name*.s3-accelerate.dualstack.amazonaws.com** to connect to the enabled bucket over IPv6. You can continue to use the regular endpoints for standard data transfer.

- You must be the bucket owner to set the transfer acceleration state. The bucket owner can assign permissions to other users to allow them to set the acceleration state on a bucket. The `s3:PutAccelerateConfiguration` permission permits users to enable or disable Transfer Acceleration on a bucket. The `s3:GetAccelerateConfiguration` permission permits users to return the Transfer Acceleration state of a bucket, which is either Enabled or Suspended.

The following sections describe how to get started and use Amazon S3 Transfer Acceleration for transferring data.

Topics

- [Getting started with Amazon S3 Transfer Acceleration](#)
- [Enabling and using S3 Transfer Acceleration](#)
- [Using the Amazon S3 Transfer Acceleration Speed Comparison tool](#)

Getting started with Amazon S3 Transfer Acceleration

You can use Amazon S3 Transfer Acceleration for fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration uses the globally distributed edge locations in Amazon CloudFront. As the data arrives at an edge location, data is routed to Amazon S3 over an optimized network path.

To get started using Amazon S3 Transfer Acceleration, perform the following steps:

1. Enable Transfer Acceleration on a bucket

You can enable Transfer Acceleration on a bucket any of the following ways:

- Use the Amazon S3 console.
- Use the REST API [PutBucketAccelerateConfiguration](#) operation.
- Use the AWS CLI and AWS SDKs. For more information, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

For more information, see [Enabling and using S3 Transfer Acceleration](#).

Note

For your bucket to work with transfer acceleration, the bucket name must conform to DNS naming requirements and must not contain periods (.).

2. Transfer data to and from the acceleration-enabled bucket

Use one of the following s3-accelerate endpoint domain names:

- To access an acceleration-enabled bucket, use *bucket-name*.s3-accelerate.amazonaws.com.
- To access an acceleration-enabled bucket over IPv6, use *bucket-name*.s3-accelerate.dualstack.amazonaws.com.

Amazon S3 dual-stack endpoints support requests to S3 buckets over IPv6 and IPv4. The Transfer Acceleration dual-stack endpoint only uses the virtual hosted-style type of endpoint name. For more information, see [Making requests to Amazon S3 over IPv6](#) in the *Amazon S3 API Reference* and [Using Amazon S3 dual-stack endpoints](#) in the *Amazon S3 API Reference*.

Note

Your data transfer application must use one of the following two types of endpoints to access the bucket for faster data transfer: .s3-accelerate.amazonaws.com or .s3-accelerate.dualstack.amazonaws.com for the dual-stack endpoint. If you want to use standard data transfer, you can continue to use the regular endpoints.

You can point your Amazon S3 PUT object and GET object requests to the s3-accelerate endpoint domain name after you enable Transfer Acceleration. For example, suppose that you currently have a REST API application using [PutObject](#) that uses the hostname *amzn-s3-demo-bucket*.s3.us-east-1.amazonaws.com in the PUT request. To accelerate the PUT, you change the hostname in your request to *amzn-s3-demo-bucket*.s3-accelerate.amazonaws.com. To go back to using the standard upload speed, change the name back to *amzn-s3-demo-bucket*.s3.us-east-1.amazonaws.com.

After Transfer Acceleration is enabled, it can take up to 20 minutes for you to realize the performance benefit. However, the accelerate endpoint is available as soon as you enable Transfer Acceleration.

You can use the accelerate endpoint in the AWS CLI, AWS SDKs, and other tools that transfer data to and from Amazon S3. If you are using the AWS SDKs, some of the supported languages use an accelerate endpoint client configuration flag so you don't need to explicitly set the endpoint for Transfer Acceleration to `bucket-name.s3-accelerate.amazonaws.com`. For examples of how to use an accelerate endpoint client configuration flag, see [Enabling and using S3 Transfer Acceleration](#).

You can use all Amazon S3 operations through the transfer acceleration endpoints *except* for the following:

- [ListBuckets](#)
- [CreateBucket](#)
- [DeleteBucket](#)

Also, Amazon S3 Transfer Acceleration does not support cross-Region copies using [CopyObject](#).

Enabling and using S3 Transfer Acceleration

You can use Amazon S3 Transfer Acceleration to transfer files quickly and securely over long distances between your client and an S3 general purpose bucket. You can enable Transfer Acceleration using the S3 console, the AWS Command Line Interface (AWS CLI), API, or the AWS SDKs.

This section provides examples of how to enable Amazon S3 Transfer Acceleration on a bucket and use the acceleration endpoint for the enabled bucket.

For more information about Transfer Acceleration requirements, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

Using the S3 console

Note

If you want to compare accelerated and non-accelerated upload speeds, open the [Amazon S3 Transfer Acceleration Speed Comparison tool](#).

The Speed Comparison tool uses multipart upload to transfer a file from your browser to various AWS Regions with and without Amazon S3 transfer acceleration. You can compare the upload speed for direct uploads and transfer accelerated uploads by Region.

To enable transfer acceleration for an S3 general purpose bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that you want to enable transfer acceleration for.
4. Choose **Properties**.
5. Under **Transfer acceleration**, choose **Edit**.
6. Choose **Enable**, and choose **Save changes**.

To access accelerated data transfers

1. After Amazon S3 enables transfer acceleration for your bucket, view the **Properties** tab for the bucket.
2. Under **Transfer acceleration**, **Accelerated endpoint** displays the transfer acceleration endpoint for your bucket. Use this endpoint to access accelerated data transfers to and from your bucket.

If you suspend transfer acceleration, the accelerate endpoint no longer works.

Using the AWS CLI

The following are examples of AWS CLI commands used for Transfer Acceleration. For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the *Amazon S3 API Reference*.

Enabling Transfer Acceleration on a bucket

Use the AWS CLI [put-bucket-accelerate-configuration](#) command to enable or suspend Transfer Acceleration on a bucket.

The following example sets Status=Enabled to enable Transfer Acceleration on a bucket named *amzn-s3-demo-bucket*. To suspend Transfer Acceleration, use Status=Suspended.

Example

```
$ aws s3api put-bucket-accelerate-configuration --bucket amzn-s3-demo-bucket --accelerate-configuration Status=Enabled
```

Using Transfer Acceleration

You can direct all Amazon S3 requests made by `s3` and `s3api` AWS CLI commands to the accelerate endpoint: `s3-accelerate.amazonaws.com`. To do this, set the configuration value `use_accelerate_endpoint` to `true` in a profile in your AWS Config file. Transfer Acceleration must be enabled on your bucket to use the accelerate endpoint.

All requests are sent using the virtual style of bucket addressing: `amzn-s3-demo-bucket.s3-accelerate.amazonaws.com`. Any `ListBuckets`, `CreateBucket`, and `DeleteBucket` requests are not sent to the accelerate endpoint because the endpoint doesn't support those operations.

For more information about `use_accelerate_endpoint`, see [AWS CLI S3 Configuration](#) in the [AWS CLI Command Reference](#).

The following example sets `use_accelerate_endpoint` to `true` in the default profile.

Example

```
$ aws configure set default.s3.use_accelerate_endpoint true
```

If you want to use the accelerate endpoint for some AWS CLI commands but not others, you can use either one of the following two methods:

- Use the accelerate endpoint for any `s3` or `s3api` command by setting the `--endpoint-url` parameter to `https://s3-accelerate.amazonaws.com`.
- Set up separate profiles in your AWS Config file. For example, create one profile that sets `use_accelerate_endpoint` to `true` and a profile that does not set `use_accelerate_endpoint`. When you run a command, specify which profile you want to use, depending upon whether you want to use the accelerate endpoint.

Uploading an object to a bucket enabled for Transfer Acceleration

The following example uploads a file to a bucket named *amzn-s3-demo-bucket* that's been enabled for Transfer Acceleration by using the default profile that has been configured to use the accelerate endpoint.

Example

```
$ aws s3 cp file.txt s3://amzn-s3-demo-bucket/key-name --region region
```

The following example uploads a file to a bucket enabled for Transfer Acceleration by using the `--endpoint-url` parameter to specify the accelerate endpoint.

Example

```
$ aws configure set s3.addressing_style virtual
$ aws s3 cp file.txt s3://amzn-s3-demo-bucket/key-name --region region --endpoint-url
https://s3-accelerate.amazonaws.com
```

Using the AWS SDKs

The following are examples of using Transfer Acceleration to upload objects to Amazon S3 using the AWS SDK. Some of the AWS SDK supported languages (for example, Java and .NET) use an accelerate endpoint client configuration flag so you don't need to explicitly set the endpoint for Transfer Acceleration to *bucket-name*.s3-accelerate.amazonaws.com.

Java

To use an accelerate endpoint to upload an object to Amazon S3 with the AWS SDK for Java, you can:

- Create an S3Client that is configured to use accelerate endpoints. All buckets that the client accesses must have Transfer Acceleration enabled.
- Enable Transfer Acceleration on a specified bucket. This step is necessary only if the bucket you specify doesn't already have Transfer Acceleration enabled.
- Verify that transfer acceleration is enabled for the specified bucket.
- Upload a new object to the specified bucket using the bucket's accelerate endpoint.

For more information about using Transfer Acceleration, see [Getting started with Amazon S3 Transfer Acceleration](#).

The following code example shows how to configure Transfer Acceleration with the AWS SDK for Java.

```
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.regions.Region;

        String bucketName = "*** Provide bucket name ***";
        String keyName = "*** Provide key name ***";

        try {
            // Create an Amazon S3 client that is configured to use the accelerate

            S3Client s3Client = S3Client.builder()
                .region(clientRegion)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .accelerate(true)
                .build();

            // Enable Transfer Acceleration for the specified bucket.
            s3Client.putBucketAccelerateConfiguration(
                PutBucketAccelerateConfigurationRequest.builder()
                    .bucket(bucketName)

                .accelerateConfiguration(AccelerateConfiguration.builder()
                    .status(BucketAccelerateStatus.ENABLED)

```

.NET

The following example shows how to use the AWS SDK for .NET to enable Transfer Acceleration on a bucket. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

Example

```
using Amazon;\nusing Amazon.S3;\nusing Amazon.S3.Model;\nusing System;
```

```
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class TransferAccelerationTest
    {
        private const string bucketName = "**** bucket name ****";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            EnableAccelerationAsync().Wait();
        }

        static async Task EnableAccelerationAsync()
        {
            try
            {
                var putRequest = new PutBucketAccelerateConfigurationRequest
                {
                    BucketName = bucketName,
                    AccelerateConfiguration = new AccelerateConfiguration
                    {
                        Status = BucketAccelerateStatus.Enabled
                    }
                };
                await
s3Client.PutBucketAccelerateConfigurationAsync(putRequest);

                var getRequest = new GetBucketAccelerateConfigurationRequest
                {
                    BucketName = bucketName
                };
                var response = await
s3Client.GetBucketAccelerateConfigurationAsync(getRequest);

                Console.WriteLine("Acceleration state = '{0}'",
response.Status);
            }
            catch (AmazonS3Exception amazonS3Exception)
            {

```

```
        Console.WriteLine(
            "Error occurred. Message: '{0}' when setting transfer
acceleration",
            amazonS3Exception.Message);
    }
}
}
```

When uploading an object to a bucket that has Transfer Acceleration enabled, you specify using the acceleration endpoint at the time of creating a client.

```
var client = new AmazonS3Client(new AmazonS3Config
{
    RegionEndpoint = TestRegionEndpoint,
    UseAccelerateEndpoint = true
})
```

JavaScript

For an example of enabling Transfer Acceleration by using the AWS SDK for JavaScript, see [PutBucketAccelerateConfiguration command](#) in the *AWS SDK for JavaScript API Reference*.

Python (Boto)

For an example of enabling Transfer Acceleration by using the SDK for Python, see [put_bucket_accelerate_configuration](#) in the *AWS SDK for Python (Boto3) API Reference*.

Other

For information about using other AWS SDKs, see [Sample Code and Libraries](#).

Using the REST API

Use the REST API PutBucketAccelerateConfiguration operation to enable accelerate configuration on an existing bucket.

For more information, see [PutBucketAccelerateConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Using the Amazon S3 Transfer Acceleration Speed Comparison tool

You can use the [Amazon S3 Transfer Acceleration Speed Comparison tool](#) to compare accelerated and non-accelerated upload speeds across Amazon S3 Regions. The Speed Comparison tool uses multipart uploads to transfer a file from your browser to various Amazon S3 Regions with and without using Transfer Acceleration.

You can access the Speed Comparison tool by using either of the following methods:

- Copy the following URL into your browser window, replacing *region* with the AWS Region that you are using (for example, us-west-2) and *amzn-s3-demo-bucket* with the name of the bucket that you want to evaluate:

```
https://s3-accelerate-speedtest.s3-accelerate.amazonaws.com/en/
accelerate-speed-comparsion.html?region=region&origBucketName=amzn-s3-
demo-bucket
```

For a list of the Regions supported by Amazon S3, see [Amazon S3 endpoints and quotas](#) in the *AWS General Reference*.

- Use the Amazon S3 console.

Using Requester Pays general purpose buckets for storage transfers and usage

In general, bucket owners pay for all Amazon S3 storage and data transfer costs that are associated with their bucket. However, you can configure a general purpose bucket to be a *Requester Pays* bucket. With Requester Pays buckets, the requester instead of the bucket owner pays the cost of the request and the data download from the bucket. The bucket owner always pays the cost of storing data.

Typically, you configure buckets to be Requester Pays buckets when you want to share data but not incur charges associated with others accessing the data. For example, you might use Requester Pays buckets when making available large datasets, such as zip code directories, reference data, geospatial information, or web crawling data.

⚠️ Important

If you enable Requester Pays on a general purpose bucket, anonymous access to that bucket is not allowed.

You must authenticate all requests involving Requester Pays buckets. The request authentication enables Amazon S3 to identify and charge the requester for their use of the Requester Pays bucket.

When the requester assumes an AWS Identity and Access Management (IAM) role before making their request, the account to which the role belongs is charged for the request. For more information about IAM roles, see [IAM roles](#) in the *IAM User Guide*.

After you configure a bucket to be a Requester Pays bucket, requesters must show they understand that they will be charged for the request and for the data download. To show they accept the charges, requesters must either include `x-amz-request-payer` as a header in their API request for DELETE, GET, HEAD, POST, and PUT requests, or add the `RequestPayer` parameter in their REST request. For CLI requests, requesters can use the `--request-payer` parameter.

Example – Using Requester Pays when deleting an object

To use the following [DeleteObjectVersion](#) API example, replace the *user input placeholders* with your own information.

```
DELETE /Key+?versionId=VersionId HTTP/1.1
Host: Bucket.s3.amazonaws.com
x-amz-mfa: MFA
x-amz-request-payer: RequestPayer
x-amz-bypass-governance-retention: BypassGovernanceRetention
x-amz-expected-bucket-owner: ExpectedBucketOwner
```

If the requester restores objects by using the [RestoreObject](#) API, Requester Pays is supported as long as the `x-amz-request-payer` header or the `RequestPayer` parameter are in the request; however, the requester only pays for the cost of the request. The bucket owner pays the retrieval charges.

Requester Pays buckets do not support the following:

- Anonymous requests

- SOAP requests
- Using a Requester Pays bucket as the target bucket for end-user logging, or vice versa. However, you can turn on end-user logging on a Requester Pays bucket where the target bucket is not a Requester Pays bucket.

How Requester Pays charges work

The charge for successful Requester Pays requests is straightforward: The requester pays for the data transfer and the request, and the bucket owner pays for the data storage. However, the bucket owner is charged for the request under the following conditions:

- The request returns an AccessDenied (HTTP 403 Forbidden) error and the request is initiated inside the bucket owner's individual AWS account or AWS organization.
- The request is a SOAP request.

For more information about Requester Pays, see the following topics.

Configuring Requester Pays on a bucket

You can configure an Amazon S3 bucket to be a *Requester Pays* bucket so that the requester pays the cost of the request and data download instead of the bucket owner.

This section provides examples of how to configure Requester Pays on an Amazon S3 bucket using the console and the REST API.

Using the S3 console

To enable Requester Pays for an S3 general purpose bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that you want to enable Requester Pays for.
4. Choose **Properties**.
5. Under **Requester pays**, choose **Edit**.
6. Choose **Enable**, and choose **Save changes**.

Amazon S3 enables Requester Pays for your bucket and displays your **Bucket overview**. Under **Requester pays**, you see **Enabled**.

Using the REST API

Only the bucket owner can set the `RequestPaymentConfiguration.payer` configuration value of a bucket to `BucketOwner` (the default) or `Requester`. Setting the `requestPayment` resource is optional. By default, the bucket is not a Requester Pays bucket.

To revert a Requester Pays bucket to a regular bucket, you use the value `BucketOwner`. Typically, you would use `BucketOwner` when uploading data to the Amazon S3 bucket, and then you would set the value to `Requester` before publishing the objects in the bucket.

To set `requestPayment`

- Use a PUT request to set the `Payer` value to `Requester` on a specified bucket.

```
PUT ?requestPayment HTTP/1.1
Host: [BucketName].s3.amazonaws.com
Content-Length: 173
Date: Wed, 01 Mar 2009 12:00:00 GMT
Authorization: AWS [Signature]

<RequestPaymentConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Payer>Requester</Payer>
</RequestPaymentConfiguration>
```

If the request succeeds, Amazon S3 returns a response similar to the following.

```
HTTP/1.1 200 OK
x-amz-id-2: [id]
```

```
x-amz-request-id: [request_id]
Date: Wed, 01 Mar 2009 12:00:00 GMT
Content-Length: 0
Connection: close
Server: AmazonS3
x-amz-request-charged:requester
```

You can set Requester Pays only at the bucket level. You can't set Requester Pays for specific objects within the bucket.

You can configure a bucket to be BucketOwner or Requester at any time. However, there might be a few minutes before the new configuration value takes effect.

 **Note**

Bucket owners who give out presigned URLs should consider carefully before configuring a bucket to be Requester Pays, especially if the URL has a long lifetime. The bucket owner is charged each time the requester uses a presigned URL that uses the bucket owner's credentials.

Retrieving the requestPayment configuration using the REST API

You can determine the Payer value that is set on a bucket by requesting the resource `requestPayment`.

To return the `requestPayment` resource

- Use a GET request to obtain the `requestPayment` resource, as shown in the following request.

```
GET ?requestPayment HTTP/1.1
Host: [BucketName].s3.amazonaws.com
Date: Wed, 01 Mar 2009 12:00:00 GMT
Authorization: AWS [Signature]
```

If the request succeeds, Amazon S3 returns a response similar to the following.

```
HTTP/1.1 200 OK
x-amz-id-2: [id]
```

```
x-amz-request-id: [request_id]
Date: Wed, 01 Mar 2009 12:00:00 GMT
Content-Type: [type]
Content-Length: [length]
Connection: close
Server: AmazonS3

<?xml version="1.0" encoding="UTF-8"?>
<RequestPaymentConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Payer>Requester</Payer>
</RequestPaymentConfiguration>
```

This response shows that the `payer` value is set to Requester.

Downloading objects from Requester Pays buckets

Because requesters are charged for downloading data from Requester Pays buckets, the requests must contain a special parameter, `x-amz-request-payer`, which confirms that the requester knows that they will be charged for the download. To access objects in Requester Pays buckets, requests must include one of the following.

- For DELETE, GET, HEAD, POST, and PUT requests, include `x-amz-request-payer : requester` in the header
- For signed URLs, include `x-amz-request-payer=requester` in the request

If the request succeeds and the requester is charged, the response includes the header `x-amz-request-charged:requester`. If `x-amz-request-payer` is not in the request, Amazon S3 returns a 403 error and charges the bucket owner for the request.

Note

Bucket owners do not need to add `x-amz-request-payer` to their requests. Ensure that you have included `x-amz-request-payer` and its value in your signature calculation. For more information, see [Using an Authorization Header](#) in the *Amazon S3 API Reference*.

Using the REST API

To download objects from a Requester Pays bucket

- Use a GET request to download an object from a Requester Pays bucket, as shown in the following request.

```
GET / [destinationObject] HTTP/1.1
Host: [BucketName].s3.amazonaws.com
x-amz-request-payer : requester
Date: Wed, 01 Mar 2009 12:00:00 GMT
Authorization: AWS [Signature]
```

If the GET request succeeds and the requester is charged, the response includes `x-amz-request-charged:requester`.

Amazon S3 can return an Access Denied error for requests that try to get objects from a Requester Pays bucket. For more information, see [Error Responses](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS CLI

To download objects from a Requester Pays bucket using the AWS CLI, you specify `--request-payer requester` as part of your `get-object` request. For more information, see [get-object](#) in the *AWS CLI Reference*.

Working with objects in Amazon S3

To store your data in Amazon S3, you work with resources known as buckets and objects. A *bucket* is a container for objects. An *object* is a file and any metadata that describes that file.

To store an object in Amazon S3, you create a bucket and then upload the object to a bucket. When the object is in the bucket, you can open it, download it, and copy it. When you no longer need an object or a bucket, you can clean up these resources.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Important

In the Amazon S3 console, when you choose **Open** or **Download As** for an object, these operations create presigned URLs. For the duration of five minutes, your object will be accessible to anyone who has access to these presigned URLs. For more information about presigned URLs, see [Using presigned URLs](#).

With Amazon S3, you pay only for what you use. For more information about Amazon S3 features and pricing, see [Amazon S3](#). If you are a new Amazon S3 customer, you can get started with Amazon S3 for free. For more information, see [AWS Free Tier](#).

Amazon S3 objects overview

Amazon S3 is an object store that uses unique key-values to store as many objects as you want. You store these objects in one or more buckets, and each object can be up to 50 TB in size. An object consists of the following:

Key

The name that you assign to an object. You use the object key to retrieve the object. For more information, see [Working with object metadata](#).

Version ID

Within a bucket, a key and version ID uniquely identify an object. The version ID is a string that Amazon S3 generates when you add an object to a bucket. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Value

The content that you are storing.

An object value can be any sequence of bytes. Objects can range in size from zero to 50 TB. For more information, see [Uploading objects](#).

Note

While Amazon S3 documentation commonly references 50 TB object size limit, the actual maximum object size is 53.7 TB (48.8 TiB). This limit is determined by multipart upload constraints: 10,000 maximum parts x 5 GiB per part = 50,000 GiB (53.7 TB)

Metadata

A set of name-value pairs with which you can store information regarding the object. You can assign metadata, referred to as user-defined metadata, to your objects in Amazon S3. Amazon S3 also assigns system-metadata to these objects, which it uses for managing objects. For more information, see [Working with object metadata](#).

Subresources

Amazon S3 uses the subresource mechanism to store object-specific additional information. Because subresources are subordinates to objects, they are always associated with some other entity such as an object or a bucket. For more information, see [Object subresources](#).

Access control information

You can control access to the objects you store in Amazon S3. Amazon S3 supports both the resource-based access control, such as an access control list (ACL) and bucket policies, and user-based access control. For more information about access control, see the following:

- [Access control in Amazon S3](#)
- [Identity and Access Management for Amazon S3](#)
- [Configuring ACLs](#)

Your Amazon S3 resources (for example, buckets and objects) are private by default. You must explicitly grant permission for others to access these resources. For more information about sharing objects, see [Sharing objects with presigned URLs](#).

Tags

You can use tags to categorize your stored objects, for access control, or cost allocation. For more information, see [Categorizing your objects using tags](#).

Object subresources

Amazon S3 defines a set of subresources associated with buckets and objects. Subresources are subordinates to objects. This means that subresources don't exist on their own. They are always associated with some other entity, such as an object or a bucket.

The following table lists the subresources associated with Amazon S3 objects.

Subresource	Description
acl	Contains a list of grants identifying the grantees and the permissions granted. When you create an object, the acl identifies the object owner as having full control over the object. You can retrieve an object ACL or replace it with an updated list of grants. Any update to an ACL requires you to replace the existing ACL. For more information about ACLs, see Access control list (ACL) overview .

Naming Amazon S3 objects

The *object key* (or key name) uniquely identifies the object in an Amazon S3 bucket. When you create an object, you specify the key name. For example, on the [Amazon S3 console](#), when you select a bucket, a list of objects in your bucket appears. These names are the *object keys*.

The object key name consists of a sequence of Unicode characters encoded in UTF-8, with a maximum length of 1,024 bytes or approximately 1,024 Latin characters. In some locales, a single character may require 2 bytes for encoding. When naming your objects, be aware of the following:

- Object key names are case sensitive.
- Object key names include any prefixes (known as *folders* in the console). For example, Development/Projects.xls is the full object key name of the Projects.xls object located within the Development prefix (or folder). The prefix, the delimiter (/), and the name of the object are included in the 1,024 byte limitation for the object key name. For more information about prefixes and folders, see [the section called “Choosing object key names”](#).
- Certain characters might require special handling when they're used in object key names. For more information, see [the section called “Object key naming guidelines”](#).

Note

Object key names with the value "soap" aren't supported for [virtual-hosted-style requests](#). For object key name values where "soap" is used, a [path-style URL](#) must be used instead.

Choosing object key names

The Amazon S3 data model is a flat structure: You create a bucket, and the bucket stores objects. There is no hierarchy of subbuckets or subfolders. However, you can infer logical hierarchy using key name prefixes and delimiters as the Amazon S3 console does. The Amazon S3 console supports a concept of folders. For more information about how to edit metadata from the Amazon S3 console, see [Editing object metadata in the Amazon S3 console](#).

Suppose that your bucket (admin-created) has four objects with the following object keys:

Development/Projects.xls

Finance/statement1.pdf

Private/taxdocument.pdf

s3-dg.pdf

The console uses the key name prefixes (Development/, Finance/, and Private/) and delimiter (/) to present a folder structure. The s3-dg.pdf key doesn't contain a slash-delimited prefix, so its object appears directly at the root level of the bucket. If you open the Development/ folder, you see the Projects.xlsx object in it.

- Amazon S3 supports buckets and objects, and there is no hierarchy. However, by using prefixes and delimiters in an object key name, the Amazon S3 console and the AWS SDKs can infer hierarchy and introduce the concept of folders.
- The Amazon S3 console implements folder object creation by creating a zero-byte object with the folder *prefix and delimiter* value as the key. These folder objects don't appear in the console. Otherwise they behave like any other objects and can be viewed and manipulated through the REST API, AWS CLI, and AWS SDKs.

Object key naming guidelines

You can use any UTF-8 character in an object key name. However, using certain characters in key names can cause problems with some applications and protocols. The following guidelines help you maximize compliance with DNS, web-safe characters, XML parsers, and other APIs.

Safe characters

The following character sets are generally safe for use in key names:

Alphanumeric characters	<ul style="list-style-type: none">• 0-9• a-z• A-Z
Special characters	<ul style="list-style-type: none">• Exclamation point (!)• Hyphen (-)• Underscore (_)• Period (.)• Asterisk (*)• Single quotation mark (')• Opening parenthesis ((• Closing parenthesis))

The following are examples of valid object key names:

- 4my-organization
- my.great_photos-2014/jan/myvacation.jpg
- videos/2014/birthday/video1.wmv

Note

If you use the Amazon S3 console to download objects that have key names that end with periods (.), the periods are removed from the ends of the key names of the downloaded objects. To retain periods at the ends of key names in downloaded objects, you must use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

In addition, be aware of the following prefix limitations:

- Objects with a prefix of ./ must be uploaded or downloaded with the AWS CLI, AWS SDKs, or REST API. You can't use the Amazon S3 console to upload these objects.
- Object keys that contain relative path elements (for example, ../) are valid if, when parsed left-to-right, the cumulative count of relative path segments never exceeds the number of non-relative path elements encountered. This rule applies to all requests made by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, and AWS SDKs.

For example:

- `videos/2014/.../video1.wmv` is valid.
- `videos/.../video1.wmv` isn't valid.
- `videos/.../2014/video1.wmv` isn't valid.

Period-only path segments

Object keys containing period-only path segments (.
or ..) can cause unexpected behavior when processed by applications, SDKs, or tools that interpret these as relative path references.

The following patterns can cause issues:

- `folder./file.txt` - Contains current directory reference
- `folder../file.txt` - Contains parent directory reference
- `./file.txt` - Starts with current directory reference
- `../file.txt` - Starts with parent directory reference

The following patterns work normally:

- `folder/.hidden/file.txt` - Period is part of filename, not standalone
- `folder/..backup/file.txt` - Periods are part of filename, not standalone

When applications process object keys with period-only segments, the following behavioral impacts can occur:

- *Path normalization* - Many systems automatically resolve . and .. references, potentially changing the effective path (for example, `folder./file.txt` becomes `folder/file.txt`)
- *Access issues* - Applications might fail to locate objects due to path resolution differences
- *Inconsistent behavior* - Different tools and SDKs might handle these patterns differently

⚠ Important

To avoid these issues, we recommend avoiding period-only path segments in object key names. Use alternative naming conventions for organizational purposes.

Characters that might require special handling

The following characters in a key name might require additional code handling and most likely must be URL encoded or referenced as HEX. Some of these characters are non-printable characters that your browser might not handle, which also require special handling:

- Ampersand (&)
- Dollar sign (\$)
- ASCII character ranges 00–1F hex (0–31 decimal) and 7F (127 decimal)
- At symbol (@)
- Equal sign (=)
- Semicolon (;)
- Forward slash (/)
- Colon (:)
- Plus sign (+)
- Space – Significant sequences of spaces might be lost in some cases (especially multiple spaces)
- Comma (,)
- Question mark (?)

Characters to avoid

We recommend not using the following characters in a key name because of significant special character handling, which isn't consistent across all applications:

- Backslash (\)
- Left brace ({})
- Non-printable ASCII characters (128–255 decimal characters)
- Caret or circumflex (^)

- Right brace ({})
- Percent character (%)
- Grave accent or backtick (`)
- Right bracket (])
- Quotation mark (")
- Greater than sign (>)
- Left bracket ([)
- Tilde (~)
- Less than sign (<)
- Pound sign (#)
- Vertical bar or pipe (|)

XML-related object key constraints

As specified by the [XML standard on end-of-line handling](#), all XML text is normalized such that single carriage returns (ASCII code 13) and carriage returns immediately followed by a line feed (ASCII code 10), also known as newline characters, are replaced by a single line feed character. To ensure the correct parsing of object keys in XML requests, carriage returns and [other special characters must be replaced with their equivalent XML entity code](#) when they're inserted within XML tags.

The following is a list of such special characters and their equivalent XML entity codes:

- Apostrophe (') must be replaced with &apos ;
- Quotation mark (") must be replaced with " ;
- Ampersand (&) must be replaced with & ;
- Less than sign (<) must be replaced with < ;
- Greater than sign (>) must be replaced with > ;
- Carriage return (\r) must be replaced with  ; or  ;
- Newline (\n) must be replaced with
 ; or
 ;

Example

The following example illustrates the use of an XML entity code as a substitution for a carriage return. This DeleteObjects request deletes an object with the key parameter /some/prefix/objectwith\rcarriagereturn (where the \r is the carriage return).

```
<Delete xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Object>
    <Key>/some/prefix/objectwith<#13>carriagereturn</Key>
  </Object>
</Delete>
```

Object key sort order

Amazon S3 sorts object keys, including prefixes, lexicographically by their UTF-8 encoded byte values.

ASCII characters sort in the following order:

- Special characters (for example, !, /)
- Uppercase letters (A–Z)
- Lowercase letters (a–z)

Non-ASCII characters (for example, é, 中 文) are encoded as multi-byte UTF-8 sequences and typically sort after ASCII characters because of their higher byte values (for example, 0xC3 for é, 0xE4 for 中).

For example, prefixes such as apple/, Apple/, éclair/, # #/ would sort as:

1. Apple/ (starts with 0x41)
2. apple/ (starts with 0x61)
3. éclair/ (starts with 0xC3 0xA9)
4. # #/ (starts with 0xE4 0xB8 0xAD 0xE6 0x96 0x87)

Working with object metadata

There are two kinds of object metadata in Amazon S3: *system-defined metadata* and *user-defined metadata*. System-defined metadata includes metadata such as the object's creation date, size, and storage class. User-defined metadata is metadata that you can choose to set at the time that you upload an object. This user-defined metadata is a set of name-value pairs. For more information, see [the section called “System-defined object metadata”](#) and [the section called “User-defined object metadata”](#).

When you create an object, you specify the *object key* (or *key name*), which uniquely identifies the object in an Amazon S3 bucket. For more information, see [Naming Amazon S3 objects](#). You can also set [user-defined metadata](#) in Amazon S3 at the time that you upload the object.

After you upload the object, you can't modify this user-defined metadata. The only way to modify this metadata is to make a copy of the object and set the metadata. For more information about editing metadata by using the Amazon S3 console, see [Editing object metadata in the Amazon S3 console](#).

Query your metadata and accelerate data discovery with S3 Metadata

To easily find, store, and query metadata for your S3 objects, you can use S3 Metadata. With S3 Metadata, you can quickly prepare data for use in business analytics, content retrieval, artificial intelligence and machine learning (AI/ML) model training, and more.

S3 Metadata accelerates data discovery by automatically capturing metadata for the objects in your general purpose buckets and storing it in read-only, fully managed Apache Iceberg tables that you can query. These read-only tables are called *metadata tables*. As objects are added to, updated, and removed from your general purpose buckets, S3 Metadata automatically refreshes the corresponding metadata tables to reflect the latest changes.

By default, S3 Metadata provides [system-defined object metadata](#), such as an object's creation time and storage class, and custom metadata, such as tags and [user-defined metadata](#) that was included during object upload. S3 Metadata also provides event metadata, such as when an object is updated or deleted, and the AWS account that made the request.

Metadata tables are stored in S3 table buckets, which provide storage that's optimized for tabular data. To query your metadata, you can integrate your table bucket with AWS analytics services, such as Amazon Athena, Amazon Redshift, and Amazon Quick Suite.

For more information about S3 Metadata, see [the section called “Discovering your data with S3 Metadata tables”](#).

System-defined object metadata

For each object stored in a bucket, Amazon S3 maintains a set of system metadata. Amazon S3 processes this system metadata as needed. For example, Amazon S3 maintains object-creation date and size metadata, using this information as part of object management.

There are two categories of system metadata:

- **System controlled** – Metadata such as the object-creation date is system controlled, which means that only Amazon S3 can modify the date value.
- **User controlled** – Other system metadata, such as the storage class configured for the object and whether the object has server-side encryption enabled, are examples of system metadata whose values you control. If your bucket is configured as a website, sometimes you might want to redirect a page request either to another page or an external URL. In this case, a webpage is an object in your bucket. Amazon S3 stores the page redirect value as system metadata, which you can control.

When you create objects, you can configure the values of these system metadata items or update the values when you need to. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

Amazon S3 uses AWS KMS keys to encrypt your Amazon S3 objects. AWS KMS encrypts only the object data. The checksum and the specified algorithm are stored as part of the object's metadata. If server-side encryption is requested for the object, then the checksum is stored in encrypted form. For more information about server-side encryption, see [Protecting data with encryption](#).

Note

The PUT request header is limited to 8 KB in size. Within the PUT request header, the system-defined metadata is limited to 2 KB in size. The size of system-defined metadata is measured by taking the sum of the number of bytes in the US-ASCII encoding of each key and value.

The following table provides a list of system-defined metadata and whether you can update it.

Name	Description	Can user modify the value?
Date	The current date and time.	No
Cache-Control	A general header field used to specify caching policies.	Yes
Content-Disposition	Object presentational information.	Yes
Content-Encoding	The content encodings (like compression) that have been applied to the object's data	Yes
Content-Length	The object size in bytes.	No
Content-Type	The object type.	Yes
Last-Modified	The object creation date or the last modified date, whichever is the latest. For multipart uploads, the object creation date is the date of initiation of the multipart upload.	No
ETag	An entity tag (ETag) that represents a specific version of an object. For objects that are not uploaded as a multipart upload and are either unencrypted or encrypted by server-side encryption with Amazon S3 managed keys (SSE-S3), the ETag is an MD5 digest of the data.	No
x-amz-server-side-encryption	A header that indicates whether server-side encryption is enabled for the object, and whether that encryption is using the AWS Key Management Service (AWS KMS) keys (SSE-KMS) or using Amazon S3 managed encryption keys (SSE-S3). For more information, see Protecting data with server-side encryption .	Yes

Name	Description	Can user modify the value?
x-amz-checksum-crc64nvme , x-amz-checksum-crc32 , x-amz-checksum-crc32c , x-amz-checksum-sha1 , x-amz-checksum-sha256	Headers that contain the checksum or digest of the object. At most, one of these headers will be set at a time, depending on the checksum algorithm that you instruct Amazon S3 to use. For more information about choosing the checksum algorithm, see Checking object integrity in Amazon S3 .	No
x-amz-checksum-type	The checksum type, which determines how partial checksums are combined to create an object-level checksum for multipart objects.	Yes
x-amz-version-id	The object version. When you enable versioning on a bucket, Amazon S3 assigns a version ID to objects added to the bucket. For more information, see Retaining multiple versions of objects with S3 Versioning .	No
x-amz-delete-marker	A Boolean marker that indicates whether the object is a delete marker. This marker is used only in buckets that have versioning enabled,	No
x-amz-storage-class	The storage class used for storing the object. For more information, see Understanding and managing Amazon S3 storage classes .	Yes
x-amz-website-redirect-location	A header that redirects requests for the associated object to another object in the same bucket or to an external URL. For more information, see (Optional) Configuring a webpage redirect .	Yes

Name	Description	Can user modify the value?
x-amz-server-side-encryption-key-id	A header that indicates the ID of the AWS KMS symmetric encryption KMS key that was used to encrypt the object. This header is used only when the x-amz-server-side-encryption header is present and has the value of aws:kms.	Yes
x-amz-server-side-encryption-customer-algorithm	A header that indicates whether server-side encryption with customer-provided encryption keys (SSE-C) is enabled. For more information, see Using server-side encryption with customer-provided keys (SSE-C) .	Yes
x-amz-tagging	The tag-set for the object. The tag-set must be encoded as URL Query parameters.	Yes

User-defined object metadata

When uploading an object, you can also assign metadata to the object. You provide this optional information as a name-value (key-value) pair when you send a PUT or POST request to create the object. When you upload objects using the REST API, the optional user-defined metadata names must begin with x-amz-meta- to distinguish them from other HTTP headers. When you retrieve the object using the REST API, this prefix is returned. When you upload objects using the SOAP API, the prefix is not required. When you retrieve the object using the SOAP API, the prefix is removed, regardless of which API you used to upload the object.

 **Note**

SOAP APIs for Amazon S3 are not available for new customers, and are approaching End of Life (EOL) on August 31, 2025. We recommend that you use either the REST API or the AWS SDKs.

When metadata is retrieved through the REST API, Amazon S3 combines headers that have the same name (ignoring case) into a comma-delimited list. If some metadata contains unprintable

characters, it is not returned. Instead, the `x-amz-missing-meta` header is returned with a value of the number of unprintable metadata entries. The `HeadObject` action retrieves metadata from an object without returning the object itself. This operation is useful if you're only interested in an object's metadata. To use HEAD, you must have READ access to the object. For more information, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

User-defined metadata is a set of key-value pairs. Amazon S3 stores user-defined metadata keys in lowercase.

Amazon S3 allows arbitrary Unicode characters in your metadata values.

To avoid issues related to the presentation of these metadata values, you should conform to using US-ASCII characters when using REST and UTF-8 when using SOAP or browser-based uploads through POST.

When using non-US-ASCII characters in your metadata values, the provided Unicode string is examined for non-US-ASCII characters. Values of such headers are character decoded as per [RFC 2047](#) before storing and encoded as per [RFC 2047](#) to make them mail-safe before returning. If the string contains only US-ASCII characters, it is presented as is.

The following is an example.

```
PUT /Key HTTP/1.1
Host: amzn-s3-demo-bucket.s3.amazonaws.com
x-amz-meta-nonascii: ÄMÄZÖÑ S3

HEAD /Key HTTP/1.1
Host: amzn-s3-demo-bucket.s3.amazonaws.com
x-amz-meta-nonascii: =?UTF-8?B?w4PChE3Dg8KEWsODwpXDg8KRIFMz?=

PUT /Key HTTP/1.1
Host: amzn-s3-demo-bucket.s3.amazonaws.com
x-amz-meta-ascii: AMAZONS3

HEAD /Key HTTP/1.1
Host: amzn-s3-demo-bucket.s3.amazonaws.com
x-amz-meta-ascii: AMAZONS3
```

Note

The PUT request header is limited to 8 KB in size. Within the PUT request header, the user-defined metadata is limited to 2 KB in size. The size of user-defined metadata is measured by taking the sum of the number of bytes in the UTF-8 encoding of each key and value.

For information about changing the metadata of your object after it has been uploaded by creating a copy of the object, modifying it, and replacing the old object, or creating a new version, see [Editing object metadata in the Amazon S3 console](#).

Editing object metadata in the Amazon S3 console

You can use the Amazon S3 console to edit metadata for existing S3 objects by using the **Copy** action. To edit metadata, you copy objects to the same destination and specify the new metadata you want to apply, which replaces the old metadata for the object. Some metadata is set by Amazon S3 when you upload the object. For example, Content-Length and Last-Modified are system-defined object metadata fields that can't be modified by a user.

You can also set user-defined metadata when you upload the object and replace it as your needs change. For example, you might have a set of objects that you initially store in the STANDARD storage class. Over time, you may no longer need this data to be highly available. So, you can change the storage class to GLACIER by replacing the value of the x-amz-storage-class key from STANDARD to GLACIER.

Note

Consider the following when you are replacing object metadata in Amazon S3:

- You must specify existing metadata you want to retain, metadata you want to add, and metadata you want to edit.
- If your object is less than 5 GB, you can use the **Copy** action in the S3 console to replace object metadata. If your object is greater than 5 GB, you can replace the object metadata when you copy an object with multipart upload by using the [AWS CLI](#) or [AWS SDKs](#). For more information, see [Copying an object using multipart upload](#).
- For a list of additional permissions required to replace metadata, see [the section called “Required permissions for S3 API operations”](#). For example policies that grant this permission, see [the section called “Identity-based policy examples”](#).

- This action creates a *copy* of the object with updated settings and the last-modified date. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. If S3 Versioning isn't enabled, a new copy of the object replaces the original object. The AWS account associated with the IAM role that changes the property also becomes the owner of the new object or (object version).
- Editing metadata replaces values for existing key names.
- Objects that are encrypted with customer-provided encryption keys (SSE-C) can't be copied by using the console. You must use the AWS CLI, AWS SDK, or the Amazon S3 REST API.
- When copying an object by using the Amazon S3 console, you might receive the error message "Copied metadata can't be verified." The console uses headers to retrieve and set metadata for your object. If your network or browser configuration modifies your network requests, this behavior might cause unintended metadata (such as modified Cache-Control headers) to be written to your copied object. Amazon S3 can't verify this unintended metadata.

To address this issue, check your network and browser configuration to make sure it doesn't modify headers, such as Cache-Control. For more information, see [The Shared Responsibility Model](#).

Warning

When replacing metadata for folders, wait for the **Copy** action to finish before adding new objects to the folder. Otherwise, new objects might also be edited.

The following topics describe how to replace metadata for an object by using the **Copy** action in the Amazon S3 console.

Replacing system-defined metadata

You can replace some system-defined metadata for an S3 object. For a list of system-defined metadata and values that you can modify, see [System-defined object metadata](#).

To replace system-defined metadata of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets or Directory buckets**.
3. In the list of buckets, choose the name of the bucket that contains the objects you want to change.
4. Select the check box for the objects you want to change.
5. On the **Actions** menu, choose **Copy** from the list of options that appears.
6. To specify the destination path, choose **Browse S3**, navigate to the same destination as the source objects, and select the destination check box. Choose **Choose destination** in the lower-right corner.

Alternatively, enter the destination path.

7. If you do *not* have bucket versioning enabled, you will see a warning recommending you enable Bucket Versioning to help protect against unintentionally overwriting or deleting objects. If you want to keep all versions of objects in this bucket, select **Enable Bucket Versioning**. You can also view the default encryption and Object Lock properties in **Destination details**.
8. Under **Additional copy settings**, choose **Specify settings** to specify settings for **Metadata**.
9. Scroll to the **Metadata** section, and then choose **Replace all metadata**.
10. Choose **Add metadata**.
11. For metadata **Type**, select **System-defined**.
12. Specify a unique **Key** and the metadata **Value**.
13. To edit additional metadata, choose **Add metadata**. You can also choose **Remove** to remove a set of type-key-values.
14. Choose **Copy**. Amazon S3 saves your metadata changes.

Replacing user-defined metadata

You can replace user-defined metadata of an object by combining the metadata prefix, `x-amz-meta-`, and a name you choose to create a custom key. For example, if you add the custom name `alt-name`, the metadata key would be `x-amz-meta-alt-name`.

User-defined metadata can be as large as 2 KB total. To calculate the total size of user-defined metadata, sum the number of bytes in the UTF-8 encoding for each key and value. Both keys and their values must conform to US-ASCII standards. For more information, see [User-defined object metadata](#).

To replace user-defined metadata of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** or **Directory buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Copy** from the list of options that appears.
5. To specify the destination path, choose **Browse S3**, navigate to the same destination as the source objects, and select the destination check box. Choose **Choose destination**.

Alternatively, enter the destination path.
6. If you do *not* have bucket versioning enabled, you will see a warning recommending you enable Bucket Versioning to help protect against unintentionally overwriting or deleting objects. If you want to keep all versions of objects in this bucket, select **Enable Bucket Versioning**. You can also view the default encryption and Object Lock properties in **Destination details**.
7. Under **Additional copy settings**, choose **Specify settings** to specify settings for **Metadata**.
8. Scroll to the **Metadata** section, and then choose **Replace all metadata**.
9. Choose **Add metadata**.
10. For metadata **Type**, choose **User-defined**.
11. Enter a unique custom **Key** following x-amz-meta-. Also enter a metadata **Value**.
12. To add additional metadata, choose **Add metadata**. You can also choose **Remove** to remove a set of type-key-values.
13. Choose **Copy**. Amazon S3 saves your metadata changes.

Discovering your data with S3 Metadata tables

Amazon S3 Metadata accelerates data discovery by automatically capturing metadata for objects in your general purpose buckets and storing it in read-only, fully managed Apache Iceberg tables that you can query. These read-only tables are called *metadata tables*. As objects are added to, updated, or removed from your general purpose buckets, S3 Metadata automatically refreshes the corresponding metadata tables to reflect the latest changes.

By default, S3 Metadata provides three types of metadata:

- System-defined metadata, such as an object's creation time and storage class
- Custom metadata, such as tags and user-defined metadata that was included during object upload
- Event metadata, such as when an object is updated or deleted, and the AWS account that made the request

With S3 Metadata, you can easily find, store, and query metadata for your S3 objects, so that you can quickly prepare data for use in business analytics, content retrieval, artificial intelligence and machine learning (AI/ML) model training, and more.

For each general purpose bucket, you can create a metadata table configuration that contains two complementary metadata tables:

- **Journal table** – By default, your metadata table configuration contains a *journal table*, which captures events that occur for the objects in your bucket. The journal table records changes made to your data in near real time, helping you to identify new data uploaded to your bucket, track recently deleted objects, monitor lifecycle transitions, and more. The journal table records new objects and updates to your objects and their metadata (those updates that require either a PUT or a DELETE operation).

The journal table captures metadata only for change events (such as uploads, updates, and deletes) that happen after you create your metadata table configuration. Because this table is queryable, you can audit the changes to your bucket through simple SQL queries.

The journal table is required for each metadata table configuration. (In the initial release of S3 Metadata, the journal table was referred to as "the metadata table.")

For more information about what data is stored in journal tables, see [the section called “Journal tables schema”](#).

To help minimize your storage costs, you can choose to enable journal table record expiration.

For more information, see [the section called “Expiring journal table records”](#).

- **Live inventory table** – Optionally, you can add a *live inventory table* to your metadata table configuration. The live inventory table provides a simple, queryable inventory of all the objects and their versions in your bucket so that you can determine the latest state of your data.

You can use the live inventory table to simplify and speed up business workflows and big data jobs by identifying objects that you want to process for various workloads. For example, you can query the live inventory table to find all objects stored in a particular storage class, all objects with certain tags, all objects that aren't encrypted with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS), and more.

When you enable the live inventory table for your metadata table configuration, the table goes through a process known as *backfilling*, during which Amazon S3 scans your general purpose bucket to retrieve the initial metadata for all objects that exist in the bucket. Depending on the number of objects in your bucket, this process can take minutes (minimum 15 minutes) to hours. When the backfilling process is finished, the status of your live inventory table changes from **Backfilling** to **Active**. After backfilling is completed, updates to your objects are typically reflected in the live inventory table within one hour.

You're charged for backfilling your inventory table. If your general purpose bucket has more than one billion objects, you're also charged a monthly fee for your live inventory table. For more information, see [Amazon S3 Pricing](#).

For more information about what data is stored in live inventory tables, see [the section called “Live inventory tables schema”](#).

Your metadata tables are stored in an AWS managed S3 table bucket, which provides storage that's optimized for tabular data. To query your metadata, you can integrate your table bucket with Amazon SageMaker Lakehouse. This integration, which uses the AWS Glue Data Catalog and AWS Lake Formation, allows AWS analytics services to automatically discover and access your table data.

After your table bucket is integrated with the AWS Glue Data Catalog, you can directly query your metadata tables with AWS analytics services such as Amazon Athena, Amazon EMR, and Amazon

Redshift. You can also create interactive dashboards with your query data by using Amazon Quick Suite. For more information about integrating your AWS managed S3 table bucket with Amazon SageMaker Lakehouse, see [the section called “Integrating S3 Tables with AWS analytics services”](#).

You can also query your metadata tables with Apache Spark, Apache Trino, and any other application that supports the Apache Iceberg format by using the AWS Glue Iceberg REST endpoint, the Amazon S3 Tables Iceberg REST endpoint, or the Amazon S3 Tables Catalog for Apache Iceberg client catalog. For more information about accessing your metadata tables, see [the section called “Accessing tables”](#).

For S3 Metadata pricing, see [Amazon S3 Pricing](#).

How metadata tables work

Metadata tables are managed by Amazon S3, and can't be modified by any IAM principal outside of Amazon S3 itself. You can, however, delete your metadata tables. As a result, metadata tables are read-only, which helps ensure that they correctly reflect the contents of your general purpose bucket.

To generate and store object metadata in AWS managed metadata tables, you create a metadata table configuration for your general purpose bucket. Amazon S3 is designed to continuously update the metadata tables to reflect the latest changes to your data as long as the configuration is active on the general purpose bucket.

Before you create a metadata table configuration, make sure that you have the necessary AWS Identity and Access Management (IAM) permissions to create and manage metadata tables. For more information, see [the section called “Permissions for metadata tables”](#).

Metadata table storage, organization, and encryption

When you create your metadata table configuration, your metadata tables are stored in an AWS managed table bucket. All metadata table configurations in your account and in the same Region are stored in a single AWS managed table bucket. These AWS managed table buckets are named aws-s3 and have the following Amazon Resource Name (ARN) format:

`arn:aws:s3tables:region:account_id:bucket/aws-s3`

For example, if your account ID is 123456789012 and your general purpose bucket is in US East (N. Virginia) (us-east-1), your AWS managed table bucket is also created in US East (N. Virginia) (us-east-1) and has the following ARN:

`arn:aws:s3tables:us-east-1:123456789012:bucket/aws-s3`

By default, AWS managed table buckets are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3). After you create your first metadata configuration, you can set the default encryption setting for the AWS managed table bucket to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). For more information, see [Encryption for AWS managed table buckets](#) and [the section called “Specifying SSE-KMS”](#).

Within your AWS managed table bucket, the metadata tables for your configuration are typically stored in a namespace with the following naming format:

`b_general-purpose-bucket-name`

 **Note**

- If your general purpose bucket name contains any periods, the periods are converted to underscores (_) in the namespace name.
- If your general purpose bucket was created before March 1, 2018, its name might contain uppercase letters and underscores, and it might also be up to 255 characters long. If your bucket name has these characteristics, your metadata table namespace will have a different format. The general purpose bucket name will be prefixed with b_, truncated to 63 characters, converted to all lowercase, and suffixed with a hash.

Metadata tables have the following Amazon Resource Name (ARN) format, which includes the table ID of the metadata table:

`arn:aws:s3tables:region-code:account-id:bucket/aws-s3/table/table-id`

For example, a metadata table in the US East (N. Virginia) Region would have an ARN like the following:

`arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3/table/
a12bc345-67d8-912e-3456-7f89123g4h56`

Journal tables have the name `journal`, and live inventory tables have the name `inventory`.

When you create your metadata table configuration, you can choose to encrypt your AWS managed metadata tables with server-side encryption using AWS Key Management Service (AWS KMS) keys

(SSE-KMS). If you choose to use SSE-KMS, you must provide a customer managed KMS key in the same Region as your general purpose bucket. You can set the encryption type for your tables only during table creation. After an AWS managed table is created, you can't change its encryption setting. To specify SSE-KMS for your metadata tables, you must have certain permissions. For more information, see [Permissions for SSE-KMS](#).

The encryption setting for a metadata table takes precedence over the default bucket-level encryption setting. If you don't specify encryption for a table, it will inherit the default encryption setting from the bucket.

AWS managed table buckets don't count toward your S3 Tables quotas. For more information about working with AWS managed table buckets and AWS managed tables, see [Working with AWS managed table buckets](#).

To monitor updates to your metadata table configuration, you can use AWS CloudTrail. For more information, see [the section called "Amazon S3 bucket-level actions that are tracked by CloudTrail logging"](#).

Metadata table maintenance and record expiration

To keep your metadata tables performing at their best, Amazon S3 performs periodic maintenance activities on your tables, such as compaction and unreferenced file removal. These maintenance activities help to both minimize the cost of storing your metadata tables and optimize query performance. This table maintenance happens automatically, requiring no opt-in or ongoing management by you.

Note

- You can't control the expiration of journal table or inventory table snapshots. For each table, Amazon S3 stores a minimum of 1 snapshot for a maximum of 24 hours.
- To help minimize your costs, you can configure journal table record expiration. By default, journal table records don't expire, and journal table records must be retained for a minimum of 7 days. For more information, see [the section called "Expiring journal table records"](#).

Metadata table limitations and restrictions

Amazon S3 Metadata has the following limitations and restrictions:

- S3 Metadata is currently available only in certain Regions. For more information, see [the section called "S3 Metadata AWS Regions"](#).
- S3 Metadata supports all storage classes supported by general purpose buckets. For the S3 Intelligent-Tiering storage class, the specific tier isn't shown in the metadata table.
- When you create a metadata table configuration, your metadata tables are stored in an AWS managed table bucket. You can't store your configuration in a customer-managed table bucket.
- S3 Metadata isn't supported for directory buckets, table buckets, or vector buckets. You can create metadata table configurations only for general purpose buckets. The journal table captures metadata only for change events (such as uploads, updates, and deletes) that happen after you have created your metadata table configuration.
- You can't control the expiration of journal table or inventory table snapshots. For each table, Amazon S3 stores a minimum of 1 snapshot for a maximum of 24 hours.

To help minimize your costs, you can configure journal table record expiration. By default, journal table records don't expire, and journal table records must be retained for a minimum of 7 days.

For more information, see [the section called "Expiring journal table records"](#).

- You can create a metadata table configuration only for an entire general purpose bucket. You can't apply a metadata table configuration at the prefix level.
- You can't pause and resume updates to metadata tables. However, you can delete your associated metadata configuration for journal or live inventory tables. Deleting your configuration doesn't delete the associated journal or inventory table. To re-create your configuration, you must first delete the old journal or inventory table, and then Amazon S3 can create a new journal or inventory table. When you re-enable the inventory table, Amazon S3 creates a new inventory table, and you're charged again for backfilling the new inventory table.

- Metadata tables don't contain all the same metadata as is available through S3 Inventory or through the Amazon S3 REST API. For example, the following information isn't available in metadata tables:
 - S3 Lifecycle expiration eligibility or transition status
 - Object Lock retention period or governance mode
 - Object access control list (ACL) information
 - Replication status
- When you're using Amazon Athena or Amazon Redshift to query your metadata tables, you must surround your metadata table namespace names in quotation marks ("") or backticks (`), otherwise the query might not work. For examples, see [the section called “Example metadata table queries”](#).
- When using Apache Spark on Amazon EMR or other third-party engines to query your metadata tables, we recommend that you use the Amazon S3 Tables Iceberg REST endpoint. Your query might not run successfully if you don't use this endpoint. For more information, see [the section called “Accessing tables using the Amazon S3 Tables Iceberg REST endpoint”](#).

S3 Metadata AWS Regions

S3 Metadata journal tables schema

The journal table records changes made to your data in near real time, helping you to identify new data uploaded to your bucket, track recently deleted objects, monitor lifecycle transitions, and more. The journal table records new objects and updates to your objects and their metadata (those updates that require either a PUT or a DELETE operation). Because this table is queryable, you can audit the changes to your bucket through simple SQL queries.

You can use the journal table for security, auditing, and compliance use cases to track uploaded, deleted, and changed objects in the bucket. For example, you can query the journal table to answer questions such as:

- Which objects were deleted in the past 24 hours by S3 Lifecycle?
- Which IP addresses did the most recent PUT requests come from?
- Which AWS Key Management Service (AWS KMS) keys were used for PUT requests in the past 7 days?
- Which objects in your bucket were created by Amazon Bedrock in the last five days?

Amazon S3 Metadata journal tables contain rows and columns. Each row represents a mutation event that has created, updated, or deleted an object in your general purpose bucket. Most of these events result from user actions, but some of these events result from actions taken by Amazon S3 on your behalf, such as S3 Lifecycle expirations or storage class transitions.

S3 Metadata journal tables are eventually consistent with the changes that have occurred in your general purpose bucket. In some cases, by the time S3 Metadata is notified that an object is created or updated, that object might already have been overwritten or deleted in the bucket. In such cases, the objects can no longer be retrieved and some columns might show a NULL value to indicate missing metadata schema.

The following is an example of a journal table for a general purpose bucket named amzn-s3-demo-bucket:

bucket	key	sequence_number	record_type
record_timestamp	version_id	is_delete_marker	size
e_tag		storage_class	last_modified_date
is_bucket_key_enabled	kms_key_arn	is_multipart	encryption_status
	checksum_algorithm	object_tags	user_metadata

Journal tables have the following schema:

Column name	Required?	Data type	
bucket	Yes	String	The general purpose bucket name. For more information, see the section called "Naming rules" .
key	Yes	String	The object key name (or key) that uniquely identifies the object

Column name	Required?	Data type	
			in the bucket. For more information, see the section called "Naming objects" .
sequence_number	Yes	String	The sequence number, which is an ordinal that's included in the records for a given object. To order records of the same bucket and key, you can sort on <code>sequence_number</code> . For a given bucket and key, a lexicographically larger <code>sequence_number</code> value implies that the record was introduced to the bucket more recently.

Column name	Required?	Data type	
record_type	Yes	String	<p>The type of this record, one of CREATE, UPDATE_METADATA , or DELETE.</p> <p>CREATE records indicate that a new object (or a new version of the object) was written to the bucket.</p> <p>UPDATE_METADATA records capture changes to mutable metadata for an existing object, such as the storage class or tags.</p> <p>DELETE records indicate that this object (or this version of the object) has been deleted. When versioning is enabled, DELETE records represent either a delete marker or a permanent delete. They are further disambiguated by consulting the optional <code>is_delete_marker</code> column.</p>

Column name	Required?	Data type	
			<p>For more information, see the section called "Deleting object versions".</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> Note</p> <p>A permanent delete carries NULLs in all columns, <i>except</i> bucket, key, sequence_number , record_type , record_timestamp , and version_id (i.e. those columns marked as Required).</p> </div>
record_timestamp	Yes	Timestamp NTZ (no time zone)	The timestamp that's associated with this record.

Column name	Required?	Data type	
version_id	No	String	<p>The object's version ID. When you enable versioning on a bucket, Amazon S3 assigns a version number to objects that are added to the bucket. For more information, see the section called "Retaining multiple versions of objects".</p> <p>Objects that are stored in your bucket before you set the versioning state have a version ID of null.</p>

Column name	Required?	Data type	
is_delete_marker	No	Boolean	<p>The object's delete marker status. For DELETE records that are delete markers, this value is TRUE. For permanent deletions , this value is omitted (NULL). Other record types (CREATE and UPDATE_METADATA) have value FALSE.</p> <p>For more information, see the section called "Working with delete markers".</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p>Note</p> <p>Rows that are added for delete markers have a record_type value of DELETE, not UPDATE_METADATA . If the delete marker is created as the result of an S3 Lifecycle expiration, the requester</p> </div>

Column name	Required?	Data type	
			<p>value is s3.amazonaws.com .</p>
size	No	Long	<p>The object size in bytes, not including the size of incomplete multipart uploads or object metadata. If <code>is_delete_marker</code> is TRUE, the size is 0. For more information, see the section called "System-defined object metadata".</p>
last_modified_date	No	Timestamp NTZ (no time zone)	<p>The object creation date or the last modified date, whichever is the latest. For multipart uploads, the object creation date is the date when the multipart upload is initiated. For more information, see the section called "System-defined object metadata".</p>

Column name	Required?	Data type	
e_tag	No	String	The entity tag (ETag), which is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag can be an MD5 digest of the object data. Whether the ETag is an MD5 digest depends on how the object was created and how it's encrypted. For more information, see Object in the <i>Amazon S3 API Reference</i> .

Column name	Required?	Data type	
storage_class	No	String	The storage class that's used for storing the object. One of STANDARD, REDUCED_R EDUNDANCY , STANDARD_IA , ONEZONE_IA , INTELLIGENT_TIERING , GLACIER, DEEP_ARCHIVE , or GLACIER_IR . For more information, see the section called "Understanding and managing storage classes" .
is_multipart	No	Boolean	The object's upload type. If the object was uploaded as a multipart upload, this value is TRUE. Otherwise, it's FALSE. For more information, see the section called "Using multipart upload" .

Column name	Required?	Data type	
encryption_status	No	String	The object's server-side encryption status, depending on what kind of encryption key is used: server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If the object is unencrypted, this value is null. Possible values are SSE-S3, SSE-KMS, DSSE-KMS, SSE-C, or null. For more information, see the section called "Data encryption" .

Column name	Required?	Data type	
is_bucket _key_enabled	No	Boolean	The object's S3 Bucket Key enablement status. If the object uses an S3 Bucket Key for SSE-KMS, this value is TRUE. Otherwise, it's FALSE. For more information, see the section called "Configuring an S3 Bucket Key for an object" .

Column name	Required?	Data type	
kms_key_arn	No	String	The Amazon Resource Name (ARN) for the KMS key with which the object is encrypted, for rows where encryption_status is SSE-KMS or DSSE-KMS. If the object isn't encrypted with SSE-KMS or DSSE-KMS, the value is null. For more information, see the section called "KMS keys stored in AWS KMS (SSE-KMS)" and the section called "Dual-layer server-side encryption (DSSE-KMS)".

 **Note**

If a row represents an object version that no longer existed at the time that a delete or overwrite event was processed, kms_key_a

Column name	Required?	Data type	
			rn contains a null value, even if the encryption_status column value is SSE-KMS or DSSE-KMS.
checksum_algorithm	No	String	The algorithm that's used to create the checksum for the object, one of CRC64NVME , CRC32, CRC32C, SHA1, or SHA256. If no checksum is present, this value is null. For more information, see the section called "Using supported checksum algorithms".

Column name	Required?	Data type	
object_tags	No	Map <String, String>	<p>The object tags that are associated with the object. Object tags are stored as a map of key-value pairs. If an object has no object tags, an empty map ({}) is stored. For more information, see the section called “Categorizing objects with tags”.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p>Note</p><p>If the record_type value is DELETE, the object_tags column contains a null value. If the record_type value is CREATE or UPDATE_METADATA, rows that represent object versions that no longer</p></div>

Column name	Required?	Data type	
			existed at the time that a delete or overwrite event was processed will contain a null value in the object_tags column.

Column name	Required?	Data type	
user_metadata	No	Map <String, String>	<p>The user metadata that's associated with the object. User metadata is stored as a map of key-value pairs. If an object has no user metadata, an empty map ({}) is stored. For more information, see the section called "User-defined object metadata".</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p>Note</p><p>If the record_type value is DELETE, the user_metadata column contains a null value. If the record_type value is CREATE or UPDATE_METADATA , rows that represent object versions that</p></div>

Column name	Required?	Data type	
			no longer existed at the time that a delete or overwrite event was processed will contain a null value in the user_meta data column.
requester	No	String	The AWS account ID of the requester or the AWS service principal that made the request. For example, if the requester is S3 Lifecycle, this value is s3.amazonaws.com .

Column name	Required?	Data type	
source_ip_address	No	String	The source IP address of the request. For records that are generated by a user request, this column contains the source IP address of the request. For actions taken by Amazon S3 or another AWS service on behalf of the user, this column contains a null value.
request_id	No	String	The request ID that's associated with the request.

S3 Metadata live inventory tables schema

The live inventory table provides a simple, queryable inventory of all the objects and their versions in your bucket so that you can determine the latest state of your data. Updates to your objects are typically reflected in the inventory table within one hour.

You can use this table to simplify and speed up business workflows and big data jobs by identifying objects that you want to process for various workloads. For example, you can query the inventory table to do the following:

- Find all objects stored in the S3 Glacier Deep Archive storage class.
- Create a distribution of object tags or find objects without tags.
- Find all objects that aren't encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

When you enable the inventory table for your metadata table configuration, the table goes through a process known as *backfilling*, during which Amazon S3 scans your general purpose bucket to retrieve the initial metadata for all objects in the bucket. Depending on the number of objects in your bucket, this process can take minutes (minimum 15 minutes) to hours. When the backfilling process is finished, the status of your inventory table changes from **Backfilling** to **Active**. After backfilling is completed, updates to your objects are typically reflected in the inventory table within one hour.

 **Note**

You're charged for backfilling your inventory table. If your general purpose bucket has more than one billion objects, you're also charged a monthly fee for your inventory table. For more information, see [Amazon S3 Pricing](#).

Amazon S3 Metadata inventory tables contain rows and columns. Each row represents the current state of an object in your general purpose bucket. The inventory table provides a simple, queryable inventory of all objects in your bucket so that you can determine the current state of your data.

The following is an example of an inventory table for a general purpose bucket named amzn-s3-demo-bucket:

Inventory tables have the following schema:

Column name	Required?	Data type	
bucket	Yes	String	The general purpose bucket name. For more information, see the section called "Naming rules" .
key	Yes	String	The object key name (or key) that uniquely identifies the object in the bucket. For more information, see the section called "Naming objects" .
sequence_number	Yes	String	The sequence number, which is an ordinal that's included in the records for a given object. To order records of the same bucket and key,

Column name	Required?	Data type	
			<p>you can sort on sequence_number . For a given bucket and key, a lexicographically larger sequence_number value implies that the record was introduced to the bucket more recently.</p>
version_id	No	String	<p>The object's version ID. When you enable versioning on a bucket, Amazon S3 assigns a version number to objects that are added to the bucket. For more information, see the section called "Retaining multiple versions of objects".</p> <p>Objects that are stored in your bucket before you set the versioning state have a version ID of null.</p>

Column name	Required?	Data type	
is_delete_marker	No	Boolean	The object's delete marker status. If the object is a delete marker, this value is True. Otherwise, it's False. For more information, see the section called "Working with delete markers".

 **Note**

Rows that are added for delete markers have a record_type value of DELETE, not UPDATE_METADATA. If the delete marker is created as the result of an S3 Lifecycle expiration, the requester value is s3.amazonaws.com.

Column name	Required?	Data type	
size	No	Long	The object size in bytes, not including the size of incomplete multipart uploads or object metadata. If <code>is_delete_marker</code> is True, the size is 0. For more information, see the section called "System-defined object metadata" .
last_modified_date	No	Timestamp NTZ (no time zone)	The object creation date or the last modified date, whichever is the latest. For multipart uploads, the object creation date is the date when the multipart upload is initiated. For more information, see the section called "System-defined object metadata" .

Column name	Required?	Data type	
e_tag	No	String	The entity tag (ETag), which is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag can be an MD5 digest of the object data. Whether the ETag is an MD5 digest depends on how the object was created and how it's encrypted. For more information, see Object in the <i>Amazon S3 API Reference</i> .

Column name	Required?	Data type	
storage_class	No	String	The storage class that's used for storing the object. One of STANDARD, REDUCED_R EDUNDANCY , STANDARD_IA , ONEZONE_IA , INTELLIGENT_TIERING , GLACIER, DEEP_ARCHIVE , or GLACIER_IR . For more information, see the section called "Understanding and managing storage classes" .
is_multipart	No	Boolean	The object's upload type. If the object was uploaded as a multipart upload, this value is True. Otherwise, it's False. For more information, see the section called "Using multipart upload" .

Column name	Required?	Data type	
encryption_status	No	String	The object's server-side encryption status, depending on what kind of encryption key is used: server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If the object is unencrypted, this value is null. Possible values are SSE-S3, SSE-KMS, DSSE-KMS, SSE-C, or null. For more information, see the section called "Data encryption" .

Column name	Required?	Data type	
is_bucket _key_enabled	No	Boolean	The object's S3 Bucket Key enablement status. If the object uses an S3 Bucket Key for SSE-KMS, this value is True. Otherwise, it's False. For more information, see the section called "Configuring an S3 Bucket Key for an object".

Column name	Required?	Data type	
kms_key_arn	No	String	The Amazon Resource Name (ARN) for the KMS key with which the object is encrypted, for rows where encryption_status is SSE-KMS or DSSE-KMS. If the object isn't encrypted with SSE-KMS or DSSE-KMS, the value is null. For more information, see the section called "KMS keys stored in AWS KMS (SSE-KMS)" and the section called "Dual-layer server-side encryption (DSSE-KMS)".

 **Note**

If a row represents an object version that no longer existed at the time that a delete or overwrite event was processed, kms_key_a

Column name	Required?	Data type	
			rn contains a null value, even if the encryption_status column value is SSE-KMS or DSSE-KMS.
checksum_algorithm	No	String	The algorithm that's used to create the checksum for the object, one of CRC64-NVME , CRC32, CRC32C, SHA1, or SHA256. If no checksum is present, this value is null. For more information, see the section called "Using supported checksum algorithms".

Column name	Required?	Data type	
object_tags	No	Map <String, String>	<p>The object tags that are associated with the object. Object tags are stored as a map of key-value pairs. If an object has no object tags, an empty map ({}) is stored. For more information, see the section called “Categorizing objects with tags”.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p>Note</p><p>If the record_type value is DELETE, the object_tags column contains a null value. Column name	Required?	Data type	
			existed at the time that a delete or overwrite event was processed will contain a null value in the object_tags column.

Column name	Required?	Data type	
user_metadata	No	Map <String, String>	<p>The user metadata that's associated with the object. User metadata is stored as a map of key-value pairs. If an object has no user metadata, an empty map ({}) is stored. For more information, see the section called "User-defined object metadata".</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p>Note</p><p>If the record_type value is DELETE, the user_metadata column contains a null value. If the record_type value is CREATE or UPDATE_METADATA, rows that represent object versions that</p></div>

Column name	Required?	Data type	
			no longer existed at the time that a delete or overwrite event was processed will contain a null value in the user_meta data column.

Configuring metadata tables

Amazon S3 Metadata accelerates data discovery by automatically capturing metadata for the objects in your general purpose buckets and storing it in read-only, fully managed Apache Iceberg tables that you can query. These read-only tables are called *metadata tables*. As objects are added to, updated, and removed from your general purpose buckets, S3 Metadata automatically refreshes the corresponding metadata tables to reflect the latest changes.

With S3 Metadata, you can easily find, store, and query metadata for your S3 objects, so that you can quickly prepare data for use in business analytics, artificial intelligence and machine learning (AI/ML) model training, and more.

To generate and store object metadata in AWS managed metadata tables, you create a metadata table configuration for your general purpose bucket. Amazon S3 is designed to continuously update the metadata tables to reflect the latest changes to your data as long as the configuration is active on the bucket. Additionally, Amazon S3 continuously optimizes your metadata tables to help reduce storage costs and improve analytics query performance.

To create a metadata table configuration, make sure that you have the necessary AWS Identity and Access Management (IAM) permissions to create and manage metadata tables.

To monitor updates to your metadata table configuration, you can use AWS CloudTrail. For more information, see [the section called “Amazon S3 bucket-level actions that are tracked by CloudTrail logging”](#).

Setting up permissions for configuring metadata tables

To create a metadata table configuration, you must have the necessary AWS Identity and Access Management (IAM) permissions to both create and manage your metadata table configuration and to create and manage your metadata tables and the table bucket where your metadata tables are stored.

To create and manage your metadata table configuration, you must have these permissions:

- `s3:CreateBucketMetadataTableConfiguration` – This permission allows you to create a metadata table configuration for your general purpose bucket. To create a metadata table configuration, additional permissions, including S3 Tables permissions, are required, as explained in the following sections. For a summary of the required permissions, see [the section called “Bucket operations and permissions”](#).
- `s3:GetBucketMetadataTableConfiguration` – This permission allows you to retrieve information about your metadata table configuration.
- `s3>DeleteBucketMetadataTableConfiguration` – This permission allows you to delete your metadata table configuration.
- `s3:UpdateBucketMetadataJournalTableConfiguration` – This permission allows you to update your journal table configuration to expire journal table records.

- `s3:UpdateBucketMetadataInventoryTableConfiguration` – This permission allows you to update your inventory table configuration to enable or disable the inventory table. To update an inventory table configuration, additional permissions, including S3 Tables permissions, are required. For a list of the required permissions, see [the section called “Bucket operations and permissions”](#).

 **Note**

The `s3:CreateBucketMetadataTableConfiguration`, `s3:GetBucketMetadataTableConfiguration`, and `s3:DeleteBucketMetadataTableConfiguration` permissions are used for both V1 and V2 S3 Metadata configurations. For V2, the names of the corresponding API operations are `CreateBucketMetadataConfiguration`, `GetBucketMetadataConfiguration`, and `DeleteBucketMetadataConfiguration`.

To create and work with tables and table buckets, you must have certain `s3tables` permissions. At a minimum, to create a metadata table configuration, you must have the following `s3tables` permissions:

- `s3tables:CreateTableBucket` – This permission allows you to create an AWS managed table bucket. All metadata table configurations in your account and in the same Region are stored in a single AWS managed table bucket named `aws-s3`. For more information, see [the section called “How metadata tables work”](#) and [Working with AWS managed table buckets](#).
- `s3tables:CreateNamespace` – This permission allows you to create a namespace in a table bucket. Metadata tables typically use the `b_general_purpose_bucket_name` namespace. For more information about metadata table namespaces, see [the section called “How metadata tables work”](#).
- `s3tables:CreateTable` – This permission allows you to create your metadata tables.
- `s3tables:GetTable` – This permission allows you to retrieve information about your metadata tables.
- `s3tables:PutTablePolicy` – This permission allows you to add or update your metadata table policies.
- `s3tables:PutTableEncryption` – This permission allows you to set server-side encryption for your metadata tables. Additional permissions are required if you want to encrypt your

metadata tables with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). For more information, see [Permissions for SSE-KMS](#).

- `kms:DescribeKey` – This permission allows you to retrieve information about a KMS key.
- `s3tables:PutTableBucketPolicy` – This permission allows you to create or update a new table bucket policy.

For detailed information about all table and table bucket permissions, see [Access management for S3 Tables](#).

Important

If you also want to integrate your table bucket with AWS analytics services so that you can query your metadata table, you need additional permissions. For more information, see [Integrating Amazon S3 Tables with AWS analytics services](#).

Permissions for SSE-KMS

To encrypt your metadata tables with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you must have additional permissions.

1. The user or AWS Identity and Access Management (IAM) role needs the following permissions. You can grant these permissions by using the IAM console: <https://console.aws.amazon.com/iam/>.
 - a. `s3tables:PutTableEncryption` to configure table encryption
 - b. `kms:DescribeKey` on the AWS KMS key used
2. On the resource policy for the KMS key, you need the following permissions. You can grant these permissions by using the AWS KMS console: <https://console.aws.amazon.com/kms>.
 - a. Grant `kms:GenerateDataKey` permission to `metadata.s3.amazonaws.com` and `maintenance.s3tables.amazonaws.com`.
 - b. Grant `kms:Decrypt` permission to `metadata.s3.amazonaws.com` and `maintenance.s3tables.amazonaws.com`.
 - c. Grant `kms:DescribeKey` permission to the invoking AWS principal.

In addition to these permissions, make sure that the customer managed KMS key used to encrypt the tables still exists, is active, is in the same Region as your general purpose bucket.

Example policy

To create and work with metadata tables and table buckets, you can use the following example policy. In this policy, the general purpose bucket that you're applying the metadata table configuration to is referred to as *amzn-s3-demo-bucket*. To use this policy, replace the *user input placeholders* with your own information.

When you create your metadata table configuration, your metadata tables are stored in an AWS managed table bucket. All metadata table configurations in your account and in the same Region are stored in a single AWS managed table bucket named aws-s3.

                "s3tables:*",
                "kms:DescribeKey"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3",
                "arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3/table/*"
            ]
        }
    ]
}
```

To query metadata tables, you can use the following example policy. If your metadata tables have been encrypted with SSE-KMS, you will need the `kms:Decrypt` permission as shown. To use this policy, replace the *user input placeholders* with your own information.

Creating metadata table configurations

To generate and store Amazon S3 Metadata in fully managed Apache Iceberg metadata tables, you create a metadata table configuration for your general purpose bucket. Amazon S3 is designed to continuously update the metadata tables to reflect the latest changes to your data as long as the configuration is active on the bucket. Additionally, Amazon S3 continuously optimizes your metadata tables to help reduce storage costs and improve analytics query performance.

For each general purpose bucket, you can create a metadata table configuration that contains two complementary metadata tables:

- **Journal table** – By default, your metadata table configuration contains a *journal table*, which captures events that occur for the objects in your bucket. The journal table records changes made to your data in near real time, helping you to identify new data uploaded to your bucket,

track recently deleted objects, monitor lifecycle transitions, and more. The journal table records new objects and updates to your objects and their metadata (those updates that require either a PUT or a DELETE operation).

The journal table captures metadata only for change events (such as uploads, updates, and deletes) that happen after you create your metadata table configuration. Because this table is queryable, you can audit the changes to your bucket through simple SQL queries.

The journal table is required for each metadata table configuration. (In the initial release of S3 Metadata, the journal table was referred to as "the metadata table.")

For more information about what data is stored in journal tables, see [the section called "Journal tables schema"](#).

To help minimize your storage costs, you can choose to enable journal table record expiration. For more information, see [the section called "Expiring journal table records"](#).

- **Live inventory table** – Optionally, you can add a *live inventory table* to your metadata table configuration. The live inventory table provides a simple, queryable inventory of all the objects and their versions in your bucket so that you can determine the latest state of your data.

You can use the live inventory table to simplify and speed up business workflows and big data jobs by identifying objects that you want to process for various workloads. For example, you can query the live inventory table to find all objects stored in a particular storage class, all objects with certain tags, all objects that aren't encrypted with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS), and more.

When you enable the live inventory table for your metadata table configuration, the table goes through a process known as *backfilling*, during which Amazon S3 scans your general purpose bucket to retrieve the initial metadata for all objects that exist in the bucket. Depending on the number of objects in your bucket, this process can take minutes (minimum 15 minutes) to hours. When the backfilling process is finished, the status of your live inventory table changes from **Backfilling to Active**. After backfilling is completed, updates to your objects are typically reflected in the live inventory table within one hour.

You're charged for backfilling your live inventory table. If your general purpose bucket has more than one billion objects, you're also charged a monthly fee for your live inventory table. For more information, see [Amazon S3 Pricing](#).

For more information about what data is stored in live inventory tables, see [the section called “Live inventory tables schema”](#).

Metadata tables have the following Amazon Resource Name (ARN) format, which includes the table ID of the metadata table:

`arn:aws:s3tables:region-code:account-id:bucket/aws-s3/table/table-id`

For example, a metadata table in the US East (N. Virginia) Region would have an ARN like the following:

`arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3/table/a12bc345-67d8-912e-3456-7f89123g4h56`

Journal tables have the name `journal`, and live inventory tables have the name `inventory`.

When you create your metadata table configuration, your metadata tables are stored in an AWS managed table bucket. All metadata table configurations in your account and in the same Region are stored in a single AWS managed table bucket. These AWS managed table buckets are named `aws-s3` and have the following Amazon Resource Name (ARN) format:

`arn:aws:s3tables:region:account_id:bucket/aws-s3`

For example, if your account ID is `123456789012` and your general purpose bucket is in US East (N. Virginia) (`us-east-1`), your AWS managed table bucket is also created in US East (N. Virginia) (`us-east-1`) and has the following ARN:

`arn:aws:s3tables:us-east-1:123456789012:bucket/aws-s3`

By default, AWS managed table buckets are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3). After you create your first metadata configuration, you can set the default encryption setting for the AWS managed table bucket to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). For more information, see [Encryption for AWS managed table buckets](#) and [the section called “Specifying SSE-KMS”](#).

Within your AWS managed table bucket, the metadata tables for your configuration are typically stored in a namespace with the following naming format:

`b_general-purpose-bucket-name`

For more information about metadata table namespaces, see [the section called “How metadata tables work”](#).

When you create your metadata table configuration, you can choose to encrypt your AWS managed metadata tables with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). If you choose to use SSE-KMS, you must provide a customer managed KMS key in the same Region as your general purpose bucket. You can set the encryption type for your tables only during table creation. After an AWS managed table is created, you can't change its encryption setting. To specify SSE-KMS for your metadata tables, you must have certain permissions. For more information, see [Permissions for SSE-KMS](#).

The encryption setting for a metadata table takes precedence over the default bucket-level encryption setting. If you don't specify encryption for a table, it will inherit the default encryption setting from the bucket.

AWS managed table buckets don't count toward your S3 Tables quotas. For more information about working with AWS managed table buckets and AWS managed tables, see [Working with AWS managed table buckets](#).

You can create a metadata table configuration by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

 **Note**

- If you created your S3 Metadata configuration before July 15, 2025, we recommend that you delete and re-create your configuration so that you can expire journal table records and create an inventory table. For more information, see [the section called “Enabling inventory tables on metadata configurations created before July 15, 2025”](#).
- If you've deleted your metadata table configuration and want to re-create a configuration for the same general purpose bucket, you must first manually delete the old journal and inventory tables from your AWS managed table bucket. Otherwise, creating the new metadata table configuration fails because those tables already exist. To delete your metadata tables, see [the section called “Delete a metadata table”](#).

Deleting a metadata table configuration deletes only the configuration. The AWS managed table bucket and your metadata tables still exist, even if you delete the metadata table configuration.

Prerequisites

Before you create a metadata table configuration make sure that you've met the following prerequisites:

- Before you create a metadata table configuration make sure that you have the necessary AWS Identity and Access Management (IAM) permissions to create and manage metadata tables. For more information, see [the section called “Permissions for metadata tables”](#).
- If you plan to query your metadata tables with Amazon Athena or another AWS query engine, make sure that you integrate your AWS managed table bucket with AWS analytics services. For more information, see [the section called “Integrating S3 Tables with AWS analytics services”](#).

If you've already integrated an existing table bucket in this Region, your AWS managed table bucket is also automatically integrated. To determine the integration status for your table buckets in this Region, open the Amazon S3 console, and choose **Table buckets** in the left navigation pane. Under **Integration with AWS analytics services**, check the Region and whether the integration status says **Enabled**.

Create a metadata table configuration

Using the S3 console

To create a metadata table configuration

Before you create a metadata table configuration, make sure that you've reviewed and met the [prerequisites](#) and that you've reviewed [the section called “Limitations and restrictions”](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. Choose the general purpose bucket that you want to create a metadata table configuration for.

Note

Make sure that this general purpose bucket is an AWS Region where table buckets are available. Table buckets are available only in the US East (N. Virginia), US East (Ohio), and US West (Oregon) Regions.

4. On the bucket's details page, choose the **Metadata** tab.

5. On the **Metadata** tab, choose **Create metadata configuration**.
6. On the **Create metadata configuration** page, under **Journal table**, you can choose whether to encrypt your table with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). By default, journal tables are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3).

If you choose to use SSE-KMS, you must provide a customer managed KMS key in the same Region as your general purpose bucket.

⚠ Important

You can set the encryption type for your metadata tables only during table creation. After an AWS managed table is created, you can't change its encryption setting.

- To encrypt your journal table with SSE-S3 (the default), choose **Don't specify encryption type**.
- To encrypt your journal table with SSE-KMS, choose **Specify encryption type**. Under **Encryption type**, choose **Server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS)**. Under **AWS KMS key**, either choose from your existing KMS keys, or enter your KMS key ARN. If you don't already have a KMS key, choose **Enter KMS key ARN**, and then choose **Create a KMS key**.

Make sure that you've set up the necessary permissions for SSE-KMS. For more information, see [Permissions for SSE-KMS](#).

7. (Optional) By default, the records in your journal table don't expire. To help minimize the storage costs for your journal table, choose **Enabled** for **Record expiration**.

If you enable journal table record expiration, you can set the number of days to retain your journal table records. To set the **Days after which records expire** value, you can specify any whole number between 7 and 2147483647. For example, to retain your journal table records for one year, set this value to 365.

Records will be expired within 24 to 48 hours after they become eligible for expiration.

⚠️ Important

After journal table records expire, they can't be recovered.

Under **Journal table records will expire after the specified number of days**, select the checkbox.

8. (Optional) If you want to add an inventory table to your metadata table configuration, under **Live inventory table**, choose **Enabled** for **Configuration status**.

You can choose whether to encrypt your table with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). By default, inventory tables are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3).

If you choose to use SSE-KMS, you must provide a customer managed KMS key in the same Region as your general purpose bucket.

⚠️ Important

You can set the encryption type for your metadata tables only during table creation. After an AWS managed table is created, you can't change its encryption setting.

- To encrypt your inventory table with SSE-S3 (the default), choose **Don't specify encryption type**.
- To encrypt your inventory table with SSE-KMS, choose **Specify encryption type**. Under **Encryption type**, choose **Server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS)**. Under **AWS KMS key**, either choose from your existing KMS keys, or enter your KMS key ARN. If you don't already have a KMS key, choose **Enter KMS key ARN**, and then choose **Create a KMS key**.

Make sure that you've set up the necessary permissions for SSE-KMS. For more information, see [Permissions for SSE-KMS](#).

9. Choose **Create metadata table configuration**.

If your metadata table configuration was successful, the names and ARNs for your metadata tables are displayed on the **Metadata** tab, along with the name of your AWS managed table bucket and namespace.

If you chose to enable an inventory table for your metadata table configuration, the table goes through a process known as *backfilling*, during which Amazon S3 scans your general purpose bucket to retrieve the initial metadata for all objects that exist in the bucket. Depending on the number of objects in your bucket, this process can take minutes (minimum 15 minutes) to hours. When the backfilling process is finished, the status of your inventory table changes from **Backfilling to Active**. After backfilling is completed, updates to your objects are typically reflected in the inventory table within one hour.

To monitor updates to your metadata table configuration, you can use AWS CloudTrail. For more information, see [the section called “Amazon S3 bucket-level actions that are tracked by CloudTrail logging”](#).

Using the AWS CLI

To run the following commands, you must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see [Install or update to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Alternatively, you can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) and [Getting started with AWS CloudShell](#) in the *AWS CloudShell User Guide*.

To create a metadata table configuration by using the AWS CLI

Before you create a metadata table configuration, make sure that you've reviewed and met the [prerequisites](#) and that you've reviewed [the section called “Limitations and restrictions”](#).

To use the following example commands, replace the *user input placeholders* with your own information.

1. Create a JSON file that contains your metadata table configuration, and save it (for example, `metadata-config.json`). The following is a sample configuration.

You must specify whether to enable or disable journal table record expiration. If you choose to enable record expiration, you must also specify the number of days after which your journal table records will expire. To set the Days value, you can specify any whole number between 7

and 2147483647. For example, to retain your journal table records for one year, set this value to 365.

You can optionally choose to configure an inventory table.

For both journal tables and inventory tables, you can optionally specify an encryption configuration. By default, metadata tables are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3), which you can specify by setting `SseAlgorithm` to AES256.

To encrypt your metadata tables with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS), set `SseAlgorithm` to `aws:kms`. You must also set `KmsKeyArn` to the ARN of a customer managed KMS key in the same Region where your general purpose bucket is located.

```
{  
    "JournalTableConfiguration": {  
        "RecordExpiration": {  
            "Expiration": "ENABLED",  
            "Days": 10  
        },  
        "EncryptionConfiguration": {  
            "SseAlgorithm": "AES256"  
        }  
    },  
    "InventoryTableConfiguration": {  
        "ConfigurationState": "ENABLED",  
        "EncryptionConfiguration": {  
            "SseAlgorithm": "aws:kms",  
            "KmsKeyArn": "arn:aws:kms:us-east-2:account-id:key/key-id"  
        }  
    }  
}
```

2. Use the following command to apply the metadata table configuration to your general purpose bucket (for example, *amzn-s3-demo-bucket*):

```
aws s3api create-bucket-metadata-configuration \  
--bucket amzn-s3-demo-bucket \  
--metadata-configuration file://./metadata-config.json \  
--region us-east-2
```

- To verify that the configuration was created, use the following command:

```
aws s3api get-bucket-metadata-configuration \
--bucket amzn-s3-demo-bucket \
--region us-east-2
```

To monitor updates to your metadata table configuration, you can use AWS CloudTrail. For more information, see [the section called “Amazon S3 bucket-level actions that are tracked by CloudTrail logging”](#).

Using the REST API

You can send REST requests to create a metadata table configuration. For more information, see [CreateBucketMetadataConfiguration](#) in the *Amazon S3 API Reference*.

Using the AWS SDKs

You can use the AWS SDKs to create a metadata table configuration in Amazon S3. For information, see the [list of supported SDKs](#) in the *Amazon S3 API Reference*.

Enabling inventory tables on metadata configurations created before July 15, 2025

If you created your S3 Metadata configuration before July 15, 2025, we recommend that you delete and re-create your configuration so that you can expire journal table records and create an inventory table. Any changes to your general purpose bucket that occur between deleting the old configuration and creating the new one aren't recorded in either of your journal tables.

To migrate from an old metadata configuration to a new configuration, do the following:

- Delete your existing metadata table configuration. For step-by-step instructions, see [the section called “Deleting metadata table configurations”](#).
- Create a new metadata table configuration. For step-by-step instructions, see [the section called “Creating metadata tables”](#).

If you need assistance with migrating your configuration, contact AWS Support.

After you create your new metadata configuration, you will have two journal tables. If you no longer need the old journal table, you can delete it. For step-by-step instructions, see [the section called “Deleting metadata tables”](#). If you've retained your old journal table and want to join it with

your new one, see [the section called “Joining custom metadata”](#) for examples of how to join two tables.

After migration, you can do the following:

1. To view your configuration, you can now use the GetBucketMetadataConfiguration API operation. To determine whether your configuration is old or new, you can look at the following attribute of your GetBucketMetadataConfiguration API response. An AWS managed bucket type ("aws") indicates a new configuration, and a customer-managed bucket type ("customer") indicates an old configuration.

```
"MetadataTableConfigurationResult": {  
    "TableBucketType": ["aws" | "customer"]}
```

For more information, see [the section called “Viewing metadata table configurations”](#).

 **Note**

You can use the GetBucketMetadataConfiguration and DeleteBucketMetadataConfiguration API operations with old or new metadata table configurations. However, if you try to use the GetBucketMetadataTableConfiguration and DeleteBucketMetadataTableConfiguration API operations with new configurations, you will receive HTTP 405 Method Not Allowed errors. Make sure that you update your processes to use the new API operations (CreateBucketMetadataConfiguration, GetBucketMetadataConfiguration, and DeleteBucketMetadataConfiguration) instead of the old API operations.

2. If you plan to query your metadata tables with Amazon Athena or another AWS query engine, make sure that you integrate your AWS managed table bucket with AWS analytics services. If you've already integrated an existing table bucket in this Region, your AWS managed table bucket is also automatically integrated. For more information, see [the section called “Integrating S3 Tables with AWS analytics services”](#).

Controlling access to metadata tables

To control access to your Amazon S3 metadata tables, you can use AWS Identity and Access Management (IAM) resource-based policies that are attached to your table bucket and to your

metadata tables. In other words, you can control access to your metadata tables at both the table bucket level and the table level.

For more information about controlling access to your table buckets and tables, see [Access management for S3 Tables](#).

Important

When you're creating or updating table bucket or table policies, make sure that you don't restrict the Amazon S3 service principals `metadata.s3.amazonaws.com` and `maintenance.s3tables.amazonaws.com` from writing to your table bucket or your metadata tables.

If Amazon S3 is unable to write to your table bucket or your metadata tables, you must delete your metadata configuration, delete your metadata tables, and then create a new configuration. If you had an inventory table in your configuration, a new inventory table has to be created, and you will be charged again for backfilling the new inventory table.

You can also control access to the rows and columns in your metadata tables through AWS Lake Formation. For more information, see [Managing Lake Formation permissions](#) and [Data filtering and cell-level security in Lake Formation](#) in the *AWS Lake Formation Developer Guide*.

Epiring journal table records

By default, the records in your journal table don't expire. To help minimize the storage costs for your journal table, you can enable journal table record expiration.

Note

If you created your S3 Metadata configuration before July 15, 2025, you can't enable journal table record expiration on that configuration. We recommend that you delete and re-create your configuration so that you can expire journal table records and create an inventory table. For more information, see [the section called “Enabling inventory tables on metadata configurations created before July 15, 2025”](#).

If you enable journal table record expiration, you can set the number of days to retain your journal table records. To set this value, specify any whole number between 7 and 2147483647. For example, to retain your journal table records for one year, set this value to 365.

Important

After journal table records expire, they can't be recovered.

Records are expired within 24 to 48 hours after they become eligible for expiration. Journal records are removed from the latest snapshot. The data and storage for the deleted records is removed through table maintenance operations.

If you've enabled journal table record expiration, you can disable it at any time to stop expiring your journal table records.

You can expire journal table records by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

How to expire journal table records

Using the S3 console

To expire journal table records

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. Choose the general purpose bucket that contains the metadata table configuration with the journal table that you want to expire records from.
4. On the bucket's details page, choose the **Metadata** tab.
5. On the **Metadata** tab, choose **Edit**, then choose **Edit journal table record expiration**.
6. On the **Edit journal table record expiration** page, choose **Enabled** under **Record expiration**.
7. Set the number of days to retain your journal table records. To set the **Days after which records expire** value, specify any whole number between 7 and 2147483647. For example, to retain your journal table records for one year, set this value to 365.

Important

After journal table records expire, they can't be recovered.

8. Under **Journal table records will expire after the specified number of days**, select the checkbox.
9. Choose **Save changes**.

If you want to disable journal table record expiration, repeat the preceding steps, but choose **Disabled** instead of **Enabled** for step 6.

Using the AWS CLI

To run the following commands, you must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see [Install or update to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

You can also run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) and [Getting started with AWS CloudShell](#) in the *AWS CloudShell User Guide*.

To expire journal table records by using the AWS CLI

To use the following example commands, replace the *user input placeholders* with your own information.

1. Create a JSON file that contains your journal table configuration, and save it (for example, `journal-config.json`). The following is a sample configuration.

To set the Days value, specify any whole number between 7 and 2147483647. For example, to retain your journal table records for one year, set this value to 365.

```
{  
    "RecordExpiration": {  
        "Expiration": "ENABLED",  
        "Days": 10  
    }  
}
```

To disable journal table record expiration, create the following sample configuration instead. If `Expiration` is set to `DISABLED`, you must not specify a `Days` value in the configuration.

```
{
```

```
"RecordExpiration": {  
    "Expiration": "DISABLED"  
}  
}
```

2. Use the following command to expire records from the journal table in your general purpose bucket (for example, *amzn-s3-demo-bucket*):

```
aws s3api update-bucket-metadata-journal-table-configuration \  
--bucket amzn-s3-demo-bucket \  
--journal-table-configuration file://./journal-config.json \  
--region us-east-2
```

Using the REST API

You can send REST requests to expire journal table records. For more information, see [UpdateBucketMetadataJournalTableConfiguration](#).

Using the AWS SDKs

You can use the AWS SDKs to expire journal table records in Amazon S3. For information, see the [list of supported SDKs](#).

Enabling or disabling live inventory tables

By default, your metadata table configuration contains a *journal table*, which records the events that occur for the objects in your bucket. The journal table is required for each metadata table configuration.

Optionally, you can add a *live inventory table* to your metadata table configuration. The live inventory table provides a simple, queryable inventory of all the objects and their versions in your bucket so that you can determine the latest state of your data.

Note

If you created your S3 Metadata configuration before July 15, 2025, you can't enable an inventory table on that configuration. We recommend that you delete and re-create your configuration so that you can create an inventory table and expire journal table records.

For more information, see [the section called “Enabling inventory tables on metadata configurations created before July 15, 2025”](#).

The inventory table contains the latest metadata for all objects in your bucket. You can use this table to simplify and speed up business workflows and big data jobs by identifying objects that you want to process for various workloads. For example, you can query the inventory table to do the following:

- Find all objects stored in the S3 Glacier Deep Archive storage class.
- Create a distribution of object tags or find objects without tags.
- Find all objects that aren't encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).
- Compare your inventory table at two different points in time to understand the growth in objects with specific tags.

If you chose to enable an inventory table for your metadata table configuration, the table goes through a process known as *backfilling*, during which Amazon S3 scans your general purpose bucket to retrieve the initial metadata for all objects that exist in the bucket. Depending on the number of objects in your bucket, this process can take minutes (minimum 15 minutes) to hours. When the backfilling process is finished, the status of your inventory table changes from **Backfilling to Active**. After backfilling is completed, updates to your objects are typically reflected in the inventory table within one hour.

 **Note**

- You're charged for backfilling your inventory table. If your general purpose bucket has more than one billion objects, you're also charged a monthly fee for your inventory table. For more information, see [Amazon S3 Pricing](#).
- You can't pause updates to your inventory table and then resume them. However, you can disable the inventory table configuration. Disabling the inventory table doesn't delete it. The inventory table is retained for your records until you decide to delete it.

If you've disabled your inventory table and later want to re-enable it, you must first delete the old inventory table from your AWS managed table bucket. When you re-enable the inventory table configuration, Amazon S3 creates a new inventory table, and you're charged again for backfilling the new inventory table.

You can enable or disable inventory tables by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

Prerequisites

If you've disabled your inventory table and now want to re-enable it, you must first manually delete the old inventory table from your AWS managed table bucket. Otherwise, re-enabling the inventory table fails because an inventory table already exists in the table bucket. To delete your inventory table, see [the section called "Delete a metadata table"](#).

When you re-enable the inventory table configuration, Amazon S3 creates a new inventory table, and you're charged again for backfilling the new inventory table.

Enable or disable inventory tables

Using the S3 console

To enable or disable inventory tables

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. Choose the general purpose bucket with the metadata table configuration that you want to enable or disable an inventory table for.
4. On the bucket's details page, choose the **Metadata** tab.
5. On the **Metadata** tab, choose **Edit**, then choose **Edit inventory table configuration**.
6. On the **Edit inventory table configuration** page, choose **Enabled** or **Disabled** under **Inventory table**.

 **Note**

Before you choose **Enabled**, make sure that you've reviewed and met the [prerequisites](#).

- If you chose **Enabled**, you can choose whether to encrypt your table with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). By default, inventory tables are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3).

If you choose to use SSE-KMS, you must provide a customer managed KMS key in the same Region as your general purpose bucket.

 **Important**

You can set the encryption type for your metadata tables only during table creation. After an AWS managed table is created, you can't change its encryption setting.

- To encrypt your inventory table with SSE-S3 (the default), choose **Don't specify encryption type**.
- To encrypt your inventory table with SSE-KMS, choose **Specify encryption type**. Under **Encryption type**, choose **Server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS)**. Under **AWS KMS key**, either choose from your existing KMS keys, or enter your KMS key ARN. If you don't already have a KMS key, choose **Enter KMS key ARN**, and then choose **Create a KMS key**.
- If you chose **Disabled**, under **After the inventory table is disabled, the table will no longer be updated, and updates can't be resumed**, select the checkbox.

7. Choose **Save changes**.

Using the AWS CLI

To run the following commands, you must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see [Install or update to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Alternatively, you can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) and [Getting started with AWS CloudShell](#) in the *AWS CloudShell User Guide*.

To enable or disable inventory tables by using the AWS CLI

To use the following example commands, replace the *user input placeholders* with your own information.

Note

Before enabling an inventory configuration, make sure that you've reviewed and met the [prerequisites](#).

1. Create a JSON file that contains your inventory table configuration, and save it (for example, `inventory-config.json`). The following is a sample configuration to enable a new inventory table.

If you're enabling an inventory table, you can optionally specify an encryption configuration. By default, metadata tables are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3), which you can specify by setting `SseAlgorithm` to AES256.

To encrypt your inventory table with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS), set `SseAlgorithm` to `aws:kms`. You must also set `KmsKeyArn` to the ARN of a customer managed KMS key in the same Region where your general purpose bucket is located.

```
{  
    "ConfigurationState": "ENABLED",  
    "EncryptionConfiguration": {  
        "SseAlgorithm": "aws:kms",  
        "KmsKeyArn": "arn:aws:kms:us-east-2:account-id:key/key-id"  
    }  
}
```

If you want to disable an existing inventory table, use the following configuration:

```
{  
    "ConfigurationState": "DISABLED"  }  
}
```

2. Use the following command to update the inventory table configuration for your general purpose bucket (for example, `amzn-s3-demo-bucket`):

```
aws s3api update-bucket-metadata-inventory-table-configuration \  
--bucket amzn-s3-demo-source-bucket \  
--inventory-table-configuration file://./inventory-config.json \  

```

```
--region us-east-2
```

Using the REST API

You can send REST requests to enable or disable inventory tables. For more information, see [UpdateBucketMetadataInventoryTableConfiguration](#).

Using the AWS SDKs

You can use the AWS SDKs to enable or disable inventory tables in Amazon S3. For information, see the [list of supported SDKs](#).

Viewing metadata table configurations

If you've created a metadata table configuration for a general purpose bucket, you can view information about the configuration, such as whether an inventory table has been enabled, or whether journal table record expiration has been enabled. You can also view the status of your journal and inventory tables.

You can view your metadata table configuration for a general purpose bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

View a metadata table configuration

Using the S3 console

To view a metadata table configuration

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. Choose the general purpose bucket that contains the metadata table configuration that you want to view.
4. On the bucket's details page, choose the **Metadata** tab.
5. On the **Metadata** tab, scroll down to the **Metadata configuration** section. In the **Journal table** and **Inventory table** sections, you can view various information for these configurations, such as their Amazon Resource Names (ARNs), the status of your tables, and whether you've enabled journal table record expiration or an inventory table.

Using the AWS CLI

To run the following commands, you must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see [Install or update to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Alternatively, you can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) and [Getting started with AWS CloudShell](#) in the *AWS CloudShell User Guide*.

To view a metadata table configuration by using the AWS CLI

To use the following example command, replace the *user input placeholders* with your own information.

1. Use the following command to view the metadata table configuration for your general purpose bucket (for example, *amzn-s3-demo-bucket*):

```
aws s3api get-bucket-metadata-configuration \
--bucket amzn-s3-demo-bucket \
--region us-east-2
```

2. View the output of this command to see the status of your metadata table configuration. For example:

```
{  
    "GetBucketMetadataConfigurationResult": {  
        "MetadataConfigurationResult": {  
            "DestinationResult": {  
                "TableBucketType": "aws",  
                "TableBucketArn": "arn:aws:s3tables:us-east-2:111122223333:bucket/

                "TableNameSpace": "b_general-purpose-bucket-name"  
            },  
            "JournalTableConfigurationResult": {  
                "TableStatus": "ACTIVE",  
                "TableName": "journal",  
                "TableArn": "arn:aws:s3tables:us-east-2:111122223333:bucket/aws-

                "EncryptionConfiguration": {  
                    "SseAlgorithm": "AES256"  
                }  
            }  
        }  
    }  
}
```

```
        },
        "RecordExpiration": {
            "Expiration": "ENABLED",
            "Days": 10
        }
    },
    "InventoryTableConfigurationResult": {
        "ConfigurationState": "ENABLED",
        "TableStatus": "BACKFILL_COMPLETE",
        "TableName": "inventory",
        "TableArn": "arn:aws:s3tables:us-east-2:111122223333:bucket/aws-

        "EncryptionConfiguration": {
            "SseAlgorithm": "AES256"
        }
    }
}
```

Using the REST API

You can send REST requests to view a metadata table configuration. For more information, see [GetBucketMetadataTableConfiguration](#).

Note

You can use the V2 GetBucketMetadataConfiguration API operation with V1 or V2 metadata table configurations. However, if you try to use the V1 GetBucketMetadataTableConfiguration API operation with V2 configurations, you will receive an HTTP 405 Method Not Allowed error.

Using the AWS SDKs

You can use the AWS SDKs to view a metadata table configuration in Amazon S3. For information, see the [list of supported SDKs](#).

Deleting metadata table configurations

If you want to stop updating the metadata table configuration for an Amazon S3 general purpose bucket, you can delete the metadata table configuration that's attached to your bucket. Deleting a metadata table configuration deletes only the configuration. The AWS managed table bucket and your metadata tables still exist, even if you delete the metadata table configuration. However, the metadata tables will no longer be updated.

Note

If you delete your metadata table configuration and want to re-create a configuration for the same general purpose bucket, you must first manually delete the old journal and inventory tables from your AWS managed table bucket. Otherwise, creating the new metadata table configuration fails because those tables already exist. To delete your metadata tables, see [the section called “Deleting metadata tables”](#).

To delete your metadata tables, see [the section called “Delete a metadata table”](#). To delete your table bucket, see [Deleting table buckets](#) and [DeleteTableBucket](#) in the *Amazon S3 API Reference*.

You can delete a metadata table configuration by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

Delete a metadata table configuration

Using the S3 console

To delete a metadata table configuration

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. Choose the general purpose bucket that you want to remove a metadata table configuration from.
4. On the bucket's details page, choose the **Metadata** tab.
5. On the **Metadata** tab, choose **Delete**.
6. In the **Delete metadata configuration** dialog box, enter **confirm** to confirm that you want to delete the configuration. Then choose **Delete**.

Using the AWS CLI

To run the following commands, you must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see [Install or update to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Alternatively, you can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) and [Getting started with AWS CloudShell](#) in the *AWS CloudShell User Guide*.

To delete a metadata table configuration by using the AWS CLI

To use the following example commands, replace the *user input placeholders* with your own information.

1. Use the following command to delete the metadata table configuration from your general purpose bucket (for example, *amzn-s3-demo-bucket*):

```
aws s3api delete-bucket-metadata-configuration \
--bucket amzn-s3-demo-bucket \
--region us-east-2
```

2. To verify that the configuration was deleted, use the following command:

```
aws s3api get-bucket-metadata-configuration \
--bucket amzn-s3-demo-bucket \
--region us-east-2
```

Using the REST API

You can send REST requests to delete a metadata table configuration. For more information, see [DeleteBucketMetadataConfiguration](#).

Note

You can use the V2 DeleteBucketMetadataConfiguration API operation with V1 or V2 metadata table configurations. However, if you try to use the V1

DeleteBucketMetadataTableConfiguration API operation with V2 configurations, you will receive an HTTP 405 Method Not Allowed error.

Using the AWS SDKs

You can use the AWS SDKs to delete a metadata table configuration in Amazon S3. For information, see the [list of supported SDKs](#).

Deleting metadata tables

If you want to delete the metadata tables that you created for an Amazon S3 general purpose bucket, you can delete the metadata tables from your AWS managed table bucket.

Important

- Deleting a table is permanent and can't be undone. Before deleting a table, make sure that you have backed up any important data.
- Before you delete a metadata table, we recommend that you first delete the associated metadata table configuration on your general purpose bucket. For more information, see [the section called "Deleting metadata table configurations"](#).

To delete your AWS managed table bucket, see [Deleting table buckets](#) and [DeleteTableBucket](#) in the *Amazon S3 API Reference*. Before you delete your AWS managed table bucket, we recommend that you first delete all metadata table configurations that are associated with this bucket. You must also first delete all metadata tables in the bucket.

You can delete a metadata table by using the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

Delete a metadata table

Using the AWS CLI

To run the following commands, you must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see [Install or update to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Alternatively, you can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) and [Getting started with AWS CloudShell](#) in the *AWS CloudShell User Guide*.

To delete a metadata table configuration by using the AWS CLI

To use the following example commands, replace the *user input placeholders* with your own information.

1. Use the following command to delete the metadata table from your AWS managed table bucket:

```
aws s3tables delete-table \
--table-bucket-arn arn:aws:s3tables:us-east-2:111122223333:bucket/aws-s3 \
--namespace b_general-purpose-bucket-name \
--name journal \
--region us-east-2
```

2. To verify that the table was deleted, use the following command:

```
aws s3tables get-table \
--table-bucket-arn arn:aws:s3tables:us-east-2:111122223333:bucket/aws-s3 \
--namespace b_general-purpose-bucket-name \
--name journal \
--region us-east-2
```

Using the REST API

You can send REST requests to delete a metadata table configuration. For more information, see [DeleteTable](#) in the *Amazon S3 API Reference*.

Using the AWS SDKs

You can use the AWS SDKs to delete a metadata table configuration in Amazon S3. For information, see the [list of supported SDKs](#) in the *Amazon S3 API Reference*.

Querying metadata tables

Your Amazon S3 Metadata tables are stored in an AWS managed S3 table bucket, which provides storage that's optimized for tabular data. To query your metadata, you can integrate your table

bucket with Amazon SageMaker Lakehouse. This integration, which uses the AWS Glue Data Catalog and AWS Lake Formation, allows AWS analytics services to automatically discover and access your table data.

After your table bucket is integrated with the AWS Glue Data Catalog, you can directly query your metadata tables with AWS analytics services such as Amazon Athena, Amazon EMR, and Amazon Redshift. You can also create interactive dashboards with your query data by using Amazon Quick Suite.

For more information about integrating your AWS managed S3 table bucket with Amazon SageMaker Lakehouse, see [the section called “Integrating S3 Tables with AWS analytics services”](#).

You can also query your metadata tables with Apache Spark, Apache Trino, and any other application that supports the Apache Iceberg format by using the AWS Glue Iceberg REST endpoint, Amazon S3 Tables Iceberg REST endpoint, or the Amazon S3 Tables Catalog for Apache Iceberg client catalog. For more information about accessing your metadata tables, see [the section called “Accessing tables”](#).

You can analyze your metadata tables with any query engine that supports the Apache Iceberg format. For example, you can query your metadata tables to do the following:

- Discover storage usage patterns and trends
- Audit AWS Key Management Service (AWS KMS) encryption key usage across your objects
- Search for objects by user-defined metadata and object tags
- Understand object metadata changes over time
- Learn when objects are updated or deleted, including the AWS account ID or IP address that made the request

You can also join S3 managed metadata tables and custom metadata tables, allowing you to query across multiple datasets.

Query pricing considerations

Additional pricing applies for running queries on your metadata tables. For more information, see pricing information for the query engine that you're using.

For information on making your queries more cost effective, see [Optimizing metadata table query performance](#).

Permissions for querying metadata tables

Before you can query your S3 Metadata journal and live inventory tables, you must have certain S3 Tables permissions. If your metadata tables have been encrypted with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS), you must also have the kms:Decrypt permission to decrypt the table data.

When you create your metadata table configuration, your metadata tables are stored in an AWS managed table bucket. All metadata table configurations in your account and in the same Region are stored in a single AWS managed table bucket named aws-s3.

To query metadata tables, you can use the following example policy. To use this policy, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PermissionsToQueryMetadataTables",  
            "Effect": "Allow",  
            "Action": [  
                "s3tables:GetTable",  
                "s3tables:GetTableData",  
                "s3tables:GetTableMetadataLocation",  
                "kms:Decrypt"  
            ],  
            "Resource": [  
                "arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3",

                "arn:aws:kms:us-east-1:111122223333:key/01234567-89ab-cdef-0123-456789abcdef"  
            ]  
        }

```

Querying metadata tables with AWS analytics services

You can query your S3 managed metadata tables with AWS analytics services such as Amazon Athena, Amazon Redshift, and Amazon EMR.

Before you can run queries, you must first [integrate the AWS managed S3 table buckets](#) in your AWS account and Region with AWS analytics services.

Querying metadata tables with Amazon Athena

After you [integrate your AWS managed S3 table buckets](#) with AWS analytics services, you can start querying your metadata tables in Athena. In your queries, do the following:

- Specify your catalog as s3tablescatalog/aws-s3 and your database as b_*general_purpose_bucket_name* (which is typically the namespace for your metadata tables).
- Make sure to surround your metadata table namespace names in quotation marks ("") or backticks (`), otherwise the query might not work.

For more information, see [Querying Amazon S3 tables with Athena](#).

You can also run queries in Athena from the Amazon S3 console.

Using the S3 console and Amazon Athena

The following procedure uses the Amazon S3 console to access the Athena query editor so that you can query a table with Amazon Athena.

To query a metadata table

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. On the **General purpose buckets** tab, choose the bucket that contains the metadata configuration for the metadata table that you want to query.

4. On the bucket details page, choose the **Metadata** tab.
5. Choose **Query table with Athena**, and then choose one of the sample queries for journal or inventory tables.
6. The Amazon Athena console opens and the Athena query editor appears with a sample query loaded for you. Modify this query as needed for your use case.

In the query editor, the **Catalog** field should be populated with `s3tablescatalog/aws-s3`.

The **Database** field should be populated with the namespace where your table is stored (for example, `b_general-purpose-bucket-name`).

 **Note**

If you don't see these values in the **Catalog** and **Database** fields, make sure that you've integrated your AWS managed table bucket with AWS analytics services in this Region. For more information, see [the section called "Integrating S3 Tables with AWS analytics services"](#).

7. To run the query, choose **Run**.

 **Note**

- If you receive the error "Insufficient permissions to execute the query. Principal does not have any privilege on specified resource" when you try to run a query in Athena, you must be granted the necessary Lake Formation permissions on the table. For more information, see [the section called "Granting Lake Formation permission on a table or database"](#).

Also make sure that you have the appropriate AWS Identity and Access Management (IAM) permissions to query metadata tables. For more information, see [the section called "Permissions for querying metadata tables"](#).

- If you receive the error "Iceberg cannot access the requested resource" when you try to run the query, go to the AWS Lake Formation console and make sure that you've granted yourself permissions on the table bucket catalog and database (namespace) that you created. Don't specify a table when granting these permissions. For more information, see [the section called "Granting Lake Formation permission on a table or database"](#).

Querying metadata tables with Amazon Redshift

After you [integrate your AWS managed S3 table buckets](#) with AWS analytics services, do the following:

- [Create a resource link](#) to your metadata table namespace (typically `b_general_purpose_bucket_name`).
- Make sure to surround your metadata table namespace names in quotation marks ("") or backticks (`), otherwise the query might not work.

After that's done, you can start querying your metadata tables in the Amazon Redshift console. For more information, see [Accessing Amazon S3 tables with Amazon Redshift](#).

Querying metadata tables with Amazon EMR

To query your metadata tables by using Amazon EMR, you create an Amazon EMR cluster configured for Apache Iceberg and connect to your metadata tables using Apache Spark. You can set this up by integrating your AWS managed S3 table buckets with AWS analytics services or using the open-source Amazon S3 Tables Catalog for Iceberg client catalog.

Note

When using Apache Spark on Amazon EMR or other third-party engines to query your metadata tables, we recommend that you use the Amazon S3 Tables Iceberg REST endpoint. Your query might not run successfully if you don't use this endpoint. For more information, see [the section called "Accessing tables using the Amazon S3 Tables Iceberg REST endpoint"](#).

For more information, see [Accessing Amazon S3 tables with Amazon EMR](#).

Querying metadata tables with open-source query engines

You can query your S3 managed metadata tables by using open-source query engines, such as Apache Spark. When using Apache Spark on Amazon EMR or other third-party engines to query your metadata tables, we recommend that you use the Amazon S3 Tables Iceberg REST endpoint. Your query might not run successfully if you don't use this endpoint. For more information, see [the section called "Accessing tables using the Amazon S3 Tables Iceberg REST endpoint"](#).

Optimizing metadata table query performance

Because S3 Metadata is based on the Apache Iceberg table format, you can optimize the performance and [cost](#) of your journal table queries by using specific time ranges.

For example, the following SQL query provides the sensitivity level of new objects in an S3 general purpose bucket:

```
SELECT key, object_tags['SensitivityLevel']
FROM "b_general-purpose-bucket-name"."journal"
WHERE record_type = 'CREATE'
GROUP BY object_tags['SensitivityLevel']
```

This query scans the entire journal table, which might take a long time to run. To improve performance, you can include the `record_timestamp` column to focus on a specific time range. We also recommend using the fully qualified table name, which you can find in the Amazon S3 console on the metadata configuration details page on the general purpose bucket's **Metadata** tab. Here's an updated version of the previous query that looks at new objects from the past month:

```
SELECT key, object_tags['SensitivityLevel']
FROM b_general-purpose-bucket-name"."aws-s3.b_general-purpose-bucket-name.journal"
WHERE record_type = 'CREATE'
AND record_timestamp > (CURRENT_TIMESTAMP - interval '1' month)
GROUP BY object_tags['SensitivityLevel']
```

To improve the performance of queries on inventory tables, make sure that you query only on the minimum columns that you need.

Example metadata table queries

The following examples show how you can get different types information from your S3 Metadata tables by using standard SQL queries.

Remember when using these examples:

- The examples are written to work with Amazon Athena. You might have to modify the examples to work with a different query engine.
- Make sure that you understand how to [optimize your queries](#).
- Replace `b_general-purpose-bucket-name` with the name of your namespace.

- For a full list of supported columns, see the [S3 Metadata journal tables schema](#) and [the section called “Live inventory tables schema”](#).

Journal table example queries

You can use the following example queries to query your journal tables.

Finding objects by file extension

The following query returns objects with a specific file extension (.jpg in this case):

```
SELECT key FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal"
WHERE key LIKE '%.jpg'
AND record_type = 'CREATE'
```

Listing object deletions

The following query returns object deletion events, including the AWS account ID or AWS service principal that made the request:

```
SELECT DISTINCT bucket, key, sequence_number, record_type, record_timestamp, requester,
    source_ip_address, version_id
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal"
WHERE record_type = 'DELETE';
```

Listing AWS KMS encryption keys used by your objects

The following query returns the ARNs of the AWS Key Management Service (AWS KMS) keys encrypting your objects:

```
SELECT DISTINCT kms_key_arn
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal";
```

Listing objects that don't use KMS keys

The following query returns objects that aren't encrypted with AWS KMS keys:

```
SELECT DISTINCT kms_key_arn
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal"
WHERE encryption_status NOT IN ('SSE-KMS', 'DSSE-KMS')
AND record_type = 'CREATE';
```

Listing AWS KMS encryption keys used for PUT operations in the last 7 days

The following query returns the ARNs of the AWS Key Management Service (AWS KMS) keys encrypting your objects:

```
SELECT DISTINCT kms_key_arn
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal"
WHERE record_timestamp > (current_date - interval '7' day)
AND kms_key_arn is NOT NULL;
```

Listing objects deleted in the last 24 hours by S3 Lifecycle

The following query returns lists the objects expired in the last day by S3 Lifecycle:

```
SELECT bucket, key, version_id, last_modified_date, record_timestamp, requester
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal"
WHERE requester = 's3.amazonaws.com'
AND record_type = 'DELETE'
AND record_timestamp > (current_date - interval '1' day)
```

Viewing metadata provided by Amazon Bedrock

Some AWS services (such as [Amazon Bedrock](#)), upload objects to Amazon S3. You can query the object metadata provided by these services. For example, the following query includes the `user_metadata` column to determine if there are objects uploaded by Amazon Bedrock to a general purpose bucket:

```
SELECT DISTINCT bucket, key, sequence_number, record_type, record_timestamp,
    user_metadata
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal"
WHERE record_type = 'CREATE'
AND user_metadata['content-source'] = 'AmazonBedrock';
```

If Amazon Bedrock uploaded an object to your bucket, the `user_metadata` column will display the following metadata associated with the object in the query result:

```
user_metadata
{content-additional-params -> requestid="CVK8FWYRW0M9JW65",
 signedContentSHA384="38b060a751ac96384cd9327eb1b1e36a21fdb71114be07434c0cc7bf63f6e1da274edebfe
 content-model-id -> bedrock-model-arn, content-source -> AmazonBedrock}
```

Understanding the current state of your objects

The following query can help you determine the current state of your objects. The query identifies the most recent version of each object, filters out deleted objects, and marks the latest version of each object based on sequence numbers. Results are ordered by the `bucket`, `key`, and `sequence_number` columns.

```
WITH records_of_interest AS (
    -- Start with a query that can narrow down the records of interest.
    SELECT * FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal"
),
version_stacks AS (
    SELECT *,
```

```
-- Introduce a column called 'next_sequence_number', which is the next larger
-- sequence_number for the same key version_id in sorted order.
    LEAD(sequence_number, 1) over (partition by (bucket, key,
coalesce(version_id, '')) order by sequence_number ASC) as next_sequence_number
    from records_of_interest
),

-- Pick the 'tip' of each version stack triple: (bucket, key, version_id).
-- The tip of the version stack is the row of that triple with the largest sequencer.
-- Selecting only the tip filters out any row duplicates.
-- This isn't typical, but some events can be delivered more than once to the table
-- and include rows that might no longer exist in the bucket (since the
-- table contains rows for both extant and extinct objects).
-- In the next subquery, eliminate the rows that contain deleted objects.
current_versions as (
    SELECT * from version_stacks where next_sequence_number is NULL
),
-- Eliminate the rows that are extinct from the bucket by filtering with
-- record_type. An object version has been deleted from the bucket if its tip is
-- record_type==DELETE.
existing_current_versions as (
    SELECT * from current_versions where not (record_type = 'DELETE' and
is_delete_marker = FALSE)
),
-- Optionally, to determine which of several object versions is the 'latest',
-- you can compare their sequence numbers. A version_id is the latest if its
-- tip's sequencer is the largest among all other tips in the same key.
with_is_latest as (
    SELECT *,
        -- Determine if the sequence_number of this row is the same as the largest
        -- sequencer for the key that still exists.
        sequence_number = (MAX(sequence_number) over (partition by (bucket, key)))
    as is_latest_version
    FROM existing_current_versions
)

SELECT * from with_is_latest
ORDER BY bucket, key, sequence_number;
```

Inventory table example queries

You can use the following example queries to query your inventory tables.

Discovering datasets that use specific tags

The following query returns the dataset that uses the specified tags:

```
SELECT *
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."inventory"
WHERE object_tags['key1'] = 'value1'
AND object_tags['key2'] = 'value2';
```

List objects not encrypted with SSE-KMS

The following query returns objects that aren't encrypted with SSE-KMS:

```
SELECT key, encryption_status
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."inventory"
WHERE encryption_status != 'SSE-KMS';
```

List objects that aren't encrypted

The following query returns objects that aren't encrypted:

```
SELECT bucket, key, version_id
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."inventory"
WHERE encryption_status IS NULL;
```

List objects generated by Amazon Bedrock

The following query lists objects that were generated by Amazon Bedrock:

```
SELECT DISTINCT bucket, key, sequence_number, user_metadata
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."inventory"
WHERE user_metadata['content-source'] = 'AmazonBedrock';
```

Reconciling the inventory table with the journal table

The following query generates an inventory-table-like list that's up to date with the current contents of the bucket. More precisely, the resulting list combines the latest snapshot of the inventory table with the latest events in the journal table.

For this query to produce the most accurate results, both the journal and inventory tables must be in Active status.

We recommend using this query for general purpose buckets containing fewer than a billion (10^9) objects.

This example query applies the following simplifications to the list results (compared to the inventory table):

- **Column omissions** – The columns `bucket`, `is_multipart`, `encryption_status`, `is_bucket_key_enabled`, `kms_key_arn`, and `checksum_algorithm` aren't part of the final results. Keeping the set of optional columns to a minimum improves performance.
- **Inclusion of all records** – The query returns all object keys and versions, including the null version (in unversioned or versioning-suspended buckets) and delete markers. For examples of how to filter the results to show only the keys that you're interested in, see the `WHERE` clause at the end of the query.
- **Accelerated reconciliation** – The query could, in rare cases, temporarily report objects that are no longer in the bucket. Those discrepancies are eliminated as soon as the next snapshot of the inventory table becomes available. This behavior is a tradeoff between performance and accuracy.

To run this query in Amazon Athena, make sure to select the `s3tablescatalog/aws-s3` catalog and the `b_general-purpose-bucket-name` database for the general purpose bucket metadata configuration that contains your journal and inventory tables.

```
WITH inventory_time_cte AS (
    SELECT COALESCE(inventory_time_from_property, inventory_time_default) AS

```

Finding the current versions of your objects

The following query uses the inventory table to generate a new output table that shows which object versions are current. The output table is intentionally similar to an S3 Inventory report. The output table includes an `is_latest` field, which indicates if an object is the current version. The `is_latest` field is equivalent to the **IsLatest** field in an [S3 Inventory report](#).

This query works for general purpose buckets with [S3 Versioning](#) in a versioning-enabled or versioning-suspended state.

Prerequisites

The query outputs the results to a new S3 table to support further queries and for higher performance versus outputting rows on screen. Therefore, before running this query, make sure you've met the following conditions. If you choose not to output the results to a new table, you can skip these steps.

- You must have an existing customer-managed table bucket with an existing namespace as a place to output the new table. For more information, see [the section called “Create a table bucket”](#) and [the section called “Create a namespace”](#).
- To query your new output table, you must set up an access method for querying it. For more information, see [the section called “Accessing tables”](#). If you want to query the output table with AWS analytics services such as Amazon Athena, your customer-managed table bucket must be

integrated with AWS analytics services. For more information, see [the section called “S3 Tables integration overview”](#).

To use this query, replace *amzn-s3-demo-table-bucket* with the name of the existing customer-managed table bucket where you want the new output table to be created. Replace *existing_namespace* with the name of the namespace where you want the output table to be created in your table bucket. Replace *new_table* with the name that you want to use for the output table. Make sure that the name of your output table follows the [table naming rules](#).

To run this query in Amazon Athena, make sure to select the s3tablescatalog/aws-s3 catalog and the b_*general-purpose-bucket-name* database for the general purpose bucket metadata configuration that contains your inventory table.

```
-- If you don't want to output the results to a new table, remove the following two
-- lines
-- (everything before the WITH clause).
CREATE TABLE "s3tablescatalog/amzn-s3-demo-table-
bucket"."existing_namespace"."new_table"
as (
WITH
my_inventory AS (
  SELECT
    bucket,
    key,
    version_id,
    sequence_number,
    is_delete_marker,
    size,
    last_modified_date,
    storage_class
  FROM inventory
-- For prefix filtering, use a WHERE clause with % at the end.
--   WHERE key LIKE 'prefix%'
),
inventory_with_is_latest AS (
  SELECT *,
    ROW_NUMBER() OVER (
      PARTITION BY key
      ORDER BY sequence_number DESC
    ) = 1 AS is_latest
)
```

```
FROM my_inventory
)

SELECT
    bucket,
    key,
    version_id,
    sequence_number,
    is_delete_marker,
    size,
    last_modified_date,
    storage_class,
    is_latest

FROM inventory_with_is_latest

-- If you want only the current version of each key, uncomment the following WHERE
-- clause.
-- WHERE is_latest = TRUE
-- If you aren't outputting the results to a new table, remove the next line:
);
```

Joining custom metadata with S3 metadata tables

You can analyze data across your AWS managed metadata tables and customer (self-managed) metadata tables. By using a standard SQL JOIN operator, you can query data from these multiple sources.

The following example SQL query finds matching records between an AWS managed journal table ("journal") and a self-managed metadata table (*my_self_managed_metadata_table*). The query also filters information based on CREATE events, which indicate that a new object (or a new version of the object) was written to the bucket. (For more information, see the [S3 Metadata journal tables schema](#).)

```
SELECT *
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."journal" a
JOIN "my_namespace"."my_self_managed_metadata_table" b
ON a.bucket = b.bucket AND a.key = b.key AND a.version_id = b.version_id
WHERE a.record_type = 'CREATE';
```

The following example SQL query finds matching records between an AWS managed inventory table ("inventory") and a self-managed metadata table (*my_self_managed_metadata_table*):

```
SELECT *
FROM "s3tablescatalog/aws-s3"."b_general-purpose-bucket-name"."inventory" a
JOIN "my_namespace"."my_self_managed_metadata_table" b
ON a.bucket = b.bucket AND a.key = b.key AND a.version_id = b.version_id;
```

Visualizing metadata table data with Amazon Quick Suite

With Amazon Quick Suite, you can create interactive dashboards to analyze and visualize SQL query results about your S3 managed metadata tables. Quick Suite dashboards can help you monitor statistics, track changes, and get operational insights about your metadata tables.

A dashboard about your journal table might show you:

- What's the percentage of object uploads compared to deletions?
- Which objects were deleted by S3 Lifecycle in the past 24 hours?
- Which IP addresses did the most recent PUT requests come from?

A dashboard about your inventory table might show you:

- How many objects are in different storage classes?
- What percentage of your storage data is small objects compared to large objects?
- What types of objects are in my bucket?

After you [integrate your S3 table buckets](#) with AWS analytics services, you can create datasets from your metadata tables and work with them in Amazon Quick Suite using SPICE or direct SQL queries from your query engine. Quick Suite supports Amazon Athena and Amazon Redshift as data sources.

For more information, see [Visualizing table data with Amazon Quick Suite](#).

Troubleshooting S3 Metadata

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon S3 Metadata.

I'm unable to delete my AWS managed table bucket and metadata tables

Before you can delete a metadata table, you must first delete the associated metadata table configuration on your general purpose bucket. For more information, see [the section called “Deleting metadata table configurations”](#).

Before you can delete your AWS managed table bucket, you must delete all metadata table configurations that are associated with this bucket and all metadata tables in the bucket. For more information, see [the section called “Deleting metadata table configurations”](#) and [the section called “Deleting metadata tables”](#).

I'm unable to set or change the encryption settings for my AWS managed metadata table

When you create your metadata table configuration, you can choose to encrypt your AWS managed metadata tables with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). If you choose to use SSE-KMS, you must provide a customer managed KMS key in the same Region as your general purpose bucket. You can set the encryption type for your tables only during table creation. After an AWS managed table is created, you can't change its encryption setting. To specify SSE-KMS for your metadata tables, you must have certain permissions. For more information, see [Permissions for SSE-KMS](#).

The encryption setting for a metadata table takes precedence over the default bucket-level encryption setting. If you don't specify encryption for a table, it will inherit the default encryption setting from the bucket.

By default, AWS managed table buckets are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3). After you create your first metadata configuration, you can set the default encryption setting for the AWS managed table bucket to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). For more information, see [Encryption for AWS managed table buckets](#) and [the section called “Specifying SSE-KMS”](#).

When I try to re-create my metadata table configuration, I get an error

Deleting a metadata table configuration deletes only the configuration. The AWS managed table bucket and your metadata tables still exist, even if you delete the metadata table configuration.

If you delete your metadata table configuration and want to re-create a configuration for the same general purpose bucket, you must first manually delete the old journal and inventory tables from your AWS managed table bucket. Otherwise, creating the new metadata table configuration fails because those tables already exist.

To delete your metadata tables, see [the section called “Deleting metadata tables”](#).

I can't enable an inventory table on my configuration

If you created your S3 Metadata configuration before July 15, 2025, you can't enable an inventory table on that configuration. We recommend that you delete and re-create your configuration so that you can create an inventory table and expire journal table records. For more information, see [the section called “Enabling inventory tables on metadata configurations created before July 15, 2025”](#).

I can't enable journal table record expiration on my configuration

If you created your S3 Metadata configuration before July 15, 2025, you can't enable journal table record expiration on that configuration. We recommend that you delete and re-create your configuration so that you can expire journal table records and create an inventory table. For more information, see [the section called “Enabling inventory tables on metadata configurations created before July 15, 2025”](#).

I can't query my metadata tables

If you're unable to query your metadata tables, check the following:

- When you're using Amazon Athena or Amazon Redshift to query your metadata tables, you must surround your metadata table namespace names in quotation marks ("") or backticks (`), otherwise the query might not work.
- When using Apache Spark on Amazon EMR or other third-party engines to query your metadata tables, we recommend that you use the Amazon S3 Tables Iceberg REST endpoint. Your query might not run successfully if you don't use this endpoint. For more information, see [the section called “Accessing tables using the Amazon S3 Tables Iceberg REST endpoint”](#).
- Make sure that you have the appropriate AWS Identity and Access Management (IAM) permissions to query metadata tables. For more information, see [the section called “Permissions for querying metadata tables”](#).
- If you're using Amazon Athena and receive errors when you try to run your queries, do the following:
 - If you receive the error "Insufficient permissions to execute the query. Principal does not have any privilege on specified resource" when you try to run a query in Athena, you must be granted the necessary Lake Formation permissions on the table. For more information, see [the section called “Granting Lake Formation permission on a table or database”](#).

- If you receive the error "Iceberg cannot access the requested resource" when you try to run the query, go to the AWS Lake Formation console and make sure that you've granted yourself permissions on the table bucket catalog and database (namespace) that you created. Don't specify a table when granting these permissions. For more information, see [the section called "Granting Lake Formation permission on a table or database"](#).

I'm receiving 405 errors when I try to use certain S3 Metadata AWS CLI commands and API operations

Calling the V1 GetBucketMetadataTableConfiguration API operation or using the get-bucket-metadata-table-configuration AWS Command Line Interface (AWS CLI) command against a V2 metadata table configuration results in an HTTP 405 Method Not Allowed error. Likewise, calling the V1 DeleteBucketMetadataTableConfiguration API operation or using the delete-bucket-metadata-table-configuration AWS CLI command also causes a 405 error.

You can use the V2 GetBucketMetadataConfiguration API operation or the get-bucket-metadata-configuration AWS CLI command against a V1 or V2 metadata table configuration. Likewise, you can use the V2 DeleteBucketMetadataConfiguration API operation or the delete-bucket-metadata-configuration AWS CLI command against a V1 or V2 metadata table configuration.

We recommend updating your processes to use the new V2 API operations (`CreateBucketMetadataConfiguration`, `GetBucketMetadataConfiguration`, and `DeleteBucketMetadataConfiguration`) instead of the V1 API operations. For more information about migrating from V1 of S3 Metadata to V2, see [the section called "Enabling inventory tables on metadata configurations created before July 15, 2025"](#).

To determine whether your configuration is V1 or V2, you can look at the following attribute of your `GetBucketMetadataConfiguration` API response. An AWS managed bucket type ("aws") indicates a V2 configuration, and a customer-managed bucket type ("customer") indicates a V1 configuration.

```
"MetadataTableConfigurationResult": {  
    "TableBucketType": ["aws" | "customer"]}
```

For more information, see [the section called "Viewing metadata table configurations"](#).

Uploading objects

When you upload a file to Amazon S3, it is stored as an *S3 object*. Objects consist of the file data and metadata that describes the object. You can have an unlimited number of objects in a bucket. Before you can upload files to an Amazon S3 bucket, you need write permissions for the bucket. For more information about access permissions, see [Identity and Access Management for Amazon S3](#).

You can upload any file type—images, backups, data, movies, and so on—into an S3 bucket. The maximum size of a file that you can upload by using the Amazon S3 console is 160 GB. To upload a file larger than 160 GB, use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

If you upload an object with a key name that already exists in a versioning-enabled bucket, Amazon S3 creates another version of the object instead of replacing the existing object. For more information about enabling versioning, see [Enabling versioning on buckets](#).

Depending on the size of the data that you're uploading, Amazon S3 offers the following options:

- **Upload an object in a single operation by using the AWS SDKs, REST API, or AWS CLI** – With a single PUT operation, you can upload a single object up to 5 GB in size.
- **Upload a single object by using the Amazon S3 console** – With the Amazon S3 console, you can upload a single object up to 160 GB in size.
- **Upload an object in parts by using the AWS SDKs, REST API, or AWS CLI** – Using the multipart upload API operation, you can upload a single large object, up to 50 TB in size.

The multipart upload API operation is designed to improve the upload experience for larger objects. You can upload an object in parts. These object parts can be uploaded independently, in any order, and in parallel. You can use a multipart upload for objects from 5 MB to 50 TB in size. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).

To upload files greater than 5 TB, use the S3 Transfer Manager in the Java v1/v2, Python, or AWS CLI SDKs. For the best performance, use the latest AWS Common Runtime (CRT) with these SDKs, which has been optimized for better resource utilization.

When uploading large objects from memory stream, CRT buffers each part up to 5 GB in memory, limiting overall throughput by allocated memory. You can adjust the CRT memory limit using configuration options such as `maxNativeMemoryLimitInBytes` for Java SDK. For uploads from

disk, CRT automatically switches to direct disk streaming instead of intermediate part buffering, improving memory usage. This behavior is automatically enabled for large objects, but can also be enabled for smaller files via request parameters such as `should_stream` for AWS CLI and `CRT_MEMORY_BUFFER_DISABLED` for Java SDK.

When you upload an object, the object is automatically encrypted using server-side encryption with Amazon S3 managed keys (SSE-S3) by default. When you download it, the object is decrypted. For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#) and [Protecting data with encryption](#).

When you're uploading an object, if you want to use a different type of default encryption, you can also specify server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) in your S3 PUT requests or set the default encryption configuration in the destination bucket to use SSE-KMS to encrypt your data. For more information about SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#). If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

If you encounter an Access Denied (403 Forbidden) error in Amazon S3, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#) to learn more about its common causes.

Upload an object

Using the S3 console

This procedure explains how to upload objects and folders to an Amazon S3 bucket by using the console.

When you upload an object, the object key name is the file name and any optional prefixes. In the Amazon S3 console, you can create folders to organize your objects. In Amazon S3, folders are represented as prefixes that appear in the object key name. If you upload an individual object to a folder in the Amazon S3 console, the folder name is included in the object key name.

For example, if you upload an object named `sample1.jpg` to a folder named `backup`, the key name is `backup/sample1.jpg`. However, the object is displayed in the console as `sample1.jpg` in the `backup` folder. For more information about key names, see [Working with object metadata](#).

Note

If you rename an object or change any of the properties in the Amazon S3 console, for example **Storage Class**, **Encryption**, or **Metadata**, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

When you upload a folder, Amazon S3 uploads all of the files and subfolders from the specified folder to your bucket. It then assigns an object key name that is a combination of the uploaded file name and the folder name. For example, if you upload a folder named /images that contains two files, sample1.jpg and sample2.jpg, Amazon S3 uploads the files and then assigns the corresponding key names, images/sample1.jpg and images/sample2.jpg. The key names include the folder name as a prefix. The Amazon S3 console displays only the part of the key name that follows the last /. For example, within an images folder, the images/sample1.jpg and images/sample2.jpg objects are displayed as sample1.jpg and a sample2.jpg.

To upload folders and files to an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to upload your folders or files to.
4. Choose **Upload**.
5. In the **Upload** window, do one of the following:
 - Drag and drop files and folders to the **Upload** window.
 - Choose **Add file** or **Add folder**, choose the files or folders to upload, and choose **Open**.
6. To enable versioning, under **Destination**, choose **Enable Bucket Versioning**.
7. To upload the listed files and folders without configuring additional upload options, at the bottom of the page, choose **Upload**.

Amazon S3 uploads your objects and folders. When the upload is finished, you see a success message on the **Upload: status** page.

To configure additional object properties

1. To change access control list permissions, choose **Permissions**.
2. Under **Access control list (ACL)**, edit the permissions.

For information about object access permissions, see [Using the S3 console to set ACL permissions for an object](#). You can grant read access to your objects to the public (everyone in the world) for all of the files that you're uploading. However, we recommend not changing the default setting for public read access. Granting public read access is applicable to a small subset of use cases, such as when buckets are used for websites. You can always change the object permissions after you upload the object.

3. To configure other additional properties, choose **Properties**.
4. Under **Storage class**, choose the storage class for the files that you're uploading.

For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

5. To update the encryption settings for your objects, under **Server-side encryption settings**, do the following.
 - a. Choose **Specify an encryption key**.
 - b. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
 - c. If you chose **Override bucket settings for default encryption**, you must configure the following encryption settings.
 - To encrypt the uploaded files by using keys that are managed by Amazon S3, choose **Amazon S3 managed key (SSE-S3)**.

For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

- To encrypt the uploaded files by using keys stored in AWS Key Management Service (AWS KMS), choose **AWS Key Management Service key (SSE-KMS)**. Then choose one of the following options for **AWS KMS key**:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

6. To use additional checksums, choose **On**. Then for **Checksum function**, choose the function that you would like to use. Amazon S3 calculates and stores the checksum value after it receives the entire object. You can use the **Precalculated value** box to supply a precalculated value. If you do, Amazon S3 compares the value that you provided to the value that it calculates. If the two values do not match, Amazon S3 generates an error.

Additional checksums enable you to specify the checksum algorithm that you would like to use to verify your data. For more information about additional checksums, see [Checking object integrity in Amazon S3](#).

7. To add tags to all of the objects that you are uploading, choose **Add tag**. Enter a tag name in the **Key** field. Enter a value for the tag.

Object tagging gives you a way to categorize storage. Each tag is a key-value pair. Key and tag values are case sensitive. You can have up to 10 tags per object. A tag key can be up to 128

Unicode characters in length, and tag values can be up to 255 Unicode characters in length.

For more information about object tags, see [Categorizing your objects using tags](#).

8. To add metadata, choose **Add metadata**.

a. Under **Type**, choose **System defined** or **User defined**.

For system-defined metadata, you can select common HTTP headers, such as **Content-Type** and **Content-Disposition**. For a list of system-defined metadata and information about whether you can add the value, see [System-defined object metadata](#). Any metadata starting with the prefix `x-amz-meta-` is treated as user-defined metadata. User-defined metadata is stored with the object and is returned when you download the object. Both the keys and their values must conform to US-ASCII standards. User-defined metadata can be as large as 2 KB. For more information about system-defined and user-defined metadata, see [Working with object metadata](#).

b. For **Key**, choose a key.

c. Type a value for the key.

9. To upload your objects, choose **Upload**.

Amazon S3 uploads your object. When the upload completes, you can see a success message on the **Upload: status** page.

10. Choose **Exit**.

Using the AWS CLI

You can send a PUT request to upload an object of up to 5 GB in a single operation. For more information, see the [PutObject](#) example in the *AWS CLI Command Reference*.

Using the REST API

You can send REST requests to upload an object. You can send a PUT request to upload data in a single operation. For more information, see [PUT Object](#).

Using the AWS SDKs

For examples of how to upload an object with the AWS SDKs, see [Code Examples](#) in the *Amazon Simple Storage Service API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon Simple Storage Service API Reference*.

Prevent uploading objects with identical key names

You can check for the existence of an object in your bucket before creating it using a conditional write on upload operations. This can prevent overwrites of existing data. Conditional writes will validate there is no existing object with the same key name already in your bucket while uploading.

You can use conditional writes for [PutObject](#) or [CompleteMultipartUpload](#) requests.

For more information about conditional requests see, [Add preconditions to S3 operations with conditional requests](#).

Uploading and copying objects using multipart upload in Amazon S3

Multipart upload allows you to upload a single object to Amazon S3 as a set of parts. Each part is a contiguous portion of the object's data. You can upload these object parts independently, and in any order. For uploads, your updated AWS client automatically calculates a checksum of the object and sends it to Amazon S3 along with the size of the object as a part of the request. If transmission of any part fails, you can retransmit that part without affecting other parts. After all parts of your object are uploaded, Amazon S3 assembles them to create the object. It's a best practice to use multipart upload for objects that are 100 MB or larger instead of uploading them in a single operation.

Using multipart upload provides the following advantages:

- **Improved throughput** – You can upload parts in parallel to improve throughput.
- **Quick recovery from any network issues** – Smaller part size minimizes the impact of restarting a failed upload due to a network error.
- **Pause and resume object uploads** – You can upload object parts over time. After you initiate a multipart upload, there is no expiry; you must explicitly complete or stop the multipart upload.
- **Begin an upload before you know the final object size** – You can upload an object as you create it.

We recommend that you use multipart upload in the following ways:

- If you upload large objects over a stable high-bandwidth network, use multipart upload to maximize the use of your available bandwidth by uploading object parts in parallel for multi-threaded performance.

- If you upload over a spotty network, use multipart upload to increase resiliency against network errors by avoiding upload restarts. When using multipart upload, you only need to retry uploading the parts that are interrupted during the upload. You don't need to restart uploading your object from the beginning.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#). For more information about using multipart upload with S3 Express One Zone and directory buckets, see [Using multipart uploads with directory buckets](#).

Multipart upload process

Multipart upload is a three-step process: You initiate the upload, upload the object parts, and—after you've uploaded all the parts—complete the multipart upload. Upon receiving the complete multipart upload request, Amazon S3 constructs the object from the uploaded parts, and you can access the object just as you would any other object in your bucket.

You can list all of your in-progress multipart uploads or get a list of the parts that you have uploaded for a specific multipart upload. Each of these operations is explained in this section.

Multipart upload initiation

When you send a request to initiate a multipart upload, make sure to specify a checksum type. Amazon S3 will then return a response with an upload ID, which is a unique identifier for your multipart upload. This upload ID is required when you upload parts, list parts, complete an upload, or stop an upload. If you want to provide metadata describing the object being uploaded, you must provide it in the request to initiate the multipart upload. Anonymous users cannot initiate multipart uploads.

Parts upload

When uploading a part, you must specify a part number in addition to the upload ID. You can choose any part number between 1 and 10,000. A part number uniquely identifies a part and its position in the object you are uploading. The part number that you choose doesn't need to be in a consecutive sequence (for example, it can be 1, 5, and 14). Be aware that if you upload a new

part using the same part number as a previously uploaded part, the previously uploaded part gets overwritten.

When you upload a part, Amazon S3 returns the checksum algorithm type with the checksum value for each part as a header in the response. For each part upload, you must record the part number and the ETag value. You must include these values in the subsequent request to complete the multipart upload. Each part will have its own ETag at the time of upload. However, once the multipart upload is complete and all parts are consolidated, all parts belong to one ETag as a checksum of checksums.

Important

After you initiate a multipart upload and upload one or more parts, you must either complete or stop the multipart upload to stop incurring charges for storage of the uploaded parts. Only *after* you complete or stop a multipart upload will Amazon S3 free up the parts storage and stop billing you for the parts storage.

After stopping a multipart upload, you can't upload any part using that upload ID again. If part uploads were in progress, they can still succeed or fail even after you stop the upload. To make sure you free all storage consumed by all parts, you must stop a multipart upload only after all part uploads have completed.

Multipart upload completion

When you complete a multipart upload, Amazon S3 creates an object by concatenating the parts in ascending order based on the part number. If any object metadata was provided in the *initiate multipart upload* request, Amazon S3 associates that metadata with the object. After a successful *complete* request, the parts no longer exist.

Your *complete multipart upload* request must include the upload ID and a list of part numbers and their corresponding ETag values. The Amazon S3 response includes an ETag that uniquely identifies the combined object data. This ETag is not necessarily an MD5 hash of the object data.

When you provide a full object checksum during a multipart upload, the AWS SDK passes the checksum to Amazon S3, and S3 validates the object integrity server-side, comparing it to the received value. Then, S3 stores the object if the values match. If the two values don't match, Amazon S3 fails the request with a `BadDigest` error. The checksum of your object is also stored in object metadata that you'll later use to validate an object's data integrity.

Sample multipart upload calls

For this example, assume that you're generating a multipart upload for a 100 GB file. In this case, you would have the following API calls for the entire process. There would be a total of 1,002 API calls.

- A [CreateMultipartUpload](#) call to start the process.
- 1,000 individual [UploadPart](#) calls, each uploading a part of 100 MB, for a total size of 100 GB.
- A [CompleteMultipartUpload](#) call to complete the process.

Multipart upload listings

You can list the parts of a specific multipart upload or all in-progress multipart uploads. The list parts operation returns the parts information that you uploaded for a specific multipart upload. For each list parts request, Amazon S3 returns the parts information for the specified multipart upload, up to a maximum of 1,000 parts. If there are more than 1,000 parts in the multipart upload, you must send a series of list part requests to retrieve all of the parts. Note that the returned list of parts doesn't include parts that haven't finished uploading. Using the *list multipart uploads* operation, you can obtain a list of multipart uploads that are in progress.

An in-progress multipart upload is an upload that you have initiated, but have not yet completed or stopped. Each request returns at most 1,000 multipart uploads. If there are more than 1,000 multipart uploads in progress, you must send additional requests to retrieve the remaining multipart uploads. Use the returned listing only for verification.

Important

Do not use the result of this listing when sending a *complete multipart upload* request. Instead, maintain your own list of the part numbers that you specified when uploading parts and the corresponding ETag values that Amazon S3 returns.

Checksums with multipart upload operations

When you upload an object to Amazon S3, you can specify a checksum algorithm for Amazon S3 to use. By default, the AWS SDK and S3 console use an algorithm for all object uploads, which you can override. If you're using an older SDK and your uploaded object doesn't have a specified checksum,

Amazon S3 automatically uses the CRC-64/NVME (CRC64NVME) checksum algorithm. (This is also the recommended option for efficient data integrity verification.) When using CRC-64/NVME, Amazon S3 calculates the checksum of the full object after the multipart or single part upload is complete. The CRC-64/NVME checksum algorithm is used to calculate either a direct checksum of the entire object, or a checksum of the checksums, for each individual part.

After you upload an object to S3 using multipart upload, Amazon S3 calculates the checksum value for each part, or for the full object—and stores the values. You can use the S3 API or AWS SDK to retrieve the checksum value in the following ways:

- For individual parts, you can use [GetObject](#) or [HeadObject](#). If you want to retrieve the checksum values for individual parts of multipart uploads while they're still in process, you can use [ListParts](#).
- For the entire object, you can use [PutObject](#). If you want to perform a multipart upload with a full object checksum, use [CreateMultipartUpload](#) and [CompleteMultipartUpload](#) by specifying the full object checksum type. To validate the checksum value of the entire object or to confirm which checksum type is being used in the multipart upload, use [ListParts](#).

Important

If you're using a multipart upload with **Checksums**, the part numbers for each part upload (in the multipart upload) must use consecutive part numbers and begin with 1. When using **Checksums**, if you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates an HTTP 500 Internal Server error.

For more information about how checksums work with multipart upload objects, see [Checking object integrity in Amazon S3](#).

For an end-to-end procedure that demonstrates how to upload an object using multipart upload with an additional checksum, see [Tutorial: Upload an object through multipart upload and verify its data integrity](#).

Concurrent multipart upload operations

In a distributed development environment, it is possible for your application to initiate several updates on the same object at the same time. Your application might initiate several multipart uploads using the same object key. For each of these uploads, your application can then upload

parts and send a complete upload request to Amazon S3 to create the object. When the buckets have S3 Versioning enabled, completing a multipart upload always creates a new version. When you initiate multiple multipart uploads that use the same object key in a versioning-enabled bucket, the current version of the object is determined by which upload started most recently (`createdDate`).

For example, you start a `CreateMultipartUpload` request for an object at 10:00 AM. Then, you submit a second `CreateMultipartUpload` request for the same object at 11:00 AM. Because the second request was submitted the most recently, the object uploaded by the 11:00 AM request becomes the current version, even if the first upload is completed after the second one. For buckets that don't have versioning enabled, it's possible that any other request received between the time when the multipart upload is initiated and when it completes, the other request might take precedence.

Another example of when a concurrent multipart upload request can take precedence is if another operation deletes a key after you initiate a multipart upload with that key. Before you complete the operation, the complete multipart upload response might indicate a successful object creation without you ever seeing the object.

Prevent uploading objects with identical key names during multipart upload

You can check for the existence of an object in your bucket before creating it using a conditional write on upload operations. This can prevent overwrites of existing data. Conditional writes will validate that there is no existing object with the same key name already in your bucket while uploading.

You can use conditional writes for [PutObject](#) or [CompleteMultipartUpload](#) requests.

For more information about conditional requests see, [Add preconditions to S3 operations with conditional requests](#).

Multipart upload and pricing

After you initiate a multipart upload, Amazon S3 retains all the parts until you either complete or stop the upload. Throughout its lifetime, you are billed for all storage, bandwidth, and requests for this multipart upload and its associated parts.

These parts are billed according to the storage class specified when the parts are uploaded. However, you will not be billed for these parts if they're uploaded to S3 Glacier Flexible Retrieval

or S3 Glacier Deep Archive. In-progress multipart parts for a PUT request to the S3 Glacier Flexible Retrieval storage class are billed as S3 Glacier Flexible Retrieval staging storage at S3 Standard storage rates until the upload completes. In addition, both `CreateMultipartUpload` and `UploadPart` are billed at S3 Standard rates. Only the `CompleteMultipartUpload` request is billed at the S3 Glacier Flexible Retrieval rate. Similarly, in-progress multipart parts for a PUT to the S3 Glacier Deep Archive storage class are billed as S3 Glacier Flexible Retrieval staging storage at S3 Standard storage rates until the upload completes, with only the `CompleteMultipartUpload` request charged at S3 Glacier Deep Archive rates.

If you stop the multipart upload, Amazon S3 deletes upload artifacts and all parts that you uploaded. You will not be billed for those artifacts. There are no early delete charges for deleting incomplete multipart uploads regardless of storage class specified. For more information about pricing, see [Amazon S3 pricing](#).

 **Note**

To minimize your storage costs, we recommend that you configure a lifecycle rule to delete incomplete multipart uploads after a specified number of days by using the `AbortIncompleteMultipartUpload` action. For more information about creating a lifecycle rule to delete incomplete multipart uploads, see [Configuring a bucket lifecycle configuration to delete incomplete multipart uploads](#).

Multipart upload API and permissions

You must have the necessary permissions to use the multipart upload operations. You can use access control lists (ACLs), the bucket policy, or the user policy to grant individuals permissions to perform these operations. The following table lists the required permissions for various multipart upload operations when using ACLs, a bucket policy, or a user policy.

Action	Required permissions
Create Multipart Upload	<p>You must be allowed to perform the <code>s3:PutObject</code> action on an object to create a multipart upload request.</p> <p>The bucket owner can allow other principals to perform the <code>s3:PutObject</code> action.</p>
Initiate Multipart Upload	<p>You must be allowed to perform the <code>s3:PutObject</code> action on an object to initiate a multipart upload.</p> <p>The bucket owner can allow other principals to perform the <code>s3:PutObject</code> action.</p>
Initiator	Container element that identifies who initiated the multipart upload. If the initiator is an AWS account, this element provides the same information as the Owner element. If the initiator is an IAM user, this element provides the user ARN and display name.
Upload Part	<p>You must be allowed to perform the <code>s3:PutObject</code> action on an object to upload a part.</p> <p>The bucket owner must allow the initiator to perform the <code>s3:PutObject</code> action on an object in order for the initiator to upload a part for that object.</p>
Upload Part (Copy)	<p>You must be allowed to perform the <code>s3:PutObject</code> action on an object to upload a part. Because you are uploading a part from an existing object, you must be allowed <code>s3:GetObject</code> on the source object.</p> <p>For the initiator to upload a part for an object, the owner of the bucket must allow the initiator to perform the <code>s3:PutObject</code> action on the object.</p>
Complete Multipart Upload	<p>You must be allowed to perform the <code>s3:PutObject</code> action on an object to complete a multipart upload.</p> <p>The bucket owner must allow the initiator to perform the <code>s3:PutObject</code> action on an object in order for the initiator to complete a multipart upload for that object.</p>

Action	Required permissions
Stop Multipart Upload	<p>You must be allowed to perform the <code>s3:AbortMultipartUpload</code> action to stop a multipart upload.</p> <p>By default, the bucket owner and the initiator of the multipart upload are allowed to perform this action as a part of IAM and S3 bucket policies. If the initiator is an IAM user, that user's AWS account is also allowed to stop that multipart upload. With VPC endpoint policies, the initiator of the multipart upload doesn't automatically gain the permission to perform the <code>s3:AbortMultipartUpload</code> action.</p> <p>In addition to these defaults, the bucket owner can allow other principals to perform the <code>s3:AbortMultipartUpload</code> action on an object. The bucket owner can deny any principal the ability to perform the <code>s3:AbortMultipartUpload</code> action.</p>
List Parts	<p>You must be allowed to perform the <code>s3>ListMultipartUploadParts</code> action to list parts in a multipart upload.</p> <p>By default, the bucket owner has permission to list parts for any multipart upload to the bucket. The initiator of the multipart upload has the permission to list parts of the specific multipart upload. If the multipart upload initiator is an IAM user, the AWS account controlling that IAM user also has permission to list parts of that upload.</p> <p>In addition to these defaults, the bucket owner can allow other principals to perform the <code>s3>ListMultipartUploadParts</code> action on an object. The bucket owner can also deny any principal the ability to perform the <code>s3>ListMultipartUploadParts</code> action.</p>
List Multipart Uploads	<p>You must be allowed to perform the <code>s3>ListBucketMultipartUploads</code> action on a bucket to list multipart uploads in progress to that bucket.</p> <p>In addition to the default, the bucket owner can allow other principals to perform the <code>s3>ListBucketMultipartUploads</code> action on the bucket.</p>

Action	Required permissions
AWS KMS Encrypt and Decrypt related permissions	<p>To perform a multipart upload with encryption using an AWS Key Management Service (AWS KMS) KMS key, the requester must have the following permissions:</p> <ul style="list-style-type: none">• The <code>kms:Decrypt</code> and <code>kms:GenerateDataKey</code> actions on the key.• The <code>kms:GenerateDataKey</code> action for the CreateMultipartUpload API.• The <code>kms:Decrypt</code> action on the UploadPart and UploadPartCopy APIs. <p>These permissions are required because Amazon S3 must decrypt and read data from the encrypted file parts before it completes the multipart upload. The <code>kms:Decrypt</code> permission, and the server-side encryption with customer-provided encryption keys, are also required for you to obtain an object's checksum value. If you don't have these required permissions when you use the CompleteMultipartUpload API, the object is created without a checksum value.</p> <p>If your IAM user or role is in the same AWS account as the KMS key, then validate that you have permissions on both the key and IAM policies. If your IAM user or role belongs to a different account than the KMS key, then you must have the permissions on both the key policy and your IAM user or role.</p>
SSE-C (server-side encryption with customer-provided encryption keys)	When you use the CompleteMultipartUpload API, you must provide the SSE-C (server-side encryption with customer-provided encryption keys), or your object will be created without a checksum, and no checksum value is returned.

For information on the relationship between ACL permissions and permissions in access policies, see [Mapping of ACL permissions and access policy permissions](#). For information about IAM users, roles, and best practices, see [IAM identities \(users, user groups, and roles\)](#) in the *IAM User Guide*.

Checksums with multipart upload operations

There are three Amazon S3 APIs that are used to perform the actual multipart upload:

[CreateMultipartUpload](#), [UploadPart](#), and [CompleteMultipartUpload](#). The following table indicates which checksum headers and values must be provided for each of the APIs:

Checksum algorithm	Checksum type	CreateMultipartUpload	UploadPart	CompleteMultipartUpload
CRC-64/NVME (CRC64NVME)	Full object	Required headers: x-amz-checksum-algorithm	Optional headers: x-amz-checksum-crc64nvme	Optional headers: x-amz-checksum-algorithm x-amz-crc64
CRC-32 (CRC32) CRC 32-C (CRC32C)	Full object	Required headers: x-amz-checksum-algorithm x-amz-checksum-type	Optional headers: x-amz-checksum-crc64nvme	Optional headers: x-amz-checksum-algorithm x-amz-crc32 x-amz-crc32c
CRC-32 (CRC32) CRC-32C (CRC32C) SHA-1 (SHA1) SHA-256 (SHA256)	Composite	Required headers: x-amz-checksum-algorithm	Required headers: x-amz-checksum-crc32	All part-level checksums need to be included in the CompleteM

Checksum algorithm	Checksum type	CreateMultipartUpload	UploadPart	CompleteMultipartUpload
			x-amz-checksum-crc32c	ultiPartUpload request.
			x-amz-checksum-sha1	Optional headers:
			x-amz-checksum-sha256	x-amz-crc32
				x-amz-crc32c
				x-amz-sha1
				x-amz-sha256

Configuring a bucket lifecycle configuration to delete incomplete multipart uploads

As a best practice, we recommend that you configure a lifecycle rule by using the AbortIncompleteMultipartUpload action to minimize your storage costs. For more information about aborting a multipart upload, see [Aborting a multipart upload](#).

Amazon S3 supports a bucket lifecycle rule that you can use to direct Amazon S3 to stop multipart uploads that aren't completed within a specified number of days after being initiated. When a multipart upload isn't completed within the specified time frame, it becomes eligible for an abort operation. Amazon S3 then stops the multipart upload and deletes the parts associated with the multipart upload. This rule applies to both existing multipart uploads and those that you create later.

The following is an example lifecycle configuration that specifies a rule with the AbortIncompleteMultipartUpload action.

```
<LifecycleConfiguration>
  <Rule>
    <ID>sample-rule</ID>
    <Prefix></Prefix>
    <Status>Enabled</Status>
    <AbortIncompleteMultipartUpload>
      <DaysAfterInitiation>7</DaysAfterInitiation>
    </AbortIncompleteMultipartUpload>
  </Rule>
</LifecycleConfiguration>
```

In the example, the rule doesn't specify a value for the Prefix element (the [object key name prefix](#)). Therefore, the rule applies to all objects in the bucket for which you initiated multipart uploads. Any multipart uploads that were initiated and weren't completed within seven days become eligible for an abort operation. The abort action has no effect on completed multipart uploads.

For more information about the bucket lifecycle configuration, see [Managing the lifecycle of objects](#).

Note

If the multipart upload is completed within the number of days specified in the rule, the AbortIncompleteMultipartUpload lifecycle action does not apply (that is, Amazon S3 doesn't take any action). Also, this action doesn't apply to objects. No objects are deleted by this lifecycle action. Additionally, you will not incur early delete charges for S3 Lifecycle when you remove any incomplete multipart upload parts.

Using the S3 console

To automatically manage incomplete multipart uploads, you can use the S3 console to create a lifecycle rule to expire incomplete multipart upload bytes from your bucket after a specified number of days. The following procedure shows you how to add a lifecycle rule to delete incomplete multipart uploads after 7 days. For more information about adding lifecycle rules, see [Setting an S3 Lifecycle configuration on a bucket](#).

To add a lifecycle rule to abort incomplete multipart uploads that are more than 7 days old

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to create a lifecycle rule for.
3. Choose the **Management** tab, and choose **Create lifecycle rule**.
4. In **Lifecycle rule name**, enter a name for your rule.

The name must be unique within the bucket.

5. Choose the scope of the lifecycle rule:
 - To create a lifecycle rule for all objects with a specific prefix, choose **Limit the scope of this rule using one or more filters**, and enter the prefix in the **Prefix** field.
 - To create a lifecycle rule for all objects in the bucket, choose **This rule applies to all objects in the bucket**, and choose **I acknowledge that this rule applies to all objects in the bucket**.
6. Under **Lifecycle rule actions**, select **Delete expired object delete markers or incomplete multipart uploads**.
7. Under **Delete expired object delete markers or incomplete multipart uploads**, select **Delete incomplete multipart uploads**.

8. In the **Number of days** field, enter the number of days after which to delete incomplete multipart uploads (for this example, 7 days).
9. Choose **Create rule**.

Using the AWS CLI

The following put-bucket-lifecycle-configuration AWS Command Line Interface (AWS CLI) command adds the lifecycle configuration for the specified bucket. To use this command, replace the *user input placeholders* with your information.

```
aws s3api put-bucket-lifecycle-configuration \
--bucket amzn-s3-demo-bucket \
--lifecycle-configuration filename-containing-lifecycle-configuration
```

The following example shows how to add a lifecycle rule to abort incomplete multipart uploads by using the AWS CLI. It includes an example JSON lifecycle configuration to abort incomplete multipart uploads that are more than 7 days old.

To use the CLI commands in this example, replace the *user input placeholders* with your information.

To add a lifecycle rule to abort incomplete multipart uploads

1. Set up the AWS CLI. For instructions, see [Developing with Amazon S3 using the AWS CLI](#) in the [Amazon S3 API Reference](#).
2. Save the following example lifecycle configuration in a file (for example, *lifecycle.json*). This example configuration specifies an empty prefix, and therefore it applies to all objects in the bucket. To restrict the configuration to a subset of objects, you can specify a prefix.

```
{
    "Rules": [
        {
            "ID": "Test Rule",
            "Status": "Enabled",
            "Filter": {
                "Prefix": ""
            },
            "AbortIncompleteMultipartUpload": {
                "DaysAfterInitiation": 7
            }
        }
    ]
}
```

```
        }
    }
]
```

- Run the following CLI command to set this lifecycle configuration on your bucket.

```
aws s3api put-bucket-lifecycle-configuration \
--bucket amzn-s3-demo-bucket \
--lifecycle-configuration file://lifecycle.json
```

- To verify that the lifecycle configuration has been set on your bucket, retrieve the lifecycle configuration by using the following get-bucket-lifecycle command.

```
aws s3api get-bucket-lifecycle \
--bucket amzn-s3-demo-bucket
```

- To delete the lifecycle configuration, use the following delete-bucket-lifecycle command.

```
aws s3api delete-bucket-lifecycle \
--bucket amzn-s3-demo-bucket
```

Uploading an object using multipart upload

You can use the multipart upload to programmatically upload a single object to Amazon S3. Each object is uploaded as a set of parts. Each part is a contiguous portion of the object's data. You can upload these object parts independently and in any order. If transmission of any part fails, you can retransmit that part without affecting other parts. After all parts of your object are uploaded, Amazon S3 assembles these parts and creates the object. Anonymous users cannot initiate multipart uploads.

For an end-to-end procedure on uploading an object with multipart upload with an additional checksum, see [Tutorial: Upload an object through multipart upload and verify its data integrity](#).

The following section show how to use multipart upload with the AWS Command Line Interface, and AWS SDKs.

Using the S3 console

You can upload any file type—images, backups, data, movies, and so on—into an S3 bucket. The maximum size of a file that you can upload by using the Amazon S3 console is 160 GB. To upload a file larger than 160 GB, use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

For instructions on uploading an object via the AWS Management Console, see [Uploading objects](#).

Using the AWS CLI

The following describe the Amazon S3 operations for multipart upload using the AWS CLI.

- [Upload Part](#)
- [Upload Part \(Copy\)](#)
- [Complete Multipart Upload](#)
- [Abort Multipart Upload](#)

Using the REST API

- [Initiate Multipart Upload](#)
- [Upload Part](#)
- [Complete Multipart Upload](#)
- [Stop Multipart Upload](#)

- [List Multipart Uploads](#)

Using the AWS SDKs (high-level API)

Some AWS SDKs expose a high-level API that simplifies multipart upload by combining the different API operations required to complete a multipart upload into a single operation. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).

If you need to pause and resume multipart uploads, vary part sizes during the upload, or do not know the size of the data in advance, use the low-level API methods. The low-level API methods for multipart uploads offer additional functionality, for more information, see [Using the AWS SDKs \(low-level API\)](#).

Java

For examples of how to perform a multipart upload with the AWS SDK for Java, see [Upload or download large files to and from Amazon S3 using an AWS SDK](#) in the *Amazon S3 API Reference*.

.NET

To upload a file to an S3 bucket, use the `TransferUtility` class. When uploading data from a file, you must provide the object's key name. If you don't, the API uses the file name for the key name. When uploading data from a stream, you must provide the object's key name.

To set advanced upload options—such as the part size, the number of threads when uploading the parts concurrently, metadata, the storage class, or ACL—use the `TransferUtilityUploadRequest` class.

Note

When you're using a stream for the source of data, the `TransferUtility` class does not do concurrent uploads.

The following C# example uploads a file to an Amazon S3 bucket in multiple parts. It shows how to use various `TransferUtility.Upload` overloads to upload a file. Each successive call to upload replaces the previous upload. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

JavaScript

Example

Upload a large file.

```
import { S3Client } from "@aws-sdk/client-s3";
```

```
import { Upload } from "@aws-sdk/lib-storage";

import {

PHP

This topic explains how to use the high-level Aws\S3\Model\MultipartUpload\UploadBuilder class from the AWS SDK for PHP for multipart file uploads. For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

The following PHP example uploads a file to an Amazon S3 bucket. The example demonstrates how to set parameters for the MultipartUploader object.

```
require 'vendor/autoload.php';  
  
use Aws\Exception\MultipartUploadException;  
use Aws\S3\MultipartUploader;  
use Aws\S3\S3Client;  
  
$bucket = '*** Your Bucket Name ***';  
$keyname = '*** Your Object Key ***';  
  
$s3 = new S3Client([  
    'version' => 'latest',  
    'region'  => 'us-east-1'  
]);
```

```
// Prepare the upload parameters.  
$uploader = new MultipartUploader($s3, '/path/to/large/file.zip', [  
    'bucket' => $bucket,  
    'key'     => $keyname  
]);  
  
// Perform the upload.  
try {  
    $result = $uploader->upload();  
    echo "Upload complete: {$result['ObjectURL']}\" . PHP_EOL;  
} catch (MultipartUploadException $e) {  
    echo $e->getMessage() . PHP_EOL;  
}
```

Using the AWS SDKs (low-level API)

The AWS SDK exposes a low-level API that closely resembles the Amazon S3 REST API for multipart uploads (see [Uploading and copying objects using multipart upload in Amazon S3](#)). Use the low-level API when you need to pause and resume multipart uploads, vary part sizes during the upload, or do not know the size of the upload data in advance. When you don't have these requirements, use the high-level API (see [Using the AWS SDKs \(high-level API\)](#)).

Java

The following example shows how to use the low-level Java classes to upload a file. It performs the following steps:

- Initiates a multipart upload using the `AmazonS3Client.initiateMultipartUpload()` method, and passes in an `InitiateMultipartUploadRequest` object.
- Saves the upload ID that the `AmazonS3Client.initiateMultipartUpload()` method returns. You provide this upload ID for each subsequent multipart upload operation.
- Uploads the parts of the object. For each part, you call the `AmazonS3Client.uploadPart()` method. You provide part upload information using an `UploadPartRequest` object.
- For each part, saves the ETag from the response of the `AmazonS3Client.uploadPart()` method in a list. You use the ETag values to complete the multipart upload.
- Calls the `AmazonS3Client.completeMultipartUpload()` method to complete the multipart upload.

.NET

The following C# example shows how to use the low-level SDK for .NET multipart upload API to upload a file to an S3 bucket. For information about Amazon S3 multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

 **Note**

When you use the SDK for .NET API to upload large objects, a timeout might occur while data is being written to the request stream. You can set an explicit timeout using the `UploadPartRequest`.

The following C# example uploads a file to an S3 bucket using the low-level multipart upload API. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

PHP

This topic shows how to use the low-level uploadPart method from version 3 of the AWS SDK for PHP to upload a file in multiple parts. For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

The following PHP example uploads a file to an Amazon S3 bucket using the low-level PHP API multipart upload.

```
require 'vendor/autoload.php';

use Aws\S3\Exception\S3Exception;
use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';
$filename = '*** Path to and Name of the File to Upload ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

$result = $s3->createMultipartUpload([
    'Bucket'      => $bucket,
    'Key'         => $keyname,
    'StorageClass' => 'REDUCED_REDUNDANCY',
    'Metadata'    => [
        'param1' => 'value 1',
        'param2' => 'value 2',
        'param3' => 'value 3'
    ]
]);
$uploadId = $result['UploadId'];
```

```
// Upload the file in parts.
try {
    $file = fopen($filename, 'r');
    $partNumber = 1;
    while (!feof($file)) {
        $result = $s3->uploadPart([
            'Bucket'      => $bucket,
            'Key'         => $keyname,
            'UploadId'    => $uploadId,
            'PartNumber'  => $partNumber,
            'Body'        => fread($file, 5 * 1024 * 1024),
        ]);
        $parts['Parts'][$partNumber] = [
            'PartNumber' => $partNumber,
            'ETag'        => $result['ETag'],
        ];
        $partNumber++;
    }
    echo "Uploading part $partNumber of $filename." . PHP_EOL;
}
fclose($file);
} catch (S3Exception $e) {
    $result = $s3->abortMultipartUpload([
        'Bucket'      => $bucket,
        'Key'         => $keyname,
        'UploadId'    => $uploadId
    ]);

    echo "Upload of $filename failed." . PHP_EOL;
}

// Complete the multipart upload.
$result = $s3->completeMultipartUpload([
    'Bucket'      => $bucket,
    'Key'         => $keyname,
    'UploadId'    => $uploadId,
    'MultipartUpload' => $parts,
]);
$url = $result['Location'];

echo "Uploaded $filename to $url." . PHP_EOL;
```

Using the AWS SDK for Ruby

The AWS SDK for Ruby version 3 supports Amazon S3 multipart uploads in two ways. For the first option, you can use managed file uploads. For more information, see [Uploading Files to Amazon S3](#) in the *AWS Developer Blog*. Managed file uploads are the recommended method for uploading files to a bucket. They provide the following benefits:

- Manage multipart uploads for objects larger than 15MB.
- Correctly open files in binary mode to avoid encoding issues.
- Use multiple threads for uploading parts of large objects in parallel.

Alternatively, you can use the following multipart upload client operations directly:

- [create_multipart_upload](#) – Initiates a multipart upload and returns an upload ID.
- [upload_part](#) – Uploads a part in a multipart upload.
- [upload_part_copy](#) – Uploads a part by copying data from an existing object as data source.
- [complete_multipart_upload](#) – Completes a multipart upload by assembling previously uploaded parts.
- [abort_multipart_upload](#) – Stops a multipart upload.

Uploading a directory using the high-level .NET TransferUtility class

You can use the `TransferUtility` class to upload an entire directory. By default, the API uploads only the files at the root of the specified directory. You can, however, specify recursively uploading files in all of the sub directories.

To select files in the specified directory based on filtering criteria, specify filtering expressions. For example, to upload only the PDF files from a directory, specify the "`*.pdf`" filter expression.

When uploading files from a directory, you don't specify the key names for the resulting objects. Amazon S3 constructs the key names using the original file path. For example, assume that you have a directory called `c:\myFolder` with the following structure:

Example

```
C:\myFolder  
  \a.txt  
  \b.pdf
```

```
\media\  
  An.mp3
```

When you upload this directory, Amazon S3 uses the following key names:

Example

```
a.txt  
b.pdf  
media/An.mp3
```

Example

The following C# example uploads a directory to an Amazon S3 bucket. It shows how to use various `TransferUtility.UploadDirectory` overloads to upload the directory. Each successive call to upload replaces the previous upload. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

        private const string existingBucketName = "*** bucket name ***";  
        private const string directoryPath = @ "*** directory path ***";  
        // The example uploads only .txt files.  
        private const string wildCard = "*.txt";  
        // Specify your bucket region (an example region is shown).

Listing multipart uploads

You can use the AWS CLI, REST API, or AWS SDKs, to retrieve a list of in-progress multipart uploads in Amazon S3. You can use the multipart upload to programmatically upload a single object to Amazon S3. Multipart uploads move objects into Amazon S3 by moving a portion of an object's data at a time. For more general information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

For an end-to-end procedure on uploading an object with multipart upload with an additional checksum, see [Tutorial: Upload an object through multipart upload and verify its data integrity](#).

The following section show how to list in-progress multipart uploads with the AWS Command Line Interface, the Amazon S3 REST API, and AWS SDKs.

Listing multipart uploads using the AWS CLI

The following sections in the AWS Command Line Interface describe the operations for listing multipart uploads.

- [list-parts](#)-list the uploaded parts for a specific multipart upload.
- [list-multipart-uploads](#)-list in-progress multipart uploads.

Listing multipart uploads using the REST API

The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API for listing multipart uploads:

- [ListParts](#)-list the uploaded parts for a specific multipart upload.
- [ListMultipartUploads](#)-list in-progress multipart uploads.

Listing multipart uploads using the AWS SDK (low-level API)

Java

To list all in-progress multipart uploads on a bucket using the AWS SDK for Java, you can use the low-level API classes to:

Low-level API multipart uploads listing process

- 1 Create an instance of the `ListMultipartUploadsRequest` class and provide the bucket name.
- 2 Run the `S3Client.listMultipartUploads` method. The method returns an instance of the `ListMultipartUploadsResponse` class that gives you information about the multipart uploads in progress.

For examples of how to list multipart uploads with the AWS SDK for Java, see [List multipart uploads](#) in the *Amazon S3 API Reference*.

.NET

To list all of the in-progress multipart uploads on a specific bucket, use the SDK for .NET low-level multipart upload API's `ListMultipartUploadsRequest` class.

The `AmazonS3Client.ListMultipartUploads` method returns an instance of the `ListMultipartUploadsResponse` class that provides information about the in-progress multipart uploads.

An in-progress multipart upload is a multipart upload that has been initiated using the initiate multipart upload request, but has not yet been completed or stopped. For more information about Amazon S3 multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

The following C# example shows how to use the SDK for .NET to list all in-progress multipart uploads on a bucket. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
ListMultipartUploadsRequest request = new ListMultipartUploadsRequest
{
    BucketName = bucketName // Bucket receiving the uploads.
};
```

```
ListMultipartUploadsResponse response = await  
AmazonS3Client.ListMultipartUploadsAsync(request);
```

PHP

This topic shows how to use the low-level API classes from version 3 of the AWS SDK for PHP to list all in-progress multipart uploads on a bucket. For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

The following PHP example demonstrates listing all in-progress multipart uploads on a bucket.

```
require 'vendor/autoload.php';  
  
use Aws\S3\S3Client;  
  
$bucket = '*** Your Bucket Name ***';  
  
$s3 = new S3Client([  
    'version' => 'latest',  
    'region'  => 'us-east-1'  
]);  
  
// Retrieve a list of the current multipart uploads.  
$result = $s3->listMultipartUploads([  
    'Bucket' => $bucket  
]);  
  
// Write the list of uploads to the page.  
print_r($result->toArray());
```

Tracking a multipart upload with the AWS SDKs

You can track an object's upload progress to Amazon S3 with a listen interface. The high-level multipart upload API provides such a listen interface, called `ProgressListener`. Progress events occur periodically and notify the listener that bytes have been transferred. For more general information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

For an end-to-end procedure on uploading an object with multipart upload with an additional checksum, see [Tutorial: Upload an object through multipart upload and verify its data integrity](#).

The following section show how to track a multipart upload with the AWS SDKs.

Java

Example

The following Java code uploads a file and uses the `ExecutionInterceptor` to track the upload progress. For instructions on how to create and test a working sample, see [Getting Started](#) in the AWS SDK for Java 2.x Developer Guide.

```
import java.nio.file.Paths;

import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.core.async.AsyncRequestBody;
import software.amazon.awssdk.core.interceptor.Context;
import software.amazon.awssdk.core.interceptor.ExecutionAttributes;
import software.amazon.awssdk.core.interceptor.ExecutionInterceptor;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;

public class TrackMPUProgressUsingHighLevelAPI {

    static class ProgressListener implements ExecutionInterceptor {
        private long transferredBytes = 0;

        @Override
        public void beforeTransmission(Context.BeforeTransmission context,
                                       ExecutionAttributes executionAttributes) {
            if (context.httpRequest().firstMatchingHeader("Content-
Length").isPresent()) {
                String contentLength =
context.httpRequest().firstMatchingHeader("Content-Length").get();
                long partSize = Long.parseLong(contentLength);
                transferredBytes += partSize;
                System.out.println("Transferred bytes: " + transferredBytes);
            }
        }
    }

    public static void main(String[] args) throws Exception {
        String existingBucketName = "*** Provide bucket name ***";
        String keyName = "*** Provide object key ***";
        String filePath = "*** file to upload ***";
    }
}
```

```
S3AsyncClient s3Client = S3AsyncClient.builder()
    .credentialsProvider(ProfileCredentialsProvider.create())
    .overrideConfiguration(c -> c.addExecutionInterceptor(new
ProgressListener()))
    .build();

// For more advanced uploads, you can create a request object
// and supply additional request parameters (ex: progress listeners,
// canned ACLs, etc.)
PutObjectRequest request = PutObjectRequest.builder()
    .bucket(existingBucketName)
    .key(keyName)
    .build();

AsyncRequestBody requestBody =
AsyncRequestBody.fromFile(Paths.get(filePath));

// You can ask the upload for its progress, or you can
// add a ProgressListener to your request to receive notifications
// when bytes are transferred.
// S3AsyncClient processes all transfers asynchronously,
// so this call will return immediately.
var upload = s3Client.putObject(request, requestBody);

try {
    // You can block and wait for the upload to finish
    upload.join();
} catch (Exception exception) {
    System.out.println("Unable to upload file, upload aborted.");
    exception.printStackTrace();
} finally {
    s3Client.close();
}
}
```

.NET

The following C# example uploads a file to an S3 bucket using the `TransferUtility` class, and tracks the progress of the upload. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

}  
}  
}
```

Aborting a multipart upload

After you initiate a multipart upload, you begin uploading parts. Amazon S3 stores these parts, and only creates the object after you upload all parts and send a request to complete the multipart upload. Upon receiving the complete multipart upload request, Amazon S3 assembles the parts and creates an object. If you don't send the complete multipart upload request successfully, S3 does not assemble the parts and does not create any object. If you wish to not complete a multipart upload after uploading parts you should abort the multipart upload.

You are billed for all storage associated with uploaded parts. It's recommended to always either complete the multipart upload or stop the multipart upload to remove any uploaded parts. For more information about pricing, see [Multipart upload and pricing](#).

You can also stop an incomplete multipart upload using a bucket lifecycle configuration. For more information, see [Configuring a bucket lifecycle configuration to delete incomplete multipart uploads](#).

The following section show how to stop an in-progress multipart upload in Amazon S3 using the AWS Command Line Interface, REST API, or AWS SDKs.

Using the AWS CLI

For more information about using the AWS CLI to stop a multipart upload, see [abort-multipart-upload](#) in the *AWS CLI Command Reference*.

Using the REST API

For more information about using the REST API to stop a multipart upload, see [AbortMultipartUpload](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs (high-level API)

Java

To stop multipart uploads in progress using the AWS SDK for Java, you can abort uploads that were initiated before a specified date and are still in progress. An upload is considered to be in progress after you initiate it and until you complete it or stop it.

To stop multipart uploads, you can:

1 Create an S3Client instance.

2 Use the client's abort methods by passing the bucket name and other required parameters.

Note

You can also stop a specific multipart upload. For more information, see [Using the AWS SDKs \(low-level API\)](#).

For examples of how to abort multipart uploads with the AWS SDK for Java, see [Cancel a multipart upload](#) in the *Amazon S3 API Reference*.

.NET

The following C# example stops all in-progress multipart uploads that were initiated on a specific bucket over a week ago. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Transfer;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class AbortMPUUsingHighLevelAPITest
    {
        private const string bucketName = "**** provide bucket name ****";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            AbortMPUAsync().Wait();
        }

        private static async Task AbortMPUAsync()
        {
            try
            {
                var transferUtility = new TransferUtility(s3Client);

                // Abort all in-progress uploads initiated before the specified
date.
                await transferUtility.AbortMultipartUploadsAsync(
                    bucketName, DateTime.Now.AddDays(-7));
            }
            catch (AmazonS3Exception e)
            {
```

```
        Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
    catch (Exception e)
    {
        Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
}
}
```

Note

You can also stop a specific multipart upload. For more information, see [Using the AWS SDKs \(low-level API\)](#).

Using the AWS SDKs (low-level API)

You can stop an in-progress multipart upload by calling the `AmazonS3.abortMultipartUpload` method. This method deletes any parts that were uploaded to Amazon S3 and frees up the resources. You must provide the upload ID, bucket name, and key name. The following Java code example demonstrates how to stop an in-progress multipart upload.

To stop a multipart upload, you provide the upload ID, and the bucket and key names that are used in the upload. After you have stopped a multipart upload, you can't use the upload ID to upload additional parts. For more information about Amazon S3 multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

Java

To stop a specific in-progress multipart upload using the AWS SDK for Java, you can use the low-level API to abort the upload by providing the bucket name, object key, and upload ID.

Note

Instead of aborting a specific multipart upload, you can stop all multipart uploads initiated before a specific time that are still in progress. This clean-up operation is useful

to stop old multipart uploads that you initiated but did not complete or stop. For more information, see [Using the AWS SDKs \(high-level API\)](#).

For examples of how to abort a specific multipart upload with the AWS SDK for Java, see [Cancel a multipart upload](#) in the *Amazon S3 API Reference*.

.NET

The following C# example shows how to stop a multipart upload. For a complete C# sample that includes the following code, see [Using the AWS SDKs \(low-level API\)](#).

```
AbortMultipartUploadRequest abortMPURequest = new AbortMultipartUploadRequest
{
    BucketName = existingBucketName,
    Key = keyName,
    UploadId = initResponse.UploadId
};
await AmazonS3Client.AbortMultipartUploadAsync(abortMPURequest);
```

You can also abort all in-progress multipart uploads that were initiated prior to a specific time. This clean-up operation is useful for aborting multipart uploads that didn't complete or were aborted. For more information, see [Using the AWS SDKs \(high-level API\)](#).

PHP

This example shows how to use a class from version 3 of the AWS SDK for PHP to abort a multipart upload that is in progress. For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#). The example the `abortMultipartUpload()` method.

For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';
$uploadId = '*** Upload ID of upload to Abort ***';

$s3 = new S3Client([
    'version' => 'latest',
```

```
    'region' => 'us-east-1'  
]);  
  
// Abort the multipart upload.  
$s3->abortMultipartUpload([  
    'Bucket' => $bucket,  
    'Key'     => $keyname,  
    'UploadId' => $uploadId,  
]);
```

Copying an object using multipart upload

Multipart upload allows you to copy objects as a set of parts. The examples in this section show you how to copy objects greater than 5 GB using the multipart upload API. For information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

You can copy objects less than 5 GB in a single operation without using the multipart upload API. You can copy objects less than 5 GB using the AWS Management Console, AWS CLI, REST API, or AWS SDKs. For more information, see [Copying, moving, and renaming objects](#).

For an end-to-end procedure on uploading an object with multipart upload with an additional checksum, see [Tutorial: Upload an object through multipart upload and verify its data integrity](#).

The following section show how to copy an object with multipart upload with the REST API or AWS SDKs.

Using the REST API

The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API for multipart upload. For copying an existing object, use the Upload Part (Copy) API and specify the source object by adding the x-amz-copy-source request header in your request.

- [Initiate Multipart Upload](#)
- [Upload Part](#)
- [Upload Part \(Copy\)](#)
- [Complete Multipart Upload](#)
- [Abort Multipart Upload](#)
- [List Parts](#)
- [List Multipart Uploads](#)

You can use these APIs to make your own REST requests, or you can use one of the SDKs we provide. For more information about using Multipart Upload with the AWS CLI, see [Using the AWS CLI](#). For more information about the SDKs, see [AWS SDK support for multipart upload](#).

Using the AWS SDKs

To copy an object using the low-level API, do the following:

- Initiate a multipart upload by calling the `AmazonS3Client.initiateMultipartUpload()` method.
- Save the upload ID from the response object that the `AmazonS3Client.initiateMultipartUpload()` method returns. You provide this upload ID for each part-upload operation.
- Copy all of the parts. For each part that you need to copy, create a new instance of the `CopyPartRequest` class. Provide the part information, including the source and destination bucket names, source and destination object keys, upload ID, locations of the first and last bytes of the part, and part number.
- Save the responses of the `AmazonS3Client.copyPart()` method calls. Each response includes the ETag value and part number for the uploaded part. You need this information to complete the multipart upload.
- Call the `AmazonS3Client.completeMultipartUpload()` method to complete the copy operation.

Java

For examples of how to copy objects using multipart upload with the AWS SDK for Java, see [Copy part of an object from another object](#) in the *Amazon S3 API Reference*.

.NET

The following C# example shows how to use the SDK for .NET to copy an Amazon S3 object that is larger than 5 GB from one source location to another, such as from one bucket to another. To copy objects that are smaller than 5 GB, use the single-operation copy procedure described in [Using the AWS SDKs](#). For more information about Amazon S3 multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

This example shows how to copy an Amazon S3 object that is larger than 5 GB from one S3 bucket to another using the SDK for .NET multipart upload API.

Tutorial: Upload an object through multipart upload and verify its data integrity

Multipart upload allows you to upload a single object as a set of parts. Each part is a contiguous portion of the object's data. You can upload these object parts independently and in any order. If transmission of any part fails, you can retransmit that part without affecting other parts. After all parts of your object are uploaded, Amazon S3 assembles these parts and creates the object. In general, when your object size reaches 100 MB, you should consider using multipart uploads instead of uploading the object in a single operation. For more information about multipart

uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#). For limits related to multipart uploads, see [Amazon S3 multipart upload limits](#).

You can use checksums to verify that assets are not altered when they are copied. Performing a checksum consists of using an algorithm to iterate sequentially over every byte in a file. Amazon S3 offers multiple checksum options for checking the integrity of data. We recommend that you perform these integrity checks as a durability best practice and to confirm that every byte is transferred without alteration. Amazon S3 also supports the following algorithms: SHA-1, SHA-256, CRC32, and CRC32C. Amazon S3 uses one or more of these algorithms to compute an additional checksum value and store it as part of the object metadata. For more information about checksums, see [Checking object integrity in Amazon S3](#).

Objective

In this tutorial, you will learn how to upload an object to Amazon S3 by using a multipart upload and an additional SHA-256 checksum through the AWS Command Line Interface (AWS CLI). You'll also learn how to check the object's data integrity by calculating the MD5 hash and SHA-256 checksum of the uploaded object.

- [Step 8: Verify object integrity with an MD5 checksum](#)
- [Step 9: Verify object integrity with an additional checksum](#)
- [Step 10: Clean up your resources](#)

Prerequisites

- Before you start this tutorial, make sure that you have access to an Amazon S3 bucket that you can upload to. For more information, see [Creating a general purpose bucket](#).

- You must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see [Install or update to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
- Alternatively, you can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) and [Getting started with AWS CloudShell](#) in the *AWS CloudShell User Guide*.

Step 1: Create a large file

If you already have a file ready for upload, you can use the file for this tutorial. Otherwise, create a 15 MB file using the following steps. For limits related to multipart uploads, see [Amazon S3 multipart upload limits](#).

To create a large file

Use one of the following commands to create your file, depending on which operating system you're using.

Linux or macOS

To create a 15 MB file, open your local terminal and run the following command:

```
dd if=/dev/urandom of=census-data.bin bs=1M count=15
```

This command creates a file named `census-data.bin` filled with random bytes, with a size of 15 MB.

Windows

To create a 15 MB file, open your local terminal and run the following command:

```
fsutil file createnew census-data.bin 15728640
```

This command creates a file named `census-data.bin` with a size of 15 MB of arbitrary data (15728640 bytes).

Step 2: Split the file into multiple files

To perform the multipart upload, you have to split your large file into smaller parts. You can then upload the smaller parts by using the multipart upload process. This step demonstrates how to

split the large file created in [Step 1](#) into smaller parts. The following example uses a 15 MB file named census-data.bin.

To split a large file into parts

Linux or macOS

To divide the large file into 5 MB parts, use the `split` command. Open your terminal and run the following:

```
split -b 5M -d census-data.bin census-part
```

This command splits `census-data.bin` into 5 MB parts named `census-part**`, where `**` is a numeric suffix starting from `00`.

Windows

To split the large file, use PowerShell. Open [Powershell](#), and run the following script:

```
$inputFile = "census-data.bin"
$outputFilePrefix = "census-part"
$chunkSize = 5MB

$fs = [System.IO.File]::OpenRead($inputFile)
$buffer = New-Object byte[] $chunkSize
$fileNumber = 0

while ($fs.Position -lt $fs.Length) {
    $bytesRead = $fs.Read($buffer, 0, $chunkSize)
    $outputFile = "{0}{1:D2}" -f $outputFilePrefix, $fileNumber
    $fileStream = [System.IO.File]::Create($outputFile)
    $fileStream.Write($buffer, 0, $bytesRead)
    $fileStream.Close()
    $fileNumber++
}

$fs.Close()
```

This PowerShell script reads the large file in chunks of 5 MB and writes each chunk to a new file with a numeric suffix.

After running the appropriate command, you should see the parts in the directory where you executed the command. Each part will have a suffix corresponding to its part number, for example:

```
census-part00 census-part01 census-part02
```

Step 3: Create the multipart upload with an additional checksum

To begin the multipart upload process, you need to create the multipart upload request. This step involves initiating the multipart upload and specifying an additional checksum for data integrity. The following example uses the SHA-256 checksum. If you want to provide any metadata describing the object being uploaded, you must provide it in the request to initiate the multipart upload.

Note

In this step and subsequent steps, this tutorial uses the SHA-256 additional algorithm. You might optionally use another additional checksum for these steps, such as CRC32, CRC32C, or SHA-1. If you use a different algorithm, you must use it throughout the tutorial steps.

To start the multipart upload

In your terminal, use the following `create-multipart-upload` command to start a multipart upload for your bucket. Replace `amzn-s3-demo-bucket1` with your actual bucket name. Also, replace the `census_data_file` with your chosen file name. This file name becomes the object key when the upload completes.

```
aws s3api create-multipart-upload --bucket amzn-s3-demo-bucket1 --key  
'census_data_file' --checksum-algorithm sha256
```

If your request succeeds, you'll see JSON output like the following:

```
{  
    "ServerSideEncryption": "AES256",  
    "ChecksumAlgorithm": "SHA256",  
    "Bucket": "amzn-s3-demo-bucket1",  
    "Key": "census_data_file",  
    "UploadId":  
        "cNV6KCSNANFZapz1LUGPC5XwUVi1n6yUoIeSP138sNOKPeMhpKQRxbT9k0ePmgo0TCj9K83T4e2Gb5hQvNoNpCKqyb8m3
```

```
}
```

Note

When you send a request to initiate a multipart upload, Amazon S3 returns a response with an upload ID, which is a unique identifier for your multipart upload. You must include this upload ID whenever you upload parts, list the parts, complete an upload, or stop an upload. You'll need to use the UploadId, Key, and Bucket values for later steps, so make sure to save these.

Also, if you're using multipart upload with additional checksums, the part numbers must be consecutive. If you use nonconsecutive part numbers, the `complete-multipart-upload` request can result in an `HTTP 500 Internal Server Error`.

Step 4: Upload the parts of your multipart upload

In this step, you will upload the parts of your multipart upload to your S3 bucket. Use the `upload-part` command to upload each part individually. This process requires specifying the upload ID, the part number, and the file to be uploaded for each part.

To upload the parts

1. When uploading a part, in addition to the upload ID, you must specify a part number by using the `--part-number` argument. You can choose any part number between 1 and 10,000. A part number uniquely identifies a part and its position in the object you are uploading. The part number that you choose must be in a consecutive sequence (for example, it can be 1, 2, or 3). If you upload a new part using the same part number as a previously uploaded part, the previously uploaded part is overwritten.
2. Use the `upload-part` command to upload each part of your multipart upload. The `--upload-id` is the same as it was in the output created by the `create-multipart-upload` command in [Step 3](#). To upload the first part of your data, use the following command:

```
aws s3api upload-part --bucket amzn-s3-demo-bucket1 --key  
  'census_data_file' --part-number 1 --body census-part00 --upload-id  
  "CNV6KCSNANFZapz1LUGPC5XwUVi1n6yUoTeSP138sNOKPeMhpKQRibT9k0ePmgoOTCj9K83T4e2Gb5hQvNoNpCKqy"  
  --checksum-algorithm SHA256
```

Upon completion of each `upload-part` command, you should see output like the following example:

```
{  
    "ServerSideEncryption": "AES256",  
    "ETag": "\"e611693805e812ef37f96c9937605e69\"",  
    "ChecksumSHA256": "QL18R4i4+SaJlr18ZIcutc5TbZtwt2NwB81TXkd3GH0="  
}
```

3. For subsequent parts, increment the part number accordingly:

```
aws s3api upload-part --bucket amzn-s3-demo-bucket1 --key 'census_data_file' --part-number <part-number> --body <file-path> --upload-id "<your-upload-id>" --checksum-algorithm SHA256
```

For example, use the following command to upload the second part:

```
aws s3api upload-part --bucket amzn-s3-demo-bucket1 --key 'census_data_file' --part-number 2 --body census-part01 --upload-id "cNV6KCSNANFZapz1LUGPC5XwUVi1n6yUoIeSP138sNOKPeMhpKQRrbT9k0ePmgoOTCj9K83T4e2Gb5hQvNoNpCKqy" --checksum-algorithm SHA256
```

Amazon S3 returns an entity tag (ETag) and additional checksums for each uploaded part as a header in the response.

4. Continue using the `upload-part` command until you have uploaded all the parts of your object.

Step 5: List all the parts of your multipart upload

To complete the multipart upload, you will need a list of all the parts that have been uploaded for that specific multipart upload. The output from the `list-parts` command provides information such as bucket name, key, upload ID, part number, ETag, additional checksums, and more. It's helpful to save this output in a file so that you can use it for the next step when completing the multipart upload process. You can create a JSON output file called `parts.json` by using the following method.

To create a file that lists all of the parts

1. To generate a JSON file with the details of all the uploaded parts, use the following `list-parts` command. Replace `amzn-s3-demo-bucket1` with your actual bucket name and `<your-upload-id>` with the upload ID that you received in [Step 3](#). For more information on the `list-parts` command, see [list-parts](#) in the *AWS Command Line Interface User Guide*.

```
aws s3api list-parts --bucket amzn-s3-demo-bucket1 --key 'census_data_file' --upload-id <your-upload-id> --query '{Parts: Parts[*].{PartNumber: PartNumber, ETag: ETag, ChecksumSHA256: ChecksumSHA256}}' --output json > parts.json
```

A new file called `parts.json` is generated. The file contains the JSON formatted information for all of your uploaded parts. The `parts.json` file includes essential information for each part of your multipart upload, such as the part numbers and their corresponding ETag values, which are necessary for completing the multipart upload process.

2. Open `parts.json` by using any text editor or through the terminal. Here's the example output:

```
{  
    "Parts": [  
        {  
            "PartNumber": 1,  
            "ETag": "\"3c3097f89e2a2fece47ac54b243c9d97\"",  
            "ChecksumSHA256": "fTPVHfyNHdv5VkR4S3EewdyioXECv7JBxN+d4FXYYTw=\""  
        },  
        {  
            "PartNumber": 2,  
            "ETag": "\"03c71cc160261b20ab74f6d2c476b450\"",  
            "ChecksumSHA256": "VDWTa8enj0vULBA03W2a6C+5/7ZnNjrnlApa1QVc3FE=\""  
        },  
        {  
            "PartNumber": 3,  
            "ETag": "\"81ae0937404429a97967dff7eb4affb\"",  
            "ChecksumSHA256": "cVVkXehUlzcwrBrXgPIM+EKQXPUvWist8mlUTCs4bg8=\""  
        }  
    ]  
}
```

Step 6: Complete the multipart upload

After uploading all parts of your multipart upload and listing them, the final step is to complete the multipart upload. This step merges all the uploaded parts into a single object in your S3 bucket.

Note

You can calculate the object checksum before calling `complete-multipart-upload` by including `--checksum-sha256` in your request. If the checksums don't match, Amazon S3 fails the request. For more information, see [complete-multipart-upload](#) in the *AWS Command Line Interface User Guide*.

To complete the multipart upload

To finalize the multipart upload, use the `complete-multipart-upload` command. This command requires the `parts.json` file created in [Step 5](#), your bucket name, and the upload ID. Replace `<amzn-s3-demo-bucket1>` with your bucket name and `<your-upload-id>` with the upload ID of `parts.json`.

```
aws s3api complete-multipart-upload --multipart-upload file://parts.json --bucket amzn-s3-demo-bucket1 --key 'census_data_file' --upload-id <your-upload-id>
```

Here's the example output:

```
{  
    "ServerSideEncryption": "AES256",  
    "Location": "https://amzn-s3-demo-bucket1.s3.us-east-2.amazonaws.com/  
census_data_file",  
    "Bucket": "amzn-s3-demo-bucket1",  
    "Key": "census_data_file",  
    "ETag": "\"f453c6dcca969c457efdf9b1361e291-3\"",  
    "ChecksumSHA256": "aI8EoktCdotjU8Bq46DrPCxQCGuGcPIhJ51noWs6hvK=-3"  
}
```

Note

Don't delete the individual part files yet. You will need the individual parts so that you can perform checksums on them to verify the integrity of the merged-together object.

Step 7: Confirm that the object is uploaded to your bucket

After completing the multipart upload, you can verify that the object has been successfully uploaded to your S3 bucket. To list the objects in your bucket and confirm the presence of your newly uploaded file, use the `list-objects-v2` command

To list the uploaded object

To list the objects in your, use the `list-objects-v2` command bucket. Replace **amzn-s3-demo-bucket1** with your actual bucket name:

```
aws s3api list-objects-v2 --bucket amzn-s3-demo-bucket1
```

This command returns a list of objects in your bucket. Look for your uploaded file (for example, `census_data_file`) in the list of objects.

For more information, see the [Examples](#) section for the `list-objects-v2` command in the *AWS Command Line Interface User Guide*.

Step 8: Verify object integrity with an MD5 checksum

When you upload an object, you can specify a checksum algorithm for Amazon S3 to use. By default, Amazon S3 stores the MD5 digest of bytes as the object's ETag. For multipart uploads, the ETag is not the checksum for the entire object, but rather a composite of checksums for each individual part.

To verify object integrity by using an MD5 checksum

1. To retrieve the ETag of the uploaded object, perform a `head-object` request:

```
aws s3api head-object --bucket amzn-s3-demo-bucket1 --key census_data_file
```

Here's the example output:

```
{  
    "AcceptRanges": "bytes",  
    "LastModified": "2024-07-26T19:04:13+00:00",  
    "ContentLength": 16106127360,  
    "ETag": "\"f453c6dcca969c457efdf9b1361e291-3\"",  
    "ContentType": "binary/octet-stream",  
    "ServerSideEncryption": "AES256",  
    "Metadata": {}  
}
```

This ETag has "-3" appended to the end. This indicates that the object was uploaded in three parts using multipart upload.

2. Next, calculate the MD5 checksum of each part using the `md5sum` command. Make sure that you provide the correct path to your part files:

```
md5sum census-part*
```

Here's the example output:

```
e611693805e812ef37f96c9937605e69 census-part00  
63d2d5da159178785bfd6b6a5c635854 census-part01  
95b87c7db852451bb38b3b44a4e6d310 census-part02
```

3. For this step, manually combine the MD5 hashes into one string. Then, run the following command to convert the string to binary and calculate the MD5 checksum of the binary value:

```
echo  
"e611693805e812ef37f96c9937605e6963d2d5da159178785bfd6b6a5c63585495b87c7db852451bb38b3b44a4e6d310"  
| xxd -r -p | md5sum
```

Here's the example output:

```
f453c6dcca969c457efdf9b1361e291 -
```

This hash value should match the hash value of the original ETag value in [Step 1](#), which validates the integrity of the census_data_file object.

When you instruct Amazon S3 to use additional checksums, Amazon S3 calculates the checksum value for each part and stores the values. If you want to retrieve the checksum values for individual parts of multipart uploads that are still in progress, you can use `list-parts`.

For more information about how checksums work with multipart upload objects, see [Checking object integrity in Amazon S3](#).

Step 9: Verify object integrity with an additional checksum

In this step, this tutorial uses SHA-256 as an additional checksum to validate object integrity. If you've used a different additional checksum, use that checksum value instead.

To verify object integrity with SHA256

- Run the following command in your terminal, including the `--checksum-mode enabled` argument, to display the ChecksumSHA256 value of your object:

```
aws s3api head-object --bucket amzn-s3-demo-bucket1 --key census_data_file --checksum-mode enabled
```

Here's the example output:

```
{  
    "AcceptRanges": "bytes",  
    "LastModified": "2024-07-26T19:04:13+00:00",  
    "ContentLength": 16106127360,  
    "ChecksumSHA256": "aI8EoktCdotjU8Bq46DrPCxQCGuGcPIhJ51noWs6hvK=-3",  
    "ETag": "\"f453c6dccca969c457efdf9b1361e291-3\"",  
    "ContentType": "binary/octet-stream",  
    "ServerSideEncryption": "AES256",  
    "Metadata": {}  
}
```

- Use the following commands to decode the ChecksumSHA256 values for the individual parts into base64 and save them into a binary file called `outfile`. These values can be found in

your parts.json file. Replace the example base64 strings with your actual ChecksumSHA256 values.

```
echo "QL18R4i4+SaJlrl8ZIcutc5TbZtwt2NwB8lTXkd3GH0=" | base64 --decode >> outfile  
echo "xCdgs1K5Bm4jWETYw/CmGYr+m602DcGfpckx5NVokvE=" | base64 --decode >> outfile  
echo "f5wsfsa5bB+yXuwzqG1Bst91uYneqGD3CCidpb54mAo=" | base64 --decode >> outfile
```

- Run the following command to calculate the SHA256 checksum of the outfile:

```
sha256sum outfile
```

Here's the example output:

```
688f04a24b42768b6353c06ae3a0eb3c2c50086b8670f221279d67a16b3a86f9 outfile
```

In the next step, take the hash value and convert it into a binary value. This binary value should match the ChecksumSHA256 value from [Step 1](#).

- Convert the SHA256 checksum from [Step 3](#) into binary, and then encode it to base64 to verify that it matches the ChecksumSHA256 value from [Step 1](#):

```
echo "688f04a24b42768b6353c06ae3a0eb3c2c50086b8670f221279d67a16b3a86f9" | xxd -r -p  
| base64
```

Here's the example output:

```
aI8EoktCdotjU8Bq46DrPCxQCGuGcPIhJ51noWs6hvk=
```

This output should confirm that the base64 output matches the ChecksumSHA256 value from the head-object command output. If the output matches the checksum value, then the object is valid.

Important

- When you instruct Amazon S3 to use additional checksums, Amazon S3 calculates the checksum values for each part and stores these values.

- If you want to retrieve the checksum values for individual parts of multipart uploads that are still in progress, you can use the `list-parts` command.

Step 10: Clean up your resources

If you want to clean up the files created in this tutorial, use the following method. For instructions on deleting the files uploaded to your S3 bucket, see [Deleting Amazon S3 objects](#).

Delete local files created in [Step 1](#):

To remove the files that you created for your multipart upload, run the following command from your working directory:

```
rm census-data.bin census-part* outfile parts.json
```

Amazon S3 multipart upload limits

Multipart upload allows you to upload a single object as a set of parts. Each part is a contiguous portion of the object's data. After all parts of your object are uploaded, Amazon S3 assembles these parts and creates the object. In general, when your object size reaches 100 MB, you should consider using multipart uploads instead of uploading the object in a single operation. For more information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

The following table provides multipart upload core specifications. These include maximum object size, maximum number of parts, maximum part size, and more. There is no minimum size limit on the last part of your multipart upload.

Item	Specification
Maximum object size	48.8 TiB
Maximum number of parts per upload	10,000
Part numbers	1 to 10,000 (inclusive)

Item	Specification
Part size	5 MiB to 5 GiB. There is no minimum size limit on the last part of your multipart upload.
Maximum number of parts returned for a list parts request	1000
Maximum number of multipart uploads returned in a list multipart uploads request	1000

Add preconditions to S3 operations with conditional requests

You can use conditional requests to add preconditions to your S3 operations. To use conditional requests, you add an additional header to your Amazon S3 API operation. This header specifies a condition that, if not met, will result in the S3 operation failing.

Conditional reads are supported for GET, HEAD, and COPY requests. You can add preconditions to return or copy an object based on its Entity tag (ETag) or last modified date. This can limit an S3 operation to objects updated since a specified date. You can also limit an S3 operation to a specific ETag. This could ensure you only return or copy a specific object version. For more information about the object metadata, see [Working with object metadata](#).

Conditional writes can ensure there is no existing object with the same key name in your bucket during PUT operations. This prevents overwriting of existing objects with identical key names. Similarly, you can use conditional writes to check if an object's ETag is unchanged before updating the object. This prevents unintentional overwrites on an object without knowing the state of its content. You can use conditional writes for [PutObject](#), [CompleteMultipartUpload](#), or [CopyObject](#) requests. For more information about key names, see [Naming Amazon S3 objects](#).

Conditional deletes evaluate if your object exists or is unchanged before deleting it. You can perform conditional deletes using the DeleteObject or DeleteObjects APIs in general purpose and directory buckets. For more information on conditional deletes, see [How to perform conditional deletes](#). There is no additional charge for conditional reads, conditional writes or conditional deletes. You are only charged existing rates for the applicable requests, including for failed requests. For information about Amazon S3 features and pricing, see [Amazon S3 pricing](#).

How to retrieve or copy objects based on metadata with conditional reads

With conditional reads, you can add an additional header to your read request in order to add preconditions to your S3 operation. If these preconditions are not met the read request will fail.

You can use conditional reads on GET, HEAD, or COPY requests to only return an object based on its metadata.

When you upload an object, Amazon S3 creates system controlled metadata that can only be modified by S3. Entity tags (ETags) and Last-Modified are examples of system controlled metadata. An object's ETag is a string representing a specific version of an object. Last-Modified date is metadata representing an object's creation date or the last modified date, whichever is the latest.

With conditional reads, you can return an object based on the object's ETag or Last-Modified date. You can specify an ETag value with your request and return the object only if the ETag value matches. This can ensure you only return or copy a specific version of an object. You can specify a Last-Modified value with your read request and return an object only if that object has been modified since a date you provide.

Supported APIs

The following S3 APIs support using conditional reads:

- [GetObject](#)
- [HeadObject](#)
- [CopyObject](#)

You can use the following headers to return an object dependent on the entity tag (ETag) or last modified date. For more information about object metadata such as ETags and Last-Modified, see [the section called "System-defined object metadata"](#).

GetObject

- **If-Match** — Return the object only if its ETag matches the one provided.
- **If-Modified-Since** — Return the object only if it has been modified since the time specified.
- **If-None-Match** — Return the object only if its ETag does not match the one provided.
- **If-Unmodified-Since** — Return the object only if it has not been modified since the time specified.

For more information about these headers, errors returned, and the order S3 handles multiple conditional headers in a single request, see [GetObject](#) in the Amazon Simple Storage Service API Reference.

HeadObject

- **If-Match** — Return the object only if its ETag matches the one provided.
- **If-Modified-Since** — Return the object only if it has been modified since the time specified.
- **If-None-Match** — Return the object only if its ETag does not match the one provided.
- **If-Unmodified-Since** — Return the object only if it has not been modified since the time specified.

For more information about these headers, errors returned, and the order S3 handles multiple conditional headers in a single request, see [HeadObject](#) in the Amazon Simple Storage Service API Reference.

CopyObject

- **x-amz-copy-source-if-match** — Copies the source object only if its ETag matches the one provided.
- **x-amz-copy-source-if-modified-since** — Copies the source object only if it has been modified since the time specified.
- **x-amz-copy-source-if-none-match** — Copies the source object only if its ETag does not match the one provided.
- **x-amz-copy-source-if-unmodified-since** — Copies the source object only if it has not been modified since the time specified.

- **If-Match** — Copies the object only if its ETag matches the one provided. If-Match expects the ETag value as a string.
- **If-None-Match** — Copies the object only if its ETag does not match the one provided. If-None-Match expects the '*' (asterisk) character.

For more information about these headers, errors returned, and the order S3 handles multiple conditional headers in a single request, see [CopyObject](#) in the Amazon Simple Storage Service API Reference.

How to prevent object overwrites with conditional writes

By using conditional writes, you can add an additional header to your WRITE requests to specify preconditions for your Amazon S3 operation. To conditionally write objects, add the HTTP If-None-Match or If-Match header.

The If-None-Match header prevents overwrites of existing data by validating that there's not an object with the same key name already in your bucket.

Alternatively, you can add the If-Match header to check an object's entity tag (ETag) before writing an object. With this header, Amazon S3 compares the provided ETag value with the ETag value of the object in S3. If the ETag values don't match, the operation fails.

Bucket owners can use bucket policies to enforce conditional writes for uploaded objects. For more information, see [the section called “Enforce conditional writes”](#).

Note

To use conditional writes, you must make the requests over HTTPS (TLS) or use AWS Signature Version 4 to sign the request.

How to prevent object overwrites based on key names

You can use the HTTP If-None-Match conditional header to check whether an object already exists in the specified bucket based on its key name before creating it or copying it to the destination bucket.

Conditional writes with the HTTP If-None-Match header check for the existence of an object during the WRITE operation. If an identical key name is found in the bucket, the operation fails. Without the HTTP If-None-Match header, if you upload or copy an object with an identical key name in an unversioned or version-suspended bucket, the object is overwritten. For more information about using key names, see [the section called “Naming objects”](#).

 **Note**

The HTTP If-None-Match header only applies to the current version of an object in a version bucket.

To perform conditional writes with the HTTP If-None-Match header you must have the s3:PutObject permission. This enables the caller to check for the presence of objects in the bucket. The If-None-Match header expects the * (asterisk) value.

You can use the If-None-Match header with the following APIs:

- [PutObject](#)
- [CompleteMultipartUpload](#)
- [CopyObject](#)

Conditional Put Using the AWS CLI

The following put-object example command attempts to perform a conditional write for an object with the key name dir-1/my_images.tar.bz2.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key dir-1/my_images.tar.bz2 --body my_images.tar.bz2 --if-none-match "*"
```

For more information, see [put-object](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

Conditional Copy Using the AWS CLI

The following copy-object example command attempts to copy an object to a destination bucket with a conditional write for an object with the key name dir-1/my_images.tar.bz2.

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket/key --key dir-1/  
my_images.tar.bz2 --bucket amzn-s3-demo-bucket2 --if-none-match "*"
```

For more information, see [copy-object](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

Conditional multipart upload Using the AWS CLI

The following complete-multipart-upload example command attempts to complete a multipart upload with a conditional write for an object with the key name dir-1/my_images.tar.bz2. In this example, the file:// prefix is used to load the JSON structure from a file in the local folder named mpustruct which list of all the parts that have been uploaded for this specific multipart upload.

```
aws s3api complete-multipart-upload --multipart-upload file://mpustruct --bucket amzn-  
s3-demo-bucket --key dir-1/my_images.tar.bz2 --upload-id upload-id --if-none-match "*"
```

For more information, see [complete-multipart-upload](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

How to prevent overwrites if the object has changed

An object's ETag is a string that's unique to the object and reflects a change to the object's content. You can use the If-Match header to compare the ETag value of an object in an Amazon S3 bucket with one that you provide during the WRITE operation. If the ETag values don't match, the

operation fails. For more information about ETags, see [the section called “Using Content-MD5 and the ETag to verify uploaded objects”](#).

To perform conditional writes with an HTTP If-Match header you must have the s3:PutObject and s3:GetObject permissions. This enables the caller to check the ETag and verify the state of the objects in the bucket. The If-Match header expects the ETag value as a string.

You can use the If-Match header with the following APIs:

- [PutObject](#)
- [CompleteMultipartUpload](#)
- [CopyObject](#)

Conditional Put Using the AWS CLI

The following put-object example command attempts to perform a conditional write with the provided ETag value 6805f2cfc46c0f04559748bb039d69ae.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key dir-1/my_images.tar.bz2 --body my_images.tar.bz2 --if-match "6805f2cfc46c0f04559748bb039d69ae"
```

Conditional Copy Using the AWS CLI

The following copy-object example command attempts to perform a conditional write with the provided ETag value 6805f2cfc46c0f04559748bb039d69ae.

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket/key --key dir-1/my_images.tar.bz2 --bucket amzn-s3-demo-bucket2 --if-match "6805f2cfc46c0f04559748bb039d69ae"
```

For more information, see [copy-object](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

Conditional multipart upload Using the AWS CLI

The following complete-multipart-upload example command attempts to complete a multipart upload with a conditional write using the provided ETag value 6805f2cfc46c0f04559748bb039d69ae. In this example, the file:// prefix is used to load the JSON structure from a file in the local folder named mpustruct which list of all the parts that have been uploaded for this specific multipart upload.

```
aws s3api complete-multipart-upload --multipart-upload file://mpustruct --bucket amzn-s3-demo-bucket --key dir-1/my_images.tar.bz2 --upload-id upload-id --if-match "6805f2cfc46c0f04559748bb039d69ae"
```

Conditional write behavior

Conditional writes or copies with If-None-Match header

Conditional writes with the If-None-Match header evaluate against existing objects in a bucket. If there's no existing object with the same key name in the bucket, the write operation succeeds, resulting in a 200 OK response. If there's an existing object, the write operation fails, resulting in a 412 Precondition Failed response.

For buckets with versioning enabled, if there's no current object version with the same name, or if the current object version is a delete marker, the write operation succeeds. Otherwise, it results in a failed write operation with a 412 Precondition Failed response.

If multiple conditional writes or copies occur for the same object name, the first write operation to finish succeeds. Amazon S3 then fails subsequent writes with a 412 Precondition Failed response.

You can also receive a 409 Conflict response in the case of concurrent requests if a delete request to an object succeeds before a conditional write operation on that object completes. When using conditional writes with PutObject, uploads may be retried after receiving a 409 Conflict error. When using CompleteMultipartUpload, the entire multipart upload must be re-initiated with CreateMultipartUpload to upload the object again after receiving a 409 Conflict error.

Conditional writes or copies with If-Match header

The If-Match header evaluates against existing objects in a bucket. If there's an existing object with the same key name and matching ETag, the write operation succeeds, resulting in a 200 OK response. If the ETag doesn't match, the write operation fails with a 412 Precondition Failed response.

You can also receive a 409 Conflict response in the case of concurrent requests.

You will receive a 404 Not Found response if a concurrent delete request to an object succeeds before a conditional write operation on that object completes, as the object key no longer exists. You should reupload the object when you receive a 404 Not Found response.

If there's no current object version with the same name, or if the current object version is a delete marker, the operation fails with a 404 Not Found error.

Conditional write scenarios

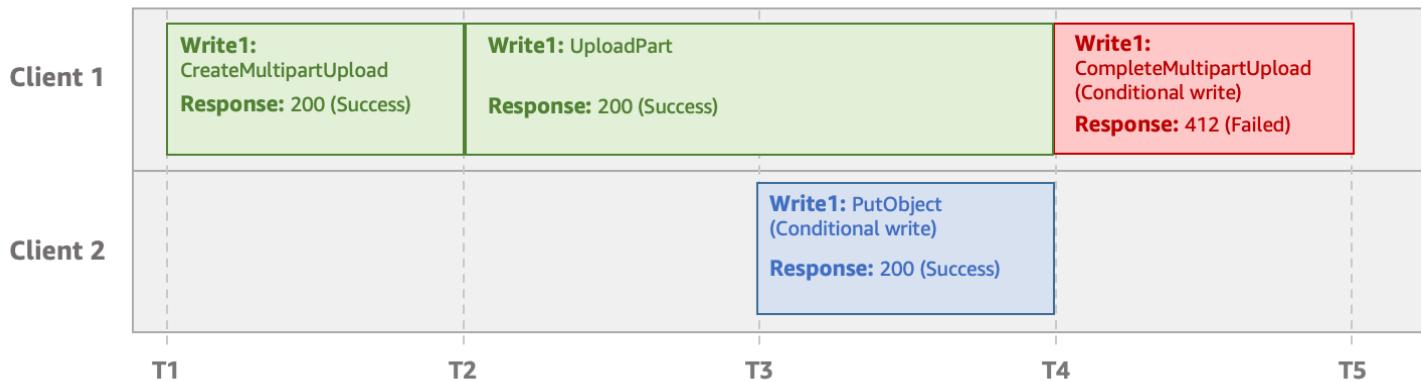

Consider the following scenarios where two clients are running operations on the same bucket.

Conditional writes during multipart uploads

Conditional writes do not consider any in-progress multipart uploads requests since those are not yet fully written objects. Consider the following example where Client 1 is uploading an object using multipart upload. During the multipart upload, Client 2 is able to successfully write the same object with the conditional write operation. Subsequently, when Client 1 tries to complete the multipart upload using a conditional write the upload fails.

Note

This scenario will result in a 412 Precondition Failed response for both If-None-Match and If-Match headers.

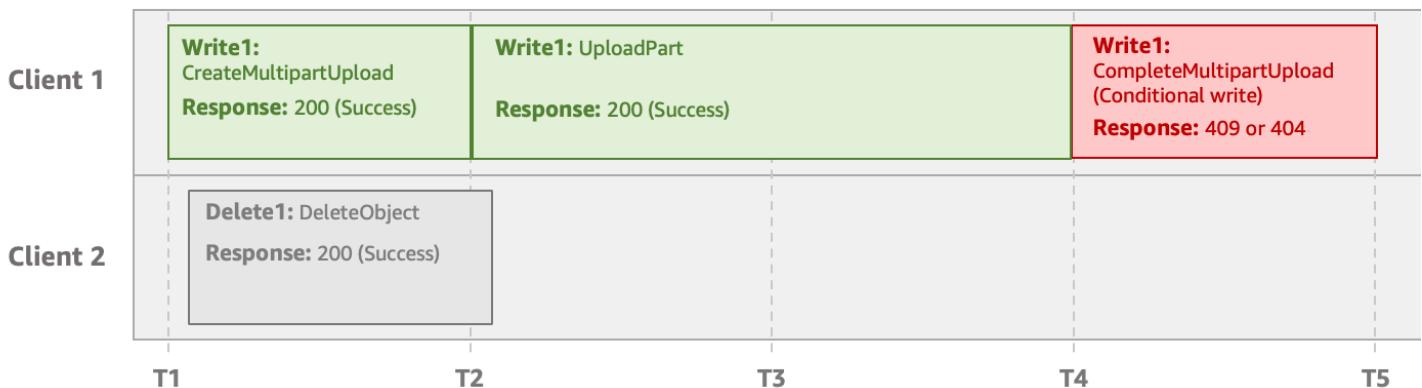

Concurrent deletes during multipart uploads

If a delete request succeeds before a conditional write request can complete, Amazon S3 returns a **409 Conflict** or **404 Not Found** response for the write operation. This is because the delete request that was initiated earlier takes precedence over the conditional write operation. In such cases, you must initiate a new multipart upload.

Note

This scenario will result in a **409 Conflict** response for an **If-None-Match** header and a **404 Not Found** response for an **If-Match** header.

Note

To minimize your storage costs, we recommend that you configure a lifecycle rule to delete incomplete multipart uploads after a specified number of days by using the AbortIncompleteMultipartUpload action. For more information about creating a lifecycle rule to delete incomplete multipart uploads, see [Configuring a bucket lifecycle configuration to delete incomplete multipart uploads](#).

Enforce conditional writes on Amazon S3 buckets

By using Amazon S3 bucket policies, you can enforce conditional writes for object uploads in your general purpose buckets.

A bucket policy is a resource-based policy that you can use to grant access permissions to your Amazon S3 bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. For more information about bucket policies, see [the section called “Bucket policies”](#).

You can use the condition keys s3:if-match or s3:if-none-match as the optional Condition element or Condition block to specify when a policy is in effect. For multipart uploads you must specify the s3:ObjectCreationOperation condition key to exempt the CreateMultipartUpload, UploadPart, and UploadPartCopy operations, as these APIs don't accept conditional headers. For more information about using conditions in bucket policies, see [the section called “Condition key examples”](#).

Note

If you use a bucket policy to enforce conditional writes, you can't perform copy operations to the bucket or prefix specified in your bucket policy. CopyObject requests without an If-None-Match or If-Match HTTP header fail with a 403 Access Denied error. CopyObject requests made with those HTTP headers fail with a 501 Not Implemented response.

The following examples show how to use conditions in a bucket policy to force clients to use the If-None-Match or If-Match HTTP header.

Example 1: Only allow object uploads using PutObject and CompleteMultipartUpload requests that include the if-none-match header

This policy allows account 111122223333, user Alice, to write to the *amzn-s3-demo-bucket1* bucket if the request includes the if-none-match header, ensuring that the object key doesn't already exist in the bucket. All PutObject and CompleteMultipartUpload requests to the specified bucket must include the if-none-match header to succeed. Using this header, customers can write to this bucket only if the object key does not exist in the bucket.

Note

This policy also sets the s3:ObjectCreationOperation condition key which allows for multipart uploads using the CreateMultipartUpload, UploadPart, and UploadPartCopy APIs.

Example 2: Only allow object uploads using PutObject and CompleteMultipartUpload requests that include the if-match header

This policy allows account 111122223333, user Alice to write to *amzn-s3-demo-bucket1* only if the request includes the if-match header. This header compares the ETag value of an object in S3 with one you provide during the WRITE operation. If the ETag values do not match, the operation will fail. All PutObject and CompleteMultipartUpload requests to the specified bucket must include the if-match header to succeed.

Note

This policy also sets the s3:ObjectCreationOperation condition key which allows for multipart uploads using the CreateMultipartUpload, UploadPart, and UploadPartCopy APIs.

Example 3: Only allow object upload requests that includes the if-none-match or if-match header

This policy allows account 111122223333, user Alice to write to **amzn-s3-demo-bucket1** if the requests include the **if-none-match** or **if-match** header. This allows Alice to upload an object

if the key name does not exist in the bucket, or if the key name does exist, Alice can overwrite the object if the object ETag matches the ETag provided in the PUT request.

Note

This policy also sets the `s3:ObjectCreationOperation` condition key which allows for multipart uploads using the `CreateMultipartUpload`, `UploadPart`, and `UploadPartCopy` APIs.

How to perform conditional deletes

You can use conditional deletes to evaluate if your object exists or is unchanged before deleting it. You can perform conditional deletes using the `DeleteObject` or `DeleteObjects` API operations in S3 general purpose and directory buckets. To get started, when making a conditional delete request, you can use the `HTTP If-Match` header with the precondition value `*` to check if object exists or the `If-Match` header with your provided ETag to check if the object has been modified.

You can enforce conditional deletes at a general purpose bucket level using S3 bucket or Identity and Access Management (IAM) policies. For more information, see [Enforce conditional deletes on Amazon S3 buckets](#).

Note

Conditional delete evaluations only apply to the current version of the object.

How to check if your object has been modified before deleting it

With conditional deletes, you can protect your application from accidental deletions of objects. You can use the HTTP `If-Match` header with the ETag value to check if an object has been modified. If the ETag value of an object in an S3 bucket doesn't match with the ETag that you provide during the delete operation, the operation fails. For conditionally deleting multiple objects using the `DeleteObjects` operation, you must provide the ETag value in the `ETag` element of the object in the XML request body. For more information, see [the section called “Using Content-MD5 and the ETag to verify uploaded objects”](#).

Note

To perform conditional deletes with the `If-Match` header with the ETag value, you must have the `s3:DeleteObject` and `s3:GetObject` permissions.

The `If-Match` header with the ETag value evaluates against existing objects in a bucket. If there's an existing object with the same key name and matching ETag, the `DeleteObject` requests succeeds, and returns a `204 No content` response. If the ETag doesn't match, the delete operation fails with a `412 Precondition Failed` response. If successful, The `DeleteObjects` API responds with a `200 OK` and provides the status of each object in the response body of the batch delete request. If preconditions aren't satisfied for a `DeleteObjects` request, Amazon S3 deletes the objects and returns a `Pre-condition failed` error response.

You can also receive a `409 Conflict` error response in the case of concurrent requests if a `DELETE` or `PUT` request to an object succeeds before a conditional delete operation on that object completes. You will receive a `404 Not Found` response if a concurrent delete request to an object

succeeds before a conditional write operation on that object completes, as the object key no longer exists.

You can use the If-Match header with the ETag value for the following APIs:

- [DeleteObject](#)
- [DeleteObjects](#)

Using the AWS CLI

The following delete-object example command attempts to perform a conditional delete with the provided ETag value 6805f2cfc46c0f04559748bb039d69a1.

```
aws s3api delete-object --bucket amzn-s3-demo-bucket --key dir-1/my_images.tar.bz2 --if-match "6805f2cfc46c0f04559748bb039d69a1"
```

For more information, see [delete-object](#) in the *AWS CLI Command Reference*.

The following delete-objects example command attempts to perform a conditional delete with the provided ETag value 6805f2cfc46c0f04559748bb039d69a1.

```
aws s3api delete-objects --bucket amzn-s3-demo-bucket --delete '[{"Objects": [{"Key": "my_images.tar.bz2", "ETag": "6805f2cfc46c0f04559748bb039d69a1"}]}]
```

For more information, see [delete-objects](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

How to check if your object exists before deleting it

You can use the If-Match header with the * value to check if the object exists before attempting to delete it. The * value signifies that the operation should only proceed if the object exists, regardless of whether it has been modified or not.

Delete markers are special objects in versioned S3 general purpose buckets that indicate that an object has been deleted. They are placeholders that make the object appear deleted while preserving the previous versions. Therefore, when you use If-Match: * with a DeleteObject API, the operation will only succeed with a 204 No Content if the object exists. If the latest

version of the object is a delete marker, the object doesn't exist and the DeleteObject API will fail and return a 412 Precondition Failed response. For more information about delete markers, see [the section called "Working with delete markers"](#).

To conditionally delete multiple objects using the DeleteObjects operation, you can provide the * in the ETag element of the object in the XML request body. If the precondition succeeds, the DeleteObjects operation responds with a 200 OK and provides the status of each object in the response body. If the precondition succeeds, the response for that object will be captured in the <Deleted> element of the response body. If the precondition fails then the response for that object will be captured in the <Error> element of the response body. If the object doesn't exist when evaluating either of the preconditions, S3 rejects the request and returns a Not Found error response.

Note

To perform conditional deletes with If-Match: *, you must have s3:DeleteObject permissions.

You can use the If-Match header with the * value for the following APIs:

- [DeleteObject](#)
- [DeleteObjects](#)

Using the AWS CLI

The following delete-object example command attempts to perform a conditional delete for an object with the key name *my_images.tar.bz2* that has a value of * which represents any ETag.

```
aws s3api delete-object --bucket amzn-s3-demo-bucket --key dir-1/my_images.tar.bz2 --if-match "*"
```

For more information, see [delete-object](#) in the *AWS CLI Command Reference*.

The following delete-objects example command attempts to perform a conditional delete for an object with the key name *my_images.tar.bz2* that has a value of * which represents any ETag.

```
aws s3api delete-objects --bucket amzn-s3-demo-bucket --delete '{"Objects": [{"Key": "my_images.tar.bz2", "ETag": "*"}]}'
```

For more information, see [delete-objects](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

Enforce conditional deletes on Amazon S3 buckets

By using Amazon S3 bucket policies, you can enforce If-Match header with conditional deletes for objects in general purpose buckets. If the If-Match header doesn't exist, the request will be denied with an 403 Access Denied. A bucket policy is a resource-based policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. For more information about bucket policies, see [the section called "Bucket policies"](#).

The following examples show how to use conditions in a bucket policy to force clients to use the If-Match HTTP header.

Copying, moving, and renaming objects

The CopyObject operation creates a copy of an object that's already stored in Amazon S3.

You can create a copy of an object up to 5 GB in a single atomic operation. However, to copy an object that's larger than 5 GB, you must use a multipart upload using the AWS CLI or AWS SDKs. For more information, see [Copying an object using multipart upload](#).

 **Note**

To maintain the performance benefit of an object you uploaded using multipart upload, you must copy the object using multipart upload using the AWS CLI or AWS SDK instead of the S3 console. For more information, see [Copying an object using multipart upload](#).

Using the CopyObject operation, you can:

- Create additional copies of objects.
- Rename objects by copying them and deleting the original ones.
- Copy or move objects from one bucket to another, including across AWS Regions (for example, from us-west-1 to eu-west-2). When you move an object, Amazon S3 copies the object to the specified destination and then deletes the source object.

 **Note**

Copying or moving objects across AWS Regions incurs bandwidth charges. For more information, see [Amazon S3 Pricing](#).

- Change object metadata. Each Amazon S3 object has metadata. This metadata is a set of name-value pairs. You can set object metadata at the time you upload an object. After you upload the object, you can't modify the object metadata. The only way to modify object metadata is to make a copy of the object and set the metadata. To do so, in the copy operation, set the same object as the source and target.

Some object metadata is system metadata and other is user-defined. You can control some of the system metadata. For example, you can control the storage class and the type of server-side

encryption to use for the object. When you copy an object, user-controlled system metadata and user-defined metadata are also copied. Amazon S3 resets the system-controlled metadata. For example, when you copy an object, Amazon S3 resets the creation date of the copied object. You don't need to set any of these system-controlled metadata values in your copy request.

When copying an object, you might decide to update some of the metadata values. For example, if your source object is configured to use S3 Standard storage, you might choose to use S3 Intelligent-Tiering for the object copy. You might also decide to alter some of the user-defined metadata values present on the source object. If you choose to update any of the object's user-configurable metadata (system or user-defined) during the copy, then you must explicitly specify all of the user-configurable metadata present on the source object in your request, even if you are changing only one of the metadata values.

Note

When copying an object by using the Amazon S3 console, you might receive the error message "Copied metadata can't be verified." The console uses headers to retrieve and set metadata for your object. If your network or browser configuration modifies your network requests, this behavior might cause unintended metadata (such as modified Cache-Control headers) to be written to your copied object. Amazon S3 can't verify this unintended metadata.

To address this issue, check your network and browser configuration to make sure it doesn't modify headers, such as Cache-Control. For more information, see [The Shared Responsibility Model](#).

For more information about object metadata, see [Working with object metadata](#).

Copying archived and restored objects

If the source object is archived in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, you must first restore a temporary copy before you can copy the object to another bucket. For information about archiving objects, see [Working with archived objects](#).

The **Copy** operation in the Amazon S3 console isn't supported for restored objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. To copy these restored objects, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

Copying encrypted objects

Amazon S3 automatically encrypts all new objects that are copied to an S3 bucket. If you don't specify encryption information in your copy request, the encryption setting of the target object is set to the default encryption configuration of the destination bucket. By default, all buckets have a base level of encryption configuration that uses server-side encryption with Amazon S3 managed keys (SSE-S3). If the destination bucket has a default encryption configuration that uses server-side encryption with an AWS Key Management Service (AWS KMS) key (SSE-KMS), or a customer-provided encryption key (SSE-C), Amazon S3 uses the corresponding KMS key, or a customer-provided key to encrypt the target object copy.

When copying an object, if you want to use a different type of encryption setting for the target object, you can request that Amazon S3 encrypt the target object with a KMS key, an Amazon S3 managed key, or a customer-provided key. If the encryption setting in your request is different from the default encryption configuration of the destination bucket, the encryption setting in your request takes precedence. If the source object for the copy is encrypted with SSE-C, you must provide the necessary encryption information in your request so that Amazon S3 can decrypt the object for copying. For more information, see [Protecting data with encryption](#).

Using checksums when copying objects

When copying objects, you can choose to use a different checksum algorithm for the object. Whether you choose to use the same algorithm or a new one, Amazon S3 calculates a new checksum value after the object is copied. Amazon S3 doesn't directly copy the value of the checksum. All copied objects without checksums and specified destination checksum algorithms automatically gain a CRC-64NVME checksum algorithm. For more information about how the checksum is calculated, see [Uploading and copying objects using multipart upload in Amazon S3](#).

Copying multiple objects in a single request

To copy more than one Amazon S3 object with a single request, you can also use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

The S3 Batch Operations feature tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, serverless experience. You can use S3 Batch Operations through the Amazon S3 console, AWS CLI, AWS SDKs, or REST API. For more information, see [the section called "Batch Operations basics"](#).

Copying objects to directory buckets

For information about copying an object to a directory bucket, see [Copying objects from or to a directory bucket](#). For information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

To copy an object

To copy an object, use the following methods.

Using the S3 console

Note

The restrictions and limitations when you copy an object with the console are as follows:

- You can copy an object if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to copy an object.
- For a list of additional permissions required to copy objects, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).
- The Copy action applies to all objects within the specified folders (prefixes). Objects added to these folders while the action is in progress might be affected.
- Cross-Region copying of objects encrypted with SSE-KMS is not supported by the Amazon S3 console. To copy objects encrypted with SSE-KMS across Regions, use the AWS CLI, AWS SDK, or the Amazon S3 REST API.
- Objects encrypted with customer-provided encryption keys (SSE-C) cannot be copied by using the S3 console. To copy objects encrypted with SSE-C, use the AWS CLI, AWS SDK, or the Amazon S3 REST API.
- Copied objects will not retain the Object Lock settings from the original objects.
- If the bucket you are copying objects from uses the bucket owner enforced setting for S3 Object Ownership, object ACLs will not be copied to the specified destination.
- If you want to copy objects to a bucket that uses the bucket owner enforced setting for S3 Object Ownership, make sure that the source bucket also uses the bucket owner enforced setting, or remove any object ACL grants to other AWS accounts and groups.

To copy an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the list of buckets, choose the name of the bucket that contains the objects that you want to copy.
4. Select the check box to the left of the names of the objects that you want to copy.
5. On the **Actions** menu, choose **Copy** from the list of options that appears.
6. Select the destination type and destination account. To specify the destination path, choose **Browse S3**, navigate to the destination, and select the check box to the left of the destination. Choose **Choose destination** in the lower-right corner.

Alternatively, enter the destination path.

7. If you do *not* have bucket versioning enabled, you will see a warning recommending you enable Bucket Versioning to help protect against unintentionally overwriting or deleting objects. If you want to keep all versions of objects in this bucket, select **Enable Bucket Versioning**. You can also view the default encryption and S3 Object Lock properties in **Destination details**.
8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Copy** in the bottom-right corner. Amazon S3 copies your objects to the destination.

Using the AWS SDKs

The examples in this section show how to copy objects up to 5 GB in a single operation. To copy objects larger than 5 GB, you must use a multipart upload. For more information, see [Copying an object using multipart upload](#).

Java

For examples of how to copy objects with the AWS SDK for Java, see [Copy an object from one bucket to another](#) in the *Amazon S3 API Reference*.

.NET

The following C# example uses the high-level SDK for .NET to copy objects that are as large as 5 GB in a single operation. For objects that are larger than 5 GB, use the multipart upload copy example described in [Copying an object using multipart upload](#).

This example makes a copy of an object that is a maximum of 5 GB. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

PHP

This topic guides you through using classes from version 3 of the AWS SDK for PHP to copy a single object and multiple objects within Amazon S3, from one bucket to another or within the same bucket.

For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

The following PHP example illustrates the use of the `copyObject()` method to copy a single object within Amazon S3. It also demonstrates how to make multiple copies of an object by using a batch of calls to `CopyObject` with the `getCommand()` method.

Copying objects

- 1 Create an instance of an Amazon S3 client by using the `Aws\S3\S3Client` class constructor.

- 2 To make multiple copies of an object, you run a batch of calls to the Amazon S3 client [getCommand\(\)](#) method, which is inherited from the [Aws\CommandInterface](#) class. You provide the `CopyObject` command as the first argument and an array containing the source bucket, source key name, target bucket, and target key name as the second argument.

```
require 'vendor/autoload.php';

use Aws\CommandPool;
use Aws\Exception\AwsException;
use Aws\ResultInterface;
use Aws\S3\S3Client;

$sourceBucket = '*** Your Source Bucket Name ***';
$sourceKeyname = '*** Your Source Object Key ***';
$targetBucket = '*** Your Target Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region' => 'us-east-1'
]);

// Copy an object.
$s3->copyObject([
    'Bucket' => $targetBucket,
    'Key' => "$sourceKeyname-copy",
    'CopySource' => "$sourceBucket/$sourceKeyname",
]);

// Perform a batch of CopyObject operations.
$batch = array();
for ($i = 1; $i <= 3; $i++) {
    $batch[] = $s3->getCommand('CopyObject', [
        'Bucket' => $targetBucket,
        'Key' => "{$targetKeyname}-$i",
        'CopySource' => "$sourceBucket/$sourceKeyname",
    ]);
}
try {
    $results = CommandPool::batch($s3, $batch);
    foreach ($results as $result) {
```

```
        if ($result instanceof ResultInterface) {
            // Result handling here
        }
        if ($result instanceof AwsException) {
            // AwsException handling here
        }
    }
} catch (Exception $e) {
    // General error handling here
}
```

Python

```
class ObjectWrapper:
    """Encapsulates S3 object actions."""

    def __init__(self, s3_object):
        """
        :param s3_object: A Boto3 Object resource. This is a high-level resource in
        Boto3
                           that wraps object actions in a class-like structure.
        """
        self.object = s3_object
        self.key = self.object.key
```

```
def copy(self, dest_object):
    """
    Copies the object to another bucket.

    :param dest_object: The destination object initialized with a bucket and
    key.
                           This is a Boto3 Object resource.
    """
    try:
        dest_object.copy_from(
            CopySource={"Bucket": self.object.bucket_name, "Key": self.object.key}
        )
        dest_object.wait_until_exists()
        logger.info(
            "Copied object from %s:%s to %s:%s.",
            self.object.bucket_name, self.object.key,
            dest_object.bucket_name, dest_object.key
        )
    except ClientError as e:
        logger.error("Failed to copy object: %s", e)
```

```
        self.object.bucket_name,
        self.object.key,
        dest_object.bucket_name,
        dest_object.key,
    )
except ClientError:
    logger.exception(
        "Couldn't copy object from %s/%s to %s/%s.",
        self.object.bucket_name,
        self.object.key,
        dest_object.bucket_name,
        dest_object.key,
    )
raise
```

Ruby

The following tasks guide you through using the Ruby classes to copy an object in Amazon S3 from one bucket to another or within the same bucket.

Copying objects

- 1 Use the Amazon S3 modularized gem for version 3 of the AWS SDK for Ruby, require aws-sdk-s3 , and provide your AWS credentials. For more information about how to provide your credentials, see [Making requests using AWS account or IAM user credentials](#) in the *Amazon S3 API Reference*.
- 2 Provide the request information, such as the source bucket name, source key name, destination bucket name, and destination key.

The following Ruby code example demonstrates the preceding tasks by using the #copy_object method to copy an object from one bucket to another.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectCopyWrapper
    attr_reader :source_object
```

```
# @param source_object [Aws::S3::Object] An existing Amazon S3 object. This is
used as the source object for
#                                         copy actions.

def initialize(source_object)
  @source_object = source_object
end

# Copy the source object to the specified target bucket and rename it with the
target key.
#
# @param target_bucket [Aws::S3::Bucket] An existing Amazon S3 bucket where the
object is copied.
# @param target_object_key [String] The key to give the copy of the object.
# @return [Aws::S3::Object, nil] The copied object when successful; otherwise,
nil.

def copy_object(target_bucket, target_object_key)
  @source_object.copy_to(bucket: target_bucket.name, key: target_object_key)
  target_bucket.object(target_object_key)
rescue Aws::Errors::ServiceError => e
  puts "Couldn't copy #{@source_object.key} to #{target_object_key}. Here's why:
#{e.message}"
end
end

# Example usage:
def run_demo
  source_bucket_name = "amzn-s3-demo-bucket1"
  source_key = "my-source-file.txt"
  target_bucket_name = "amzn-s3-demo-bucket2"
  target_key = "my-target-file.txt"

  source_bucket = Aws::S3::Bucket.new(source_bucket_name)
  wrapper = ObjectCopyWrapper.new(source_bucket.object(source_key))
  target_bucket = Aws::S3::Bucket.new(target_bucket_name)
  target_object = wrapper.copy_object(target_bucket, target_key)
  return unless target_object

  puts "Copied #{source_key} from #{source_bucket_name} to
#{target_object.bucket_name}:#{target_object.key}."
end

run_demo if $PROGRAM_NAME == __FILE__
```

Using the REST API

This example describes how to copy an object by using the Amazon S3 REST API. For more information about the REST API, see [CopyObject](#).

This example copies the `flotsam` object from the `amzn-s3-demo-bucket1` bucket to the `jetsam` object of the `amzn-s3-demo-bucket2` bucket, preserving its metadata.

```
PUT /jetsam HTTP/1.1
Host: amzn-s3-demo-bucket2.s3.amazonaws.com
x-amz-copy-source: /amzn-s3-demo-bucket1/flotsam
Authorization: AWS AKIAIOSFODNN7EXAMPLE:EnoSbxYByFA0UGLZUqJN5EUnLDg=
Date: Wed, 20 Feb 2008 22:12:21 +0000
```

The signature was generated from the following information.

```
PUT\r\n
\r\n

Wed, 20 Feb 2008 22:12:21 +0000\r\n

x-amz-copy-source:/amzn-s3-demo-bucket1/flotsam\r\n
/amzn-s3-demo-bucket2/jetsam
```

Amazon S3 returns the following response that specifies the ETag of the object and when it was last modified.

```
HTTP/1.1 200 OK

```

Using the AWS CLI

You can also use the AWS Command Line Interface (AWS CLI) to copy an S3 object. For more information, see [copy-object](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

To move an object

To move an object, use the following methods.

Using the S3 console

Note

- You can move an object if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to move an object.
- For a list of additional permissions required to move objects, see [the section called “Required permissions for S3 API operations”](#). For example policies that grant this permission, see [the section called “Identity-based policy examples”](#).
- Objects encrypted with customer-provided encryption keys (SSE-C) can't be moved by using the Amazon S3 console. To move objects encrypted with SSE-C, use the AWS CLI, AWS SDKs, or the Amazon S3 REST API.
- When moving folders, wait for the **Move** operation to finish before making additional changes in the folders.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.

To move an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**. Navigate to the Amazon S3 bucket or folder that contains the objects that you want to move.
3. Select the check box for the objects that you want to move.

4. On the **Actions** menu, choose **Move**.
5. To specify the destination path, choose **Browse S3**, navigate to the destination, and select the destination check box. Choose **Choose destination**.

Alternatively, enter the destination path.
6. If you do *not* have bucket versioning enabled, you will see a warning recommending you enable Bucket Versioning to help protect against unintentionally overwriting or deleting objects. If you want to keep all versions of objects in this bucket, select **Enable Bucket Versioning**. You can also view the default encryption and Object Lock properties in **Destination details**.
7. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
8. Choose **Move** in the bottom-right corner. Amazon S3 moves your objects to the destination.

Using the AWS CLI

You can also use the AWS Command Line Interface (AWS CLI) to move an S3 object. For more information, see [mv](#) in the *AWS CLI Command Reference*.

For information about the AWS CLI, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

To rename an object

To rename an object, use the following procedure.

Note

- You can rename an object if your object is less than 5 GB. To rename objects greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to copy your object with a new name and then delete the original object.
- For a list of additional permissions required to copy objects, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).

- Renaming an object creates a copy of the object with a new last-modified date, and then adds a delete marker to the original object.
- Bucket settings for default encryption are automatically applied to any specified object that's unencrypted.
- You can't use the Amazon S3 console to rename objects with customer-provided encryption keys (SSE-C). To rename objects encrypted with SSE-C, use the AWS CLI, AWS SDKs, or the Amazon S3 REST API to copy those objects with new names.
- If this bucket uses the bucket owner enforced setting for S3 Object Ownership, object access control lists (ACLs) won't be copied.

To rename an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the object that you want to rename.
3. Select the check box for the object that you want to rename.
4. On the **Actions** menu, choose **Rename object**.
5. In the **New object name** box, enter the new name for the object.
6. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
7. Choose **Save changes**. Amazon S3 renames your object.

Downloading objects

This section explains how to download objects from an Amazon S3 bucket. With Amazon S3, you can store objects in one or more buckets, and each single object can be up to 50 TB in size. Any Amazon S3 object that is not archived is accessible in real time. Archived objects, however, must be restored before they can be downloaded. For information about downloading archived objects, see [the section called "Downloading archived objects"](#).

You can download a single object by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. To download an object up to 5 TB from S3 without writing any code or running any commands, use the S3 console. For more information, see [the section called “Downloading an object”](#).

To download objects larger than 5 TB, use concurrent GetObject requests with either Range HTTP header to read specific byte ranges or partNumber to download specific part of an object. Single GET requests are limited to 5 TB, and you will receive a 405 – Method Not Allowed error for GET requests beyond 5 TB.

For large object downloads, use the S3 Transfer Manager in the Java v1/v2, Python, or AWS CLI SDKs. For the best performance, use the latest AWS Common Runtime (CRT) with these SDKs, which has been optimized for better resource utilization. CRT automatically scales the size of individual GETs to optimize throughput. You can improve overall transfer throughput by allocating more memory using memory limit parameters such as maxNativeMemoryLimitInBytes for Java SDK. You can opt out of this behavior by setting an explicit part size using request parameters such as multipart_chunksize for AWS CLI and minimumPartSizeInBytes for Java SDK in your download request.

To download multiple objects, use AWS CloudShell, the AWS CLI, or the AWS SDKs. For more information, see [the section called “Downloading multiple objects”](#).

If you need to download part of an object, you use extra parameters with the AWS CLI or REST API to specify only the bytes that you want to download. For more information, see [the section called “Downloading part of an object”](#).

If you need to download an object that you don't own, ask the object owner to generate a presigned URL that allows you to download the object. For more information, see [the section called “Downloading an object from another AWS account”](#).

When you download objects outside of the AWS network, data-transfer fees apply. Data transfer within the AWS network is free within the same AWS Region, but you will be charged for any GET requests. For more information about data-transfer costs and data-retrieval charges, see [Amazon S3 pricing](#).

Downloading an object

You can download an object by using the Amazon S3 console, AWS CLI, AWS SDKs, or REST API.

Using the S3 console

This section explains how to use the Amazon S3 console to download an object from an S3 bucket.

Note

- You can download only one object at a time.
- If you use the Amazon S3 console to download an object whose key name ends with a period (.), the period is removed from the key name of the downloaded object. To retain the period at the end of the name of the downloaded object, you must use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

To download an object from an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the buckets list, choose the name of the bucket that you want to download an object from.
4. You can download an object from an S3 bucket in any of the following ways:
 - Select the check box next to the object, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.
 - If you want to download a specific version of the object, turn on **Show versions** (located next to the search box). Select the check box next to the version of the object that you

want, and choose **Download**. If you want to download the object to a specific folder, on the **Actions** menu, choose **Download as**.

Using the AWS CLI

The following get-object example command shows how you can use the AWS CLI to download an object from Amazon S3. This command gets the object *folder/my_image* from the bucket *amzn-s3-demo-bucket1*. You must include an outfile, which is a file name for the downloaded object, such as *my_downloaded_image.jpg*.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --key folder/  
my_image my_downloaded_image.jpg
```

For more information and examples, see [get-object](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

For examples of how to download an object with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Using the REST API

You can use the REST API to retrieve objects from Amazon S3. For more information, see [GetObject](#) in the *Amazon Simple Storage Service API Reference*.

Downloading multiple objects

You can download multiple objects by using AWS CloudShell, the AWS CLI, or the AWS SDKs.

Using AWS CloudShell in the AWS Management Console

AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console.

For more information about AWS CloudShell, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Important

With AWS CloudShell, your home directory has storage up to 1GB per AWS Region. Therefore you cannot sync buckets with objects totaling over this amount. For more limitations, see [Service quotas and restrictions](#) in the *AWS CloudShell User Guide*.

To download objects by using AWS CloudShell

1. Sign in to the AWS Management Console and open the CloudShell console at <https://console.aws.amazon.com/cloudshell/>.
2. Run the following command to sync objects in your bucket to CloudShell. The following command syncs objects from the bucket named `amzn-s3-demo-bucket1` and creates a folder named `temp` in CloudShell. CloudShell syncs your objects to this folder. To use this command, replace the `user input placeholders` with your own information.

```
aws s3 sync s3://amzn-s3-demo-bucket1 ./temp
```

Note

The sync command is not compatible with directory buckets.

To perform pattern matching to either exclude or include particular objects, you can use the `--exclude "value"` and `--include "value"` parameters with the sync command.

3. Run the following command to zip your objects in the folder named `temp` to a file named `temp.zip`.

```
zip temp.zip -r temp/
```

4. Choose **Actions**, and then choose **Download file**.
5. Enter the file name `temp.zip` and then choose **Download**.
6. (Optional) Delete the `temp.zip` file and the objects that are synced to the `temp` folder in CloudShell. With AWS CloudShell, you have persistent storage of up to 1 GB for each AWS Region.

You can use the following example command to delete your .zip file and your folder. To use this example command, replace the *user input placeholders* with your own information.

```
rm temp.zip && rm -rf temp/
```

Using the AWS CLI

The following example shows how you can use the AWS CLI to download all of the files or objects under the specified directory or prefix. This command copies all objects from the bucket *amzn-s3-demo-bucket1* to your current directory. To use this example command, use your bucket name in place of *amzn-s3-demo-bucket1*.

```
aws s3 cp s3://amzn-s3-demo-bucket1 . --recursive
```

The following command downloads all of the objects under the prefix *logs* in the bucket *amzn-s3-demo-bucket1* to your current directory. It also uses the --exclude and --include parameters to copy only objects with the suffix *.log*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3 cp s3://amzn-s3-demo-bucket1/logs/ . --recursive --exclude "*" --include "*.log"
```

For more information and examples, see [cp](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

For examples of how to download all objects in an Amazon S3 bucket with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Downloading part of an object

You can download part of an object by using the AWS CLI or REST API. To do so, you use additional parameters to specify which part of an object that you want to download.

Using the AWS CLI

The following example command performs a GET request for a range of bytes in the object named *folder/my_data* in the bucket named *amzn-s3-demo-bucket1*. In the request, the byte range must be prefixed with `bytes=`. The partial object is downloaded to the output file named *my_data_range*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --key folder/my_data --range bytes=0-500 my_data_range
```

For more information and examples, see [get-object](#) in the *AWS CLI Command Reference*.

For more information about the HTTP Range header, see [RFC 9110](#) on the RFC Editor website.

 **Note**

Amazon S3 doesn't support retrieving multiple ranges of data in a single GET request.

Using the REST API

You can use the `partNumber` and `Range` parameters in the REST API to retrieve object parts from Amazon S3. For more information, see [GetObject](#) in the *Amazon Simple Storage Service API Reference*.

Downloading an object from another AWS account

You can use a presigned URL to grant others time-limited access to your objects without updating your bucket policy.

The presigned URL can be entered in a browser or used by a program to download an object. The credentials used by the URL are those of the AWS user who generated the URL. After the URL is created, anyone with the presigned URL can download the corresponding object until the URL expires.

Using a presigned URL in the S3 console

You can use the Amazon S3 console to generate a presigned URL for sharing an object in a general purpose bucket by following these steps. When using the console, the maximum expiration time for a presigned URL is 12 hours from the time of creation.

To generate a presigned URL by using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the object that you want a presigned URL for.
4. In the **Objects** list, select the object that you want to create a presigned URL for.
5. On the **Object actions** menu, choose **Share with a presigned URL**.
6. Specify how long you want the presigned URL to be valid.
7. Choose **Create presigned URL**.
8. When a confirmation message appears, the URL is automatically copied to your clipboard. You will see a button to copy the presigned URL if you need to copy it again.
9. To download the object, paste the URL into any browser, and the object will attempt to download.

For more information about presigned URLs and other methods for creating them, see [Download and upload objects with presigned URLs](#).

Downloading archived objects

To reduce your storage costs for infrequently accessed objects, you can *archive* those objects. When you archive an object, it is moved into low-cost storage, which means that you can't access it in real time. To download an archived object, you must first restore it.

You can restore archived objects in minutes or hours, depending on the storage class. You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the Amazon S3 REST API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI).

For instructions, see [Restoring an archived object](#). After you restore the archived object, you can download it.

Downloading objects based on metadata

You can add preconditions to download an object based on its metadata using a conditional read request. You can return an object based on its Entity tag (ETag) or last modified date. This can limit an S3 operation to objects updated since a specified date or only return a specific object version.

You can use conditional writes for [GetObject](#) or [HeadObject](#) requests.

For more information about conditional requests see, [Add preconditions to S3 operations with conditional requests](#).

Troubleshooting downloading objects

Insufficient permissions or incorrect bucket or AWS Identity and Access Management (IAM) user policies can cause errors when you're trying to download objects from Amazon S3. These problems can often cause Access Denied (403 Forbidden) errors, where Amazon S3 is unable to allow access to a resource.

For common causes of Access Denied (403 Forbidden) errors, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#).

If you're getting a 404 NoSuchKey error when trying to access an object, see [How can I troubleshoot the 404 NoSuchKey error from Amazon S3?](#) in the AWS re:Post Knowledge Center.

Checking object integrity in Amazon S3

Amazon S3 provides a range of data protection capabilities throughout an object's storage lifecycle. With Amazon S3, you can use checksum values to verify the integrity of the data that you upload or download. In addition, you can request that another checksum value be calculated for any object that you store in S3.

When uploading, copying, or managing your data, you can choose from several supported checksum algorithms:

- CRC-64/NVME (CRC64NVME)

 **Note**

The CRC64NVME checksum algorithm is the default checksum algorithm used for checksum calculations.

- CRC-32 (CRC32)
- CRC-32C (CRC32C)
- SHA-1 (SHA1)
- SHA-256 (SHA256)

- MD5 (MD5)

 **Note**

For multipart uploads, the **Compute checksum** operation provides full object checksum values using MD5, which isn't possible during uploads. For single part uploads, the `content-MD5` header is only available using the S3 ETag for objects and must use SSE-S3 encryption.

When you upload an object to S3, you can specify the usage of any of these checksum algorithms. For uploads, all AWS-owned clients calculate a checksum of the object and send it with the upload request. S3 then independently calculates a checksum value of the object on the server-side, and validates it with the provided value before storing the object and checksum value. You can also provide precalculated values for these checksum algorithms when you perform a single part upload or multipart upload (using the full object checksum type for multipart uploads). To use precalculated values with multiple objects, use the AWS CLI or AWS SDKs.

Alternatively, if you want to verify datasets in S3 without the need to restore or download data, you can use the **Compute checksum** operation with S3 Batch Operations. The **Compute checksum** operation allows you to efficiently verify billions of objects in one job request. When the **Compute checksum** operation is performed, S3 calculates the checksum values for a list of objects, at rest. At the end of the job request, you'll receive an automatically generated integrity report (also known as a completion report) that you can use to confirm that your data set remains intact.

Checking object integrity for data uploads in Amazon S3

Amazon S3 uses checksum values to verify data integrity during upload and download operations. When you upload data, AWS SDK and the AWS Management Console use your chosen checksum algorithm to compute a checksum value before data transmission. S3 then independently calculates a checksum of your data and validates it against the provided checksum value. Objects are accepted only after confirming data integrity was maintained during transit. S3 stores both the checksum value as object metadata and the object itself.

To verify object integrity, you can request the checksum value during downloads. This validation works consistently across encryption modes, object sizes, storage classes, and both single part and multipart uploads. To change the checksum algorithm for an upload, you can copy an individual object or use batch copy for multiple objects.

For single part uploads, you can provide checksum values as headers. You can either provide a pre-calculated value or let the AWS SDK calculate one during upload. If the checksum value calculated by S3 matches your provided value, the request is accepted. If the values don't match, the request is rejected.

For multipart uploads, AWS SDKs can automatically create trailing checksums for chunked uploads. When you use a trailing checksum, Amazon S3 generates checksum values for every part using your specified algorithm and appends the checksum value to the end of the chunked upload request. S3 performs the verification and upload in a single pass, improving efficiency. For more information, see [Using trailing checksums](#).

Using supported checksum algorithms

With Amazon S3, you can choose a checksum algorithm to calculate the checksum values during uploads. The specified checksum algorithm is then stored with your object and can be used to validate data integrity during downloads. You can choose one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) checksum algorithms to calculate the checksum value:

- CRC-64/NVME (CRC64NVME)
- CRC-32 (CRC32)
- CRC-32C (CRC32C)
- SHA-1 (SHA1)
- SHA-256 (SHA256)
- MD5 (MD5)

 **Note**

The content-MD5 header is only available using the S3 ETag for objects uploaded in a single part upload (PUT operation) that uses the SSE-S3 encryption.

Additionally, you can provide a checksum with each request using the Content-MD5 header.

When you [upload an object](#), you specify the algorithm that you want to use:

- **When you use the AWS Management Console**, choose the checksum algorithm that you want to use. You can optionally specify the checksum value of the object. When Amazon S3 receives the object, it calculates the checksum by using the algorithm that you specified. If the two checksum values don't match, Amazon S3 generates an error.
- **When you use an SDK**, be aware of the following:
 - Set the `ChecksumAlgorithm` parameter to the algorithm that you want Amazon S3 to use. If you already have a precalculated checksum, you pass the checksum value to the AWS SDK, and the SDK includes the value in the request. If you don't pass a checksum value or don't specify a checksum algorithm, the SDK automatically calculates a checksum value for you and includes it with the request to provide integrity protections. If the individual checksum value doesn't match the set value of the checksum algorithm, Amazon S3 fails the request with a `BadDigest` error.
 - If you're using an upgraded AWS SDK, the SDK chooses a checksum algorithm for you. However, you can override this checksum algorithm.
 - If you don't specify a checksum algorithm and the SDK also doesn't calculate a checksum for you, then S3 automatically chooses the CRC-64/NVME (CRC64NVME) checksum algorithm.
- **When you use the REST API**, don't use the `x-amz-sdk-checksum-algorithm` parameter. Instead, use one of the algorithm-specific headers (for example, `x-amz-checksum-crc32`).

To apply any of these checksum values to objects that are already uploaded to Amazon S3, you can copy the object and specify whether you want to use the existing checksum algorithm or a new one. If you don't specify an algorithm, S3 uses the existing algorithm. If the source object doesn't have a specified checksum algorithm or checksum value, Amazon S3 uses the CRC-64/NVME algorithm to calculate the checksum value for the destination object. You can also specify a checksum algorithm when copying objects using [S3 Batch Operations](#).

 **Important**

If you use a multipart upload with **Checksums** for composite (or part-level) checksums, the multipart upload part numbers must be consecutive and begin with 1. If you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates an `HTTP 500 Internal Server` error.

Full object and composite checksum types

In Amazon S3, there are two types of supported checksums:

- **Full object checksums:** A full object checksum is calculated based on all of the content of a multipart upload, covering all data from the first byte of the first part to the last byte of the last part. Be aware that if you're using the AWS Management Console to upload objects that are smaller than 16 MB, only the full object checksum type is supported.

 **Note**

All PUT requests require a full object checksum type. You must specify a full object checksum type if you're uploading your object via PUT request.

- **Composite checksums:** A composite checksum is calculated based on the individual checksums of each part in a multipart upload. Instead of computing a checksum based on all of the data content, this approach aggregates the part-level checksums (from the first part to the last) to produce a single, combined checksum for the complete object. If you're using a multipart upload to upload your object, then you must specify the composite checksum type.

 **Note**

When an object is uploaded as a multipart upload, the entity tag (ETag) for the object is not an MD5 digest of the entire object. Instead, Amazon S3 calculates the MD5 digest of each individual part as it is uploaded. The MD5 digests are used to determine the ETag for the final object. Amazon S3 concatenates the bytes for the MD5 digests together and then calculates the MD5 digest of these concatenated values. During the final ETag creation step, Amazon S3 adds a dash with the total number of parts to the end.

Amazon S3 supports the following full object and composite checksum algorithm types:

- CRC-64/NVME (CRC64NVME): Supports the full object checksum type only.
- CRC-32 (CRC32): Supports both full object and composite checksum types.
- CRC-32C (CRC32C): Supports both full object and composite checksum types.
- SHA-1 (SHA1): Supports both full object and composite checksum types.
- SHA-256 (SHA256): Supports both full object and composite checksum types.

- MD5 (MD5): Supports both full object and composite checksum types.

Single part uploads

Checksums of objects that are uploaded in a single part (using [PutObject](#)) are treated as full object checksums. When you upload an object in the Amazon S3 console, you can choose the checksum algorithm that you want S3 to use and also (optionally) provide a precomputed value. Amazon S3 then validates the precomputed checksum value before storing the object and its checksum value. You can verify an object's data integrity when you request the checksum value during object downloads.

Multipart uploads

When you upload the object in multiple parts using the [MultipartUpload](#) API, you can specify the checksum algorithm that you want Amazon S3 to use and the checksum type (full object or composite).

The following table indicates which checksum algorithm type is supported for each checksum algorithm in a multipart upload:

Checksum algorithm	Full object	Composite
CRC-64/NVME (CRC64NVME)	Yes	No
CRC-32 (CRC32)	Yes	Yes
CRC-32C (CRC32C)	Yes	Yes
SHA-1 (SHA1)	No	Yes
SHA-256 (SHA256)	No	Yes

Using full object checksums for multipart upload

When creating or performing a multipart upload, you can use full object checksums for validation on upload. This means that you can provide the checksum algorithm for the [MultipartUpload](#) API, simplifying your integrity validation tooling because you no longer need to track part boundaries for uploaded objects. You can provide the checksum of the whole object in the [CompleteMultipartUpload](#) request, along with the object size.

When you provide a full object checksum during a multipart upload, the AWS SDK passes the checksum to Amazon S3, and S3 validates the object integrity server-side, comparing it to the received value. Then, Amazon S3 stores the object if the values match. If the two values don't match, S3 fails the request with a `BadDigest` error. The checksum of your object is also stored in object metadata that you use later to validate an object's data integrity.

For full object checksums, you can use CRC-64/NVME (CRC64NVME), CRC-32 (CRC32), or CRC-32C (CRC32C) checksum algorithms in S3. Full object checksums in multipart uploads are only available for CRC-based checksums because they can linearize into a full object checksum. This linearization allows Amazon S3 to parallelize your requests for improved performance. In particular, S3 can compute the checksum of the whole object from the part-level checksums. This type of validation isn't available for other algorithms, such as SHA and MD5. Because S3 has default integrity protections, if objects are uploaded without a checksum, S3 automatically attaches the recommended full object CRC-64/NVME (CRC64NVME) checksum algorithm to the object.

Note

To initiate the multipart upload, you can specify the checksum algorithm and the full object checksum type. After you specify the checksum algorithm and the full object checksum type, you can provide the full object checksum value for the multipart upload.

Using part-level checksums for multipart upload

When objects are uploaded to Amazon S3, they can be uploaded as a single object or uploaded in parts with the multipart upload process. You can choose a **Checksum** type for your multipart upload. For multipart upload part-level checksums (or composite checksums), Amazon S3 calculates the checksum for each individual part by using the specified checksum algorithm. You can use [UploadPart](#) to provide the checksum values for each part. If the object that you try to upload in the Amazon S3 console is set to use the CRC-64/NVME (CRC64NVME) checksum algorithm and exceeds 16 MB, it is automatically designated as a full object checksum.

Amazon S3 then uses the stored part-level checksum values to confirm that each part is uploaded correctly. When each part's checksum (for the whole object) is provided, S3 uses the stored checksum values of each part to calculate the full object checksum internally, comparing it with the provided checksum value. This minimizes compute costs since S3 can compute a checksum of the whole object using the checksum of the parts. For more information about multipart uploads,

see [Uploading and copying objects using multipart upload in Amazon S3](#) and [Using full object checksums for multipart upload](#).

When the object is completely uploaded, you can use the final calculated checksum to verify the data integrity of the object.

When uploading a part of the multipart upload, be aware of the following:

- To retrieve information about the object, including how many parts make up the entire object, you can use the [GetObjectAttributes](#) operation. With additional checksums, you can also recover information for each individual part that includes the part's checksum value.
- For completed uploads, you can get an individual part's checksum by using the [GetObject](#) or [HeadObject](#) operations and specifying a part number or byte range that aligns with a single part. If you want to retrieve the checksum values for individual parts of multipart uploads that are still in progress, you can use [ListParts](#).
- Because of how Amazon S3 calculates the checksum for multipart objects, the checksum value for the object might change if you copy it. If you're using an SDK or the REST API and you call [CopyObject](#), Amazon S3 copies any object up to the size limitations of the CopyObject API operation. Amazon S3 does this copy as a single action, regardless of whether the object was uploaded in a single request or as part of a multipart upload. With a copy command, the checksum of the object is a direct checksum of the full object. If the object was originally uploaded using a multipart upload, the checksum value changes even though the data doesn't.
- Objects that are larger than the size limitations of the CopyObject API operation must use [multipart upload copy commands](#).
- When you perform some operations using the AWS Management Console, Amazon S3 uses a multipart upload if the object is greater than 16 MB in size.

Checksum methods

After uploading objects, you can get the checksum value and compare it to a precomputed or previously stored checksum value of the same checksum algorithm type. The following examples show you which checksum calculation methods you can use to verify data integrity.

Using the S3 console

To learn more about using the console and specifying checksum algorithms to use when uploading objects, see [Uploading objects](#) and [Tutorial: Checking the integrity of data in Amazon S3 with additional checksums](#).

Using the AWS SDKs

The following example shows how you can use the AWS SDKs to upload a large file with multipart upload, download a large file, and validate a multipart upload file, all by using SHA-256 for file validation.

Java

Example Example: Uploading, downloading, and verifying a large file with SHA-256

Using the REST API

You can send REST requests to upload an object with a checksum value to verify the integrity of the data with [PutObject](#). You can also retrieve the checksum value for objects using [GetObject](#) or [HeadObject](#).

Using the AWS CLI

You can send a PUT request to upload an object of up to 5 GB in a single operation. For more information, see the [PutObject](#) in the *AWS CLI Command Reference*. You can also use [get-object](#) and [head-object](#) to retrieve the checksum of an already-uploaded object to verify the integrity of the data.

For information, see [Amazon S3 CLI FAQ](#) in the *AWS Command Line Interface User Guide*.

Using Content-MD5 when uploading objects

Another way to verify the integrity of your object after uploading is to provide an MD5 digest of the object when you upload it. If you calculate the MD5 digest for your object, you can provide the digest with the PUT command by using the Content-MD5 header.

After uploading the object, Amazon S3 calculates the MD5 digest of the object and compares it to the value that you provided. The request succeeds only if the two digests match.

Supplying an MD5 digest isn't required, but you can use it to verify the integrity of the object as part of the upload process.

Using Content-MD5 and the ETag to verify uploaded objects

The entity tag (ETag) for an object represents a specific version of that object. Keep in mind that the ETag only reflects changes to the content of an object, not changes to its metadata. If only the metadata of an object changes, the ETag remains the same.

Depending on the object, the ETag of the object might be an MD5 digest of the object data:

- If an object is created by the PutObject, PostObject, or CopyObject operation, or through the AWS Management Console, and that object is also plaintext or encrypted by server-side encryption with Amazon S3 managed keys (SSE-S3), that object has an ETag that is an MD5 digest of its object data.
- If an object is created by the PutObject, PostObject, or CopyObject operation, or through the AWS Management Console, and that object is encrypted by server-side encryption with customer-provided keys (SSE-C) or server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), that object has an ETag that is not an MD5 digest of its object data.
- If an object is created by either the multipart upload process or the UploadPartCopy operation, the object's ETag is not an MD5 digest, regardless of the method of encryption. If an object is larger than 16 MB, the AWS Management Console uploads or copies that object as a multipart upload, and therefore the ETag isn't an MD5 digest.

For objects where the ETag is the Content-MD5 digest of the object, you can compare the ETag value of the object with a calculated or previously stored Content-MD5 digest.

Using trailing checksums

When uploading large objects to Amazon S3, you can either provide a precalculated checksum for the object or use an AWS SDK to automatically create trailing checksums for chunked uploads, on your behalf. If you use a trailing checksum, Amazon S3 automatically generates the checksum value by using your specified algorithm to validate the integrity of the object in chunked uploads, when you upload an object.

To create a trailing checksum when using an AWS SDK, populate the ChecksumAlgorithm parameter with your preferred algorithm. The SDK uses that algorithm to calculate the checksum value for your object (or object parts) and automatically appends it to the end of your chunked

upload request. This behavior saves you time because Amazon S3 performs both the verification and upload of your data in a single pass.

Important

If you're using S3 Object Lambda, all requests to S3 Object Lambda are signed using `s3-object-lambda` instead of `s3`. This behavior affects the signature of trailing checksum values. For more information about S3 Object Lambda, see [Transforming objects with S3 Object Lambda](#).

Trailing checksum headers

To make a chunked content encoding request, Amazon S3 requires client servers to include several headers to correctly parse the request. Client servers must include the following headers:

- **`x-amz-decoded-content-length`:** This header indicates the plaintext size of the actual data that is being uploaded to Amazon S3 with the request.
- **`x-amz-content-sha256`:** This header indicates the type of chunked upload that is included in the request. For chunked uploads with trailing checksums, the header value is `STREAMING-UNSIGNED-PAYOUTLOAD-TRAILER` for requests that don't use payload signing and `STREAMING-AWS4-HMAC-SHA256-PAYOUTLOAD-TRAILER` for requests that use SigV4 payload signing. (For more information about implementing signed payloads, see [Signature calculations for the authorization header: Transferring a payload in multiple chunks](#).)
- **`x-amz-trailer`:** This header indicates the name of the trailing header in the request. If trailing checksums exist (where AWS SDKs append checksums to the encoded request bodies), the `x-amz-trailer` header value includes the `x-amz-checksum-` prefix and ends with the algorithm name. The following `x-amz-trailer` values are currently supported:
 - `x-amz-checksum-crc32`
 - `x-amz-checksum-crc32c`
 - `x-amz-checksum-crc64nvme`
 - `x-amz-checksum-sha1`
 - `x-amz-checksum-sha256`

Note

You can also include the Content-Encoding header, with the chunked value, in your request. While this header isn't required, including this header can minimize HTTP proxy issues when transmitting encoded data. If another Content-Encoding header (such as gzip) exists in the request, the Content-Encoding header includes the chunked value in a comma-separated list of encodings. For example, Content-Encoding: aws-chunked, gzip.

Chunked parts

When you upload an object to Amazon S3 using chunked encoding, the upload request includes the following types of chunks (formatted in the listed order):

- **Object body chunks:** There can be one, multiple, or zero body chunks associated with a chunked upload request.
- **Completion chunks:** There can be one, multiple, or zero body chunks associated with a chunked upload request.
- **Trailing chunks:** The trailing checksum is listed after the completion chunk. Only one trailing chunk is allowed.

Note

Every chunked upload must end with a final CRLF (such as `\r\n`) to indicate the end of the request.

For examples of chunked formatting, see [Examples: Chunked uploads with trailing checksums](#).

Object body chunks

Object body chunks are the chunks that contain the actual object data that is being uploaded to S3. These chunks have consistent size and format constraints.

Object body chunk size

These chunks must contain at least 8,192 bytes (or 8 KiB) of object data, except for the final body chunk, which can be smaller. There is no explicit maximum chunk size but you can expect all chunks

to be smaller than the 5 GB maximum upload size. Chunk sizes can vary from one chunk to the next based on your client server implementation.

Object body chunk format

Object body chunks begin with the hexadecimal encoding of the number of bytes in the object body chunk, followed by a CRLF (Carriage Return Line Feed), the object bytes for that chunk, and another CRLF.

For example:

```
hex-encoding-of-object-bytes-in-chunk\r\n
chunk-object-bytes\r\n
```

However, when the chunk is signed, the object body chunk follows a different format, where the signature is appended to the chunk size with a semicolon delimiter. For example:

```
hex-encoding-of-object-bytes-in-chunk;chunk-signature\r\n
chunk-object-bytes\r\n
```

For more information about chunk signing, see [Signature calculations for the Authorization Header: Transferring a payload in multiple chunks \(AWS Signature Version 4\)](#). For more information about chunk formatting, see [Chunked transfer encoding](#) on the *RFC Editor* website.

Completion chunks

Completion chunks are required to be the final object body chunk of every chunked upload. A completion chunk's format is similar to a body chunk, but always contains zero bytes of object data. (The zero bytes of object data indicate that all of the data has been uploaded.) Chunked uploads must include a completion chunk as its final object body chunk, following a format like this:

```
0\r\n
```

However, if the content encoding request uses payload signing, it follows this format instead:

```
0;chunk-signature\r\n
```

Trailer chunks

Trailer chunks hold the calculated checksum for all S3 upload requests. Trailer chunks include two fields: one header name field and one header value field. The header name field for an upload request must match the value passed into the `x-amz-trailer` request header. For example, if a request contains `x-amz-trailer: x-amz-checksum-crc32` and the trailer chunk has the header name `x-amz-checksum-sha1`, the request fails. The value field in the trailer chunk includes a base64 encoding of the big-endian checksum value for that object. (The big-endian ordering stores the most significant byte of data at the lowest memory address, and the least significant byte at the largest memory address). The algorithm used to calculate this checksum is the same as the suffix for the header name (for example, `crc32`).

Trailer chunk format

Trailer chunks use the following format for unsigned payload requests:

```
x-amz-checksum-lowercase-checksum-algorithm-name:base64-checksum-value\n\r\n\r\n
```

For requests with [SigV4 signed payloads](#), the trailer chunk includes a trailer signature after the trailer chunk.

```
trailer-checksum\n\r\ntrailer-signature\r\n
```

You can also add the CRLF directly to the end of the base64 checksum value. For example:

```
x-amz-checksum-lowercase-checksum-algorithm-name:base64-checksum-value\r\n\r\n\r\n
```

Examples: Chunked uploads with trailing checksums

Amazon S3 supports chunked uploads that use `aws-chunked` content encoding for `PutObject` and `UploadPart` requests with trailing checksums.

Example 1 – Unsigned chunked PutObject request with a trailing CRC-32 checksum

The following is an example of a chunked `PutObject` request with a trailing CRC-32 checksum. In this example, the client uploads a 17 KB object in three unsigned chunks and appends a trailing CRC-32 checksum chunk by using the `x-amz-checksum-crc32` header.

```
PUT /Key+ HTTP/1.1
```

```
Host: amzn-s3-demo-bucket
Content-Encoding: aws-chunked
x-amz-decoded-content-length: 17408
x-amz-content-sha256: STREAMING-UNSIGNED-PAYLOAD-TRAILER
x-amz-trailer: x-amz-checksum-crc32

2000\r\n                                // Object body chunk 1 (8192 bytes)
object-bytes\r\n
2000\r\n                                // Object body chunk 2 (8192 bytes)
object-bytes\r\n
400\r\n                                // Object body chunk 3 (1024 bytes)
object-bytes\r\n
0\r\n                                // Completion chunk
x-amz-checksum-crc32:YABb/g==\r\n                                // Trailer chunk (note optional \n
character)
\r\n                                // CRLF
```

Here's an example response:

```
HTTP/1.1 200
ETag: ETag
x-amz-checksum-crc32: YABb/g==
```

Note

The usage of the linefeed \n at the end of the checksum value might vary across clients.

Example 2 – SigV4-signed chunked PutObject request with a trailing CRC-32 (CRC32) checksum

The following is an example of a chunked PutObject request with a trailing CRC-32 checksum. This request uses SigV4 payload signing. In this example, the client uploads a 17 KB object in three signed chunks. In addition to the object body chunks, the completion chunk and trailer chunk are also signed.

```
PUT /Key+ HTTP/1.1
Host: amzn-s3-demo-bucket.s3.amazonaws.com
Content-Encoding: aws-chunked
x-amz-decoded-content-length: 17408
x-amz-content-sha256: STREAMING-AWS4-HMAC-SHA256-PAYLOAD-TRAILER
```

```
x-amz-trailer: x-amz-checksum-crc32

authorization-code                                // SigV4 headers authorization

2000;chunk-signature=signature-value...\\r\\n    // Object body chunk 1 (8192 bytes)
object-bytes\\r\\n
2000;chunk-signature\\r\\n                      // Object body chunk 2 (8192 bytes)
object-bytes\\r\\n
400;chunk-signature\\r\\n                      // Object body chunk 3 (1024 bytes)
object-bytes\\r\\n
0;chunk-signature\\r\\n                          // Completion chunk
x-amz-checksum-crc32:YABb/g==\\r\\n\\r\\n        // Trailer chunk (note optional \\n
      character)
trailer-signature\\r\\n
\\r\\n                                              // CRLF
```

Here's an example response:

```
HTTP/1.1 200
ETag: ETag
x-amz-checksum-crc32: YABb/g==
```

Checking object integrity for data at rest in Amazon S3

If you need to verify the content of datasets stored in Amazon S3, the S3 Batch Operations [Compute checksum](#) operation calculates both full object or composite checksums for objects at rest. The **Compute checksum** operation uses Batch Operations to asynchronously calculate the checksum values for a group of objects and automatically generates a consolidated integrity report, without creating new copies of your data, or restoring or downloading any data.

With the **Compute checksum** operation, you can efficiently verify billions of objects with a single job request. For each **Compute checksum** job request, S3 calculates the checksum values, and includes it in an automatically generated integrity report (also known as a completion report). You can then use the completion report to validate the integrity of your dataset.

The **Compute checksum** operation works with any object stored in S3, regardless of storage class or object size. Whether you need to verify your objects as a data preservation best practice, or meet compliance requirements, the **Compute checksum** operation reduces the cost, time, and effort required for data validation by performing checksum calculations at rest. For information about **Compute checksum** pricing, see the [Management and insights](#) tab on [Amazon S3 pricing](#).

Then, you can use the output of the generated completion report to compare against the checksum values that you've stored in your databases to verify that your datasets remain intact over time. This approach helps you maintain end-to-end data integrity for business and compliance needs. For example, you can use the **Compute checksum** operation to submit a list of stored objects in S3 Glacier storage classes for annual security audits. Additionally, the range of supported checksum algorithms allow you to maintain continuity with the algorithms that are used in your applications.

Using supported checksum algorithms

For data at rest, you can calculate checksums, using any of the supported checksum algorithms:

- CRC-64/NVME (CRC64NVME): Supports the full object checksum type only.
- CRC-32 (CRC32): Supports both full object and composite checksum types.
- CRC-32C (CRC32C): Supports both full object and composite checksum types.
- SHA-1 (SHA1): Supports both full object and composite checksum types.
- SHA-256 (SHA256): Supports both full object and composite checksum types.
- MD5 (MD5): Supports both full object and composite checksum types.

Using Compute checksum

For objects stored in Amazon S3, you can use the **Compute checksum** operation with S3 Batch Operations to check the content of stored data at rest. You can [create a Compute checksum Batch Operations job](#) by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), REST API, or AWS SDK. When the **Compute checksum** job finishes, you receive a completion report. For more information about how to use the completion report, see [Tracking job status and completion reports](#).

Before creating your **Compute checksum** job, you must create an S3 Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. You'll need to grant permissions to read the manifest file and to write a completion report to the S3 bucket. For more information, see [Compute checksums](#).

Using the S3 console

To use the Compute checksum operation

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create your job.

 **Note**

For copy operations, you must create the job in the same Region as the destination bucket. For all other operations, you must create the job in the same Region as the objects in the manifest.

3. Choose **Batch Operations** on the left navigation pane of the Amazon S3 console.
4. Choose **Create job**.
5. View the AWS Region where you want to create your job.

 **Note**

For copy operations, you must create the job in the same Region as the destination bucket. For all other operations, you must create the job in the same Region as the objects in the manifest.

6. Under **Manifest format**, choose the type of manifest object to use.
 - If you choose **S3 inventory report (manifest.json)**, enter the path to the manifest.json object, and (optionally) the **Manifest object version ID** if you want to use a specific object version. Alternatively, you can choose **Browse S3** and choose the manifest JSON file, which auto populates all the manifest object field entries.
 - If you choose **CSV**, choose the Manifest location type, Then, either enter the path to a CSV-formatted manifest object or choose **Browse S3** to select a manifest object. The manifest object must follow the format described in the console. If you want to use a specific version of the manifest object, then you can also specify the object version ID.
 - If you choose **Create manifest using S3 Replication configuration**, a list of objects will be generated using the replication configuration and optionally saved to the destination you

choose. When using a replication configuration to generate the manifest, the only operation that will be available is **Replicate**.

7. Choose **Next**.
8. Under **Operation**, choose the **Compute checksum** operation to calculate the checksums on all objects listed in the manifest. Choose the **Checksum type** and **Checksum function** for your job. Then, choose **Next**.
9. Fill out the information for **Configure additional options**, and then choose **Next**.
10. On the **Configure additional options** page, fill out the information for your **Compute checksum** job.

 **Note**

Under **Completion report**, make sure to confirm the acknowledgement statement. This acknowledgement statement confirms that you understand that the completion report contains checksum values, which are used to verify the integrity of data stored in Amazon S3. Therefore, the completion report should be shared with caution. Also, be aware that if you're creating a Compute checksum request and you specify an external account owner's bucket location to store your completion report, make sure to specify the AWS account ID of the external bucket owner.

11. Choose **Next**.
12. On the **Review** page, review and confirm your settings.
13. (Optional) If you need to make changes, choose **Previous** to go back to the previous page, or choose **Edit** to update a specific step.
14. After you've confirmed your changes, choose **Create job**.

To list and monitor the progress of all Compute checksum requests

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. On the **Batch Operations** page, you can review job details such as the job priority, job completion rate, and total objects.
4. If you want to manage or clone a specific **Compute checksum** job, click on the **Job ID** to review additional job information.

5. On the specific **Compute checksum** job page, review the job details.

Each batch operations job progresses through different [job statuses](#). You can also [enable AWS CloudTrail events](#) in the S3 console to receive alerts on any job state changes. For active jobs, you can review the running job and completion rate on the [Job details](#) page.

Example Example: Creating a Compute checksum job

The following example shows you how to create a **Compute checksum** job (as part of a **Create job** request), and how to specify a manifest:

```
// Required parameters
String accountId = "111122223333";
String roleArn = "arn:aws:iam::111122223333:role/BatchOperations";
String manifestArn = "arn:aws:s3:::my_manifests/manifest.csv";
String manifestEtag = "60e460c9d1046e73f7dde5043ac3ae85";
String reportBucketArn = "arn:aws:s3:::amzn-s3-demo-completion-report-bucket";
String reportExpectedBucketOwner = "111122223333";
String reportPrefix = "demo-report";

// Job Operation
S3ComputeObjectChecksumOperation s3ComputeObjectChecksum =
    S3ComputeObjectChecksumOperation.builder()
        .checksumAlgorithm(ComputeObjectChecksumAlgorithm.CRC64)
        .checksumType(ComputeObjectChecksumType.COMPOSITE)
        .build();

JobOperation operation = JobOperation.builder()
    .s3ComputeObjectChecksum(s3ComputeObjectChecksum)
    .build();

// Job Manifest
JobManifestLocation location = JobManifestLocation.builder()
    .eTag(manifestEtag)
    .objectArn(manifestArn)
    .build();

JobManifestSpec spec = JobManifestSpec.builder()
    .format(JobManifestFormat.S3_BATCH_OPERATIONS_CSV_20180820)
```

```
.fields(Arrays.asList(JobManifestFieldName.BUCKET, JobManifestFieldName.KEY))
.build();

JobManifest manifest = JobManifest.builder()
.location(location)
.spec(spec)
.build();

// Completion Report
JobReport report = JobReport.builder()
.bucket(reportBucketArn)
.enabled(true) // Must be true
.expectedBucketOwner(reportExpectedBucketOwner)
.format(JobReportFormat.REPORT_CSV_20180820)
.prefix(reportPrefix)
.reportScope(JobReportScope.ALL_TASKS)
.build();

// Create Job Request
CreateJobRequest request = CreateJobRequest.builder()
.accountId(accountId)
.confirmationRequired(false)
.manifest(manifest)
.operation(operation)
.priority(10)
.report(report)
.roleArn(roleArn);

// Create the client
S3ControlClient client = S3ControlClient.builder()
.credentialsProvider(new ProfileCredentialsProvider())
.region(Region.US_EAST_1)
.build();

// Send the request
try {
    CreateJobResponse response = client.createJob(request);
    System.out.println(response);
} catch (AwsServiceException e) {
    System.out.println("AwsServiceException: " + e.getMessage());
    throw new RuntimeException(e);
} catch (SdkClientException e) {
    System.out.println("SdkClientException: " + e.getMessage());
    throw new RuntimeException(e);
}
```

```
}
```

Example Example: Viewing Compute checksum job details

The following example shows how you can specify a job ID to view the job details (such as the job completion rate) for a **Compute checksum** job request:

```
DescribeJobRequest request = DescribeJobRequest.builder()
    .accountId("1234567890")
    .jobId("a16217a1-e082-48e5-b04f-31fac3a66b13")
    .build();
```

Using the AWS CLI

You can use the [create-job](#) command to create a new batch operations job, and to provide the list of objects. Then, specify the checksum algorithm and checksum type, and the destination bucket where you want to save the **Compute checksum** report. The following example creates an S3 Batch Operations **Compute checksum** job by using an S3 generated manifest for the AWS account **111122223333**.

To use this command, replace the *user input placeholders* with your own information:

```
aws s3control create-job \

```

After you submit the **Compute checksum** job, you receive the job ID as a response and it appears on the S3 Batch Operations list page. Amazon S3 processes the list of objects and calculates checksums for each object. After the job finishes, S3 provides a consolidated **Compute checksum** report at the specified destination.

To monitor the progress of your **Compute checksum** job, use the [describe-job](#) command. This command checks the status of the specified batch operations job. To use this command, replace the *user input placeholders* with your own information.

For example:

```
aws s3control describe-job --account-id 111122223333 --job-id 1234567890abcdef0
```

To [obtain a list](#) of all **Active** and **Complete** batch operations jobs, see [Listing jobs](#) or [list-jobs](#) in the [AWS CLI Command Reference](#).

Using the REST API

You can send REST requests to verify object integrity with **Compute checksum** using [CreateJob](#).

You can monitor the progress of **Compute checksum** requests by sending REST requests to the [DescribeJob](#) API operation. Each batch operations job progresses through the following statuses:

- **NEW**
- **PREPARING**
- **READY**
- **ACTIVE**
- **PAUSING**
- **PAUSED**
- **COMPLETE**
- **CANCELLING**
- **FAILED**

The API response notifies you of the current job state.

Deleting Amazon S3 objects

You can delete one or more objects directly from Amazon S3 using the Amazon S3 console, AWS SDKs, AWS Command Line Interface (AWS CLI), or REST API. For example, if you're collecting log files, it's a good idea to delete them when they're no longer needed. You can [set up an S3 Lifecycle rule](#) to automatically delete objects such as log files.

To delete an object, you can use one of the following API operations:

- **Delete a single object** – Amazon S3 provides the DELETE (DeleteObject) API operation that you can use to delete one object in a single HTTP request.
- **Delete multiple objects** – Amazon S3 provides the Multi-Object Delete (DeleteObjects) API operation that you can use to delete up to 1,000 objects in a single HTTP request.

When deleting objects from a bucket that is not versioning-enabled, you provide only the object key name. However, when deleting objects from a versioning-enabled bucket, you can provide the version ID of the object to delete a specific version of the object.

Best practices to consider before deleting an object

Before you delete an object, consider the following best practices:

- Enable [bucket versioning](#). [S3 Versioning](#) adds protection against simple DeleteObject requests to prevent accidental deletions. For versioned buckets, if you delete the current version of an object or when a delete request doesn't specify a specific version Id, Amazon S3 doesn't permanently delete the object. Instead, S3 adds a delete marker, issuing a soft delete of the object. The delete marker then becomes the current (or newest) version of the object with a new version ID. For more information, see [Deleting object versions from a versioning-enabled bucket](#).
- If you want to delete a large number of objects, or for programmatically deleting objects based on object creation date, [set a S3 Lifecycle configuration on your bucket](#). To monitor these deletions, we recommend that you [use an S3 Lifecycle event notification](#). When you configure S3 Lifecycle notifications, the `s3:LifecycleExpiration:Delete` event type notifies you when an object in a bucket is deleted. It also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration. The `s3:LifecycleExpiration:DeleteMarkerCreated` event type notifies you when S3 Lifecycle creates a delete marker. A delete marker is created when a current version of an object in a versioned bucket is deleted.
- Before making any updates to your S3 Lifecycle configuration, confirm that Lifecycle has completed the actions on all intended objects. For more information, see the **Updating, disabling, or deleting Lifecycle rules** section in [Setting an S3 Lifecycle configuration on a bucket](#).

 **Note**

The S3 Lifecycle rules must apply to the right subset of objects to prevent unintended deletions. You can filter objects by prefixes, object tags, or object sizes when creating the Lifecycle rules.

- Consider restricting users from removing or deleting objects from your bucket. To restrict users, you'll need to explicitly deny users the permissions for the following actions in your [Amazon S3 bucket policies](#):

- `s3>DeleteObject`, `s3>DeleteObjectVersion` (to control who can delete objects using API requests)
- `s3:PutLifecycleConfiguration` (to control who can add S3 Lifecycle expiration rules)
- Consider using [S3 Replication](#) to create multiple copies of your data and to replicate them to multiple locations at once. You can choose as many destination buckets as needed. Additionally, if an object is unintentionally deleted, you'll still have a copy of the data.
- Avoid sending object version IDs to unversioned buckets. Also, make sure to properly set both the `s3>DeleteObject` and `s3>DeleteObjectVersion` permissions on all buckets (including unversioned buckets).

Deleting objects from a versioning-enabled bucket

If your bucket is versioning-enabled, multiple versions of the same object can exist in the bucket. When working with versioning-enabled buckets, the Delete API operations enable the following options:

- **Specify a non-versioned delete request** – Specify only the object's key, and not the version ID. In this case, Amazon S3 creates a delete marker over the current version of the object and returns its version ID in the response. This makes your object disappear from the bucket. For information about object versioning and the delete marker concept, see [Retaining multiple versions of objects with S3 Versioning](#).
- **Specify a versioned delete request** – Specify both the key and version ID. In this case, the following outcomes are possible:
 - If the version ID maps to a specific object version, Amazon S3 deletes the specific version of the object.
 - If the version ID maps to the delete marker of an object, Amazon S3 deletes the delete marker. When the delete marker gets deleted, the object then reappears in your bucket.

Deleting objects from a versioning-suspended bucket

If your bucket is versioning-suspended, the Delete API operations behave the same way for versioning enabled buckets (except for when the current version has a null version ID). For more information, see [Deleting objects from versioning-suspended buckets](#).

Deleting objects from an unversioned bucket

If your bucket is unversioned, you can specify the object's key in the Delete API operations and Amazon S3 will permanently delete the object. To prevent permanent deletion of an object, [enable bucket versioning](#).

For unversioned buckets, if the `s3:DeleteObject` or `s3:DeleteObjectVersion` permissions are explicitly denied in your bucket policy, then any `DeleteObject`, `DeleteObjects`, or `DeleteObjectVersion` requests result in a `403 Access Denied` error.

Deleting objects from an MFA-enabled bucket

When deleting objects from a multi-factor authentication (MFA)-enabled bucket, note the following:

- If you provide an MFA token that isn't valid, the request always fails.
- If you have an MFA-enabled bucket and you make a versioned delete request (you provide an object key and version ID), the request fails if you don't provide a valid MFA token. In addition, when using the multi-object Delete API operation on an MFA-enabled bucket, if any of the deletes are a versioned delete request (that is, you specify an object key and version ID), the entire request fails if you don't provide an MFA token.

However, in the following cases, the request succeeds:

- If you have an MFA-enabled bucket and you make a non-versioned delete request (you are not deleting a versioned object), and you don't provide an MFA token, the delete succeeds.
- If you have a Multi-Object Delete request that specifies only non-versioned objects to delete from an MFA-enabled bucket and you don't provide an MFA token, the deletions succeed.

For information about MFA delete, see [Configuring MFA delete](#).

Deleting a single object

You can use the Amazon S3 console or the DELETE API to delete a single existing object from an S3 bucket. For more information about deleting objects in Amazon S3, see [Deleting Amazon S3 objects](#).

Because all objects in your S3 bucket incur storage costs, you should delete objects that you no longer need. For example, if you are collecting log files, it's a good idea to delete them when they're no longer needed. You can set up a lifecycle rule to automatically delete objects such as log files. For more information, see [the section called "Setting lifecycle configuration"](#).

For information about Amazon S3 features and pricing, see [Amazon S3 pricing](#).

Using the S3 console

Follow these steps to use the Amazon S3 console to delete a single object from a bucket.

Warning

When you permanently delete an object or specified object version in the Amazon S3 console, the deletion can't be undone.

To delete an object that has versioning enabled or suspended

Note

If the version ID for an object in a versioning-suspended bucket is marked as NULL, S3 permanently deletes the object since no previous versions exist. However, if a valid version ID is listed for the object in a versioning-suspended bucket, then S3 creates a delete marker for the deleted object, while retaining the previous versions of the object.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the bucket list, choose the name of the bucket that you want to delete an object from.
4. Select the object and then choose **Delete**.

5. To confirm deletion of the objects list under **Specified objects** in the **Delete objects?** text box, enter **delete**.

To permanently delete a specific object version in a versioning-enabled bucket

Warning

When you permanently delete a specific object version in Amazon S3, the deletion can't be undone.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Bucket name** list, choose the name of the bucket that you want to delete an object from.
3. Select the object that you want to delete.
4. Choose the **Show versions** toggle.
5. Select the object version and then choose **Delete**.
6. To confirm permanent deletion of the specific object versions listed under **Specified objects**, in the **Delete objects?** text box, enter **Permanently delete**. Amazon S3 permanently deletes the specific object version.

To permanently delete an object in an Amazon S3 bucket that *doesn't* have versioning enabled

Warning

When you permanently delete an object in Amazon S3, the deletion can't be undone. Also, for any buckets without versioning enabled, deletions are permanent.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the bucket list, choose the name of the bucket that you want to delete an object from.
4. Select the object and then choose **Delete**.

- To confirm permanent deletion of the object listed under **Specified objects**, in the **Delete objects?** text box, enter **permanently delete**.

 **Note**

If you're experiencing any issues with deleting your object, see [I want to permanently delete versioned objects](#).

Using the AWS CLI

To delete one object per request, use the DELETE API. For more information, see [DELETE Object](#). For more information about using the CLI to delete an object, see [delete-object](#).

Using the REST API

You can use the AWS SDKs to delete an object. However, if your application requires it, you can send REST requests directly. For more information, see [DELETE Object](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

The following examples show how you can use the AWS SDKs to delete an object from a bucket. For more information, see [DELETE Object](#) in the *Amazon Simple Storage Service API Reference*

If you have S3 Versioning enabled on the bucket, you have the following options:

- Delete a specific object version by specifying a version ID.
- Delete an object without specifying a version ID, in which case Amazon S3 adds a delete marker to the object.

For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

For more examples, and examples in other languages, see [Use DeleteObject with an AWS SDK or CLI](#) in the *Amazon S3 API reference*.

Java

To delete objects using the AWS SDK for Java, you can delete objects from both versioned and non-versioned buckets:

- *Non-versioned bucket*: In the delete request, you specify only the object key and not a version ID.
- *Versioned bucket*: You can delete a specific object version by specifying both the object key name and version ID. If there are no other versions of that object, Amazon S3 deletes the object entirely. Otherwise, Amazon S3 only deletes the specified version.

 **Note**

You can get the version IDs of an object by sending a `ListVersions` request.

For examples of how to delete a single object with the AWS SDK for Java, see [Delete an object in the Amazon S3 API Reference](#).

.NET

The following examples show how to delete an object from both versioned and non-versioned buckets. For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

Example Deleting an object from a non-versioned bucket

The following C# example deletes an object from a non-versioned bucket. The example assumes that the objects don't have version IDs, so you don't specify version IDs. You specify only the object key.

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the [AWS SDK for .NET Developer Guide](#).

Example Deleting an object from a versioned bucket

The following C# example deletes an object from a versioned bucket. It deletes a specific version of the object by specifying the object key name and version ID.

The code performs the following tasks:

1. Enables S3 Versioning on a bucket that you specify (if S3 Versioning is already enabled, this has no effect).
2. Adds a sample object to the bucket. In response, Amazon S3 returns the version ID of the newly added object. The example uses this version ID in the delete request.
3. Deletes the sample object by specifying both the object key name and a version ID.

Note

You can also get the version ID of an object by sending a `ListVersions` request.

```
var listResponse = client.ListVersions(new ListVersionsRequest { BucketName = bucketName, Prefix = keyName });
```

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

PHP

This example shows how to use classes from version 3 of the AWS SDK for PHP to delete an object from a non-versioned bucket. For information about deleting an object from a versioned bucket, see [Using the REST API](#).

For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

The following PHP example deletes an object from a bucket. Because this example shows how to delete objects from non-versioned buckets, it provides only the bucket name and object key (not a version ID) in the delete request.

```
<?php

require 'vendor/autoload.php';

use Aws\S3\S3Client;
use Aws\S3\Exception\S3Exception;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// 1. Delete the object from the bucket.
try
{
    echo 'Attempting to delete ' . $keyname . '...' . PHP_EOL;

    $result = $s3->deleteObject([
        'Bucket' => $bucket,
        'Key'     => $keyname
    ]);
}
```

```
if ($result['DeleteMarker'])
{
    echo $keyname . ' was deleted or does not exist.' . PHP_EOL;
} else {
    exit('Error: ' . $keyname . ' was not deleted.' . PHP_EOL);
}

try
{
    echo 'Checking to see if ' . $keyname . ' still exists...' . PHP_EOL;

    $result = $s3->getObject([
        'Bucket' => $bucket,
        'Key'     => $keyname
    ]);

    echo 'Error: ' . $keyname . ' still exists.';
}
catch (S3Exception $e) {
    exit($e->getAwsErrorMessage());
}
```

Javascript

```
import { DeleteObjectCommand } from "@aws-sdk/client-s3";
import { s3Client } from "./libs/s3Client.js" // Helper function that creates Amazon S3 service client module.

export const bucketParams = { Bucket: "BUCKET_NAME", Key: "KEY" };

export const run = async () => {
    try {
        const data = await s3Client.send(new DeleteObjectCommand(bucketParams));
        console.log("Success. Object deleted.", data);
        return data; // For unit tests.
    } catch (err) {
        console.log("Error", err);
    }
}
```

```
};  
run();
```

Deleting multiple objects

Because all objects in your S3 bucket incur storage costs, you should delete objects that you no longer need. For example, if you are collecting log files, it's a good idea to delete them when they're no longer needed. You can set up a lifecycle rule to automatically delete objects such as log files. For more information, see [the section called “Setting lifecycle configuration”](#).

For information about Amazon S3 features and pricing, see [Amazon S3 pricing](#).

You can use the Amazon S3 console, AWS SDKs, or the REST API to delete multiple objects simultaneously from an S3 bucket.

Using the S3 console

Follow these steps to use the Amazon S3 console to delete multiple objects from a bucket.

Warning

- Deleting a specified object cannot be undone.
- This action deletes all specified objects. When deleting folders, wait for the delete action to finish before adding new objects to the folder. Otherwise, new objects might be deleted as well.
- When deleting objects in a bucket without versioning enabled, including directory buckets, Amazon S3 will permanently delete the objects.
- When deleting objects in a bucket with bucket versioning **enabled** or **suspended**, Amazon S3 creates delete markers. For more information, see [Working with delete markers](#).

To delete objects that have versioning enabled or suspended

Note

If the version IDs for the object in a versioning-suspended bucket are marked as NULL, S3 permanently deletes the objects since no previous versions exist. However, if a valid version

ID is listed for the objects in a versioning-suspended bucket, then S3 creates delete markers for the deleted objects, while retaining the previous versions of the objects.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the bucket list, choose the name of the bucket that you want to delete the objects from.
4. Select the objects and then choose **Delete**.
5. To confirm deletion of the objects list under **Specified objects** in the **Delete objects?** text box, enter **delete**.

To permanently delete specific object versions in a versioning-enabled bucket

Warning

When you permanently delete specific object versions in Amazon S3, the deletion can't be undone.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the bucket list, choose the name of the bucket that you want to delete the objects from.
4. Select the objects that you want to delete.
5. Choose the **Show versions** toggle.
6. Select the object versions and then choose **Delete**.
7. To confirm permanent deletion of the specific object versions listed under **Specified objects**, in the **Delete objects?** text box, enter **Permanently delete**. Amazon S3 permanently deletes the specific object versions.

To permanently delete the objects in an Amazon S3 bucket that *don't* have versioning enabled

Warning

When you permanently delete an object in Amazon S3, the deletion can't be undone. Also, for any buckets without versioning enabled, including directory buckets, deletions are permanent.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the bucket list, choose the name of the bucket that you want to delete the objects from.
4. Select the objects and then choose **Delete**.
5. To confirm permanent deletion of the objects listed under **Specified objects**, in the **Delete objects?** text box, enter **permanently delete**.

Note

If you're experiencing any issues with deleting your objects, see [I want to permanently delete versioned objects](#).

Using the AWS SDKs

For examples of how to delete multiple objects with the AWS SDKs, see [Delete multiple objects](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Using the REST API

You can use the AWS SDKs to delete multiple objects using the Multi-Object Delete API. However, if your application requires it, you can send REST requests directly.

For more information, see [Delete Multiple Objects](#) in the *Amazon Simple Storage Service API Reference*.

Organizing, listing, and working with your objects

In Amazon S3, you can use prefixes to organize your storage. A prefix is a logical grouping of the objects in a bucket. The prefix value is similar to a directory name that enables you to store similar data under the same directory in a bucket. When you programmatically upload objects, you can use prefixes to organize your data.

In the Amazon S3 console, prefixes are called folders. You can view all your objects and folders in the S3 console by navigating to a bucket. You can also view information about each object, including object properties.

For more information about listing and organizing your data in Amazon S3, see the following topics.

Topics

- [Organizing objects using prefixes](#)
- [Listing object keys programmatically](#)
- [Organizing objects in the Amazon S3 console by using folders](#)
- [Viewing object properties in the Amazon S3 console](#)
- [Categorizing your objects using tags](#)

Organizing objects using prefixes

You can use prefixes to organize the data that you store in Amazon S3 buckets. A prefix is a string of characters at the beginning of the object key name. A prefix can be any length, subject to the maximum length of the object key name (1,024 bytes). You can think of prefixes as a way to organize your data in a similar way to directories. However, prefixes are not directories.

Searching by prefix limits the results to only those keys that begin with the specified prefix. The delimiter causes a list operation to roll up all the keys that share a common prefix into a single summary list result.

The purpose of the prefix and delimiter parameters is to help you organize and then browse your keys hierarchically. To do this, first pick a delimiter for your bucket, such as slash (/), that doesn't occur in any of your anticipated key names. You can use another character as a delimiter. There is nothing unique about the slash (/) character, but it is a very common prefix delimiter. Next,

construct your key names by concatenating all containing levels of the hierarchy, separating each level with the delimiter.

For example, if you were storing information about cities, you might naturally organize them by continent, then by country, then by province or state. Because these names don't usually contain punctuation, you might use slash (/) as the delimiter. The following examples use a slash (/) delimiter.

- Europe/France/Nouvelle-Aquitaine/Bordeaux
- North America/Canada/Quebec/Montreal
- North America/USA/Washington/Bellevue
- North America/USA/Washington/Seattle

If you stored data for every city in the world in this manner, it would become awkward to manage a flat key namespace. By using `Prefix` and `Delimiter` with the list operation, you can use the hierarchy that you've created to list your data. For example, to list all the states in USA, set `Delimiter='/'` and `Prefix='North America/USA/'`. To list all the provinces in Canada for which you have data, set `Delimiter='/'` and `Prefix='North America/Canada/'`.

For more information about delimiters, prefixes, and nested folders, see [Difference between prefixes and nested folders](#).

Listing objects using prefixes and delimiters

If you issue a list request with a delimiter, you can browse your hierarchy at only one level, skipping over and summarizing the (possibly millions of) keys nested at deeper levels. For example, assume that you have a bucket (*amzn-s3-demo-bucket*) with the following keys:

sample.jpg

photos/2006/January/sample.jpg

photos/2006/February/sample2.jpg

photos/2006/February/sample3.jpg

photos/2006/February/sample4.jpg

The sample bucket has only the `sample.jpg` object at the root level. To list only the root level objects in the bucket, you send a GET request on the bucket with the slash (/) delimiter character.

In response, Amazon S3 returns the `sample.jpg` object key because it does not contain the `/` delimiter character. All other keys contain the delimiter character. Amazon S3 groups these keys and returns a single `CommonPrefixes` element with the prefix value `photos/`, which is a substring from the beginning of these keys to the first occurrence of the specified delimiter.

For more information about listing object keys programmatically, see [Listing object keys programmatically](#).

Listing object keys programmatically

In Amazon S3, keys can be listed by prefix. You can choose a common prefix for the names of related keys and mark these keys with a special character that delimits hierarchy. You can then use the list operation to select and browse keys hierarchically. This is similar to how files are stored in directories within a file system.

Amazon S3 exposes a list operation that lets you enumerate the keys contained in a bucket. Keys are selected for listing by bucket and prefix. For example, consider a bucket named "dictionary"

that contains a key for every English word. You might make a call to list all the keys in that bucket that start with the letter "q". List results are always returned in UTF-8 binary order.

Both the SOAP and REST list operations return an XML document that contains the names of matching keys and information about the object identified by each key.

Note

SOAP APIs for Amazon S3 are not available for new customers, and are approaching End of Life (EOL) on August 31, 2025. We recommend that you use either the REST API or the AWS SDKs.

Groups of keys that share a prefix terminated by a special delimiter can be rolled up by that common prefix for the purposes of listing. This enables applications to organize and browse their keys hierarchically, much like how you would organize your files into directories in a file system.

For example, to extend the dictionary bucket to contain more than just English words, you might form keys by prefixing each word with its language and a delimiter, such as "French/logical". Using this naming scheme and the hierarchical listing feature, you could retrieve a list of only French words. You could also browse the top-level list of available languages without having to iterate through all the lexicographically intervening keys. For more information about this aspect of listing, see [Organizing objects using prefixes](#).

REST API

If your application requires it, you can send REST requests directly. You can send a GET request to return some or all of the objects in a bucket or you can use selection criteria to return a subset of the objects in a bucket. For more information, see [GET Bucket \(List Objects\) Version 2](#) in the *Amazon Simple Storage Service API Reference*.

List implementation efficiency

List performance is not substantially affected by the total number of keys in your bucket. It's also not affected by the presence or absence of the `prefix`, `marker`, `maxkeys`, or `delimiter` arguments.

Iterating through multipage results

As buckets can contain a virtually unlimited number of keys, the complete results of a list query can be extremely large. To manage large result sets, the Amazon S3 API supports pagination to

split them into multiple responses. Each list keys response returns a page of up to 1,000 keys with an indicator indicating if the response is truncated. You send a series of list keys requests until you have received all the keys. AWS SDK wrapper libraries provide the same pagination.

Examples

When you list all of the objects in your bucket, note that you must have the s3>ListBucket permission.

CLI

list-objects

The following example uses the list-objects command to display the names of all the objects in the specified bucket:

```
aws s3api list-objects --bucket text-content --query 'Contents[].{Key: Key, Size: Size}'
```

The example uses the --query argument to filter the output of list-objects down to the key value and size for each object

For more information about objects, see [Working with objects in Amazon S3](#).

- For API details, see [ListObjects](#) in *AWS CLI Command Reference*.

ls

The following example lists all objects and prefixes in a bucket by using the ls command.

To use this example command, replace *amzn-s3-demo-bucket* with the name of your bucket.

```
$ aws s3 ls s3://amzn-s3-demo-bucket
```

- For more information about the high-level command ls, see [List buckets and objects](#) in *AWS Command Line Interface User Guide*.

PowerShell

Tools for PowerShell V4

Example 1: This command retrieves the information about all of the items in the bucket "test-files".

```
Get-S3Object -BucketName amzn-s3-demo-bucket
```

Example 2: This command retrieves the information about the item "sample.txt" from bucket "test-files".

```
Get-S3Object -BucketName amzn-s3-demo-bucket -Key sample.txt
```

Example 3: This command retrieves the information about all items with the prefix "sample" from bucket "test-files".

```
Get-S3Object -BucketName amzn-s3-demo-bucket -KeyPrefix sample
```

- For API details, see [ListObjects](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This command retrieves the information about all of the items in the bucket "test-files".

```
Get-S3Object -BucketName amzn-s3-demo-bucket
```

Example 2: This command retrieves the information about the item "sample.txt" from bucket "test-files".

```
Get-S3Object -BucketName amzn-s3-demo-bucket -Key sample.txt
```

Example 3: This command retrieves the information about all items with the prefix "sample" from bucket "test-files".

```
Get-S3Object -BucketName amzn-s3-demo-bucket -KeyPrefix sample
```

- For API details, see [ListObjects](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

Organizing objects in the Amazon S3 console by using folders

In Amazon S3 general purpose buckets, objects are the primary resources, and objects are stored in buckets. Amazon S3 general purpose buckets have a flat structure instead of a hierarchy like you would see in a file system. However, for the sake of organizational simplicity, the Amazon S3 console supports the *folder* concept as a means of grouping objects. The console does this by using a shared name *prefix* for the grouped objects. In other words, the grouped objects have names that begin with a common string. This common string, or shared prefix, is the folder name. Object names are also referred to as *key names*.

For example, you can create a folder in a general purpose bucket in the console named photos and store an object named myphoto.jpg in it. The object is then stored with the key name photos/myphoto.jpg, where photos/ is the prefix.

Here are two more examples:

- If you have three objects in your general purpose bucket—logs/date1.txt, logs/date2.txt, and logs/date3.txt—the console will show a folder named logs. If you open the folder in the console, you will see three objects: date1.txt, date2.txt, and date3.txt.
- If you have an object named photos/2017/example.jpg, the console shows you a folder named photos that contains the folder 2017. The folder 2017 contains the object example.jpg.

You can have folders within folders, but not buckets within buckets. You can upload and copy objects directly into a folder. Folders can be created, deleted, and made public, but they can't be renamed. Objects can be copied from one folder to another.

Important

When you create a folder in Amazon S3 console, S3 creates a 0-byte object. This object key is set to the folder name that you provided plus a trailing forward slash (/) character. For example, in Amazon S3 console, if you create a folder named photos in your bucket, the Amazon S3 console creates a 0-byte object with the key photos/. The console creates this object to support the idea of folders.

Also, any pre-existing object that's named with a trailing forward slash character (/) appears as a folder in the Amazon S3 console. For example, an object with the key name examplekeyname/ appears as a folder in Amazon S3 console and not as an object.

Otherwise, it behaves like any other object and can be viewed and manipulated through the AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. Additionally, you can't upload an object that has a key name with a trailing forward slash character (/) by using the Amazon S3 console. However, you can upload objects that are named with a trailing forward slash (/) character by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API.

Moreover, the Amazon S3 console doesn't display the content and metadata for folder objects like it does for other objects. When you use the console to copy an object named with a trailing forward slash character (/), a new folder is created in the destination location, but the object's data and metadata aren't copied. Also, a forward slash (/) in object key names might require special handling. For more information, see [Naming Amazon S3 objects](#).

To create folders in directory buckets, upload a folder. For more information, see [Uploading objects to a directory bucket](#).

Creating a folder

This section describes how to use the Amazon S3 console to create a folder.

Important

If your bucket policy prevents uploading objects to this bucket without tags, metadata, or access control list (ACL) grantees, you can't create a folder by using the following procedure. Instead, upload an empty folder and specify the following settings in the upload configuration.

To create a folder

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a folder in.
4. On the **Objects** tab, choose **Create folder**.
5. Enter a name for the folder (for example, **favorite-pics**).

 **Note**

Folder names are subject to certain limitations and guidelines, and are considered part of an object's object key name, which is limited to 1,024 bytes. For more information, see [the section called "Naming objects"](#).

6. (Optional) If your bucket policy requires objects to be encrypted with a specific encryption key, under **Server-side encryption**, you must choose **Specify an encryption key** and specify the same encryption key when you create a folder. Otherwise, folder creation will fail.
7. Choose **Create folder**.

Making folders public

We recommend blocking all public access to your Amazon S3 folders and buckets unless you specifically require a public folder or bucket. When you make a folder public, anyone on the internet can view all the objects that are grouped in that folder.

In the Amazon S3 console, you can make a folder public. You can also make a folder public by creating a bucket policy that limits data access by prefix. For more information, see [Identity and Access Management for Amazon S3](#).

 **Warning**

After you make a folder public in the Amazon S3 console, you can't make it private again. Instead, you must set permissions on each individual object in the public folder so that the objects have no public access. For more information, see [Configuring ACLs](#).

Topics

- [Calculating folder size](#)
- [Deleting folders](#)

Calculating folder size

This section describes how to use the Amazon S3 console to calculate a folder's size.

To calculate a folder's size

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket in which your folder is stored.
4. In the **Objects** list, select the checkbox next to the name of the folder.
5. Choose **Actions**, and then choose **Calculate total size**.

Note

When you navigate away from the page, the folder information (including the total size) is no longer available. You must calculate the total size again if you want to see it again.

Important

When you use the **Calculate total size** action on specified objects or folders within your bucket, Amazon S3 calculates the total number of objects and the total storage size.

However, incomplete or in-progress multipart uploads and previous or noncurrent versions aren't calculated in the total number of objects or the total size. This action calculates only the total number of objects and the total size for the current or newest version of each object that's stored in the bucket.

For example, if there are two versions of an object in your bucket, then the storage calculator in Amazon S3 counts them as only one object. As a result, the total number of objects that's calculated in the Amazon S3 console can differ from the **Object Count** metric shown in S3 Storage Lens and from the number reported by the Amazon CloudWatch

metric, `NumberOfObjects`. Likewise, the total storage size can also differ from the **Total Storage** metric shown in S3 Storage Lens and from the `BucketSizeBytes` metric shown in CloudWatch.

Deleting folders

This section explains how to use the Amazon S3 console to delete folders from an S3 bucket.

For information about Amazon S3 features and pricing, see [Amazon S3](#).

To delete folders from an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that you want to delete folders from.
4. In the **Objects** list, select the checkboxes next to the folders and objects that you want to delete.
5. Choose **Delete**.
6. On the **Delete objects** page, verify that the names of the folders and objects that you selected for deletion are listed under **Specified objects**.
7. In the **Delete objects** box, enter **delete**, and choose **Delete objects**.

Warning

This action deletes all specified objects. When deleting folders, wait for the delete action to finish before adding new objects to the folder. Otherwise, new objects might be deleted as well.

Viewing object properties in the Amazon S3 console

You can use the Amazon S3 console to view the properties of an object, including storage class, encryption settings, tags, and metadata.

To view the properties of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the bucket list, choose the name of the bucket that contains the object.
4. In the **Objects** list, choose the name of the object you want to view properties for.

The **Object overview** for your object opens. You can scroll down to view the object properties.

5. On the **Object overview** page, you can view or configure the following properties for the object.

Note

- If you change the **Storage Class**, **Encryption**, or **Metadata** properties, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object or (object version).
- If you change the **Storage Class**, **Encryption**, or **Metadata** properties for an object that has user-defined tags, you must have the `s3:GetObjectTagging` permission. If you're changing these properties for an object that doesn't have user-defined tags but is over 16 MB in size, you must also have the `s3:GetObjectTagging` permission.

If the destination bucket policy denies the `s3:GetObjectTagging` action, these properties for the object will be updated, but the user-defined tags will be removed from the object, and you will receive an error.

- a. **Storage class** – Each object in Amazon S3 has a storage class associated with it. The storage class that you choose to use depends on how frequently you access the object. The default storage class for S3 objects in general purpose buckets is STANDARD. The default storage class for S3 objects in directory buckets is S3 Express One Zone. You choose which storage class to use when you upload an object. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

To change the storage class after you upload an object to a general purpose bucket, choose **Storage class**. Choose the storage class that you want, and then choose **Save**.

 **Note**

Storage class of objects in a directory bucket cannot be changed.

- b. **Server-side encryption settings** – You can use server-side encryption to encrypt your S3 objects. For more information, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#) or [Specifying server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).
- c. **Metadata** – Each object in Amazon S3 has a set of name-value pairs that represents its metadata. For information about adding metadata to an S3 object, see [Editing object metadata in the Amazon S3 console](#).
- d. **Tags** – You categorize storage by adding tags to an S3 object in a general purpose bucket. For more information, see [Categorizing your objects using tags](#).
- e. **Object lock legal hold and retention** – You can prevent an object in a general purpose bucket from being deleted. For more information, see [Locking objects with Object Lock](#).

Categorizing your objects using tags

Use object tagging to categorize storage. Each tag is a key-value pair.

You can add tags to new objects when you upload them, or you can add them to existing objects.

- You can associate up to 10 tags with an object. Tags that are associated with an object must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Amazon S3 object tags are internally represented in UTF-16. Note that in UTF-16, characters consume either 1 or 2 character positions.
- The key and values are case sensitive.
- For more information about tag restrictions, see [User-defined tag restrictions](#) in the *AWS Billing and Cost Management User Guide*. For basic tag restrictions, see [Tag restrictions](#) in the *Amazon EC2 User Guide*.

Examples

Consider the following tagging examples:

Example PHI information

Suppose that an object contains protected health information (PHI) data. You might tag the object using the following key-value pair.

```
PHI=True
```

or

```
Classification=PHI
```

Example Project files

Suppose that you store project files in your S3 bucket. You might tag these objects with a key named Project and a value, as shown following.

```
Project=Blue
```

Example Multiple tags

You can add multiple tags to an object, as shown following.

```
Project=x  
Classification=confidential
```

Key name prefixes and tags

Object key name prefixes also enable you to categorize storage. However, prefix-based categorization is one-dimensional. Consider the following object key names:

```
photos/photo1.jpg  
project/projectx/document.pdf  
project/projecty/document2.pdf
```

These key names have the prefixes photos/, project/projectx/, and project/projecty/. These prefixes enable one-dimensional categorization. That is, everything under a prefix is one category. For example, the prefix project/projectx identifies all documents related to project x.

With tagging, you now have another dimension. If you want photo1 in project x category, you can tag the object accordingly.

Additional benefits

In addition to data classification, tagging offers benefits such as the following:

- Object tags enable fine-grained access control of permissions. For example, you could grant a user permissions to read-only objects with specific tags.
- Object tags enable fine-grained object lifecycle management in which you can specify a tag-based filter, in addition to a key name prefix, in a lifecycle rule.
- When using Amazon S3 analytics, you can configure filters to group objects together for analysis by object tags, by key name prefix, or by both prefix and tags.
- You can also customize Amazon CloudWatch metrics to display information by specific tag filters. The following sections provide details.

A Important

It is acceptable to use tags to label objects containing confidential data, such as personally identifiable information (PII) or protected health information (PHI). However, the tags themselves shouldn't contain any confidential information.

Adding object tag sets to multiple Amazon S3 object with a single request

To add object tag sets to more than one Amazon S3 object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

The S3 Batch Operations feature tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, serverless experience. You can use S3 Batch Operations through the Amazon S3 console, AWS CLI, AWS SDKs, or REST API. For more information, see [the section called “Batch Operations basics”](#).

For more information about object tags, see [Managing object tags](#).

API operations related to object tagging

Amazon S3 supports the following API operations that are specifically for object tagging:

Object API operations

- [PUT Object tagging](#) – Replaces tags on an object. You specify tags in the request body. There are two distinct scenarios of object tag management using this API.
 - Object has no tags – Using this API you can add a set of tags to an object (the object has no prior tags).
 - Object has a set of existing tags – To modify the existing tag set, you must first retrieve the existing tag set, modify it on the client side, and then use this API to replace the tag set.

 **Note**

If you send this request with an empty tag set, Amazon S3 deletes the existing tag set on the object. If you use this method, you will be charged for a Tier 1 Request (PUT).

For more information, see [Amazon S3 Pricing](#).

The [DELETE Object tagging](#) request is preferred because it achieves the same result without incurring charges.

- [GET Object tagging](#) – Returns the tag set associated with an object. Amazon S3 returns object tags in the response body.
- [DELETE Object tagging](#) – Deletes the tag set associated with an object.

Other API operations that support tagging

- [PUT Object](#) and [Initiate Multipart Upload](#) – You can specify tags when you create objects. You specify tags using the x-amz-tagging request header.
- [GET Object](#) – Instead of returning the tag set, Amazon S3 returns the object tag count in the x-amz-tag-count header (only if the requester has permissions to read tags) because the header response size is limited to 8 K bytes. If you want to view the tags, you make another request for the [GET Object tagging](#) API operation.
- [POST Object](#) – You can specify tags in your POST request.

As long as the tags in your request don't exceed the 8 K byte HTTP request header size limit, you can use the `PUT Object` API to create objects with tags. If the tags you specify exceed the header size limit, you can use this POST method in which you include the tags in the body.

[**PUT Object - Copy**](#) – You can specify the `x-amz-tagging-directive` in your request to direct Amazon S3 to either copy (default behavior) the tags or replace tags by a new set of tags provided in the request.

Note the following:

- S3 Object Tagging is strongly consistent. For more information, see [Amazon S3 data consistency model](#).

Additional configurations

This section explains how object tagging relates to other configurations.

Object tagging and lifecycle management

In bucket lifecycle configuration, you can specify a filter to select a subset of objects to which the rule applies. You can specify a filter based on the key name prefixes, object tags, or both.

Suppose that you store photos (raw and the finished format) in your Amazon S3 bucket. You might tag these objects as shown following.

```
phototype=raw  
or  
phototype=finished
```

You might consider archiving the raw photos to Amazon Glacier sometime after they are created. You can configure a lifecycle rule with a filter that identifies the subset of objects with the key name prefix (`photos/`) that have a specific tag (`phototype=raw`).

For more information, see [Managing the lifecycle of objects](#).

Object tagging and replication

If you configured Replication on your bucket, Amazon S3 replicates tags, provided you grant Amazon S3 permission to read the tags. For more information, see [Setting up live replication overview](#).

Object tagging event notifications

You can set up an Amazon S3 event notification to receive notice when an object tag is added or deleted from an object. The `s3:ObjectTagging:Put` event type notifies you when a tag is PUT on an object or when an existing tag is updated. The `s3:ObjectTagging:Delete` event type notifies you when a tag is removed from an object. For more information, see [Enabling event notifications](#).

For more information about object tagging, see the following topics:

Topics

- [Tagging and access control policies](#)
- [Managing object tags](#)

Tagging and access control policies

You can also use permissions policies (bucket and user policies) to manage permissions related to object tagging. For policy actions see the following topics:

- [Object operations](#)
- [Bucket operations](#)

Object tags enable fine-grained access control for managing permissions. You can grant conditional permissions based on object tags. Amazon S3 supports the following condition keys that you can use to grant conditional permissions based on object tags:

- `s3:ExistingObjectTag/<tag-key>` – Use this condition key to verify that an existing object tag has the specific tag key and value.

Note

When granting permissions for the PUT Object and DELETE Object operations, this condition key is not supported. That is, you cannot create a policy to grant or deny a user permissions to delete or overwrite an object based on its existing tags.

- s3:RequestObjectTagKeys – Use this condition key to restrict the tag keys that you want to allow on objects. This is useful when adding tags to objects using the PutObjectTagging and PutObject, and POST object requests.
- s3:RequestObjectTag/*<tag-key>* – Use this condition key to restrict the tag keys and values that you want to allow on objects. This is useful when adding tags to objects using the PutObjectTagging and PutObject, and POST Bucket requests.

For a complete list of Amazon S3 service-specific condition keys, see [Bucket policy examples using condition keys](#). The following permissions policies illustrate how object tagging enables fine grained access permissions management.

Example 1: Allow a user to read only the objects that have a specific tag and key value

The following permissions policy limits a user to only reading objects that have the environment: production tag key and value. This policy uses the s3:ExistingObjectTag condition key to specify the tag key and value.

Example 2: Restrict which object tag keys that users can add

The following permissions policy grants a user permissions to perform the s3:PutObjectTagging action, which allows user to add tags to an existing object. The condition uses the s3:RequestObjectTagKeys condition key to specify the allowed tag keys, such as Owner or CreationDate. For more information, see [Creating a condition that tests multiple key values](#) in the *IAM User Guide*.

The policy ensures that every tag key specified in the request is an authorized tag key. The ForAnyValue qualifier in the condition ensures that at least one of the specified keys must be present in the request.

Managing object tags

This section explains how you can manage object tags using the AWS SDKs for Java and .NET or the Amazon S3 console.

Object tagging gives you a way to categorize storage in general purpose buckets. Each tag is a key-value pair that adheres to the following rules:

- You can associate up to 10 tags with an object. Tags that are associated with an object must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Amazon S3 object tags are internally represented in UTF-16. Note that in UTF-16, characters consume either 1 or 2 character positions.
- The key and values are case sensitive.

For more information about object tags, see [Categorizing your objects using tags](#). For more information about tag restrictions, see [User-Defined Tag Restrictions](#) in the *AWS Billing and Cost Management User Guide*.

Using the S3 console

To add tags to an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the bucket list, choose the name of the bucket that contains the object.
4. Select the check box to the left of the names of the objects you want to change.
5. In the **Actions** menu, choose **Edit tags**.
6. Review the objects listed, and choose **Add tags**.
7. Each object tag is a key-value pair. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**.

You can enter up to 10 tags for an object.

8. Choose **Save changes**.

Amazon S3 adds the tags to the specified objects.

For more information, see also [Viewing object properties in the Amazon S3 console](#) and [Uploading objects](#) in this guide.

Using the AWS SDKs

Java

To manage object tags using the AWS SDK for Java, you can set tags for a new object and retrieve or replace tags for an existing object. For more information about object tagging, see [Categorizing your objects using tags](#).

Upload an object to a bucket and set tags using an S3Client. For examples, see [Upload an object to a bucket](#) in the *Amazon S3 API Reference*.

.NET

The following example shows how to use the AWS SDK for .NET to set the tags for a new object and retrieve or replace the tags for an existing object. For more information about object tagging, see [Categorizing your objects using tags](#).

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

Download and upload objects with presigned URLs

You can use presigned URLs to grant time-limited access to objects in Amazon S3 without updating your bucket policy. A presigned URL can be entered in a browser or used by a program to download

an object. The credentials used by the presigned URL are those of the AWS Identity and Access Management (IAM) principal who generated the URL.

You can also use presigned URLs to allow someone to upload a specific object to your Amazon S3 bucket. This allows an upload without requiring another party to have AWS security credentials or permissions. If an object with the same key already exists in the bucket as specified in the presigned URL, Amazon S3 replaces the existing object with the uploaded object.

You can use the presigned URL multiple times, up to the expiration date and time.

When you create a presigned URL, you must provide your security credentials, and then specify the following:

- An Amazon S3 bucket
- An object key (if downloading this object will be in your Amazon S3 bucket, if uploading this is the file name to be uploaded)
- An HTTP method (GET for downloading objects, PUT for uploading, HEAD for reading object metadata, etc)
- An expiration time interval

When using presigned URLs to upload objects, you can verify object integrity using checksums. While presigned URLs created with AWS Signature Version 2 only support MD5 checksums, presigned URLs created with AWS Signature Version 4 support additional checksum algorithms including CRC-64/NVME, CRC32, CRC32C, SHA-1, and SHA-256. To use these additional checksum algorithms, ensure you're using AWS Signature Version 4 and include the appropriate checksum header in your upload request. For more information about object integrity, see [Checking object integrity in Amazon S3](#).

Who can create a presigned URL

Anyone with valid security credentials can create a presigned URL. But for someone to successfully access an object, the presigned URL must be created by someone who has permission to perform the operation that the presigned URL is based upon.

The following are the types of credentials that you can use to create a presigned URL:

- **IAM user** – Valid up to 7 days when you're using AWS Signature Version 4.

To create a presigned URL that's valid for up to 7 days, first delegate IAM user credentials (the access key and secret key) to the method you're using to create the presigned URL.

- **Temporary security credentials** – Can't be valid for longer than the credentials themselves. These credentials include:

- **IAM role credentials** – The presigned URL expires when the role session expires, even if you specify a longer expiration time.
- **IAM role credentials used by Amazon EC2 instances** – Valid for the duration of the role credentials (typically 6 hours).
- **AWS Security Token Service credentials** – Valid only for the duration of the temporary credentials.

 **Note**

If you created a presigned URL using a temporary credential, the URL expires when the credential expires. In general, a presigned URL expires when the credential you used to create it is revoked, deleted, or deactivated. This is true even if the URL was created with a later expiration time. For temporary security credentials lifetimes, see [Comparing AWS STS API operations](#) in the *IAM User Guide*.

Expiration time for presigned URLs

A presigned URL remains valid for the period of time specified when the URL is generated. If you create a presigned URL with the Amazon S3 console, the expiration time can be set between 1 minute and 12 hours. If you use the AWS CLI or AWS SDKs, the expiration time can be set as high as 7 days.

If you created a presigned URL by using a temporary token, then the URL expires when the token expires. In general, a presigned URL expires when the credential you used to create it is revoked, deleted, or deactivated. This is true even if the URL was created with a later expiration time. For more information about how the credentials you use affect the expiration time, see [Who can create a presigned URL](#).

Amazon S3 checks the expiration date and time of a signed URL at the time of the HTTP request. For example, if a client begins to download a large file immediately before the expiration time, the download continues even if the expiration time passes during the download. However, if the connection drops and the client tries to restart the download after the expiration time passes, the download fails.

Limits presigned URL capabilities

The capabilities of a presigned URL are limited by the permissions of the user who created it. In essence, presigned URLs are bearer tokens that grant access to those who possess them. As such, we recommend that you protect them appropriately. The following are some methods that you can use to restrict the use of your presigned URLs.

AWS Signature Version 4 (SigV4)

To enforce specific behavior when presigned URL requests are authenticated by using AWS Signature Version 4 (SigV4), you can use condition keys in bucket policies and access point policies. For example, the following bucket policy uses the `s3:signatureAge` condition to deny any Amazon S3 presigned URL request on objects in the `amzn-s3-demo-bucket` bucket if the signature is more than 10 minutes old. To use this example, replace the `user input placeholders` with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Deny a presigned URL request if the signature is more than 10  
            min old",  
            "Effect": "Deny",  
            "Principal": {  
                "AWS": "*"  
            },  
            "Condition": {

        }
    }
]
```

For more information about policy keys related AWS Signature Version 4, see [AWS Signature Version 4 Authentication](#) in the *Amazon Simple Storage Service API Reference*.

Network path restriction

If you want to restrict the use of presigned URLs and all Amazon S3 access to particular network paths, you can write AWS Identity and Access Management (IAM) policies. You can set these policies on the IAM principal that makes the call, the Amazon S3 bucket, or both.

A network-path restriction on the IAM principal requires the user of those credentials to make requests from the specified network. A restriction on the bucket or access point requires that all requests to that resource originate from the specified network. These restrictions also apply outside of the presigned URL scenario.

The IAM global condition key that you use depends on the type of endpoint. If you're using the public endpoint for Amazon S3, use `aws:SourceIp`. If you're using a virtual private cloud (VPC) endpoint to Amazon S3, use `aws:SourceVpc` or `aws:SourceVpce`.

The following IAM policy statement requires the principal to access AWS only from the specified network range. With this policy statement, all access must originate from that range. This includes the case of someone who's using a presigned URL for Amazon S3. To use this example, replace the *user input placeholders* with your own information.

```
{
    "Sid": "NetworkRestrictionForIAMPPrincipal",
    "Effect": "Deny",
    "Action": "*",
    "Resource": "*",
    "Condition": {
        "NotIpAddressIfExists": {"aws:SourceIp": "IP-address-range"},
```

```
        "BoolIfExists": {"aws:ViaAWSService": "false"}  
    }  
}
```

Frequently asked questions for presigned URLs

Q: Why do my presigned URLs expire earlier than the configured expiration time?

Presigned URLs remain valid only while their underlying credentials are valid. A presigned URL expires at either its configured expiration time or when its associated credentials expire, whichever occurs first. For Amazon Elastic Container Service tasks or containers, role credentials typically rotate every 1-6 hours. When using AWS Security Token Service (AWS STS) AssumeRole, the presigned URL expires when the role session ends, which by default is 1 hour. For Amazon EC2 instance profiles, metadata credentials rotate periodically with a maximum validity period of approximately 6 hours.

Q: Why am I getting a 403 Forbidden error when accessing a presigned URL?

Before generating a presigned URL, verify that you have the correct permissions configured. The IAM user or role generating the URL must have the required permissions, such as `s3:GetObject`, for the specific operation. Additionally, check that the Amazon S3 bucket policy doesn't explicitly deny access to the object.

Q: I'm getting SignatureDoesNotMatch errors. How do I fix this?

If you encounter `SignatureDoesNotMatch` errors when using Amazon S3 presigned URLs, consider several common causes. First, ensure that your system clock is synchronized with a Network Time Protocol (NTP) server, as even small time drifts can invalidate signatures. Next, be aware that some corporate proxies might modify headers or query strings, potentially causing signature mismatches. To troubleshoot, try testing without the proxy. Finally, verify that all request parameters—including the HTTP method, headers, and query string—match exactly between URL generation and usage. Addressing these issues can often resolve `SignatureDoesNotMatch` errors.

Q: I'm getting ExpiredToken errors. What should I do?

When you receive `ExpiredToken` errors while using presigned URLs, it indicates that the AWS credentials used to generate the URL are no longer valid. To resolve this issue, refresh your AWS credentials before generating new presigned URLs. For long-running applications, we recommend implementing credential refresh logic to maintain continuous access. Where appropriate, you can

use longer-lived credentials or implement token refresh mechanisms. If you're using AWS Security Token Service (AWS STS) AssumeRole, verify that your configured session duration meets your use case requirements. Remember that presigned URLs remain valid only for the duration of their underlying credentials, so implementing proper credential management is essential.

Sharing objects with presigned URLs

By default, all Amazon S3 objects are private, only the object owner has permission to access them. However, the object owner may share objects with others by creating a presigned URL. A presigned URL uses security credentials to grant time-limited permission to download objects. The URL can be entered in a browser or used by a program to download the object. The credentials used by the presigned URL are those of the AWS user who generated the URL.

For general information about presigned URLs, see [Download and upload objects with presigned URLs](#).

You can create a presigned URL for sharing an object without writing any code by using the Amazon S3 console, AWS Explorer for Visual Studio (Windows), or AWS Toolkit for Visual Studio Code. You can also generate a presigned URL programmatically by using the AWS Command Line Interface (AWS CLI) or the AWS SDKs.

Using the S3 console

You can use the Amazon S3 console to generate a presigned URL for sharing an object up to 5 TB by following these steps. When using the console the maximum expiration time for a presigned URL is 12 hours from the time of creation.

To generate a presigned URL by using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the general purpose bucket that contains the object that you want a presigned URL for.
4. In the **Objects** list, select the object that you want to create a presigned URL for.
5. On the **Object actions** menu, choose **Share with a presigned URL**.
6. Specify how long you want the presigned URL to be valid.
7. Choose **Create presigned URL**.

- When a confirmation appears, the URL is automatically copied to your clipboard. You will see a button to copy the presigned URL if you need to copy it again.

Using the AWS CLI

The following example AWS CLI command generates a presigned URL for sharing an object from an Amazon S3 bucket. When you use the AWS CLI, the maximum expiration time for a presigned URL is 7 days from the time of creation. To use this example, replace the *user input placeholders* with your own information.

```
aws s3 presign s3://amzn-s3-demo-bucket/mydoc.txt --expires-in 604800
```

The `--expires-in` parameter specifies the expiration time in seconds.

Note

For all AWS Regions launched after March 20, 2019 you need to specify the `endpoint-url` and `AWS Region` with the request. For a list of all the Amazon S3 Regions and endpoints, see [Regions and Endpoints](#) in the *AWS General Reference*.

```
aws s3 presign s3://amzn-s3-demo-bucket/mydoc.txt --expires-in 604800 --region af-south-1 --endpoint-url https://s3.af-south-1.amazonaws.com
```

For more information, see [presign](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

You can generate a presigned URL programmatically by using the AWS SDKs.

Python

The following Python script generates a GET presigned URL for sharing an object.

- Copy the contents of the script and save it as "`get-only-url.py`" file. To use the following examples, replace the *user input placeholders* with your own information (such as your file name).

```
import argparse
import boto3
from botocore.exceptions import ClientError

def generate_presigned_url(s3_client, client_method, method_parameters,
                           expires_in):
    """
    Generate a presigned Amazon S3 URL that can be used to perform an action.

    :param s3_client: A Boto3 Amazon S3 client.
    :param client_method: The name of the client method that the URL performs.
    :param method_parameters: The parameters of the specified client method.
    :param expires_in: The number of seconds the presigned URL is valid for.
    :return: The presigned URL.
    """

    try:
        url = s3_client.generate_presigned_url(
            ClientMethod=client_method,
            Params=method_parameters,
            ExpiresIn=expires_in
        )
    except ClientError:
        print(f"Couldn't get a presigned URL for client method "
              '{client_method}."')
        raise
    return url

def main():
    parser = argparse.ArgumentParser()
    parser.add_argument("bucket", help="The name of the bucket.")
    parser.add_argument(
        "key", help="The key (path and filename) in the S3 bucket.",
    )
    args = parser.parse_args()

    # By default, this will use credentials from ~/.aws/credentials
    s3_client = boto3.client("s3")

    # The presigned URL is specified to expire in 1000 seconds
    url = generate_presigned_url(
        s3_client,
        "get_object",
        {"Bucket": args.bucket, "Key": args.key},
```

```
    1000
)
print(f"Generated GET presigned URL: {url}")

if __name__ == "__main__":
    main()
```

2. To generate a GET presigned URL for sharing a file, run the following script with your bucket name and desired object path.

The following command uses example values. Replace the *user input placeholders* with your own information.

```
python get-only-url.py amzn-s3-demo-bucket <object-path>
```

The script will output a GET presigned URL:

```
Generated GET presigned URL: https://amzn-s3-demo-
bucket.s3.amazonaws.com/object.txt?
AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Signature=vjbyNxybdZaMmLa
%2ByT372YEAiv4%3D&Expires=1741978496
```

3. You can download the file using the generated presigned URL with curl:

```
curl -X GET "generated-presigned-url" -o "path/to/save/file"
```

For more examples of using the AWS SDKs to generate a presigned URL for sharing an object, see [Create a presigned URL for Amazon S3 by using an AWS SDK](#).

Note

For all AWS Regions launched after March 20, 2019 you need to specify the endpoint-url and AWS Region with the request. For a list of all the Amazon S3 Regions and endpoints, see [Regions and Endpoints](#) in the *AWS General Reference*.

Note

When using the AWS SDKs, the Tagging attribute must be a header and not a query parameter. All other attributes can be passed as a parameter for the presigned URL.

Using the AWS Toolkit for Visual Studio (Windows)

Note

At this time, the AWS Toolkit for Visual Studio does not support Visual Studio for Mac.

1. Install the AWS Toolkit for Visual Studio using the following instructions, [Installing and setting up the Toolkit for Visual Studio](#) in the *AWS Toolkit for Visual Studio User Guide*.
2. Connect to AWS using the following steps, [Connecting to AWS](#) in the *AWS Toolkit for Visual Studio User Guide*.
3. In the left side panel labeled **AWS Explorer**, double-click the bucket containing your object.
4. Right-click the object you wish to have a presigned URL generated for and select **Create Pre-Signed URL....**
5. In the pop-up window, set the expiration date and time for your presigned URL.
6. The **Object Key**, should pre-populate based on the object you selected.
7. Choose **GET** to specify that this presigned URL will be used for downloading an object.
8. Choose the **Generate** button.
9. To copy the URL to the clipboard, choose **Copy**.
10. To use the generated presigned URL, paste the URL into any browser.

Using AWS Toolkit for Visual Studio Code

If you're using Visual Studio Code, you can generate a presigned URL to share an object without writing any code by using AWS Toolkit for Visual Studio Code. For general information, see [AWS Toolkit for Visual Studio Code](#) in the *AWS Toolkit for Visual Studio Code User Guide*.

For instructions on how to install the AWS Toolkit for Visual Studio Code, see [Installing the AWS Toolkit for Visual Studio Code](#) in the *AWS Toolkit for Visual Studio Code User Guide*.

1. Connect to AWS using the following steps, [Connecting to AWS Toolkit for Visual Studio Code](#) in the *AWS Toolkit for Visual Studio Code User Guide*.
2. Select the AWS logo on the left panel in Visual Studio Code.
3. Under **EXPLORER**, select **S3**.
4. Choose a bucket and file and open the context menu (right-click).
5. Choose **Generate presigned URL**, and then set the expiration time (in minutes).
6. Press Enter, and the presigned URL will be copied to your clipboard.

Uploading objects with presigned URLs

You may use presigned URLs to allow someone to upload an object to your Amazon S3 bucket. Using a presigned URL will allow an upload without requiring another party to have AWS security credentials or permissions. A presigned URL is limited by the permissions of the user who creates it. That is, if you receive a presigned URL to upload an object, you can upload an object only if the creator of the URL has the necessary permissions to upload that object.

When someone uses the URL to upload an object, Amazon S3 creates the object in the specified bucket. If an object with the same key that is specified in the presigned URL already exists in the bucket, Amazon S3 replaces the existing object with the uploaded object. After upload, the bucket owner will own the object.

For general information about presigned URLs, see [Download and upload objects with presigned URLs](#).

You can create a presigned URL for uploading an object without writing any code by using AWS Explorer for Visual Studio. You can also generate a presigned URL programmatically by using the AWS SDKs.

 **Note**

At this time, the AWS Toolkit for Visual Studio doesn't support Visual Studio for Mac.

Using the AWS Toolkit for Visual Studio (Windows)

1. Install the AWS Toolkit for Visual Studio using the following instructions, [Installing and setting up the Toolkit for Visual Studio](#) in the *AWS Toolkit for Visual Studio User Guide*.

2. Connect to AWS using the following steps, [Connecting to AWS](#) in the *AWS Toolkit for Visual Studio User Guide*.
3. In the left side panel labeled **AWS Explorer**, right-click the bucket you wish to have an object uploaded to.
4. Choose **Create Pre-Signed URL....**
5. In the pop-up window, set the expiration date and time for your presigned URL.
6. For **Object Key**, set the name of the file to be uploaded. The file you're uploading must match this name exactly. If an object with the same object key already exists in the bucket, Amazon S3 will replace the existing object with the newly uploaded object.
7. Choose **PUT** to specify that this presigned URL will be used for uploading an object.
8. Choose the **Generate** button.
9. To copy the URL to the clipboard, choose **Copy**.
10. To use this URL you can send a PUT request with the `curl` command. Include the full path to your file and the presigned URL itself.

```
curl -X PUT -T "/path/to/file" "presigned URL"
```

Using the AWS SDKs to generate a PUT presigned URL for uploading a file

You can generate a presigned URL that can perform an S3 action for a limited time.

Note

If you use the AWS CLI or AWS SDKs, the expiration time for presigned URLs can be set as high as 7 days. For more information, see [Expiration time for presigned URLs](#).

Python

The following Python script generates a PUT presigned URL for uploading an object to an S3 general purpose bucket.

1. Copy the contents of the script and save it as "`put-only-url.py`" file. To use the following examples, replace the `user input placeholders` with your own information (such as your file name).

```
import argparse
import boto3
from botocore.exceptions import ClientError

def generate_presigned_url(s3_client, client_method, method_parameters,
                           expires_in):
    """
    Generate a presigned Amazon S3 URL that can be used to perform an action.

    :param s3_client: A Boto3 Amazon S3 client.
    :param client_method: The name of the client method that the URL performs.
    :param method_parameters: The parameters of the specified client method.
    :param expires_in: The number of seconds the presigned URL is valid for.
    :return: The presigned URL.
    """

    try:
        url = s3_client.generate_presigned_url(
            ClientMethod=client_method,
            Params=method_parameters,
            ExpiresIn=expires_in
        )
    except ClientError:
        print(f"Couldn't get a presigned URL for client method "
              '{client_method}."')
        raise
    return url

def main():
    parser = argparse.ArgumentParser()
    parser.add_argument("bucket", help="The name of the bucket.")
    parser.add_argument(
        "key", help="The key (path and filename) in the S3 bucket.",
    )
    parser.add_argument(
        "--region", help="The AWS region where the bucket is located.",
        default="us-east-1"
    )
    parser.add_argument(
        "--content-type", help="The content type of the file to upload.",
        default="application/octet-stream"
    )
    args = parser.parse_args()
```

```
# Create S3 client with explicit region configuration
s3_client = boto3.client("s3", region_name=args.region)

# Optionally set signature version if needed for older S3 regions
# s3_client.meta.config.signature_version = 's3v4'

# The presigned URL is specified to expire in 1000 seconds
url = generate_presigned_url(
    s3_client,
    "put_object",
    {
        "Bucket": args.bucket,
        "Key": args.key,
        "ContentType": args.content_type # Specify content type
    },
    1000
)
print(f"Generated PUT presigned URL: {url}")

if __name__ == "__main__":
    main()
```

2. To generate a PUT presigned URL for uploading a file, run the following script with your bucket name and desired object path.

The following command uses example values. Replace the *user input placeholders* with your own information.

```
python put-only-url.py amzn-s3-demo-bucket <object-path> --region us-east-1 --content-type application/octet-stream
```

The script will output a PUT presigned URL:

```
Generated PUT presigned URL: https://amzn-s3-demo-bucket.s3.amazonaws.com/object.txt?AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Signature=vjbyNxybdZaMmLa%2ByT372YEAiv4%3D&Expires=1741978496
```

3. You can now upload the file using the generated presigned URL with curl. Make sure to include the same content type that was used when generating the URL:

```
curl -X PUT -T "path/to/your/local/file" -H "Content-Type: application/octet-stream" "generated-presigned-url"
```

If you specified a different content type when generating the URL, make sure to use that same content type in the curl command.

For more examples of using the AWS SDKs to generate a presigned URL for uploading an object, see [Create a presigned URL for Amazon S3 by using an AWS SDK](#).

Troubleshooting SignatureDoesNotMatch errors

If you encounter a SignatureDoesNotMatch error when using presigned URLs, check the following:

- Verify your system time is synchronized with a reliable time server
- Ensure you're using the URL exactly as generated, without any modifications
- Check if the URL has expired and generate a new one if needed
- Make sure the content type in your upload request matches the content type specified when generating the URL
- Confirm you're using the correct region for the bucket
- When using curl, enclose the URL in quotes to properly handle special characters

Transforming objects with S3 Object Lambda

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

With Amazon S3 Object Lambda, you can add your own code to Amazon S3 GET, LIST, and HEAD requests to modify and process data as it is returned to an application. You can use custom code

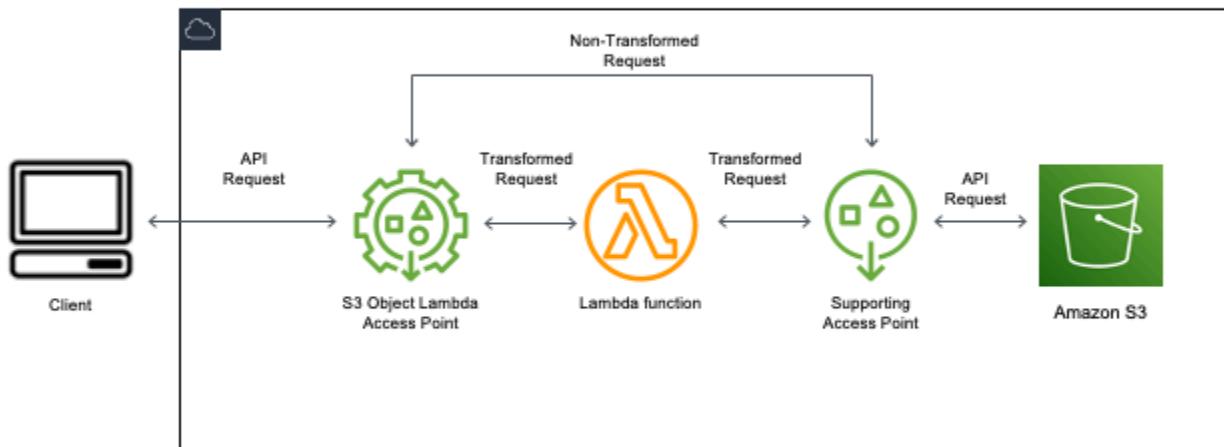

to modify the data returned by S3 GET requests to filter rows, dynamically resize and watermark images, redact confidential data, and more. You can also use S3 Object Lambda to modify the output of S3 LIST requests to create a custom view of all objects in a bucket and S3 HEAD requests to modify object metadata such as object name and size. You can use S3 Object Lambda as an origin for your Amazon CloudFront distribution to tailor data for end users, such as automatically resizing images, transcoding older formats (like from JPEG to WebP), or stripping metadata. For more information, see the AWS Blog post [Use Amazon S3 Object Lambda with Amazon CloudFront](#). Powered by AWS Lambda functions, your code runs on infrastructure that is fully managed by AWS. Using S3 Object Lambda reduces the need to create and store derivative copies of your data or to run proxies, all with no need to change your applications.

How S3 Object Lambda works

S3 Object Lambda uses AWS Lambda functions to automatically process the output of standard S3 GET, LIST, or HEAD requests. AWS Lambda is a serverless compute service that runs customer-defined code without requiring management of underlying compute resources. You can author and run your own custom Lambda functions, tailoring the data transformation to your specific use cases.

After you configure a Lambda function, you attach it to an S3 Object Lambda service endpoint, known as an *Object Lambda Access Point*. The Object Lambda Access Point uses a standard S3 access point, known as a *supporting access point*, to access data.

When you send a request to your Object Lambda Access Point, Amazon S3 automatically calls your Lambda function. Any data retrieved by using an S3 GET, LIST, or HEAD request through the Object Lambda Access Point returns a transformed result back to the application. All other requests are processed as normal, as illustrated in the following diagram.

The topics in this section describe how to work with S3 Object Lambda.

Creating Object Lambda Access Points

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

An Object Lambda Access Point is associated with exactly one standard access point, which you specify during creation. To create an Object Lambda Access Point, you need the following resources:

- **A standard S3 access point.** When you're working with Object Lambda Access Points, this standard access point is known as a *supporting access point* and is attached to an S3 bucket or Amazon FSx for OpenZFS volume. For information about creating standard access points, see [the section called "Creating an access point"](#).
- **An AWS Lambda function.** You can either create your own Lambda function, or you can use a prebuilt function. For more information about creating Lambda functions, see [the section called "Writing Lambda functions"](#). For more information about prebuilt functions, see [Using AWS built Lambda functions](#).
- **(Optional) An AWS Identity and Access Management (IAM) policy.** Amazon S3 access points support IAM resource policies that you can use to control the use of the access point by resource, user, or other conditions. For more information about creating these policies, see [the section called "Configuring IAM policies"](#).

The following sections describe how to create an Object Lambda Access Point by using:

- The AWS Management Console
- The AWS Command Line Interface (AWS CLI)
- An AWS CloudFormation template
- The AWS Cloud Development Kit (AWS CDK)

For information about how to create an Object Lambda Access Point by using the REST API, see [CreateAccessPointForObjectLambda](#) in the *Amazon Simple Storage Service API Reference*.

Create an Object Lambda Access Point

Use one of the following procedures to create your Object Lambda Access Point.

Using the S3 console

To create an Object Lambda Access Point by using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Object Lambda Access Points**.
4. On the **Object Lambda Access Points** page, choose **Create Object Lambda Access Point**.
5. For **Object Lambda Access Point name**, enter the name that you want to use for the access point.

As with standard access points, there are rules for naming Object Lambda Access Points. For more information, see [Naming rules for access points](#).

6. For **Supporting Access Point**, enter or browse to the standard access point that you want to use. The access point must be in the same AWS Region as the objects that you want to transform. For information about creating standard access points, see [the section called "Creating an access point"](#).
7. Under **Transformation configuration**, you can add a function that transforms your data for your Object Lambda Access Point. Do one of the following:
 - If you already have a AWS Lambda function in your account you can choose it under **Invoke Lambda function**. Here you may enter the Amazon Resource Name (ARN) of an Lambda function in your AWS account or choose a Lambda function from the drop-down menu.
 - If you wish to use a AWS built function choose the function name under **AWS built function** and select **Create Lambda function**. This will take you to the Lambda console where you can deploy a built function into your AWS account. For more information about built functions, see [Using AWS built Lambda functions](#).

Under **S3 APIs**, choose one or more API operations to invoke. For each API selected you must specify a Lambda function to invoke.

8. (Optional) Under **Payload**, add JSON text that you want to provide to your Lambda function as input. You can configure payloads with different parameters for different Object Lambda Access Points that invoke the same Lambda function, thereby extending the flexibility of your Lambda function.

 **Important**

When you're using Object Lambda Access Points, make sure that the payload does not contain any confidential information.

9. (Optional) For **Range and part number**, you must enable this option if you want to process GET and HEAD requests with range and part number headers. Enabling this option confirms that your Lambda function can recognize and process these requests. For more information about range headers and part numbers, see [Working with Range and partNumber headers](#).
10. (Optional) For **Request metrics**, choose **Enable** or **Disable** to add Amazon S3 monitoring to your Object Lambda Access Point. Request metrics are billed at the standard Amazon CloudWatch rate.
11. (Optional) Under **Object Lambda Access Point policy**, set a resource policy. Resource policies grant permissions for the specified Object Lambda Access Point and can control the use of the access point by resource, user, or other conditions. For more information about Object Lambda Access Point resource policies see, [Configuring IAM policies for Object Lambda Access Points](#).
12. Under **Block Public Access settings for this Object Lambda Access Point**, select the block public access settings that you want to apply. All block public access settings are enabled by default for new Object Lambda Access Points, and we recommend that you leave default settings enabled. Amazon S3 currently doesn't support changing an Object Lambda Access Point's block public access settings after the Object Lambda Access Points has been created.

For more information about using Amazon S3 Block Public Access, see [Managing public access to access points for general purpose buckets](#).

13. Choose **Create Object Lambda Access Point**.

Using the AWS CLI

To create an Object Lambda Access Point by using an AWS CloudFormation template

Note

To use the following commands, replace the *user input placeholders* with your own information.

1. Download the AWS Lambda function deployment package `s3objectlambda_deployment_package.zip` at [S3 Object Lambda default configuration](#).
2. Run the following put-object command to upload the package to an Amazon S3 bucket.

```
aws s3api put-object --bucket Amazon S3 bucket name --key  
s3objectlambda_deployment_package.zip --body release/  
s3objectlambda_deployment_package.zip
```

3. Download the AWS CloudFormation template `s3objectlambda_defaultconfig.yaml` at [S3 Object Lambda default configuration](#).
4. Run the following deploy command to deploy the template to your AWS account.

```
aws cloudformation deploy --template-file s3objectlambda_defaultconfig.yaml \  
--stack-name CloudFormation stack name \  
--parameter-overrides ObjectLambdaAccessPointName=Object Lambda Access Point name \  
\  
SupportingAccessPointName=Amazon S3 access point S3BucketName=Amazon S3 bucket \  
LambdaFunctionS3BucketName=Amazon S3 bucket containing your Lambda package \  
LambdaFunctionS3Key=Lambda object key LambdaFunctionS3ObjectVersion=Lambda object version \  
LambdaFunctionRuntime=Lambda function runtime --capabilities capability_IAM
```

You can configure this AWS CloudFormation template to invoke Lambda for GET, HEAD, and LIST API operations. For more information about modifying the template's default configuration, see [the section called "Automate S3 Object Lambda setup with AWS CloudFormation"](#).

To create an Object Lambda Access Point by using the AWS CLI

Note

To use the following commands, replace the *user input placeholders* with your own information.

The following example creates an Object Lambda Access Point named *my-object-lambda-ap* for the bucket *amzn-s3-demo-bucket1* in the account *111122223333*. This example assumes that a standard access point named *example-ap* has already been created. For information about creating a standard access point, see [the section called “Creating an access point”](#).

This example uses the AWS prebuilt function `decompress`. For more information about prebuilt functions, see [the section called “Using AWS built functions”](#).

1. Create a bucket. In this example, we will use *amzn-s3-demo-bucket1*. For information about creating buckets, see [the section called “Creating a general purpose bucket”](#).
2. Create a standard access point and attach it to your bucket. In this example, we will use *example-ap*. For information about creating standard access points, see [the section called “Creating an access point”](#).
3. Do one of the following:
 - Create a Lambda function in your account that you would like to use to transform your Amazon S3 object. For more information about creating Lambda functions, see [the section called “Writing Lambda functions”](#). To use your custom function with the AWS CLI, see [Using Lambda with the AWS CLI](#) in the *AWS Lambda Developer Guide*.
 - Use an AWS prebuilt Lambda function. For more information about prebuilt functions, see [Using AWS built Lambda functions](#).
4. Create a JSON configuration file named `my-olap-configuration.json`. In this configuration, provide the supporting access point and the Amazon Resource Name (ARN) for the Lambda function that you created in the previous steps or the ARN for the prebuilt function that you're using.

Example

{

```
"SupportingAccessPoint" : "arn:aws:s3:us-east-1:11122223333:accesspoint/example-ap",  
"TransformationConfigurations": [ {  
    "Actions" : ["GetObject", "HeadObject", "ListObjects", "ListObjectsV2"],  
    "ContentTransformation" : {  
        "AwsLambda": {  
            "FunctionPayload" : "{\"compressionType\":\"gzip\"}",  
            "FunctionArn" : "arn:aws:lambda:us-east-1:11122223333:function/  
compress"  
        }  
    }  
}]  
}
```

- Run the `create-access-point-for-object-lambda` command to create your Object Lambda Access Point.

```
aws s3control create-access-point-for-object-lambda --account-id 11122223333 --  
name my-object-lambda-ap --configuration file://my-olap-configuration.json
```

- (Optional) Create a JSON policy file named `my-olap-policy.json`.

Adding an Object Lambda Access Point resource policy can control the use of the access point by resource, user, or other conditions. This resource policy grants the `GetObject` permission for account **44445556666** to the specified Object Lambda Access Point.

Example

```
{  
    "Version": "2008-10-17",  
    "Statement": [  
        {  
            "Sid": "Grant account 44445556666 GetObject access",  
            "Effect": "Allow",  
            "Action": "s3-object-lambda:GetObject",  
            "Principal": {  
                "AWS": "arn:aws:iam::44445556666:root"  
            },  
            "Resource": "your-object-lambda-access-point-arn"  
        }  
    ]  
}
```

```
}
```

7. (Optional) Run the `put-access-point-policy-for-object-lambda` command to set your resource policy.

```
aws s3control put-access-point-policy-for-object-lambda --account-id 111122223333  
--name my-object-lambda-ap --policy file://my-olap-policy.json
```

8. (Optional) Specify a payload.

A payload is optional JSON that you can provide to your AWS Lambda function as input. You can configure payloads with different parameters for different Object Lambda Access Points that invoke the same Lambda function, thereby extending the flexibility of your Lambda function.

The following Object Lambda Access Point configuration shows a payload with two parameters.

```
{  
  "SupportingAccessPoint": "AccessPointArn",  
  "CloudWatchMetricsEnabled": false,  
  "TransformationConfigurations": [  
    {  
      "Actions": ["GetObject", "HeadObject", "ListObjects", "ListObjectsV2"],  
      "ContentTransformation": {  
        "AwsLambda": {  
          "FunctionArn": "FunctionArn",  
          "FunctionPayload": "{\"res-x\": \"100\", \"res-y\": \"100\"}"  
        }  
      }  
    }  
  ]  
}
```

The following Object Lambda Access Point configuration shows a payload with one parameter, and with `GetObject-Range`, `GetObject-PartNumber`, `HeadObject-Range`, and `HeadObject-PartNumber` enabled.

```
{  
  "SupportingAccessPoint": "AccessPointArn",  
  "CloudWatchMetricsEnabled": false,  
  "AllowedFeatures": ["GetObject-Range", "GetObject-PartNumber", "HeadObject-  
Range", "HeadObject-PartNumber"],  
  "ContentTransformation": {  
    "AwsLambda": {  
      "FunctionArn": "FunctionArn",  
      "FunctionPayload": "{\"res-x\": \"100\", \"res-y\": \"100\"}"  
    }  
  }  
}
```

```
"TransformationConfigurations": [{}  
    "Action": ["GetObject", "HeadObject", "ListObjects", "ListObjectsV2"],  
    "ContentTransformation": {  
        "AwsLambda": {  
            "FunctionArn": "FunctionArn",  
            "FunctionPayload": "{\"compression-amount\": \"5\"}"  
        }  
    }  
}]  
}
```

 **Important**

When you're using Object Lambda Access Points, make sure that the payload does not contain any confidential information.

Using the AWS CloudFormation console and template

You can create an Object Lambda Access Point by using the default configuration provided by Amazon S3. You can download an AWS CloudFormation template and Lambda function source code from the [GitHub repository](#) and deploy these resources to set up a functional Object Lambda Access Point.

For information about modifying the AWS CloudFormation template's default configuration, see [the section called "Automate S3 Object Lambda setup with AWS CloudFormation"](#).

For information about configuring Object Lambda Access Points by using CloudFormation without the template, see [AWS::S3::ObjectLambda::AccessPoint](#) in the *AWS CloudFormation User Guide*.

To upload the Lambda function deployment package

1. Download the AWS Lambda function deployment package `s3objectlambda_deployment_package.zip` at [S3 Object Lambda default configuration](#).
2. Upload the package to an Amazon S3 bucket.

To create an Object Lambda Access Point by using the AWS CloudFormation console

1. Download the AWS CloudFormation template `s3objectlambda_defaultconfig.yaml` at [S3 Object Lambda default configuration](#).
2. Sign in to the AWS Management Console and open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
3. Do one of the following:
 - If you've never used AWS CloudFormation before, on the AWS CloudFormation home page, choose **Create stack**.
 - If you have used AWS CloudFormation before, in the left navigation pane, choose **Stacks**. Choose **Create stack**, then choose **With new resources (standard)**.
4. For **Prerequisite - Prepare template**, choose **Template is ready**.
5. For **Specify template**, choose **Upload a template file** and upload `s3objectlambda_defaultconfig.yaml`.
6. Choose **Next**.
7. On the **Specify stack details** page, enter a name for the stack.
8. In the **Parameters** section, specify the following parameters that are defined in the stack template:
 - a. For **CreateNewSupportingAccessPoint**, do one of the following:
 - If you already have a supporting access point for the S3 bucket where you uploaded the template, choose **false**.
 - If you want to create a new access point for this bucket, choose **true**.
 - b. For **EnableCloudWatchMonitoring**, choose **true** or **false**, depending on whether you want to enable Amazon CloudWatch request metrics and alarms.
 - c. (Optional) For **LambdaFunctionPayload**, add JSON text that you want to provide to your Lambda function as input. You can configure payloads with different parameters for different Object Lambda Access Points that invoke the same Lambda function, thereby extending the flexibility of your Lambda function.

⚠ Important

When you're using Object Lambda Access Points, make sure that the payload does not contain any confidential information.

- d. For **LambdaFunctionRuntime**, enter your preferred runtime for the Lambda function. The available choices are nodejs14.x, python3.9, java11.
- e. For **LambdaFunctionS3BucketName**, enter the Amazon S3 bucket name where you uploaded the deployment package.
- f. For **LambdaFunctionS3Key**, enter the Amazon S3 object key where you uploaded the deployment package.
- g. For **LambdaFunctionS3ObjectVersion**, enter the Amazon S3 object version where you uploaded the deployment package.
- h. For **ObjectLambdaAccessPointName**, enter a name for your Object Lambda Access Point.
- i. For **S3BucketName**, enter the Amazon S3 bucket name that will be associated with your Object Lambda Access Point.
- j. For **SupportingAccessPointName**, enter the name of your supporting access point.

ⓘ Note

This is an access point that is associated with the Amazon S3 bucket that you chose in the previous step. If you do not have any access points associated with your Amazon S3 bucket, you can configure the template to create one for you by choosing **true** for **CreateNewSupportingAccessPoint**.

9. Choose **Next**.
10. On the **Configure stack options** page, choose **Next**.

For more information about the optional settings on this page, see [Setting AWS CloudFormation stack options](#) in the *AWS CloudFormation User Guide*.

11. On the **Review** page, choose **Create stack**.

Using the AWS Cloud Development Kit (AWS CDK)

For more information about configuring Object Lambda Access Points by using the AWS CDK, see [AWS::S3ObjectLambda Construct Library](#) in the *AWS Cloud Development Kit (AWS CDK) API Reference*.

Automate S3 Object Lambda setup with a CloudFormation template

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners. For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

You can use an AWS CloudFormation template to quickly create an Amazon S3 Object Lambda Access Point. The CloudFormation template automatically creates relevant resources, configures AWS Identity and Access Management (IAM) roles, and sets up an AWS Lambda function that automatically handles requests through the Object Lambda Access Point. With the CloudFormation template, you can implement best practices, improve your security posture, and reduce errors caused by manual processes.

This [GitHub repository](#) contains the CloudFormation template and Lambda function source code. For instructions on how to use the template, see [the section called “Creating Object Lambda Access Points”](#).

The Lambda function provided in the template does not run any transformation. Instead, it returns your objects as-is from the underlying data source. You can clone the function and add your own transformation code to modify and process data as it is returned to an application. For more information about modifying your function, see [the section called “Modifying the Lambda function”](#) and [the section called “Writing Lambda functions”](#).

Modifying the template

Creating a new supporting access point

S3 Object Lambda uses two access points, an Object Lambda Access Point and a standard S3 access point, which is referred to as the *supporting access point*. When you make a request to an Object Lambda Access Point, S3 either invokes Lambda on your behalf, or it delegates the

request to the supporting access point, depending upon the S3 Object Lambda configuration. You can create a new supporting access point by passing the following parameter as part of the `aws cloudformation deploy` command when deploying the template.

```
CreateNewSupportingAccessPoint=true
```

Configuring a function payload

You can configure a payload to provide supplemental data to the Lambda function by passing the following parameter as part of the `aws cloudformation deploy` command when deploying the template.

```
LambdaFunctionPayload="format=json"
```

Enabling Amazon CloudWatch monitoring

You can enable CloudWatch monitoring by passing the following parameter as part of the `aws cloudformation deploy` command when deploying the template.

```
EnableCloudWatchMonitoring=true
```

This parameter enables your Object Lambda Access Point for Amazon S3 request metrics and creates two CloudWatch alarms to monitor client-side and server-side errors.

Note

Amazon CloudWatch usage will incur additional costs. For more information about Amazon S3 request metrics, see [Monitoring and logging access points](#).

For pricing details, see [CloudWatch pricing](#).

Configuring provisioned concurrency

To reduce latency, you can configure provisioned concurrency for the Lambda function that's backing the Object Lambda Access Point by editing the template to include the following lines under Resources.

```
LambdaFunctionVersion:  
  Type: AWS::Lambda::Version
```

Properties:

```
  FunctionName: !Ref LambdaFunction  
  ProvisionedConcurrencyConfig:  
    ProvisionedConcurrentExecutions: Integer
```

Note

You will incur additional charges for provisioning concurrency. For more information about provisioned concurrency, see [Managing Lambda provisioned concurrency](#) in the *AWS Lambda Developer Guide*.

For pricing details, see [AWS Lambda pricing](#).

Modifying the Lambda function

Changing header values for a GetObject request

By default, the Lambda function forwards all headers, except Content-Length and ETag, from the presigned URL request to the GetObject client. Based on your transformation code in the Lambda function, you can choose to send new header values to the GetObject client.

You can update your Lambda function to send new header values by passing them in the `WriteGetObjectResponse` API operation.

For example, if your Lambda function translates text in Amazon S3 objects to a different language, you can pass a new value in the Content-Language header. You can do this by modifying the `writeResponse` function as follows:

```
async function writeResponse (s3Client: S3, requestContext: GetObjectContext,  
  transformedObject: Buffer,  
  headers: Headers): Promise<PromiseResult<{}, AWSError>> {  
  const { algorithm, digest } = getChecksum(transformedObject);  
  
  return s3Client.writeGetObjectResponse({  
    RequestRoute: requestContext.outputRoute,  
    RequestToken: requestContext.outputToken,  
    Body: transformedObject,  
    Metadata: {  
      'body-checksum-algorithm': algorithm,  
      'body-checksum-digest': digest  
    },
```

```
    ...headers,  
    ContentLanguage: 'my-new-Language'  
  }).promise();  
}
```

For a full list of supported headers, see [WriteGetObjectResponse](#) in the *Amazon Simple Storage Service API Reference*.

Returning metadata headers

You can update your Lambda function to send new header values by passing them in the [WriteGetObjectResponse](#) API operation request.

```
async function writeResponse (s3Client: S3, requestContext: GetObjectContext,  
transformedObject: Buffer,  
headers: Headers): Promise<PromiseResult<{}, AWSError>> {  
const { algorithm, digest } = getChecksum(transformedObject);  
  
return s3Client.writeGetObjectResponse({  
  RequestRoute: requestContext.outputRoute,  
  RequestToken: requestContext.outputToken,  
  Body: transformedObject,  
  Metadata: {  
    'body-checksum-algorithm': algorithm,  
    'body-checksum-digest': digest,  
    'my-new-header': 'my-new-value'  
  },  
  ...headers  
}).promise();  
}
```

Returning a new status code

You can return a custom status code to the GetObject client by passing it in the [WriteGetObjectResponse](#) API operation request.

```
async function writeResponse (s3Client: S3, requestContext: GetObjectContext,  
transformedObject: Buffer,  
headers: Headers): Promise<PromiseResult<{}, AWSError>> {  
const { algorithm, digest } = getChecksum(transformedObject);  
  
return s3Client.writeGetObjectResponse({
```

```
RequestRoute: requestContext.outputRoute,
RequestToken: requestContext.outputToken,
Body: transformedObject,
Metadata: {
    'body-checksum-algorithm': algorithm,
    'body-checksum-digest': digest
},
...headers,
StatusCode: Integer
}).promise();
}
```

For a full list of supported status codes, see [WriteGetObjectResponse](#) in the *Amazon Simple Storage Service API Reference*.

Applying Range and partNumber parameters to the source object

By default, the Object Lambda Access Point created by the CloudFormation template can handle the Range and partNumber parameters. The Lambda function applies the range or part number requested to the transformed object. To do so, the function must download the whole object and run the transformation. In some cases, your transformed object ranges might map exactly to your source object ranges. This means that requesting byte range A-B on your source object and running the transformation might produce the same result as requesting the whole object, running the transformation, and returning byte range A-B on the transformed object.

In such cases, you can change the Lambda function implementation to apply the range or part number directly to the source object. This approach reduces the overall function latency and memory required. For more information, see [the section called “Working with Range and partNumber headers”](#).

Disabling Range and partNumber handling

By default, the Object Lambda Access Point created by the CloudFormation template can handle the Range and partNumber parameters. If you don't need this behavior, you can disable it by removing the following lines from the template:

```
AllowedFeatures:
- GetObject-Range
- GetObject-PartNumber
- HeadObject-Range
- HeadObject-PartNumber
```

Transforming large objects

By default, the Lambda function processes the entire object in memory before it can start streaming the response to S3 Object Lambda. You can modify the function to stream the response as it performs the transformation. Doing so helps reduce the transformation latency and the Lambda function memory size. For an example implementation, see the [Stream compressed content example](#).

Using Amazon S3 Object Lambda Access Points

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners. For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

Making requests through Amazon S3 Object Lambda Access Points works the same as making requests through other access points. For more information about how to make requests through an access point, see [Using Amazon S3 access points for general purpose buckets](#). You can make requests through Object Lambda Access Points by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

Important

The Amazon Resource Names (ARNs) for Object Lambda Access Points use a service name of `s3-object-lambda`. Thus, Object Lambda Access Point ARNs begin with `arn:aws::s3-object-lambda`, instead of `arn:aws::s3`, which is used with other access points.

How to find the ARN for your Object Lambda Access Point

To use an Object Lambda Access Point with the AWS CLI or AWS SDKs, you need to know the Amazon Resource Name (ARN) of the Object Lambda Access Point. The following examples show how to find the ARN for an Object Lambda Access Point by using the Amazon S3 console or AWS CLI.

Using the S3 console

To find the ARN for your Object Lambda Access Point by using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. Choose the option button next to the Object Lambda Access Point whose ARN you want to copy.
4. Choose **Copy ARN**.

Using the AWS CLI

To find the ARN for your Object Lambda Access Point by using the AWS CLI

1. To retrieve a list of the Object Lambda Access Points that are associated with your AWS account, run the following command. Before running the command, replace the account ID **111122223333** with your AWS account ID.

```
aws s3control list-access-points-for-object-lambda --account-id 111122223333
```

2. Review the command output to find the Object Lambda Access Point ARN that you want to use. The output of the previous command should look similar to the following example.

```
{  
    "ObjectLambdaAccessPointList": [  
        {  
            "Name": "my-object-lambda-ap",  
            "ObjectLambdaAccessPointArn": "arn:aws:s3-object-lambda:us-  
east-1:111122223333:accesspoint/my-object-lambda-ap"  
        },  
        ...  
    ]  
}
```

How to use a bucket-style alias for your S3 bucket Object Lambda Access Point

When you create an Object Lambda Access Point, Amazon S3 automatically generates a unique alias for your Object Lambda Access Point. You can use this alias instead of an Amazon S3 bucket

name or the Object Lambda Access Point Amazon Resource Name (ARN) in a request for access point data plane operations. For a list of these operations, see [Access point compatibility](#).

An Object Lambda Access Point alias name is created within the same namespace as an Amazon S3 bucket. This alias name is automatically generated and cannot be changed. For an existing Object Lambda Access Point, an alias is automatically assigned for use. An Object Lambda Access Point alias name meets all the requirements of a valid Amazon S3 bucket name and consists of the following parts:

Object Lambda Access Point name prefix-metadata--ol-s3

 **Note**

The --ol-s3 suffix is reserved for Object Lambda Access Point alias names and can't be used for bucket or Object Lambda Access Point names. For more information about Amazon S3 bucket-naming rules, see [General purpose bucket naming rules](#).

The following examples show the ARN and the Object Lambda Access Point alias for an Object Lambda Access Point named *my-object-lambda-access-point*:

- **ARN** – `arn:aws:s3-object-lambda:region:account-id:accesspoint/my-object-lambda-access-point`
- **Object Lambda Access Point alias** – *my-object-lambda-acc-1a4n8yjrb3kda96f67zwrwiiuse1a--ol-s3*

When you use an Object Lambda Access Point, you can use the Object Lambda Access Point alias name without requiring extensive code changes.

When you delete an Object Lambda Access Point, the Object Lambda Access Point alias name becomes inactive and unprovisioned.

How to find the alias for your Object Lambda Access Point

Using the S3 console

To find the alias for your Object Lambda Access Point by using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Object Lambda Access Points**.
3. For the Object Lambda Access Point that you want to use, copy the **Object Lambda Access Point alias** value.

Using the AWS CLI

When you create an Object Lambda Access Point, Amazon S3 automatically generates an Object Lambda Access Point alias name, as shown in the following example command. To run this command, replace the *user input placeholders* with your own information. For information about how to create an Object Lambda Access Point by using the AWS CLI, see [To create an Object Lambda Access Point by using the AWS CLI](#).

```
aws s3control create-access-point-for-object-lambda --account-id 111122223333 --  
name my-object-lambda-access-point --configuration file://my-olap-configuration.json  
{  
    "ObjectLambdaAccessPointArn": "arn:aws:s3:region:111122223333:accesspoint/my-  
access-point",  
    "Alias": {  
        "Value": "my-object-lambda-acc-1a4n8yjrb3kda96f67zwrwiuse1a--ol-s3",  
        "Status": "READY"  
    }  
}
```

The generated Object Lambda Access Point alias name has two fields:

- The Value field is the alias value of the Object Lambda Access Point.
- The Status field is the status of the Object Lambda Access Point alias. If the status is PROVISIONING, Amazon S3 is provisioning the Object Lambda Access Point alias, and the alias is not yet ready for use. If the status is READY, the Object Lambda Access Point alias has been successfully provisioned and is ready for use.

For more information about the ObjectLambdaAccessPointAlias data type in the REST API, see [CreateAccessPointForObjectLambda](#) and [ObjectLambdaAccessPointAlias](#) in the *Amazon Simple Storage Service API Reference*.

How to use the Object Lambda Access Point alias

You can use an Object Lambda Access Point alias instead of an Amazon S3 bucket name for the operations listed in [Access point compatibility](#).

The following AWS CLI example for the get-bucket-location command uses the bucket's access point alias to return the AWS Region that the bucket is in. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api get-bucket-location --bucket my-object-Lambda-acc-w7i37nq6xuzgax3jw3oqtifiusw2a--ol-s3
{
    "LocationConstraint": "us-west-2"
}
```

If the Object Lambda Access Point alias in a request isn't valid, the error code `InvalidAccessPointAliasError` is returned. For more information about `InvalidAccessPointAliasError`, see [List of Error Codes](#) in the *Amazon Simple Storage Service API Reference*.

The limitations of an Object Lambda Access Point alias are the same as those of an access point alias. For more information about the limitations of an access point alias, see [Access point alias limitations](#).

Security considerations for S3 Object Lambda Access Points

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

With Amazon S3 Object Lambda, you can perform custom transformations on data as it leaves Amazon S3 by using the scale and flexibility of AWS Lambda as a compute platform. S3 and Lambda remain secure by default, but to maintain this security, special consideration by the Lambda function author is required. S3 Object Lambda requires that all access be made by authenticated principals (no anonymous access) and over HTTPS.

To mitigate security risks, we recommend the following:

- Scope the Lambda execution role to the smallest set of permissions possible.

- Whenever possible, make sure your Lambda function accesses Amazon S3 through the provided presigned URL.

Configuring IAM policies

S3 access points support AWS Identity and Access Management (IAM) resource policies that allow you to control the use of the access point by resource, user, or other conditions. For more information, see [Configuring IAM policies for Object Lambda Access Points](#).

Encryption behavior

Because Object Lambda Access Points use both Amazon S3 and AWS Lambda, there are differences in encryption behavior. For more information about default S3 encryption behavior, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

- When you're using S3 server-side encryption with Object Lambda Access Points, the object is decrypted before being sent to Lambda. After the object is sent to Lambda, it is processed unencrypted (in the case of a GET or HEAD request).
- To prevent the encryption key from being logged, S3 rejects GET and HEAD requests for objects that are encrypted by using server-side encryption with customer-provided keys (SSE-C). However, the Lambda function might still retrieve these objects if it has access to the client-provided key.
- When using S3 client-side encryption with Object Lambda Access Points, make sure that Lambda has access to the encryption key so that it can decrypt and re-encrypt the object.

Access points security

S3 Object Lambda uses two access points, an Object Lambda Access Point and a standard S3 access point, which is referred to as the *supporting access point*. When you make a request to an Object Lambda Access Point, S3 either invokes Lambda on your behalf, or it delegates the request to the supporting access point, depending upon the S3 Object Lambda configuration. When Lambda is invoked for a request S3 generates a presigned URL to your object on your behalf through the supporting access point. Your Lambda function receives this URL as input when the function is invoked.

You can set your Lambda function to use this presigned URL to retrieve the original object, instead of invoking S3 directly. By using this model, you can apply better security boundaries to your objects. You can limit direct object access through S3 buckets or S3 access points to a limited set

of IAM roles or users. This approach also protects your Lambda functions from being subject to the [confused deputy problem](#), where a misconfigured function with different permissions than the invoker could allow or deny access to objects when it should not.

Object Lambda Access Point public access

S3 Object Lambda does not allow anonymous or public access because Amazon S3 must authorize your identity to complete any S3 Object Lambda request. When invoking requests through an Object Lambda Access Point, you must have the `lambda:InvokeFunction` permission for the configured Lambda function. Similarly, when invoking other API operations through an Object Lambda Access Point, you must have the required `s3:*` permissions.

Without these permissions, requests to invoke Lambda or delegate to S3 will fail with HTTP 403 (Forbidden) errors. All access must be made by authenticated principals. If you require public access, you can use Lambda@Edge as a possible alternative. For more information, see [Customizing at the edge with Lambda@Edge](#) in the *Amazon CloudFront Developer Guide*.

Object Lambda Access Point IP addresses

The `describe-managed-prefix-lists` subnets support gateway virtual private cloud (VPC) endpoints and are related to the routing table of VPC endpoints. Since Object Lambda Access Point does not support gateway VPC its IP ranges are missing. The missing ranges belong to Amazon S3, but are not supported by gateway VPC endpoints. For more information about `describe-managed-prefix-lists`, see [DescribeManagedPrefixLists](#) in the *Amazon EC2 API Reference* and [AWS IP address ranges](#) in the *AWS General Reference*.

Configuring IAM policies for Object Lambda Access Points

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners. For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

Amazon S3 access points support AWS Identity and Access Management (IAM) resource policies that you can use to control the use of the access point by resource, user, or other conditions. You can control access through an optional resource policy on your Object Lambda Access Point, or a

resource policy on supporting access point. For step-by-step examples, see [Tutorial: Transforming data for your application with S3 Object Lambda](#) and [Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend](#).

The following four resources must have permissions granted to work with Object Lambda Access Points:

- The IAM identity, such as user or role. For more information about IAM identities and best practices, see [IAM identities \(users, user groups, and roles\)](#) in the *IAM User Guide*.
- The standard access point connected to an underlying data source such as an S3 bucket or Amazon FSx for OpenZFS volume. When you're working with Object Lambda Access Points, this standard access point is known as a *supporting access point*.
- The Object Lambda Access Point.
- The AWS Lambda function.

Important

Before you save your policy, make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices.

To learn more about validating policies by using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

The following policy examples assume that you have the following resources:

- An Amazon S3 bucket with the following Amazon Resource Name (ARN):

`arn:aws:s3:::amzn-s3-demo-bucket1`

- An Amazon S3 standard access point on this bucket with the following ARN:

`arn:aws:s3:us-east-1:1112223333:accesspoint/my-access-point`

- An Object Lambda Access Point with the following ARN:

arn:aws:s3-object-lambda:*us-east-1:111122223333*:accesspoint/*my-object-lambda-ap*

- An AWS Lambda function with the following ARN:

arn:aws:lambda:*us-east-1:111122223333*:function:*MyObjectLambdaFunction*

Note

If you're using a Lambda function from your account, you must include the specific function version in your policy statement. In the following example ARN, the version is indicated by **1**:

arn:aws:lambda:*us-east-1:111122223333*:function:*MyObjectLambdaFunction:1*

Lambda doesn't support adding IAM policies to the version \$LATEST. For more information about Lambda function versions, see [Lambda function versions](#) in the *AWS Lambda Developer Guide*.

Example – Bucket policy that delegates access control to standard access points

The following S3 bucket policy example delegates access control for a bucket to the bucket's standard access points. This policy allows full access to all access points that are owned by the bucket owner's account. Thus, all access to this bucket is controlled by the policies that are attached to its access points. Users can read from the bucket only through an access point, which means that operations can be invoked only through access points. For more information, see [Delegating access control to access points](#).

Enable permissions for Lambda execution roles

When GET requests are made to an Object Lambda Access Point, your Lambda function needs permission to send data to S3 Object Lambda Access Point. This permission is provided by enabling the `s3-object-lambda:WriteGetObjectResponse` permission on your Lambda function's execution role. You can create a new execution role or update an existing one.

Note

Your function needs the `s3-object-lambda:WriteGetObjectResponse` permission only if you're making a GET request.

To create an execution role in the IAM console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Under **Common use cases**, choose **Lambda**.
5. Choose **Next**.
6. On the **Add permissions** page, search for the AWS managed policy [AmazonS3ObjectLambdaExecutionRolePolicy](#), and then select the check box beside the policy name.

This policy should contain the `s3-object-lambda:WriteGetObjectResponse` Action.

7. Choose **Next**.
8. On the **Name, review, and create** page, for **Role name**, enter **s3-object-lambda-role**.
9. (Optional) Add a description and tags for this role.
10. Choose **Create role**.
11. Apply the newly created **s3-object-lambda-role** as your Lambda function's execution role.
This can be done during or after Lambda function creation in the Lambda console.

For more information about execution roles, see [Lambda execution role](#) in the *AWS Lambda Developer Guide*.

Using context keys with Object Lambda Access Points

S3 Object Lambda will evaluate context keys such as `s3-object-lambda:TlsVersion` or `s3-object-lambda:AuthType` that are related to the connection or signing of the request. All other context keys, such as `s3:prefix`, are evaluated by Amazon S3.

Object Lambda Access Point CORS support

When S3 Object Lambda receives a request from a browser or the request includes an `Origin` header, S3 Object Lambda always adds an `"AllowedOrigins": "*"` header field.

For more information, see [Using cross-origin resource sharing \(CORS\)](#).

Writing Lambda functions for S3 Object Lambda Access Points

Working with GetObject requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for GetObject. S3 Object Lambda includes the Amazon S3 API operation, WriteGetObjectResponse, which enables the Lambda function to provide customized data and response headers to the GetObject caller.

`WriteGetObjectResponse` gives you extensive control over the status code, response headers, and response body, based on your processing needs. You can use `WriteGetObjectResponse` to respond with the whole transformed object, portions of the transformed object, or other responses based on the context of your application. The following section shows unique examples of using the `WriteGetObjectResponse` API operation.

- **Example 1:** Respond with HTTP status code 403 (Forbidden)
- **Example 2:** Respond with a transformed image
- **Example 3:** Stream compressed content

Example 1: Respond with HTTP status code 403 (Forbidden)

You can use `WriteGetObjectResponse` to respond with the HTTP status code 403 (Forbidden) based on the content of the object.

// The 'userRequest' object has information related to the user who made this
// 'GetObject' request to S3 Object Lambda.
const { userRequest, getObjectContext } = event;
const { outputRoute, outputToken, inputS3Url } = getObjectContext;

// Check for the presence of a 'CustomHeader' header and deny or allow based on
// that header.
const isTokenPresent = Object
  .keys(userRequest.headers)
  .includes("SuperSecretToken");

if (!isTokenPresent) {
    // If the token is not present, we send an error back to the user. The
    // 'await' in front of the request
    // indicates that we want to wait for this request to finish sending before
    // moving on.
    await s3.writeGetObjectResponse({
        RequestRoute: outputRoute,
        RequestToken: outputToken,
        StatusCode: 403,
        ErrorCode: "NoSuperSecretTokenFound",
        ErrorMessage: "The request was not secret enough.",
    }).promise();
} else {
    // If the user presented our custom 'SuperSecretToken' header, we send the
    // requested object back to the user.
    // Again, note the presence of 'await'.
    const presignedResponse = await axios.get(inputS3Url);
    await s3.writeGetObjectResponse({
        RequestRoute: outputRoute,
        RequestToken: outputToken,
        Body: presignedResponse.data,
    }).promise();
}

// Gracefully exit the Lambda function.
return { statusCode: 200 };
}
```

Example 2: Respond with a transformed image

When performing an image transformation, you might find that you need all the bytes of the source object before you can start processing them. In this case, your `WriteGetObjectResponse` request returns the whole object to the requesting application in one call.

Java

```
package com.amazonaws.lambda.functions;

Example 3: Stream compressed content

When you're compressing objects, compressed data is produced incrementally. Consequently, you can use your `WriteGetObjectResponse` request to return the compressed data as soon as it's ready. As shown in this example, you don't need to know the length of the completed transformation.

 **Note**

Although S3 Object Lambda allows up to 60 seconds to send a complete response to the caller through the `WriteGetObjectResponse` request, the actual amount of time available might be less. For example, your Lambda function timeout might be less than 60 seconds. In other cases, the caller might have more stringent timeouts.

For the original caller to receive a response other than HTTP status code 500 (Internal Server Error), the `WriteGetObjectResponse` call must be completed. If the Lambda function returns, with an exception or otherwise, before the `WriteGetObjectResponse` API operation is called, the original caller receives a 500 (Internal Server Error) response. Exceptions thrown during the time it takes to complete the response result in truncated responses to the caller. If the Lambda function receives an HTTP status code 200 (OK) response from the `WriteGetObjectResponse` API call, then the original caller has sent the complete request. The Lambda function's response, whether an exception is thrown or not, is ignored by S3 Object Lambda.

When calling the `WriteGetObjectResponse` API operation, Amazon S3 requires the route and request token from the event context. For more information, see [Event context format and usage](#).

The route and request token parameters are required to connect the `WriteGetObjectResult` response with the original caller. Even though it is always appropriate to retry 500 (Internal Server Error) responses, because the request token is a single-use token, subsequent attempts to use it might result in HTTP status code 400 (Bad Request) responses. Although the call to `WriteGetObjectResponse` with the route and request tokens doesn't need to be made from the

invoked Lambda function, it must be made by an identity in the same account. The call also must be completed before the Lambda function finishes execution.

Working with HeadObject requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for HeadObject. Lambda will receive a JSON payload that contains a key called headObjectContext. Inside the context, there is a single property called inputS3Url, which is a presigned URL for the supporting access point for HeadObject.

The presigned URL will include the following properties if they're specified:

- `versionId` (in the query parameters)
- `requestPayer` (in the `x-amz-request-payer` header)
- `expectedBucketOwner` (in the `x-amz-expected-bucket-owner` header)

Other properties won't be presigned, and thus won't be included. Non-signed options sent as headers can be added manually to the request when calling the presigned URL that's found in the `userRequest` headers. Server-side encryption options are not supported for HeadObject.

For the request syntax URI parameters, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

The following example shows a Lambda JSON input payload for HeadObject.

```
{  
    "xAmzRequestId": "requestId",  
    "**headObjectContext**: {  
        ***inputS3Url***: "https://my-s3-ap-111122223333.s3-accesspoint.us-

    }  
}
```

```
    "headers": {
        "Host": "object-lambda-111122223333.s3-object-lambda.us-east-1.amazonaws.com",
        "Accept-Encoding": "identity",
        "X-Amz-Content-SHA256": "e3b0c44298fc1example"
    },
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "principalId",

Your Lambda function should return a JSON object that contains the headers and values that will be returned for the HeadObject call.

The following example shows the structure of the Lambda response JSON for HeadObject.

```
{
    "statusCode": <number>; // Required
    "errorCode": <string>;
    "errorMessage": <string>;
    "headers": {

    }
}
```

```
        "Cache-Control": <string>,
        "Content-Disposition": <string>,
        "Content-Encoding": <string>,
        "Content-Language": <string>,
        "Content-Length": <number>, // Required

The following example shows how to use the presigned URL to populate your response by modifying the header values as needed before returning the JSON.

Python

```
import requests

def lambda_handler(event, context):
    print(event)
```

```
# Extract the presigned URL from the input.  
s3_url = event["headObjectContext"]["inputS3Url"]  
  
# Get the head of the object from S3.  
response = requests.head(s3_url)  
  
# Return the error to S3 Object Lambda (if applicable).  
if (response.status_code >= 400):  
    return {  
        "statusCode": response.status_code,  
        "errorCode": "RequestFailure",  
        "errorMessage": "Request to S3 failed"  
    }  
  
# Store the headers in a dictionary.  
response_headers = dict(response.headers)  
  
# This obscures Content-Type in a transformation, it is optional to add  
response_headers["Content-Type"] = ""  
  
# Return the headers to S3 Object Lambda.  
return {  
    "statusCode": response.status_code,  
    "headers": response_headers  
}
```

Working with `ListObjects` requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for `ListObjects`. Lambda will receive the JSON payload with a new object named `listObjectContext`. `listObjectContext` contains a single property, `inputS3Url`, which is a presigned URL for the supporting access point for `ListObjects`.

Unlike `GetObject` and `HeadObject`, the presigned URL will include the following properties if they're specified:

- All the query parameters
- `requestPayer` (in the `x-amz-request-payer` header)
- `expectedBucketOwner` (in the `x-amz-expected-bucket-owner` header)

For the request syntax URI parameters, see [ListObjects](#) in the *Amazon Simple Storage Service API Reference*.

Important

We recommend that you use the newer version, [ListObjectsV2](#), when developing applications. For backward compatibility, Amazon S3 continues to support ListObjects.

The following example shows the Lambda JSON input payload for ListObjects.

```
{  
    "xAmzRequestId": "requestId",  
    "**listObjectsContext**": {  
        "**inputS3Url**": "https://my-s3-ap-111122223333.s3-accesspoint.us-  
east-1.amazonaws.com/?X-Amz-Security-Token=<snip>",  
    },  
    "configuration": {  
        "accessPointArn": "arn:aws:s3-object-lambda:us-  
east-1:111122223333:accesspoint/example-object-lambda-ap",  
        "supportingAccessPointArn": "arn:aws:s3:us-  
east-1:111122223333:accesspoint/example-ap",  
        "payload": "{}"  
    },  
    "userRequest": {  
        "url": "https://object-lambda-111122223333.s3-object-lambda.us-  
east-1.amazonaws.com/example",  
        "headers": {  
            "Host": "object-lambda-111122223333.s3-object-lambda.us-  
east-1.amazonaws.com",  
            "Accept-Encoding": "identity",  
            "X-Amz-Content-SHA256": "e3b0c44298fc1example"  
        }  
    },  
    "userIdentity": {  
        "type": "AssumedRole",  
        "principalId": "principalId",  
        "arn": "arn:aws:sts::111122223333:assumed-role/Admin/example",  
        "accountId": "111122223333",  
        "accessKeyId": "accessKeyId",  
        "sessionContext": {  
            "attributes": {  
                "attribute": "value"  
            }  
        }  
    }  
}
```

```
        "mfaAuthenticated": "false",
        "creationDate": "Wed Mar 10 23:41:52 UTC 2021"
    },
    "sessionIssuer": {
        "type": "Role",
        "principalId": "principalId",
        "arn": "arn:aws:iam::111122223333:role/Admin",
        "accountId": "111122223333",
        "userName": "Admin"
    }
},
"protocolVersion": "1.00"
}
```

Your Lambda function should return a JSON object that contains the status code, list XML result, or error information that will be returned from S3 Object Lambda.

S3 Object Lambda does not process or validate `listResultXml`, but instead forwards it to `ListObjects` caller. For `listBucketResult`, S3 Object Lambda expects certain properties to be of a specific type and will throw exceptions if it cannot parse them. `listResultXml` and `listBucketResult` can not be provided at the same time.

The following example demonstrates how to use the presigned URL to call Amazon S3 and use the result to populate a response, including error checking.

Python

```
import requests
import xmltodict

def lambda_handler(event, context):
    # Extract the presigned URL from the input.
    s3_url = event["listObjectsContext"]["inputS3Url"]

    # Get the head of the object from Amazon S3.
    response = requests.get(s3_url)

    # Return the error to S3 Object Lambda (if applicable).
    if (response.status_code >= 400):
        error = xmltodict.parse(response.content)
        return {
```

```
        "statusCode": response.status_code,
        "errorCode": error["Error"]["Code"],
        "errorMessage": error["Error"]["Message"]
    }

    # Store the XML result in a dict.
    response_dict = xmltodict.parse(response.content)

    # This obscures StorageClass in a transformation, it is optional to add
    for item in response_dict['ListBucketResult']['Contents']:
        item['StorageClass'] = ""

    # Convert back to XML.

Working with `ListObjectsV2` requests in Lambda

This section assumes that your Object Lambda Access Point is configured to call the Lambda function for `ListObjectsV2`. Lambda will receive the JSON payload with a new object named `listObjectsV2Context`. `listObjectsV2Context` contains a single property, `inputS3Url`, which is a presigned URL for the supporting access point for `ListObjectsV2`.

Unlike `GetObject` and `HeadObject`, the presigned URL will include the following properties, if they're specified:

- All the query parameters
- `requestPayer` (in the `x-amz-request-payer` header)
- `expectedBucketOwner` (in the `x-amz-expected-bucket-owner` header)

For the request syntax URI parameters, see [ListObjectsV2](#) in the *Amazon Simple Storage Service API Reference*.

The following example shows the Lambda JSON input payload for `ListObjectsV2`.

```
{
  "xAmzRequestId": "requestId",
  "**listObjectsV2Context**": {
    "**inputS3Url**": "https://my-s3-ap-111122223333.s3-accesspoint.us-east-1.amazonaws.com/?list-type=2&X-Amz-Security-Token=<snip>",

    },
},
"userIdentity": {
    "type": "AssumedRole",
    "principalId": "principalId",
    "arn": "arn:aws:sts::111122223333:assumed-role/Admin/example",
    "accountId": "111122223333",
    "accessKeyId": "accessKeyId",
    "sessionContext": {
        "attributes": {

            "principalId": "principalId",

            "accountId": "111122223333",

        }
    }
},
"protocolVersion": "1.00"
}
```

Your Lambda function should return a JSON object that contains the status code, list XML result, or error information that will be returned from S3 Object Lambda.

S3 Object Lambda does not process or validate `listResultXml`, but instead forwards it to `ListObjectsV2` caller. For `listBucketResult`, S3 Object Lambda expects certain properties to be of a specific type and will throw exceptions if it cannot parse them. `listResultXml` and `listBucketResult` can not be provided at the same time.

The following example demonstrates how to use the presigned URL to call Amazon S3 and use the result to populate a response, including error checking.

Python

```
import requests
```

```
import xmltodict

def lambda_handler(event, context):
    # Extract the presigned URL from the input.
    s3_url = event["listObjectsV2Context"]["inputS3Url"]

    # Get the head of the object from Amazon S3.
    response = requests.get(s3_url)

    # Return the error to S3 Object Lambda (if applicable).
    if (response.status_code >= 400):
        error = xmltodict.parse(response.content)
        return {
            "statusCode": response.status_code,
            "errorCode": error["Error"]["Code"],
            "errorMessage": error["Error"]["Message"]
        }

    # Store the XML result in a dict.
    response_dict = xmltodict.parse(response.content)

    # This obscures StorageClass in a transformation, it is optional to add
    for item in response_dict['ListBucketResult']['Contents']:
        item['StorageClass'] = ""

    # Convert back to XML.
    listResultXml = xmltodict.unparse(response_dict)

    # Create response with listResultXml.

    response_with_list_bucket_result = {
        'statusCode': 200,
        'listBucketResult': response_dict['ListBucketResult']
    }

    # Return the list to S3 Object Lambda.

```
# Can return response_with_list_result_xml or response_with_list_bucket_result
return response_with_list_result_xml

# Converting the response_dict's key to correct casing
def sanitize_response_dict(response_dict: dict):
    new_response_dict = dict()
    for key, value in response_dict.items():

            }  
        }  
    },  
    "protocolVersion": "1.00"  
}
```

The following fields are included in the request:

- `xAmzRequestId` – The Amazon S3 request ID for this request. We recommend that you log this value to help with debugging.
- `getObjectContext` – The input and output details for connections to Amazon S3 and S3 Object Lambda.
 - `inputS3Url` – A presigned URL that can be used to fetch the original object from Amazon S3. The URL is signed by using the original caller's identity, and that user's permissions will apply when the URL is used. If there are signed headers in the URL, the Lambda function must include these headers in the call to Amazon S3, except for the Host header.
 - `outputRoute` – A routing token that is added to the S3 Object Lambda URL when the Lambda function calls `WriteGetObjectResponse`.
 - `outputToken` – An opaque token that's used by S3 Object Lambda to match the `WriteGetObjectResponse` call with the original caller.
- `configuration` – Configuration information about the Object Lambda Access Point.
 - `accessPointArn` – The Amazon Resource Name (ARN) of the Object Lambda Access Point that received this request.
 - `supportingAccessPointArn` – The ARN of the supporting access point that is specified in the Object Lambda Access Point configuration.
 - `payload` – Custom data that is applied to the Object Lambda Access Point configuration. S3 Object Lambda treats this data as an opaque string, so it might need to be decoded before use.
- `userRequest` – Information about the original call to S3 Object Lambda.
 - `url` – The decoded URL of the request as received by S3 Object Lambda, excluding any authorization-related query parameters.
 - `headers` – A map of string to strings containing the HTTP headers and their values from the original call, excluding any authorization-related headers. If the same header appears multiple times, the values from each instance of the same header are combined into a comma-delimited list. The case of the original headers is retained in this map.
- `userIdentity` – Details about the identity that made the call to S3 Object Lambda. For more information, see [Logging data events for trails](#) in the *AWS CloudTrail User Guide*.
 - `type` – The type of identity.
 - `accountId` – The AWS account to which the identity belongs.
 - `userName` – The friendly name of the identity that made the call.
 - ~~`principalId` – The unique identifier for the identity that made the call.~~

- **arn** – The ARN of the principal who made the call. The last section of the ARN contains the user or role that made the call.
- **sessionContext** – If the request was made with temporary security credentials, this element provides information about the session that was created for those credentials.
- **invokedBy** – The name of the AWS service that made the request, such as Amazon EC2 Auto Scaling or AWS Elastic Beanstalk.
- **sessionIssuer** – If the request was made with temporary security credentials, this element provides information about how the credentials were obtained.
- **protocolVersion** – The version ID of the context provided. The format of this field is {Major Version}.{Minor Version}. The minor version numbers are always two-digit numbers. Any removal or change to the semantics of a field necessitates a major version bump and requires active opt-in. Amazon S3 can add new fields at any time, at which point you might experience a minor version bump. Because of the nature of software rollouts, you might see multiple minor versions in use at once.

Working with Range and partNumber headers

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners. For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

When working with large objects in Amazon S3 Object Lambda, you can use the Range HTTP header to download a specified byte range from an object. To fetch different byte ranges from within the same object, you can use concurrent connections to Amazon S3. You can also specify the `partNumber` parameter (an integer between 1 and 10,000), which performs a ranged request for the specified part of the object.

Because there are multiple ways that you might want to handle a request that includes the Range or `partNumber` parameters, S3 Object Lambda doesn't apply these parameters to the transformed object. Instead, your AWS Lambda function must implement this functionality as needed for your application.

To use the Range and partNumber parameters with S3 Object Lambda, you do the following:

- Enable these parameters in your Object Lambda Access Point configuration.
- Write a Lambda function that can handle requests that include these parameters.

The following steps describe how to accomplish this.

Step 1: Configure your Object Lambda Access Point

By default, Object Lambda Access Points respond with an HTTP status code 501 (Not Implemented) error to any GetObject or HeadObject request that contains a Range or partNumber parameter, either in the headers or query parameters.

To enable an Object Lambda Access Point to accept such requests, you must include GetObject-Range, GetObject-PartNumber, HeadObject-Range, or HeadObject-PartNumber in the AllowedFeatures section of your Object Lambda Access Point configuration. For more information about updating your Object Lambda Access Point configuration, see [Creating Object Lambda Access Points](#).

Step 2: Implement Range or partNumber handling in your Lambda function

When your Object Lambda Access Point invokes your Lambda function with a ranged GetObject or HeadObject request, the Range or partNumber parameter is included in the event context. The location of the parameter in the event context depends on which parameter was used and how it was included in the original request to the Object Lambda Access Point, as explained in the following table.

Parameter	Event context location
Range (header)	userRequest.headers.Range
Range (query parameter)	userRequest.url (query parameter Range)
partNumber	userRequest.url (query parameter partNumber)

Important

The provided presigned URL for your Object Lambda Access Point doesn't contain the Range or partNumber parameter from the original request. See the following options on how to handle these parameters in your AWS Lambda function.

After you extract the Range or partNumber value, you can take one of the following approaches, based on your application's needs:

A. Map the requested Range or partNumber to the transformed object (recommended).

The most reliable way to handle Range or partNumber requests is to do the following:

- Retrieve the full object from Amazon S3.
- Transform the object.
- Apply the requested Range or partNumber parameters to the transformed object.

To do this, use the provided presigned URL to fetch the entire object from Amazon S3 and then process the object as needed. For an example Lambda function that processes a Range parameter in this way, see [this sample](#) in the AWS Samples GitHub repository.

B. Map the requested Range to the presigned URL.

In some cases, your Lambda function can map the requested Range directly to the presigned URL to retrieve only part of the object from Amazon S3. This approach is appropriate only if your transformation meets both of the following criteria:

1. Your transformation function can be applied to partial object ranges.
2. Applying the Range parameter before or after the transformation function results in the same transformed object.

For example, a transformation function that converts all characters in an ASCII-encoded object to uppercase meets both of the preceding criteria. The transformation can be applied to part of an object, and applying the Range parameter before the transformation achieves the same result as applying it after the transformation.

By contrast, a function that reverses the characters in an ASCII-encoded object doesn't meet these criteria. Such a function meets criterion 1, because it can be applied to partial object

ranges. However, it doesn't meet criterion 2, because applying the Range parameter before the transformation achieves different results than applying the parameter after the transformation.

Consider a request to apply the function to the first three characters of an object with the contents abcdefg. Applying the Range parameter before the transformation retrieves only abc and then reverses the data, returning cba. But if the parameter is applied after the transformation, the function retrieves the entire object, reverses it, and then applies the Range parameter, returning gfe. Because these results are different, this function should not apply the Range parameter when retrieving the object from Amazon S3. Instead, it should retrieve the entire object, perform the transformation, and only then apply the Range parameter.

Warning

In many cases, applying the Range parameter to the presigned URL will result in unexpected behavior by the Lambda function or the requesting client. Unless you are sure that your application will work properly when retrieving only a partial object from Amazon S3, we recommend that you retrieve and transform full objects as described earlier in approach A.

If your application meets the criteria described earlier in approach B, you can simplify your AWS Lambda function by fetching only the requested object range and then running your transformation on that range.

The following Java code example demonstrates how to do the following:

- Retrieve the Range header from the GetObject request.
- Add the Range header to the presigned URL that Lambda can use to retrieve the requested range from Amazon S3.

```
private HttpRequest.Builder applyRangeHeader(ObjectLambdaEvent event,
    HttpRequest.Builder presignedRequest) {
    var header = event.getUserRequest().getHeaders().entrySet().stream()
        .filter(e -> e.getKey().toLowerCase(Locale.ROOT).equals("range"))
        .findFirst();

    // Add check in the query string itself.
    header.ifPresent(entry -> presignedRequest.header(entry.getKey(),
        entry.getValue()));
    return presignedRequest;
```

}

Using AWS built Lambda functions

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

AWS provides some prebuilt AWS Lambda functions that you can use with Amazon S3 Object Lambda to detect and redact personally identifiable information (PII) and decompress S3 objects. These Lambda functions are available in the AWS Serverless Application Repository. You can select these functions through the AWS Management Console when you create your Object Lambda Access Point.

For more information about how to deploy serverless applications from the AWS Serverless Application Repository, see [Deploying Applications](#) in the *AWS Serverless Application Repository Developer Guide*.

Note

The following examples can be used only with GetObject requests.

Example 1: PII access control

This Lambda function uses Amazon Comprehend, a natural language processing (NLP) service that uses machine learning to find insights and relationships in text. This function automatically detects personally identifiable information (PII), such as names, addresses, dates, credit card numbers, and social security numbers in documents in your Amazon S3 bucket. If you have documents in your bucket that include PII, you can configure the PII Access Control function to detect these PII entity types and restrict access to unauthorized users.

To get started, deploy the following Lambda function in your account and add the Amazon Resource Name (ARN) for the function to your Object Lambda Access Point configuration.

The following is an example ARN for this function:

```
arn:aws:serverlessrepo:us-east-1:111122223333:applications/  
ComprehendPiiAccessControlS3ObjectLambda
```

You can add or view this function on the AWS Management Console by using the following AWS Serverless Application Repository link: [ComprehendPiiAccessControlS3ObjectLambda](#).

To view this function on GitHub, see [Amazon Comprehend S3 Object Lambda](#).

Example 2: PII redaction

This Lambda function uses Amazon Comprehend, a natural language processing (NLP) service that uses machine learning to find insights and relationships in text. This function automatically redacts personally identifiable information (PII), such as names, addresses, dates, credit card numbers, and social security numbers from documents in your Amazon S3 bucket.

If you have documents in your bucket that include information such as credit card numbers or bank account information, you can configure the PII Redaction S3 Object Lambda function to detect PII and then return a copy of these documents in which PII entity types are redacted.

To get started, deploy the following Lambda function in your account and add the ARN for the function to your Object Lambda Access Point configuration.

The following is an example ARN for this function:

```
arn:aws:serverlessrepo:us-east-1:111122223333:applications/  
ComprehendPiiRedactionS3ObjectLambda
```

You can add or view this function on the AWS Management Console by using the following AWS Serverless Application Repository link: [ComprehendPiiRedactionS3ObjectLambda](#).

To view this function on GitHub, see [Amazon Comprehend S3 Object Lambda](#).

To learn about complete end-to-end procedures for some S3 Object Lambda tasks in PII redaction, see [Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend](#).

Example 3: Decompression

The Lambda function S3ObjectLambdaDecompression can decompress objects that are stored in Amazon S3 in one of six compressed file formats: bzip2, gzip, snappy, zlib, zstandard, and ZIP.

To get started, deploy the following Lambda function in your account and add the ARN for the function to your Object Lambda Access Point configuration.

The following is an example ARN for this function:

```
arn:aws:serverlessrepo:us-east-1:111122223333::applications/S3ObjectLambdaDecompression
```

You can add or view this function on the AWS Management Console by using the following AWS Serverless Application Repository link: [S3ObjectLambdaDecompression](#).

To view this function on GitHub, see [S3 Object Lambda Decompression](#).

Best practices and guidelines for S3 Object Lambda

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

When using S3 Object Lambda, follow these best practices and guidelines to optimize operations and performance.

Working with S3 Object Lambda

S3 Object Lambda supports processing only GET, LIST, and HEAD requests. Any other requests don't invoke AWS Lambda and instead return standard, non-transformed API responses. You can create a maximum of 1,000 Object Lambda Access Points per AWS account per Region. The AWS

Lambda function that you use must be in the same AWS account and Region as the Object Lambda Access Point.

S3 Object Lambda allows up to 60 seconds to stream a complete response to its caller. Your function is also subject to AWS Lambda default quotas. For more information, see [Lambda quotas in the AWS Lambda Developer Guide](#).

When S3 Object Lambda invokes your specified Lambda function, you are responsible for ensuring that any data that is overwritten or deleted from Amazon S3 by your specified Lambda function or application is intended and correct.

You can use S3 Object Lambda only to perform operations on objects. You cannot use S3 Object Lambda to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see [Access points compatibility with S3 operations](#).

In addition to this list, Object Lambda Access Points do not support the [POST Object](#), [CopyObject](#) (as the source), and [SelectObjectContent](#) API operations.

AWS services used in connection with S3 Object Lambda

S3 Object Lambda connects Amazon S3, AWS Lambda, and optionally, other AWS services of your choosing to deliver objects relevant to the requesting applications. All AWS services used with S3 Object Lambda are governed by their respective Service Level Agreements (SLAs). For example, if any AWS service does not meet its Service Commitment, you are eligible to receive a Service Credit, as documented in the service's SLA.

Range and partNumber headers

When working with large objects, you can use the Range HTTP header to download a specified byte-range from an object. When you use the Range header, your request fetches only the specified portion of the object. You can also use the partNumber header to perform a ranged request for the specified part from the object.

For more information, see [Working with Range and partNumber headers](#).

Transforming the expiry-date

You can open or download transformed objects from your Object Lambda Access Point on the AWS Management Console. These objects must be non-expired. If your Lambda function transforms

the expiry-date of your objects, you might see expired objects that cannot be opened or downloaded. This behavior applies only to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive restored objects.

Working with the AWS CLI and AWS SDKs

AWS Command Line Interface (AWS CLI) S3 subcommands (cp, mv, and sync) and the use of the AWS SDK for Java TransferManager class are not supported for use with S3 Object Lambda.

S3 Object Lambda tutorials

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

The following tutorials present complete end-to-end procedures for some S3 Object Lambda tasks.

With S3 Object Lambda, you can add your own code to process data retrieved from S3 before returning it to an application. Each of the following tutorials will modify data as it is retrieved from Amazon S3, without changing the existing object or maintaining multiple copies of the data. The first tutorial will walk through how to add an AWS Lambda function to a S3 GET request to modify an object retrieved from S3. The second tutorial demonstrates how to use a prebuilt Lambda function powered by Amazon Comprehend to protect personally identifiable information (PII) retrieved from S3 before returning it to an application. The third tutorial uses S3 Object Lambda to add a watermark to an image as it is retrieved from Amazon S3.

Tutorial: Transforming data for your application with S3 Object Lambda

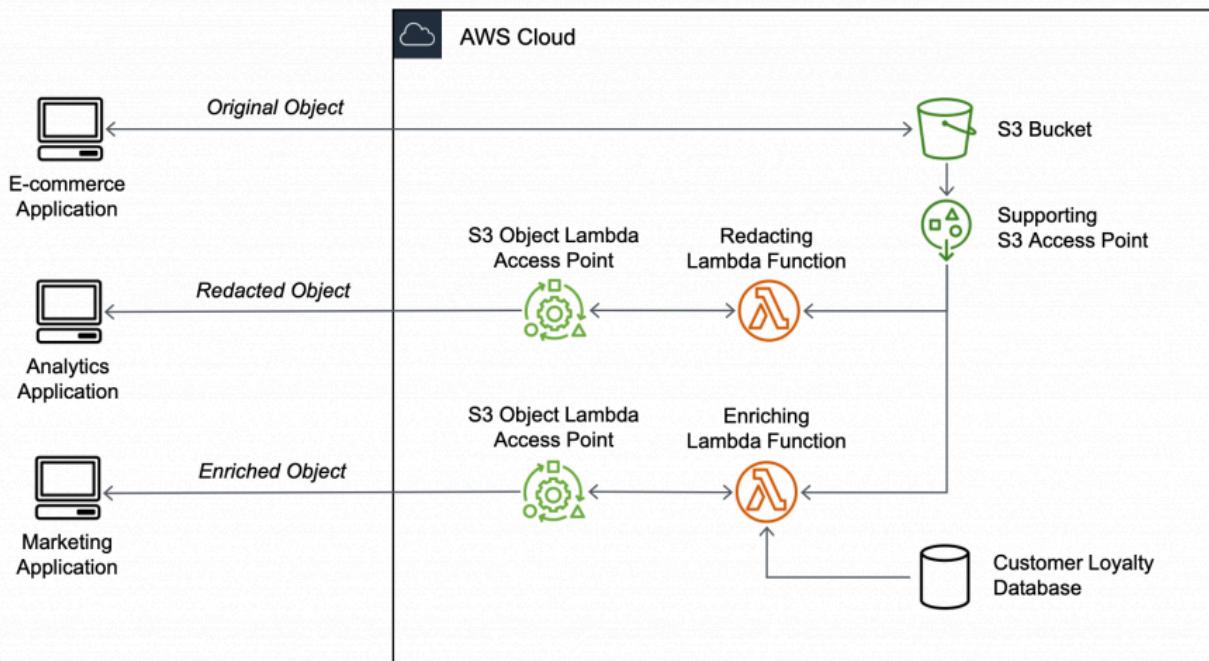

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

When you store data in Amazon S3, you can easily share it for use by multiple applications. However, each application might have unique data format requirements, and might need modification or processing of your data for a specific use case. For example, a dataset created by an ecommerce application might include personally identifiable information (PII). When the same data is processed for analytics, this PII is not needed and should be redacted. However, if the same dataset is used for a marketing campaign, you might need to enrich the data with additional details, such as information from the customer loyalty database.

With [S3 Object Lambda](#), you can add your own code to process data retrieved from S3 before returning it to an application. Specifically, you can configure an AWS Lambda function and attach it to an S3 Object Lambda Access Point. When an application sends [standard S3 GET requests](#) through the S3 Object Lambda Access Point, the specified Lambda function is invoked to process any data retrieved from the underlying data source through the supporting S3 access point. Then, the S3 Object Lambda Access Point returns the transformed result back to the application. You can author and execute your own custom Lambda functions, tailoring the S3 Object Lambda data transformation to your specific use case, all with no changes required to your applications.

Objective

In this tutorial, you learn how to add custom code to standard S3 GET requests to modify the requested object retrieved from S3 so that the object suit the needs of the requesting client or application. Specifically, you learn how to transform all the text in the original object stored in an S3 bucket to uppercase through S3 Object Lambda.

Note

This tutorial uses Python code to transform the data, for examples using other AWS SDKs see [Transform data for your application with S3 Object Lambda](#) in the AWS SDK Code Examples Library.

Topics

- [Prerequisites](#)
- [Step 1: Create an S3 bucket](#)
- [Step 2: Upload a file to the S3 bucket](#)
- [Step 3: Create an S3 access point](#)
- [Step 4: Create a Lambda function](#)

- [Step 5: Configure an IAM policy for your Lambda function's execution role](#)
- [Step 6: Create an S3 Object Lambda Access Point](#)
- [Step 7: View the transformed data](#)
- [Step 8: Clean up](#)
- [Next steps](#)

Prerequisites

Before you start this tutorial, you must have an AWS account that you can sign in to as an AWS Identity and Access Management (IAM) user with correct permissions. You also must install Python version 3.8 or later.

Substeps

- [Create an IAM user with permissions in your AWS account \(console\)](#)
- [Install Python 3.8 or later on your local machine](#)

Create an IAM user with permissions in your AWS account (console)

You can create an IAM user for the tutorial. To complete this tutorial, your IAM user must attach the following IAM policies to access relevant AWS resources and perform specific actions. For more information about how to create an IAM user, see [Creating IAM users \(console\)](#) in the *IAM User Guide*.

Your IAM user requires the following policies:

- [AmazonS3FullAccess](#) – Grants permissions to all Amazon S3 actions, including permissions to create and use an Object Lambda Access Point.
- [AWSLambda_FullAccess](#) – Grants permissions to all Lambda actions.
- [IAMFullAccess](#) – Grants permissions to all IAM actions.
- [IAMAccessAnalyzerReadOnlyAccess](#) – Grants permissions to read all access information provided by IAM Access Analyzer.
- [CloudWatchLogsFullAccess](#) – Grants full access to CloudWatch Logs.

Note

For simplicity, this tutorial creates and uses an IAM user. After completing this tutorial, remember to [Delete the IAM user](#). For production use, we recommend that you follow the [Security best practices in IAM](#) in the *IAM User Guide*. A best practice requires human users to use federation with an identity provider to access AWS with temporary credentials. Another best practice is to require workloads to use temporary credentials with IAM roles to access AWS. To learn about using AWS IAM Identity Center to create users with temporary credentials, see [Getting started](#) in the *AWS IAM Identity Center User Guide*. This tutorial also uses full-access AWS managed policies. For production use, we recommend that you instead grant only the minimum permissions necessary for your use case, in accordance with [security best practices](#).

Install Python 3.8 or later on your local machine

Use the following procedure to install Python 3.8 or later on your local machine. For more installation instructions, see the [Downloading Python](#) page in the *Python Beginners Guide*.

1. Open your local terminal or shell and run the following command to determine whether Python is already installed, and if so, which version is installed.

```
python --version
```

2. If you don't have Python 3.8 or later, download the [official installer](#) of Python 3.8 or later that's suitable for your local machine.
3. Run the installer by double-clicking the downloaded file, and follow the steps to complete the installation.

For Windows users, choose **Add Python 3.X to PATH** in the installation wizard before choosing **Install Now**.

4. Restart your terminal by closing and reopening it.
5. Run the following command to verify that Python 3.8 or later is installed correctly.

For macOS users, run this command:

```
python3 --version
```

For Windows users, run this command:

```
python --version
```

6. Run the following command to verify that the pip3 package manager is installed. If you see a pip version number and python 3.8 or later in the command response, that means the pip3 package manager is installed successfully.

```
pip --version
```

Step 1: Create an S3 bucket

Create a bucket to store the original data that you plan to transform.

Note

Access points may be attached for another data source, such as an Amazon FSx for OpenZFS volume, however this tutorial uses a supporting access point attached to an S3 bucket.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.

The **Create bucket** page opens.

4. For **Bucket name**, enter a name (for example, **tutorial-bucket**) for your bucket.

For more information about naming buckets in Amazon S3, see [General purpose bucket naming rules](#).

5. For **Region**, choose the AWS Region where you want the bucket to reside.

For more information about the bucket Region, see [General purpose buckets overview](#).

6. For **Block Public Access settings for this bucket**, keep the default settings (**Block all public access** is enabled).

We recommend that you keep all Block Public Access settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

7. For the remaining settings, keep the defaults.

(Optional) If you want to configure additional bucket settings for your specific use case, see [Creating a general purpose bucket](#).

8. Choose **Create bucket**.

Step 2: Upload a file to the S3 bucket

Upload a text file to the S3 bucket. This text file contains the original data that you will transform to uppercase later in this tutorial.

For example, you can upload a `tutorial.txt` file that contains the following text:

Amazon S3 Object Lambda Tutorial:

You can add your own code to process data retrieved from S3 before returning it to an application.

To upload a file to a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you created in [Step 1](#) (for example, `tutorial-bucket`) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**. For example, you can upload the `tutorial.txt` file example mentioned earlier.
7. Choose **Upload**.

Step 3: Create an S3 access point

To use an S3 Object Lambda Access Point to access and transform the original data, you must create an S3 access point and associate it with the S3 bucket that you created in [Step 1](#). The access point must be in the same AWS Region as the objects that you want to transform.

Later in this tutorial, you'll use this access point as a supporting access point for your Object Lambda Access Point.

To create an access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points**.
3. On the **Access Points** page, choose **Create access point**.
4. In the **Access point name** field, enter the name (for example, **tutorial-access-point**) for the access point.

For more information about naming access points, see [Naming rules for access points](#).

5. In the **Data source** field, enter the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**). S3 attaches the access point to this bucket.

(Optional) You can choose **Browse S3** to browse and search the buckets in your account. If you choose **Browse S3**, choose the desired bucket, and then choose **Choose path** to populate the **Bucket name** field with that bucket's name.

6. For **Network origin**, choose **Internet**.

For more information about network origins for access points, see [Creating access points restricted to a virtual private cloud](#).

7. By default, all Block Public Access settings are turned on for your access point. We recommend that you keep **Block all public access** enabled.

For more information, see [Managing public access to access points for general purpose buckets](#).

8. For all other access point settings, keep the default settings.

(Optional) You can modify the access point settings to support your use case. For this tutorial, we recommend keeping the default settings.

(Optional) If you need to manage access to your access point, you can specify an access point policy. For more information, see [Policy examples for access points](#).

9. Choose **Create access point**.

Step 4: Create a Lambda function

To transform original data, create a Lambda function for use with your S3 Object Lambda Access Point.

Substeps

- [Write Lambda function code and create a deployment package with a virtual environment](#)
- [Create a Lambda function with an execution role \(console\)](#)
- [Deploy your Lambda function code with .zip file archives and configure the Lambda function \(console\)](#)

Write Lambda function code and create a deployment package with a virtual environment

1. On your local machine, create a folder with the folder name object-lambda for the virtual environment to use later in this tutorial.
2. In the object-lambda folder, create a file with a Lambda function that changes all text in the original object to uppercase. For example, you can use the following function written in Python. Save this function in a file named transform.py.

```
import boto3
import requests
from botocore.config import Config

# This function capitalizes all text in the original object
def lambda_handler(event, context):
    object_context = event["getObjectContext"]
    # Get the presigned URL to fetch the requested original object
    # from S3
    s3_url = object_context["inputS3Url"]
    # Extract the route and request token from the input context
    request_route = object_context["outputRoute"]
    request_token = object_context["outputToken"]

    # Get the original S3 object using the presigned URL
```

```
response = requests.get(s3_url)
original_object = response.content.decode("utf-8")

# Transform all text in the original object to uppercase
# You can replace it with your custom code based on your use case
transformed_object = original_object.upper()

# Write object back to S3 Object Lambda
s3 = boto3.client('s3', config=Config(signature_version='s3v4'))
# The WriteGetObjectResponse API sends the transformed data
# back to S3 Object Lambda and then to the user
s3.write_get_object_response(
    Body=transformed_object,
    RequestRoute=request_route,
    RequestToken=request_token)

# Exit the Lambda function: return the status code
return {'status_code': 200}
```

Note

The preceding example Lambda function loads the entire requested object into memory before transforming it and returning it to the client. Alternatively, you can stream the object from S3 to avoid loading the entire object into memory. This approach can be useful when working with large objects. For more information about streaming responses with Object Lambda Access Points, see the [streaming examples in Working with GetObject requests in Lambda](#).

When you're writing a Lambda function for use with an S3 Object Lambda Access Point, the function is based on the input event context that S3 Object Lambda provides to the Lambda function. The event context provides information about the request being made in the event passed from S3 Object Lambda to Lambda. It contains the parameters that you use to create the Lambda function.

The fields used to create the preceding Lambda function are as follows:

The field of `getObjectContext` means the input and output details for connections to Amazon S3 and S3 Object Lambda. It has the following fields:

- `inputS3Url` – A presigned URL that the Lambda function can use to download the original object from the supporting access point. By using a presigned URL, the Lambda function doesn't need to have Amazon S3 read permissions to retrieve the original object and can only access the object processed by each invocation.
- `outputRoute` – A routing token that is added to the S3 Object Lambda URL when the Lambda function calls `WriteGetObjectResponse` to send back the transformed object.
- `outputToken` – A token used by S3 Object Lambda to match the `WriteGetObjectResponse` call with the original caller when sending back the transformed object.

For more information about all the fields in the event context, see [Event context format and usage](#) and [Writing Lambda functions for S3 Object Lambda Access Points](#).

3. In your local terminal, enter the following command to install the `virtualenv` package:

```
python -m pip install virtualenv
```

4. In your local terminal, open the `object-lambda` folder that you created earlier, and then enter the following command to create and initialize a virtual environment called `venv`.

```
python -m virtualenv venv
```

5. To activate the virtual environment, enter the following command to execute the `activate` file from the environment's folder:

For **macOS users**, run this command:

```
source venv/bin/activate
```

For **Windows users**, run this command:

```
.\venv\Scripts\activate
```

Now, your command prompt changes to show (`venv`), indicating that the virtual environment is active.

6. To install the required libraries, run the following commands line by line in the `venv` virtual environment.

These commands install updated versions of the dependencies of your `lambda_handler` Lambda function. These dependencies are the AWS SDK for Python (Boto3) and the requests module.

```
pip3 install boto3
```

```
pip3 install requests
```

7. To deactivate the virtual environment, run the following command:

```
deactivate
```

8. To create a deployment package with the installed libraries as a .zip file named `lambda.zip` at the root of the `object-lambda` directory, run the following commands line by line in your local terminal.

 **Tip**

The following commands might need to be adjusted to work in your particular environment. For example, a library might appear in `site-packages` or `dist-packages`, and the first folder might be `lib` or `lib64`. Also, the `python` folder might be named with a different Python version. To locate a specific package, use the `pip show` command.

For **macOS users**, run these commands:

```
cd venv/lib/python3.8/site-packages
```

```
zip -r ../../../../lambda.zip .
```

For **Windows users**, run these commands:

```
cd .\venv\Lib\site-packages\
```

```
powershell Compress-Archive * ../../lambda.zip
```

The last command saves the deployment package to the root of the object-lambda directory.

9. Add the function code file `transform.py` to the root of your deployment package.

For **macOS users**, run these commands:

```
cd ../../..
```

```
zip -g lambda.zip transform.py
```

For **Windows users**, run these commands:

```
cd ..\..\..\..
```

```
powershell Compress-Archive -update transform.py lambda.zip
```

After you complete this step, you should have the following directory structure:

```
lambda.zip$  
# transform.py  
# __pycache__  
| boto3/  
# certifi/  
# pip/  
# requests/  
...
```

Create a Lambda function with an execution role (console)

1. Sign in to the AWS Management Console and open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. In the left navigation pane, choose **Functions**.
3. Choose **Create function**.
4. Choose **Author from scratch**.
5. Under **Basic information**, do the following:

- a. For **Function name**, enter **tutorial-object-lambda-function**.
- b. For **Runtime**, choose **Python 3.8** or a later version.
6. Expand the **Change default execution role** section. Under **Execution role**, choose **Create a new role with basic Lambda permissions**.

In [Step 5](#) later in this tutorial, you attach the **AmazonS3ObjectLambdaExecutionRolePolicy** to this Lambda function's execution role.

7. Keep the remaining settings set to the defaults.
8. Choose **Create function**.

Deploy your Lambda function code with .zip file archives and configure the Lambda function (console)

1. In the AWS Lambda console at <https://console.aws.amazon.com/lambda/>, choose **Functions** in the left navigation pane.
2. Choose the Lambda function that you created earlier (for example, **tutorial-object-lambda-function**).
3. On the Lambda function's details page, choose the **Code** tab. In the **Code Source** section, choose **Upload from** and then **.zip file**.
4. Choose **Upload** to select your local .zip file.
5. Choose the lambda.zip file that you created earlier, and then choose **Open**.
6. Choose **Save**.
7. In the **Runtime settings** section, choose **Edit**.
8. On the **Edit runtime settings** page, confirm that **Runtime** is set to **Python 3.8** or a later version.
9. To tell the Lambda runtime which handler method in your Lambda function code to invoke, enter **transform.lambda_handler** for **Handler**.

When you configure a function in Python, the value of the handler setting is the file name and the name of the handler module, separated by a dot. For example, `transform.lambda_handler` calls the `lambda_handler` method defined in the `transform.py` file.

10. Choose **Save**.

11. (Optional) On your Lambda function's details page, choose the **Configuration** tab. In the left navigation pane, choose **General configuration**, then choose **Edit**. In the **Timeout** field, enter **1 min 0 sec**. Keep the remaining settings set to the defaults, and choose **Save**.

Timeout is the amount of time that Lambda allows a function to run for an invocation before stopping it. The default is 3 seconds. The maximum duration for a Lambda function used by S3 Object Lambda is 60 seconds. Pricing is based on the amount of memory configured and the amount of time that your code runs.

Step 5: Configure an IAM policy for your Lambda function's execution role

To enable your Lambda function to provide customized data and response headers to the `GetObject` caller, your Lambda function's execution role must have IAM permissions to call the `WriteGetObjectResponse` API.

To attach an IAM policy to your Lambda function role

1. In the AWS Lambda console at <https://console.aws.amazon.com/lambda/>, choose **Functions** in the left navigation pane.
2. Choose the function that you created in [Step 4](#) (for example, **tutorial-object-lambda-function**).
3. On your Lambda function's details page, choose the **Configuration** tab, and then choose **Permissions** in the left navigation pane.
4. Under **Execution role**, choose the link of the **Role name**. The IAM console opens.
5. On the IAM console's **Summary** page for your Lambda function's execution role, choose the **Permissions** tab. Then, from the **Add Permissions** menu, choose **Attach policies**.
6. On the **Attach Permissions** page, enter **AmazonS3ObjectLambdaExecutionRolePolicy** in the search box to filter the list of policies. Select the check box next to the name of the **AmazonS3ObjectLambdaExecutionRolePolicy** policy.
7. Choose **Attach policies**.

Step 6: Create an S3 Object Lambda Access Point

An S3 Object Lambda Access Point provides the flexibility to invoke a Lambda function directly from an S3 GET request so that the function can process data retrieved from an S3 access point.

When creating and configuring an S3 Object Lambda Access Point, you must specify the Lambda function to invoke and provide the event context in JSON format as custom parameters for Lambda to use.

To create an S3 Object Lambda Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose **Create Object Lambda Access Point**.
4. For **Object Lambda Access Point name**, enter the name that you want to use for the Object Lambda Access Point (for example, **tutorial-object-lambda-accesspoint**).
5. For **Supporting Access Point**, enter or browse to the standard access point that you created in [Step 3](#) (for example, **tutorial-access-point**), and then choose **Choose supporting Access Point**.
6. For **S3 APIs**, to retrieve objects from the S3 bucket for Lambda function to process, select **GetObject**.
7. For **Invoke Lambda function**, you can choose either of the following two options for this tutorial.
 - Choose **Choose from functions in your account**, and then choose the Lambda function that you created in [Step 4](#) (for example, **tutorial-object-lambda-function**) from the **Lambda function** dropdown list.
 - Choose **Enter ARN**, and then enter the Amazon Resource Name (ARN) of the Lambda function that you created in [Step 4](#).
8. For **Lambda function version**, choose **\$LATEST** (the latest version of the Lambda function that you created in [Step 4](#)).
9. (Optional) If you need your Lambda function to recognize and process GET requests with range and part number headers, select **Lambda function supports requests using range** and **Lambda function supports requests using part numbers**. Otherwise, clear these two check boxes.

For more information about how to use range or part numbers with S3 Object Lambda, see [Working with Range and partNumber headers](#).
10. (Optional) Under **Payload - optional**, add JSON text to provide your Lambda function with additional information.

A payload is optional JSON text that you can provide to your Lambda function as input for all invocations coming from a specific S3 Object Lambda Access Point. To customize the behaviors for multiple Object Lambda Access Points that invoke the same Lambda function, you can configure payloads with different parameters, thereby extending the flexibility of your Lambda function.

For more information about payload, see [Event context format and usage](#).

11. (Optional) For **Request metrics - *optional***, choose **Disable** or **Enable** to add Amazon S3 monitoring to your Object Lambda Access Point. Request metrics are billed at the standard Amazon CloudWatch rate. For more information, see [CloudWatch pricing](#).

12. Under **Object Lambda Access Point policy - *optional***, keep the default setting.

(Optional) You can set a resource policy. This resource policy grants the GetObject API permission to use the specified Object Lambda Access Point.

13. Keep the remaining settings set to the defaults, and choose **Create Object Lambda Access Point**.

Step 7: View the transformed data

Now, S3 Object Lambda is ready to transform your data for your use case. In this tutorial, S3 Object Lambda transforms all the text in your object to uppercase.

Substeps

- [View the transformed data in your S3 Object Lambda Access Point](#)
- [Run a Python script to print the original and transformed data](#)

View the transformed data in your S3 Object Lambda Access Point

When you request to retrieve a file through your S3 Object Lambda Access Point, you make a GetObject API call to S3 Object Lambda. S3 Object Lambda invokes the Lambda function to transform your data, and then returns the transformed data as the response to the standard S3 GetObject API call.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Object Lambda Access Points**.

3. On the **Object Lambda Access Points** page, choose the S3 Object Lambda Access Point that you created in [Step 6](#) (for example, **tutorial-object-lambda-accesspoint**).
4. On the **Objects** tab of your S3 Object Lambda Access Point, select the file that has the same name (for example, `tutorial.txt`) as the one that you uploaded to the S3 bucket in [Step 2](#).

This file should contain all the transformed data.
5. To view the transformed data, choose **Open** or **Download**.

Run a Python script to print the original and transformed data

You can use S3 Object Lambda with your existing applications. To do so, update your application configuration to use the new S3 Object Lambda Access Point ARN that you created in [Step 6](#) to retrieve data from S3.

The following example Python script prints both the original data from the S3 bucket and the transformed data from the S3 Object Lambda Access Point.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the radio button to the left of the S3 Object Lambda Access Point that you created in [Step 6](#) (for example, **tutorial-object-lambda-accesspoint**).
4. Choose **Copy ARN**.
5. Save the ARN for use later.
6. Write a Python script on your local machine to print both the original data (for example, `tutorial.txt`) from your S3 Bucket and the transformed data (for example, `tutorial.txt`) from your S3 Object Lambda Access Point. You can use the following example script.

```
import boto3
from botocore.config import Config

s3 = boto3.client('s3', config=Config(signature_version='s3v4'))

def get0bject(bucket, key):
    objectBody = s3.get_object(Bucket = bucket, Key = key)

7. Save your Python script with a custom name (for example, `tutorial_print.py`) in the folder (for example, `object-lambda`) that you created in [Step 4](#) on your local machine.
8. In your local terminal, run the following command from the root of the directory (for example, `object-lambda`) that you created in [Step 4](#).

```
python3 tutorial_print.py
```

You should see both the original data and the transformed data (all text as uppercase) through the terminal. For example, you should see something like the following text.

Original object from the S3 bucket:
Amazon S3 Object Lambda Tutorial:
You can add your own code to process data retrieved from S3 before returning it to an application.

Object transformed by S3 Object Lambda:
AMAZON S3 OBJECT LAMBDA TUTORIAL:
YOU CAN ADD YOUR OWN CODE TO PROCESS DATA RETRIEVED FROM S3 BEFORE RETURNING IT TO AN APPLICATION.

Step 8: Clean up

If you transformed your data through S3 Object Lambda only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

Substeps

- [Delete the Object Lambda Access Point](#)
- [Delete the S3 access point](#)
- [Delete the execution role for your Lambda function](#)
- [Delete the Lambda function](#)
- [Delete the CloudWatch log group](#)
- [Delete the original file in the S3 source bucket](#)
- [Delete the S3 source bucket](#)
- [Delete the IAM user](#)

Delete the Object Lambda Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the radio button to the left of the S3 Object Lambda Access Point that you created in [Step 6](#) (for example, **tutorial-object-lambda-accesspoint**).
4. Choose **Delete**.
5. Confirm that you want to delete your Object Lambda Access Point by entering its name in the text field that appears, and then choose **Delete**.

Delete the S3 access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points**.
3. Navigate to the access point that you created in [Step 3](#) (for example, **tutorial-access-point**), and choose the radio button next to the name of the access point.

4. Choose **Delete**.
5. Confirm that you want to delete your access point by entering its name in the text field that appears, and then choose **Delete**.

Delete the execution role for your Lambda function

1. Sign in to the AWS Management Console and open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. In the left navigation pane, choose **Functions**.
3. Choose the function that you created in [Step 4](#) (for example, **tutorial-object-lambda-function**).
4. On your Lambda function's details page, choose the **Configuration** tab, and then choose **Permissions** in the left navigation pane.
5. Under **Execution role**, choose the link of the **Role name**. The IAM console opens.
6. On the IAM console's **Summary** page of your Lambda function's execution role, choose **Delete role**.
7. In the **Delete role** dialog box, choose **Yes, delete**.

Delete the Lambda function

1. In the AWS Lambda console at <https://console.aws.amazon.com/lambda/>, choose **Functions** in the left navigation pane.
2. Select the check box to the left of the name of the function that you created in [Step 4](#) (for example, **tutorial-object-lambda-function**).
3. Choose **Actions**, and then choose **Delete**.
4. In the **Delete function** dialog box, choose **Delete**.

Delete the CloudWatch log group

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the left navigation pane, choose **Log groups**.
3. Find the log group whose name ends with the Lambda function that you created in [Step 4](#) (for example, **tutorial-object-lambda-function**).
4. Select the check box to the left of the name of the log group.

5. Choose **Actions**, and then choose **Delete log group(s)**.
6. In the **Delete log group(s)** dialog box, choose **Delete**.

Delete the original file in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the original file to in [Step 2](#) (for example, **tutorial-bucket**).
4. Select the check box to the left of the name of the object that you want to delete (for example, `tutorial.txt`).
5. Choose **Delete**.
6. On the **Delete objects** page, in the **Permanently delete objects?** section, confirm that you want to delete this object by entering **permanently delete** in the text box.
7. Choose **Delete objects**.

Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the radio button next to the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

Delete the IAM user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Users**, and then select the check box next to the user name that you want to delete.

3. At the top of the page, choose **Delete**.
4. In the **Delete user name?** dialog box, enter the user name in the text input field to confirm the deletion of the user. Choose **Delete**.

Next steps

After completing this tutorial, you can customize the Lambda function for your use case to modify the data returned by standard S3 GET requests.

The following is a list of common use cases for S3 Object Lambda:

- Masking sensitive data for security and compliance.

For more information, see [Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend](#).

- Filtering certain rows of data to deliver specific information.
- Augmenting data with information from other services or databases.
- Converting across data formats, such as converting XML to JSON for application compatibility.
- Compressing or decompressing files as they are being downloaded.
- Resizing and watermarking images.

For more information, see [Tutorial: Using S3 Object Lambda to dynamically watermark images as they are retrieved](#).

- Implementing custom authorization rules to access data.

For more information about S3 Object Lambda, see [Transforming objects with S3 Object Lambda](#).

Tutorial: Detecting and redacting PII data with S3 Object Lambda and Amazon Comprehend

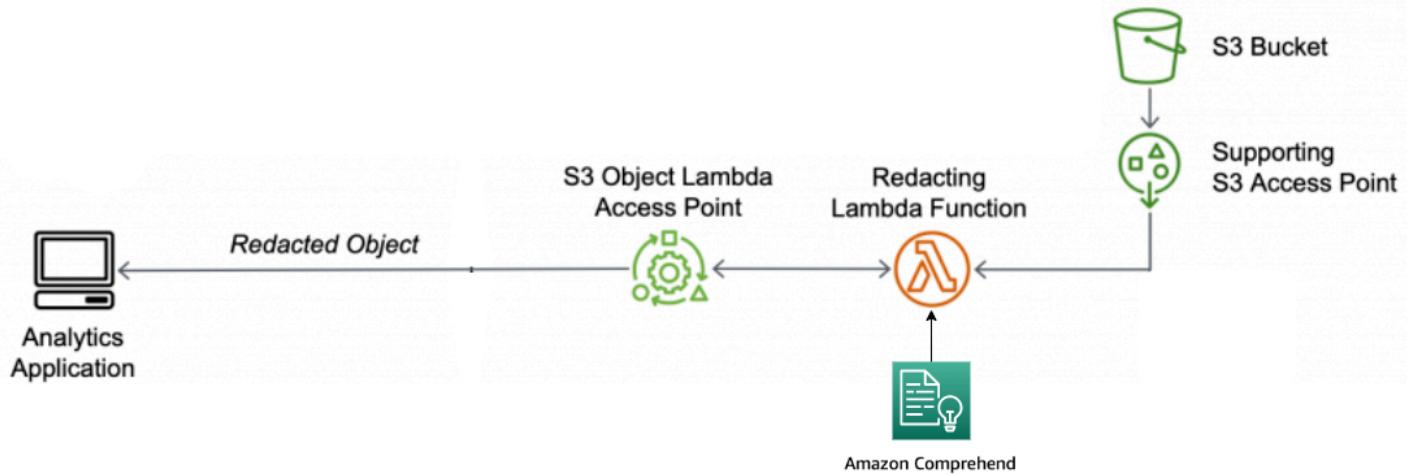

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

When you're using Amazon S3 for shared datasets for multiple applications and users to access, it's important to restrict privileged information, such as personally identifiable information (PII), to only authorized entities. For example, when a marketing application uses some data containing PII, it might need to first mask PII data to meet data privacy requirements. Also, when an analytics application uses a production order inventory dataset, it might need to first redact customer credit card information to prevent unintended data leakage.

With [S3 Object Lambda](#) and a prebuilt AWS Lambda function powered by Amazon Comprehend, you can protect PII data retrieved from S3 before returning it to an application. Specifically, you can use the prebuilt [Lambda function](#) as a redacting function and attach it to an S3 Object Lambda Access Point. When an application (for example, an analytics application) sends [standard S3 GET requests](#), these requests made through the S3 Object Lambda Access Point invoke the prebuilt redacting Lambda function to detect and redact PII data retrieved from an underlying data source through a supporting S3 access point. Then, the S3 Object Lambda Access Point returns the redacted result back to the application.

In the process, the prebuilt Lambda function uses [Amazon Comprehend](#), a natural language processing (NLP) service, to capture variations in how PII is represented, regardless of how PII exists in text (such as numerically or as a combination of words and numbers). Amazon Comprehend can even use context in the text to understand if a 4-digit number is a PIN, the last four numbers of a Social Security number (SSN), or a year. Amazon Comprehend processes any text file in UTF-8 format and can protect PII at scale without affecting accuracy. For more information, see [What is Amazon Comprehend?](#) in the *Amazon Comprehend Developer Guide*.

Objective

In this tutorial, you learn how to use S3 Object Lambda with the prebuilt Lambda function `ComprehendPiiRedactionS3ObjectLambda`. This function uses Amazon Comprehend to detect PII entities. It then redacts these entities by replacing them with asterisks. By redacting PII, you conceal sensitive data, which can help with security and compliance.

You also learn how to use and configure a prebuilt AWS Lambda function in the [AWS Serverless Application Repository](#) to work together with S3 Object Lambda for easy deployment.

Topics

- [Prerequisites: Create an IAM user with permissions](#)
- [Step 1: Create an S3 bucket](#)
- [Step 2: Upload a file to the S3 bucket](#)
- [Step 3: Create an S3 access point](#)
- [Step 4: Configure and deploy a prebuilt Lambda function](#)
- [Step 5: Create an S3 Object Lambda Access Point](#)
- [Step 6: Use the S3 Object Lambda Access Point to retrieve the redacted file](#)
- [Step 7: Clean up](#)
- [Next steps](#)

Prerequisites: Create an IAM user with permissions

Before you start this tutorial, you must have an AWS account that you can sign in to as an AWS Identity and Access Management user (IAM user) with correct permissions.

You can create an IAM user for the tutorial. To complete this tutorial, your IAM user must attach the following IAM policies to access relevant AWS resources and perform specific actions.

Note

For simplicity, this tutorial creates and uses an IAM user. After completing this tutorial, remember to [Delete the IAM user](#). For production use, we recommend that you follow the [Security best practices in IAM](#) in the *IAM User Guide*. A best practice requires human users to use federation with an identity provider to access AWS with temporary credentials. Another best practice is to require workloads to use temporary credentials with IAM roles to access AWS. To learn about using AWS IAM Identity Center to create users with temporary credentials, see [Getting started](#) in the *AWS IAM Identity Center User Guide*.

This tutorial also uses full-access policies. For production use, we recommend that you instead grant only the minimum permissions necessary for your use case, in accordance with [security best practices](#).

Your IAM user requires the following AWS managed policies:

- [AmazonS3FullAccess](#) – Grants permissions to all Amazon S3 actions, including permissions to create and use an Object Lambda Access Point.
- [AWSLambda_FullAccess](#) – Grants permissions to all Lambda actions.
- [AWSCloudFormationFullAccess](#) – Grants permissions to all AWS CloudFormation actions.
- [IAMFullAccess](#) – Grants permissions to all IAM actions.
- [IAMAccessAnalyzerReadOnlyAccess](#) – Grants permissions to read all access information provided by IAM Access Analyzer.

You can directly attach these existing policies when creating an IAM user. For more information about how to create an IAM user, see [Creating IAM users \(console\)](#) in the *IAM User Guide*.

In addition, your IAM user requires a customer managed policy. To grant the IAM user permissions to all AWS Serverless Application Repository resources and actions, you must create an IAM policy and attach the policy to the IAM user.

To create and attach an IAM policy to your IAM user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, for **Service**, choose **Choose a service**. Then, choose **Serverless Application Repository**.
5. For **Actions**, under **Manual actions**, select **All Serverless Application Repository actions (serverlessrepo:*)** for this tutorial.

As a security best practice, you should allow permissions to only those actions and resources that a user needs, based on your use case. For more information, see [Security best practices in IAM in the IAM User Guide](#).

6. For **Resources**, choose **All resources** for this tutorial.

As a best practice, you should define permissions for only specific resources in specific accounts. Alternatively, you can grant least privilege using condition keys. For more information, see [Grant least privilege](#) in the *IAM User Guide*.

7. Choose **Next: Tags**.
8. Choose **Next: Review**.
9. On the **Review policy** page, enter a **Name** (for example, **tutorial-serverless-application-repository**) and a **Description** (optional) for the policy that you are creating. Review the policy summary to make sure that you have granted the intended permissions, and then choose **Create policy** to save your new policy.
10. In the left navigation pane, choose **Users**. Then, choose the IAM user for this tutorial.
11. On the **Summary** page of the chosen user, choose the **Permissions** tab, and then choose **Add permissions**.
12. Under **Grant permissions**, choose **Attach existing policies directly**.
13. Select the check box next to the policy that you just created (for example, **tutorial-serverless-application-repository**) and then choose **Next: Review**.
14. Under **Permissions summary**, review the summary to make sure that you attached the intended policy. Then, choose **Add permissions**.

Step 1: Create an S3 bucket

Create a bucket to store the original data that you plan to transform.

 **Note**

Access points may be attached for another data source, such as an Amazon FSx for OpenZFS volume, however this tutorial uses a supporting access point attached to an S3 bucket.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.

3. Choose **Create bucket**.

The **Create bucket** page opens.

4. For **Bucket name**, enter a name (for example, **tutorial-bucket**) for your bucket.

For more information about naming buckets in Amazon S3, see [General purpose bucket naming rules](#).

5. For **Region**, choose the AWS Region where you want the bucket to reside.

For more information about the bucket Region, see [General purpose buckets overview](#).

6. For **Block Public Access settings for this bucket**, keep the default settings (**Block all public access** is enabled).

We recommend that you keep all Block Public Access settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

7. For the remaining settings, keep the defaults.

(Optional) If you want to configure additional bucket settings for your specific use case, see [Creating a general purpose bucket](#).

8. Choose **Create bucket**.

Step 2: Upload a file to the S3 bucket

Upload a text file containing known PII data of various types, such as names, banking information, phone numbers, and SSNs, to the S3 bucket as the original data that you will redact PII from later in this tutorial.

For example, you can upload following the `tutorial.txt` file. This is an example input file from Amazon Comprehend.

```
Hello Zhang Wei, I am John. Your AnyCompany Financial Services,  
LLC credit card account 1111-0000-1111-0008 has a minimum payment  
of $24.53 that is due by July 31st. Based on your autopay settings,  
we will withdraw your payment on the due date from your  
bank account number XXXXXX1111 with the routing number XXXXX0000.
```

```
Your latest statement was mailed to 100 Main Street, Any City,  
WA 98121.
```

After your payment is received, you will receive a confirmation text message at 206-555-0100.

If you have questions about your bill, AnyCompany Customer Service is available by phone at 206-555-0199 or email at support@anycompany.com.

To upload a file to a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**. For example, you can upload the `tutorial.txt` file example mentioned earlier.
7. Choose **Upload**.

Step 3: Create an S3 access point

To use an S3 Object Lambda Access Point to access and transform the original data, you must create an S3 access point and associate it with the S3 bucket that you created in [Step 1](#). The access point must be in the same AWS Region as the objects you want to transform.

Later in this tutorial, you'll use this access point as a supporting access point for your Object Lambda Access Point.

To create an access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points**.
3. On the **Access Points** page, choose **Create access point**.
4. In the **Access point name** field, enter the name (for example, **tutorial-pii-access-point**) for the access point.

For more information about naming access points, see [Naming rules for access points](#).

5. In the **Data source** field, enter the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**). S3 attaches the access point to this bucket.

(Optional) You can choose **Browse S3** to browse and search the buckets in your account. If you choose **Browse S3**, choose the desired bucket, and then choose **Choose path** to populate the **Bucket name** field with that bucket's name.

6. For **Network origin**, choose **Internet**.

For more information about network origins for access points, see [Creating access points restricted to a virtual private cloud](#).

7. By default, all block public access settings are turned on for your access point. We recommend that you keep **Block all public access** enabled. For more information, see [Managing public access to access points for general purpose buckets](#).
8. For all other access point settings, keep the default settings.

(Optional) You can modify the access point settings to support your use case. For this tutorial, we recommend keeping the default settings.

(Optional) If you need to manage access to your access point, you can specify an access point policy. For more information, see [Policy examples for access points](#).

9. Choose **Create access point**.

Step 4: Configure and deploy a prebuilt Lambda function

To redact PII data, configure and deploy the prebuilt AWS Lambda function `ComprehendPiiRedactionS3ObjectLambda` for use with your S3 Object Lambda Access Point.

To configure and deploy the Lambda function

1. Sign in to the AWS Management Console and view the [ComprehendPiiRedactionS3ObjectLambda](#) function in the AWS Serverless Application Repository.
2. For **Application settings**, under **Application name**, keep the default value (`ComprehendPiiRedactionS3ObjectLambda`) for this tutorial.

(Optional) You can enter the name that you want to give to this application. You might want to do this if you plan to configure multiple Lambda functions for different access needs for the same shared dataset.

3. For **MaskCharacter**, keep the default value (*). The mask character replaces each character in the redacted PII entity.
4. For **MaskMode**, keep the default value (**MASK**). The **MaskMode** value specifies whether the PII entity is redacted with the MASK character or the PII_ENTITY_TYPE value.
5. To redact the specified types of data, for **PiiEntityTypes**, keep the default value **ALL**. The **PiiEntityTypes** value specifies the PII entity types to be considered for redaction.

For more information about the list of supported PII entity types, see [Detect Personally Identifiable Information \(PII\)](#) in the *Amazon Comprehend Developer Guide*.

6. Keep the remaining settings set to the defaults.

(Optional) If you want to configure additional settings for your specific use case, see the **Readme file** section on the left side of the page.

7. Select the check box next to **I acknowledge that this app creates custom IAM roles**.
8. Choose **Deploy**.
9. On the new application's page, under **Resources**, choose the **Logical ID** of the Lambda function that you deployed to review the function on the Lambda function page.

Step 5: Create an S3 Object Lambda Access Point

An S3 Object Lambda Access Point provides the flexibility to invoke a Lambda function directly from an S3 GET request so that the function can redact PII data retrieved from an S3 access point. When creating and configuring an S3 Object Lambda Access Point, you must specify the redacting Lambda function to invoke and provide the event context in JSON format as custom parameters for Lambda to use.

The event context provides information about the request being made in the event passed from S3 Object Lambda to Lambda. For more information about all the fields in the event context, see [Event context format and usage](#).

To create an S3 Object Lambda Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose **Create Object Lambda Access Point**.
4. For **Object Lambda Access Point name**, enter the name that you want to use for the Object Lambda Access Point (for example, **tutorial-pii-object-lambda-accesspoint**).
5. For **Supporting Access Point**, enter or browse to the standard access point that you created in [Step 3](#) (for example, **tutorial-pii-access-point**), and then choose **Choose supporting Access Point**.
6. For **S3 APIs**, to retrieve objects from the S3 bucket for Lambda function to process, select **GetObject**.
7. For **Invoke Lambda function**, you can choose either of the following two options for this tutorial.
 - Choose **Choose from functions in your account** and choose the Lambda function that you deployed in [Step 4](#) (for example, **serverlessrepo-ComprehendPiiRedactionS3ObjectLambda**) from the **Lambda function** dropdown list.
 - Choose **Enter ARN**, and then enter the Amazon Resource Name (ARN) of the Lambda function that you created in [Step 4](#).
8. For **Lambda function version**, choose **\$LATEST** (the latest version of the Lambda function that you deployed in [Step 4](#)).
9. (Optional) If you need your Lambda function to recognize and process GET requests with range and part number headers, select **Lambda function supports requests using range** and **Lambda function supports requests using part numbers**. Otherwise, clear these two check boxes.

For more information about how to use range or part numbers with S3 Object Lambda, see [Working with Range and partNumber headers](#).

10. (Optional) Under **Payload - optional**, add JSON text to provide your Lambda function with additional information.

A payload is optional JSON text that you can provide to your Lambda function as input for all invocations coming from a specific S3 Object Lambda Access Point. To customize the behaviors

for multiple Object Lambda Access Points that invoke the same Lambda function, you can configure payloads with different parameters, thereby extending the flexibility of your Lambda function.

For more information about payload, see [Event context format and usage](#).

11. (Optional) For **Request metrics - optional**, choose **Disable** or **Enable** to add Amazon S3 monitoring to your Object Lambda Access Point. Request metrics are billed at the standard Amazon CloudWatch rate. For more information, see [CloudWatch pricing](#).

12. Under **Object Lambda Access Point policy - optional**, keep the default setting.

(Optional) You can set a resource policy. This resource policy grants the GetObject API permission to use the specified Object Lambda Access Point.

13. Keep the remaining settings set to the defaults, and choose **Create Object Lambda Access Point**.

Step 6: Use the S3 Object Lambda Access Point to retrieve the redacted file

Now, S3 Object Lambda is ready to redact PII data from your original file.

To use the S3 Object Lambda Access Point to retrieve the redacted file

When you request to retrieve a file through your S3 Object Lambda Access Point, you make a GetObject API call to S3 Object Lambda. S3 Object Lambda invokes the Lambda function to redact your PII data and returns the transformed data as the response to the standard S3 GetObject API call.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Object Lambda Access Points**.
3. On the **Object Lambda Access Points** page, choose the S3 Object Lambda Access Point that you created in [Step 5](#) (for example, **tutorial-pii-object-lambda-accesspoint**).
4. On the **Objects** tab of your S3 Object Lambda Access Point, select the file that has the same name (for example, `tutorial.txt`) as the one that you uploaded to the S3 bucket in [Step 2](#).

This file should contain all the transformed data.

5. To view the transformed data, choose **Open** or **Download**.

You should be able to see the redacted file, as shown in the following example.

Hello *****. Your AnyCompany Financial Services, LLC credit card account ***** has a minimum payment of \$24.53 that is due by *****. Based on your autopay settings, we will withdraw your payment on the due date from your bank account ***** with the routing number *****.

Your latest statement was mailed to *****. After your payment is received, you will receive a confirmation text message at *****. If you have questions about your bill, AnyCompany Customer Service is available by phone at ***** or email at *****.

Step 7: Clean up

If you redacted your data through S3 Object Lambda only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

Substeps

Delete the IAM role for your Lambda function

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**, and then select the check box next to the role name that you want to delete. The role name starts with the name of the

Lambda function that you deployed in [Step 4](#) (for example, **serverlessrepo-ComprehendPiiRedactionS3ObjectLambda**).

3. Choose **Delete**.
4. In the **Delete** dialog box, enter the role name in the text input field to confirm deletion. Then, choose **Delete**.

Delete the customer managed policy for your IAM user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**.
3. On the **Policies** page, enter the name of the customer managed policy that you created in the [Prerequisites](#) (for example, **tutorial-serverless-application-repository**) in the search box to filter the list of policies. Select the option button next to the name of the policy that you want to delete.
4. Choose **Actions**, and then choose **Delete**.
5. Confirm that you want to delete this policy by entering its name in the text field that appears, and then choose **Delete**.

Delete the IAM user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Users**, and then select the check box next to the user name that you want to delete.
3. At the top of the page, choose **Delete**.
4. In the **Delete user name?** dialog box, enter the user name in the text input field to confirm the deletion of the user. Choose **Delete**.

Next steps

After completing this tutorial, you can further explore the following related use cases:

- You can create multiple S3 Object Lambda Access Points and enable them with prebuilt Lambda functions that are configured differently to redact specific types of PII depending on the data accessors' business needs.

Each type of user assumes an IAM role and only has access to one S3 Object Lambda Access Point (managed through IAM policies). Then, you attach each ComprehendPiiRedactionS3ObjectLambda Lambda function configured for a different redaction use case to a different S3 Object Lambda Access Point. For each S3 Object Lambda Access Point, you can have a supporting S3 access point to read data from an S3 bucket that stores the shared dataset.

For more information about how to create an S3 bucket policy that allows users to read from the bucket only through S3 access points, see [Configuring IAM policies for using access points](#).

For more information about how to grant a user permission to access the Lambda function, the S3 access point, and the S3 Object Lambda Access Point, see [Configuring IAM policies for Object Lambda Access Points](#).

- You can build your own Lambda function and use S3 Object Lambda with your customized Lambda function to meet your specific data needs.

For example, to explore various data values, you can use S3 Object Lambda and your own Lambda function that uses additional [Amazon Comprehend features](#), such as entity recognition, key phrase recognition, sentiment analysis, and document classification, to process data. You can also use S3 Object Lambda together with [Amazon Comprehend Medical](#), a HIPAA-eligible NLP service, to analyze and extract data in a context-aware manner.

For more information about how to transform data with S3 Object Lambda and your own Lambda function, see [Tutorial: Transforming data for your application with S3 Object Lambda](#).

Debugging and troubleshooting S3 Object Lambda

Note

As of November 7th, 2025, S3 Object Lambda is available only to existing customers that are currently using the service as well as to select AWS Partner Network (APN) partners.

For capabilities similar to S3 Object Lambda, learn more here - [Amazon S3 Object Lambda availability change](#).

Requests to Amazon S3 Object Lambda access points might result in a new error response when something goes wrong with the Lambda function invocation or execution. These errors follow the same format as standard Amazon S3 errors. For information about S3 Object Lambda errors, see [S3 Object Lambda Error Code List](#) in the *Amazon Simple Storage Service API Reference*.

For more information about general Lambda function debugging, see [Monitoring and troubleshooting Lambda applications](#) in the *AWS Lambda Developer Guide*.

For information about standard Amazon S3 errors, see [Error Responses](#) in the *Amazon Simple Storage Service API Reference*.

You can enable request metrics in Amazon CloudWatch for your Object Lambda Access Points. These metrics help you monitor the operational performance of your access point. You can enable request metrics during or after creation of your Object Lambda Access Point. For more information, see [S3 Object Lambda request metrics in CloudWatch](#).

To get more granular logging about requests made to your Object Lambda Access Points, you can enable AWS CloudTrail data events. For more information, see [Logging data events for trails](#) in the *AWS CloudTrail User Guide*.

Performing object operations in bulk with Batch Operations

You can use S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. S3 Batch Operations can perform a single operation on lists of Amazon S3 objects that you specify. A single job can perform a specified operation on billions of objects containing exabytes of data. Amazon S3 tracks progress, sends notifications, and stores a detailed completion report of all

actions, providing a fully managed, auditable, and serverless experience. You can use S3 Batch Operations through the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Use S3 Batch Operations to copy objects and set object tags or access control lists (ACLs). You can also initiate object restores from S3 Glacier Flexible Retrieval or invoke an AWS Lambda function to perform custom actions using your objects. You can perform these operations on a custom list of objects, or you can use an Amazon S3 Inventory report to easily generate lists of objects. Amazon S3 Batch Operations use the same Amazon S3 API operations that you already use with Amazon S3.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#). For more information about using Batch Operations with S3 Express One Zone and directory buckets, see [Using Batch Operations with directory buckets](#).

S3 Batch Operations basics

You can use S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. S3 Batch Operations can run a single operation or action on lists of Amazon S3 objects that you specify.

Terminology

This section uses the terms *manifests*, *jobs*, *operations*, and *tasks*, which are defined as follows:

Manifest

A manifest is an Amazon S3 object that contains the object keys that you want Amazon S3 to act upon. If you want to create a Batch Operations job, you must supply a manifest. Your user-generated manifest must contain the bucket name, object key, and optionally, the object version for each object. If you supply a user-generated manifest, it must be in the form of an Amazon S3 Inventory report or a CSV file.

You can also have Amazon S3 generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for Batch Operations jobs that you create by using the Amazon S3 console, or for any job type that you create by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

Job

A job is the basic unit of work for S3 Batch Operations. A job contains all of the information necessary to run the specified operation on the objects listed in the manifest. After you provide this information and request that the job begin, the job performs the operation for each object in the manifest.

Operation

The operation is the type of API [action](#), such as copying objects, that you want the Batch Operations job to run. Each job performs a single type of operation across all objects that are specified in the manifest.

Task

A task is the unit of execution for a job. A task represents a single call to an Amazon S3 or AWS Lambda API operation to perform the job's operation on a single object. Over the course of a job's lifetime, S3 Batch Operations create one task for each object specified in the manifest.

How an S3 Batch Operations job works

A job is the basic unit of work for S3 Batch Operations. A job contains all of the information necessary to run the specified operation on a list of objects. To create a job, you give S3 Batch Operations a list of objects and specify the action to perform on those objects. For information about the operations that S3 Batch Operations supports, see [Operations supported by S3 Batch Operations](#).

A batch job performs a specified operation on every object that's included in its *manifest*. A manifest lists the objects that you want a batch job to process and it is stored as an object in a bucket. You can use a comma-separated values (CSV)-formatted [Cataloging and analyzing your data with S3 Inventory](#) report as a manifest, which makes it easy to create large lists of objects located in a bucket. You can also specify a manifest in a simple CSV format that enables you to perform batch operations on a customized list of objects contained within a single bucket.

After you create a job, Amazon S3 processes the list of objects in the manifest and runs the specified operation against each object. While a job is running, you can monitor its progress programmatically or through the Amazon S3 console. You can also configure a job to generate a completion report when it finishes. The completion report describes the results of each task that was performed by the job. For more information about monitoring jobs, see [Managing S3 Batch Operations jobs](#).

There are costs associated with S3 Batch Operations. You are billed for creating Batch Operations jobs, including jobs that are canceled before completion. For more information, see [Amazon S3 pricing](#).

S3 Batch Operations jobs by default can process up to 4 billion objects for all operations. Specifically Copy, Object Tagging, Object Lock, invoking an AWS Lambda function, and Batch Replication jobs can support up to 20 billion objects. There is a limit of 6 active Batch Replication jobs per AWS account. To get started creating a Batch Operations job, see [Creating an S3 Batch Operations job](#).

S3 Batch Operations tutorial

The following tutorial presents complete end-to-end procedures for some Batch Operations tasks.

- [Tutorial: Batch-transcoding videos with S3 Batch Operations](#)

Granting permissions for Batch Operations

Before creating and running S3 Batch Operations jobs, you must grant required permissions. To create an Amazon S3 Batch Operations job, the `s3:CreateJob` user permission is required. The same entity that creates the job must also have the `iam:PassRole` permission to pass the AWS Identity and Access Management (IAM) role that's specified for the job to Batch Operations.

The following sections provide information about creating an IAM role and attaching policies. For general information about specifying IAM resources, see [IAM JSON policy elements: Resource](#) in the [IAM User Guide](#).

Topics

- [Creating an S3 Batch Operations IAM role](#)
- [Attaching permissions policies](#)

Creating an S3 Batch Operations IAM role

Amazon S3 must have permissions to perform S3 Batch Operations on your behalf. You grant these permissions through an AWS Identity and Access Management (IAM) role. When you create an S3 Batch Operations job, you specify the IAM role that you want the job to use. This can be an existing IAM role. Or, if you use the Amazon S3 console to create the job, it can be an IAM role that Amazon S3 creates for you.

If you choose to let Amazon S3 create the IAM role for you, it automatically creates and attaches trust and permissions policies to the role. The trust policy allows the S3 Batch Operations service principal (`batchoperations.s3.amazonaws.com`) to assume the role. The permissions policy allows all the requisite actions for running the job, based on the settings that you specify for the job. For example, if you configure a job to copy objects from one bucket to another bucket in your AWS account, the permissions policy allows actions such as `s3:GetObject` and `s3:PutObject`. You can review the trust and permissions policies for the role before you submit the job. This option is available only if you use the Amazon S3 console to create a job, and you configure the job to use an S3 generated object list that uses filters or is based on a replication configuration. After you submit the job, the IAM role persists in your account. You can then use it again for subsequent jobs that perform the same operation, or delete it when the job finishes running.

If you prefer to create the IAM role manually, the policy examples in this section can help you create the role. For more information about creating and configuring roles, see [IAM roles](#) in the *IAM User Guide*. For information about permissions for S3 API operations by S3 resource type, see [Required permissions for Amazon S3 API operations](#). For additional examples, see [Controlling permissions for Batch Operations using job tags](#) and [Copying objects using S3 Batch Operations](#).

In your IAM policies, you can also use condition keys to filter access permissions for S3 Batch Operations jobs. For more information and a complete list of condition keys that are specific to Amazon S3, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

Trust policy

To allow the S3 Batch Operations service principal to assume the IAM role, attach the following trust policy to the role.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "batchoperations.s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

```
]  
}
```

Attaching permissions policies

Depending on the type of operations, you can attach one of the following policies.

Before you configure permissions, note the following:

- Regardless of the operation, Amazon S3 needs permissions to read your manifest object from your S3 bucket and optionally write a report to your bucket. Therefore, all of the following policies include these permissions.
- For Amazon S3 Inventory report manifests, S3 Batch Operations requires permission to read the manifest.json object and all associated CSV data files.
- Version-specific permissions such as s3:GetObjectVersion are only required when you are specifying the version ID of the objects.
- If you are running S3 Batch Operations on encrypted objects, the IAM role must also have access to the AWS KMS keys used to encrypt them.
- If you submit an inventory report manifest that's encrypted with AWS KMS, your IAM policy must include the permissions "kms:Decrypt" and "kms:GenerateDataKey" for the manifest.json object and all associated CSV data files.
- If the Batch Operations job generates a manifest in a bucket that has access control lists (ACLs) enabled and is in a different AWS account, you must grant the s3:PutObjectAcl permission in the IAM policy of the IAM role configured for the batch job. If you don't include this permission, the batch job fails with the error Error occurred when preparing manifest: Failed to write manifest.

Creating an S3 Batch Operations job

With Amazon S3 Batch Operations, you can perform large-scale batch operations on a list of specific Amazon S3 objects. This section describes the information that you need to create an S3 Batch Operations job and the results of a `CreateJob` request. It also provides instructions for creating a Batch Operations job by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

When you create an S3 Batch Operations job, you can request a completion report for all tasks or only failed tasks. As long as at least one task has been invoked successfully, S3 Batch Operations generates a report for jobs that have been completed, have failed, or have been canceled. For more information, see [Examples: S3 Batch Operations completion reports](#).

Batch Operations job request elements

To create an S3 Batch Operations job, you must provide the following information:

Operation

Specify the operation that you want S3 Batch Operations to run against the objects in the manifest. Each operation type accepts parameters that are specific to that operation. With Batch Operations, you can perform an operation in bulk, with the same results as if you performed that operation one-by-one on each object.

Manifest

A *manifest* is an Amazon S3 object list that contains the object keys that you want Amazon S3 to act upon. You can use the following methods to specify a manifest for a Batch Operations job:

- Direct Batch Operations to generate an object list based on metadata that you specify. You can save this list as a manifest file and use it when you create your job. This option is available for any job type that you create by using the Amazon S3 console, the AWS CLI, AWS SDKs, or Amazon S3 REST API.
- Generate an object list automatically based on an existing replication configuration. You can save this list as a manifest file and use it again for future jobs.
- Create a new manifest file manually.
- Use an existing manifest.

Note

- Regardless of how you specify the objects to work on, the manifest itself must be stored in a general purpose bucket. Batch Operations can't import existing manifests from, or save generated object lists as manifests to directory buckets. Objects described within the manifest, however, can be stored in directory buckets. For more information, see [Directory buckets](#).
- If the objects in your manifest are in a versioned bucket, specifying the version IDs for the objects directs Batch Operations to perform the operation on a specific version. If no version IDs are specified, Batch Operations performs the operation on the latest version of the objects. If your manifest includes a version ID field, you must provide a version ID for all objects in the manifest.

For more information, see [Specifying a manifest](#).

Priority

Use job priorities to indicate the relative priority of this job to others running in your account. A higher number indicates higher priority.

Job priorities only have meaning relative to the priorities that are set for other jobs in the same account and Region. You can choose whatever numbering system works for you. For example, you might want to assign all **Restore** (RestoreObject) jobs a priority of 1, all **Copy** (CopyObject) jobs a priority of 2, and all **Replace access control lists (ACLs)** (PutObjectAcl) jobs a priority of 3.

S3 Batch Operations prioritizes jobs according to priority numbers, but strict ordering isn't guaranteed. Therefore, don't use job priorities to ensure that any one job starts or finishes before any other job. If you must ensure strict ordering, wait until one job has finished before starting the next.

RoleArn

Specify an AWS Identity and Access Management (IAM) role to run the job. The IAM role that you use must have sufficient permissions to perform the operation specified in the job. For example, to run a CopyObject job, the IAM role must have the s3:GetObject permission for the source bucket and the s3:PutObject permission for the destination bucket. The role also needs permissions to read the manifest and write the completion report.

The IAM role can be an existing role. Or, if you use the Amazon S3 console to create the job, it can be an IAM role that Amazon S3 creates automatically for you. For more information, see [Granting permissions for Batch Operations](#).

For more information about IAM roles, see [IAM roles in the IAM User Guide](#). For more information about Amazon S3 permissions, see [Policy actions for Amazon S3](#).

Note

Batch Operations jobs that perform actions on directory buckets require specific permissions. For more information, see [AWS Identity and Access Management \(IAM\) for S3 Express One Zone](#).

Report

Specify whether you want S3 Batch Operations to generate a completion report. If you request a completion report, you must also provide the parameters for the report in this element. The following information is required:

- The bucket where you want to store the report

 **Note**

The report must be stored in a general purpose bucket. Batch Operations can't save reports to directory buckets. For more information, see [Directory buckets](#).

- The format of the report
- Whether you want the report to include the details of all tasks or only failed tasks
- An optional prefix string

If the `CreateJob.Report.ExpectedBucketOwner` field is supplied, it requires that the completion report bucket owner matches. If it doesn't match, then the job fails.

 **Note**

Completion reports are always encrypted with server-side encryption with Amazon S3 managed keys (SSE-S3).

Tags (optional)

You can label and control access to your S3 Batch Operations jobs by adding *tags*. You can use tags to identify who is responsible for a Batch Operations job, or to control how users interact with Batch Operations jobs. The presence of job tags can grant or limit a user's ability to cancel a job, activate a job in the confirmation state, or change a job's priority level. For example, you could grant a user permission to invoke the `CreateJob` operation, provided that the job is created with the tag "Department=Finance".

You can create jobs with tags attached to them, and you can add tags to jobs after you create them.

For more information, see [the section called "Using tags"](#).

Description (optional)

To track and monitor your job, you can also provide a description of up to 256 characters. Amazon S3 includes this description whenever it returns information about a job or displays job details on the Amazon S3 console. You can then easily sort and filter jobs according to the descriptions that you assigned. Descriptions don't need to be unique, so you can use descriptions as categories (for example, "Weekly Log Copy Jobs") to help you track groups of similar jobs.

Specifying a manifest

A *manifest* is an Amazon S3 object list that contains the object keys that you want Amazon S3 to act upon. You can use the following methods to specify a manifest for a Batch Operations job:

- Direct Batch Operations to generate an object list based on metadata that you specify. You can save this list as a manifest and use it when you create your job. This option is available for any job type that you create by using the Amazon S3 console, the AWS CLI, AWS SDKs, or Amazon S3 REST API.
- Generate an object list automatically based on an existing replication configuration. You can save this list as a manifest and use it again for future jobs.
- Create a new manifest file manually.
- Use an existing manifest.

Note

- Amazon S3 Batch Operations does not support cross-Region object list generation.
- Regardless of how you specify the objects to work on, the manifest itself must be stored in a general purpose bucket. Batch Operations can't import existing manifests from, or save generated object lists as manifests to directory buckets. Objects described within the manifest, however, can be stored in directory buckets. For more information, see [Directory buckets](#).

Generating an object list automatically and saving it as a manifest file

You can direct Amazon S3 to generate an object list automatically based on metadata that you specify. You can save this list as a manifest and use it when you create your job. This option is available for any job type that you create by using the Amazon S3 console, the AWS CLI, AWS SDKs, or Amazon S3 REST API.

To generate an object list automatically and save it as a manifest file, you specify the following elements as part of your job creation request:

- Information about the bucket that contains your source objects, including the bucket owner and Amazon Resource Name (ARN).
- Information about the manifest output, including a flag to create a manifest file, the output bucket owner, the ARN, the prefix, the file format, and the encryption type.
- Optional criteria to filter objects by their creation date, key name, size, encryption type, KMS key ARN, Bucket Key and storage class, In the case of replication jobs, you can also use tags to filter objects.

Object filter criteria

To filter the list of objects to be included in an automatically generated object list, you can specify the following criteria. For more information, see [JobManifestGeneratorFilter](#) in the *Amazon S3 API Reference*.

CreatedAfter

If provided, the generated manifest includes only source bucket objects that were created after this time.

CreatedBefore

If provided, the generated manifest includes only source bucket objects that were created before this time.

EligibleForReplication

If provided, the generated manifest includes objects only if they are eligible for replication according to the replication configuration on the source bucket.

KeyNameConstraint

If provided, the generated manifest includes only source bucket objects whose object keys match the string constraints specified for **MatchAnySubstring**, **MatchAnyPrefix**, and **MatchAnySuffix**.

MatchAnySubstring – If provided, the generated manifest includes objects if the specified string appears anywhere within the object key string.

MatchAnyPrefix – If provided, the generated manifest includes objects if the specified string appears at the start of the object key string.

MatchAnySuffix – If provided, the generated manifest includes objects if the specified string appears at the end of the object key string.

MatchAnyObjectEncryption

If provided, the generated object list saved as a manifest file includes only source bucket objects with the indicated server-side encryption type (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C, or NOT-SSE). If you select SSE- KMS or DSSE-KMS, you can optionally further filter your results by specifying a specific KMS key ARN. If you select SSE-KMS, you can also optionally further filter your results by Bucket Key enabled status.

MatchAnyStorageClass

If provided, the generated manifest includes only source bucket objects that are stored with the specified storage class.

ObjectReplicationStatuses

If provided, the generated manifest includes only source bucket objects that have one of the specified replication statuses.

ObjectSizeGreater ThanBytes

If provided, the generated manifest includes only source bucket objects whose file size is greater than the specified number of bytes.

ObjectSizeLess ThanBytes

If provided, the generated manifest includes only source bucket objects whose file size is less than the specified number of bytes.

Note

You can't clone most jobs that have automatically generated object lists saved as manifests. Batch replication jobs can be cloned, except when they use the `KeyNameConstraint`, `MatchAnyStorageClass`, `ObjectSizeGreater ThanBytes`, or `ObjectSizeLessThanBytes` manifest filter criteria.

The syntax for specifying manifest criteria varies depending on the method that you use to create your job. For examples, see [Creating a job](#).

Creating a manifest file

To create a manifest file manually, you specify the manifest object key, ETag (entity tag), and optional version ID in a CSV-formatted list. The contents of the manifest must be URL-encoded.

By default, Amazon S3 automatically uses server-side encryption with Amazon S3 managed keys (SSE-S3) to encrypt a manifest that's uploaded to an Amazon S3 bucket. Manifests that use server-side encryption with customer-provided keys (SSE-C) are not supported. Manifests that use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) are supported only when you're using CSV-formatted inventory reports. Using a manually created manifest with AWS KMS is not supported.

Your manifest must contain the bucket name, object key, and optionally, the object version for each object. Any other fields in the manifest are not used by S3 Batch Operations.

Note

If the objects in your manifest are in a versioned bucket, specifying the version IDs for the objects directs Batch Operations to perform the operation on a specific version. If no version IDs are specified, Batch Operations performs the operation on the latest version of the objects. If your manifest includes a version ID field, you must provide a version ID for all objects in the manifest.

The following is an example manifest in CSV format without version IDs.

```
amzn-s3-demo-bucket1,objectkey1
```

```
amzn-s3-demo-bucket1,objectkey2
amzn-s3-demo-bucket1,objectkey3
amzn-s3-demo-bucket1,photos/jpgs/objectkey4
amzn-s3-demo-bucket1,photos/jpgs/newjersey/objectkey5
amzn-s3-demo-bucket1,object%20key%20with%20spaces
```

The following is an example manifest in CSV format that includes version IDs.

```
amzn-s3-demo-bucket1,objectkey1,PZ9ibn9D5lP6p298B7S9_ceqx1n5EJ0p
amzn-s3-demo-bucket1,objectkey2,YY_ouuAJByNW1LRBffMfxMge7XQWxMBF
amzn-s3-demo-bucket1,objectkey3,jbo9_jhdPEyB4Rrm0xWS0kU0EoNrU_oI
amzn-s3-demo-bucket1,photos/jpgs/objectkey4,6EqlikJJxLTsHsnbZbSRffn24_eh5Ny4
amzn-s3-demo-bucket1,photos/jpgs/newjersey/objectkey5,imHf3FAiRsvBW_EHB8G0u.NHunH01gVs
amzn-s3-demo-bucket1,object%20key%20with%20spaces,9HkPvDaZY5MVbMhn6TMn1YTb5ArQAo3w
```

Using an existing manifest

You can specify an existing manifest to create a Batch Operations job by using one of the following two formats:

- **Amazon S3 Inventory report** – Must be a CSV-formatted Amazon S3 Inventory report. You must specify the manifest.json file that is associated with the inventory report. For more information about inventory reports, see [Cataloging and analyzing your data with S3 Inventory](#). If the inventory report includes version IDs, S3 Batch Operations operates on the specific object versions.

 **Note**

- S3 Batch Operations supports CSV *inventory reports* that are encrypted with SSE-KMS.
- If you submit an inventory report manifest that's encrypted with SSE-KMS, your IAM policy must include the permissions "kms:Decrypt" and "kms:GenerateDataKey" for the manifest.json object and all associated CSV data files.

- **CSV file** – Each row in the file must include the bucket name, object key, and optionally, the object version. Object keys must be URL-encoded, as shown in the following examples. The manifest must either include version IDs for all objects or omit version IDs for all objects. For more information about the CSV manifest format, see [JobManifestSpec](#) in the *Amazon Simple Storage Service API Reference*.

Note

S3 Batch Operations doesn't support CSV *manifest files* that are encrypted with SSE-KMS.

Important

When you're using a manually created manifest and a versioned bucket, we recommend that you specify the version IDs for the objects. When you create a job, S3 Batch Operations parses the entire manifest before running the job. However, it doesn't take a "snapshot" of the state of the bucket.

Because manifests can contain billions of objects, jobs might take a long time to run, which can affect which version of an object that the job acts upon. Suppose that you overwrite an object with a new version while a job is running and you didn't specify a version ID for that object. In this case, Amazon S3 performs the operation on the latest version of the object, not on the version that existed when you created the job. The only way to avoid this behavior is to specify version IDs for the objects that are listed in the manifest.

Creating a job

You can create S3 Batch Operations jobs by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

For more information about creating a job request, see [Batch Operations job request elements](#).

Prerequisites

Before you create a Batch Operations job, confirm that you have configured the relevant permissions. For more information, see [Granting permissions for Batch Operations](#).

Using the S3 console

To create a Batch Operations job using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. Choose **Batch Operations** on the left navigation pane of the Amazon S3 console.
3. Choose **Create job**.
4. Under **Choose Region and scope**, choose and view the AWS Region where you want to create your job.

 **Note**

For copy operations, you must create the job in the same Region as the destination bucket. For all other operations, you must create the job in the same Region as the objects in the manifest.

5. For **Scope**, specify the list of objects that your Batch Operations job will act upon.

Under **Object list**, you can choose to generate a manifest using an object list, generate a manifest using a replication configuration, or use an existing manifest.

- If you choose **Generate an object list**, an object list is automatically generated based on the source location and metadata that you specify. You can save this list as a manifest and use it again for future jobs.

 **Note**

To generate an object list, you must have the `s3:PutInventoryConfiguration` permission. The source bucket must be a general purpose bucket.

- If you choose **Use an existing manifest**, you can import an object list from an existing manifest. A manifest is an S3 Inventory report or CV file that lists the specific objects that you want Batch Operations to act upon.
- If you choose **Use a replication configuration**, you can generate an object list automatically based on an existing replication configuration. You can save this list as a manifest and use it again for future jobs.

For this example, choose **Generate an object list**.

6. For **Source account**, choose the account that owns the source objects.
7. Under **Source**, enter the path to your source, for example, `s3://amzn-s3-demo-bucket`.
8. Under **Object filters**, you can use filters to filter by any portion of the object key or to filter by the end of the object key. The **Object key filters** assist in refining the list of objects to be

- used in the manifest. For **Object metadata filters**, choose filters to further define the scope of objects to include in the manifest.
9. Under **Choose operation**, choose the operation type that you want to perform on all objects listed in the manifest. If your manifest references objects stored in a directory bucket, only use the copy or invoke AWS Lambda function operations. All other operations aren't supported.
 10. After selecting your operation type, choose **Next**.
 11. Fill out the information for **Configure additional options**.

For **Permissions**, specify the AWS Identity and Access Management (IAM) role that you want the job to use. This can be an existing role, or a role that Amazon S3 creates automatically for you. For more information, see [Granting permissions for Batch Operations](#). Amazon S3 can create the role for you if you configured the job to use an S3 generated object list with filters or an object list based on a replication configuration.

12. When you finish configuring the additional options, choose **Next**.
13. For **Review**, verify the settings. If you need to make changes, choose **Previous**. Otherwise, you can choose **Submit job**.

Using the AWS CLI

To create your Batch Operations job with the AWS CLI, choose one of the following examples, depending on whether you're specifying an existing manifest or generating a manifest automatically.

Specify manifest

The following example shows how to use the AWS CLI to create an S3 Batch Operations S3PutObjectTagging job that acts on objects that are listed in an existing manifest file.

To create a Batch Operations S3PutObjectTagging job by specifying a manifest

1. Use the following commands to create an AWS Identity and Access Management (IAM) role, and then create an IAM policy to assign the relevant permissions. The following role and policy grant Amazon S3 permission to add object tags, which you will need when you create the job in a subsequent step.
 - a. Use the following example command to create an IAM role for Batch Operations to use. To use this example command, replace *S3BatchJobRole* with the name that you want to give to the role.

```
aws iam create-role \
--role-name S3BatchJobRole \
--assume-role-policy-document '{
    "Version": "2012-10-17" ,
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "batchoperations.s3.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}'
```

Record the role's Amazon Resource Name (ARN). You will need the ARN when you create a job.

- b. Use the following example command to create an IAM policy with the necessary permissions and attach it to the IAM role that you created in the previous step. For more information about the necessary permissions, see [Granting permissions for Batch Operations](#).

 **Note**

Batch Operations jobs that perform actions on directory buckets require specific permissions. For more information, see [AWS Identity and Access Management \(IAM\) for S3 Express One Zone](#).

To use this example command, replace the *user input placeholders* as follows:

- Replace *S3BatchJobRole* with the name of your IAM role. Make sure that this name matches the name that you used earlier.
- Replace *PutObjectTaggingBatchJobPolicy* with the name that you want to give your IAM policy.
- Replace *amzn-s3-demo-destination-bucket* with the name of the bucket that contains the objects that you want to apply tags to.

- Replace *amzn-s3-demo-manifest-bucket* with the name of the bucket that contains the manifest.
- Replace *amzn-s3-demo-completion-report-bucket* with the name of the bucket where you want the completion report to be delivered to.

```
aws iam put-role-policy \
--role-name S3BatchJobRole \
--policy-name PutObjectTaggingBatchJobPolicy \
--policy-document '{
    "Version": "2012-10-17" ,           TCX5-2025-waiver;,
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObjectTagging",
                "s3:PutObjectVersionTagging"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket",
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-completion-report-bucket",
                "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*"
            ]
        }
    ]
}'
```

```
    }  
]  
}'
```

2. Use the following example command to create an S3PutObjectTagging job.

The `manifest.csv` file provides a list of bucket and object key values. The job applies the specified tags to the objects that are identified in the manifest. The ETag is the ETag of the `manifest.csv` object, which you can get from the Amazon S3 console. This request specifies the `no-confirmation-required` parameter, so that you can run the job without having to confirm it with the `update-job-status` command. For more information, see [create-job](#) in the *AWS CLI Command Reference*.

To use this example command, replace the *user input placeholders* with your own information. Replace *IAM-role* with the ARN of the IAM role that you created earlier.

```
aws s3control create-job \  
  --region us-west-2 \  
  --account-id acct-id \  
  --operation '{"S3PutObjectTagging": { "TagSet": [{"Key":"keyOne",  
"Value":"ValueOne"}] }}' \  
  --manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820","Fields":  
["Bucket","Key"]},"Location":{"ObjectArn":"arn:aws:s3:::amzn-s3-demo-manifest-  
bucket/manifest.csv","ETag":"60e460c9d1046e73f7dde5043ac3ae85"}}' \  
  --report '{"Bucket":arn:aws:s3:::amzn-s3-demo-  
completion-report-bucket","Prefix":"final-reports",  
"Format":Report_CSV_20180820,"Enabled":true,"ReportScope":AllTasks}' \  
  --priority 42 \  
  --role-arn IAM-role \  
  --client-request-token $(uuidgen) \  
  --description "job description" \  
  --no-confirmation-required
```

In response, Amazon S3 returns a job ID (for example, `00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c`). You will need the job ID to identify, monitor, and modify the job.

Generate manifest

The following example shows how to create an S3 Batch Operations `S3DeleteObjectTagging` job that automatically generates a manifest based on your object filter criteria. This criteria includes the creation date, key name, size, storage class, and tags.

To create a Batch Operations S3DeleteObjectTagging job by generating a manifest

1. Use the following commands to create an AWS Identity and Access Management (IAM) role, and then create an IAM policy to assign permissions. The following role and policy grant Amazon S3 permission to delete object tags, which you will need when you create the job in a subsequent step.
 - a. Use the following example command to create an IAM role for Batch Operations to use. To use this example command, replace *S3BatchJobRole* with the name that you want to give to the role.

```
aws iam create-role \
--role-name S3BatchJobRole \
--assume-role-policy-document '{ \
    "Version": "2012-10-17" , \
    "Statement": [ \
        { \
            "Effect": "Allow", \
            "Principal": { \
                "Service": "batchoperations.s3.amazonaws.com" \
            }, \
            "Action": "sts:AssumeRole" \
        } \
    ] \
}'
```

Record the role's Amazon Resource Name (ARN). You will need the ARN when you create a job.

- b. Use the following example command to create an IAM policy with the necessary permissions and attach it to the IAM role that you created in the previous step. For more information about the necessary permissions, see [Granting permissions for Batch Operations](#).

 **Note**

Batch Operations jobs that perform actions on directory buckets require specific permissions. For more information, see [AWS Identity and Access Management \(IAM\) for S3 Express One Zone](#).

To use this example command, replace the *user input placeholders* as follows:

- Replace *S3BatchJobRole* with the name of your IAM role. Make sure that this name matches the name that you used earlier.
- Replace *DeleteObjectTaggingBatchJobPolicy* with the name that you want to give your IAM policy.
- Replace *amzn-s3-demo-destination-bucket* with the name of the bucket that contains the objects that you want to apply tags to.
- Replace *amzn-s3-demo-manifest-bucket* with the name of the bucket where you want to save the manifest.
- Replace *amzn-s3-demo-completion-report-bucket* with the name of the bucket where you want the completion report to be delivered to.

```
aws iam put-role-policy \  
  --role-name S3BatchJobRole \  
  --policy-name DeleteObjectTaggingBatchJobPolicy \  
  --policy-document '{  
    "Version": "2012-10-17" , TCX5-2025-waiver;,  
    "Statement": [  
      {  
        "Effect": "Allow",  
        "Action": [  
          "s3:DeleteObjectTagging",  
          "s3:DeleteObjectVersionTagging"  
        ],  
        "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
      },  
      {  
        "Effect": "Allow",  
        "Action": [  
          "s3:PutInventoryConfiguration"  
        ],  
        "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket"  
      },  
      {  
        "Effect": "Allow",  
        "Action": [  
          "s3:GetObject",  
          "s3:ListBucket"  
        ]  
      }  
    ]  
  }'
```

```
        "s3:GetObjectVersion",
        "s3>ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::amzn-s3-demo-manifest-bucket",
        "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3>ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::amzn-s3-demo-completion-report-bucket",
        "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*",
        "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
    ]
}
]
}'
```

2. Use the following example command to create the S3DeleteObjectTagging job.

In this example, the values in the `--report` section specify the bucket, prefix, format, and scope of the job report that will be generated. The `--manifest-generator` section specifies information about the source bucket that contains the objects the job will act upon, information about the manifest output list that will be generated for the job, and filter criteria to narrow the scope of objects to be included in the manifest by creation date, name constraints, size, and storage class. The command also specifies the job's priority, IAM role, and AWS Region.

For more information, see [create-job](#) in the *AWS CLI Command Reference*.

To use this example command, replace the `user input placeholders` with your own information. Replace `IAM-role` with the ARN of the IAM role that you created earlier.

```
aws s3control create-job \
--account-id 012345678901 \
--operation '{
```

```
        "S3DeleteObjectTagging": {}  
    }' \  
    --report '{  
        "Bucket": "arn:aws:s3:::amzn-s3-demo-completion-report-bucket",  
        "Prefix": "reports",  
        "Format": "Report_CSV_20180820",  
        "Enabled": true,  
        "ReportScope": "AllTasks"  
    }' \  
    --manifest-generator '{  
        "S3JobManifestGenerator": {  
            "ExpectedBucketOwner": "012345678901",  
            "SourceBucket": "arn:aws:s3:::amzn-s3-demo-source-bucket",

                "Bucket": "arn:aws:s3:::amzn-s3-demo-manifest-bucket",  
                "ManifestPrefix": "prefix",  
                "ManifestFormat": "S3InventoryReport_CSV_20211130"  
            },  
            "Filter": {  
                "CreatedAfter": "2023-09-01",

            }  
        }  
    }' \  
    --priority 2 \  
    --role-arn IAM-role \  
    --region us-east-1
```

In response, Amazon S3 returns a job ID (for example, `00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c`). You will need this job ID to identify, monitor, or modify the job.

Using the AWS SDK for Java

To create your Batch Operations job with the AWS SDK for Java, you can choose between two approaches depending on whether you're specifying an existing manifest or generating a manifest automatically:

- *Specify existing manifest:* Create an S3 Batch Operations job (such as `S3PutObjectTagging`) that acts on objects listed in an existing manifest file. This approach requires you to provide the manifest location, ETag, and format specifications.
- *Generate manifest automatically:* Create an S3 Batch Operations job (such as `s3PutObjectCopy`) that automatically generates a manifest based on object filter criteria, including creation date, key name, and size constraints.

Both approaches use the `S3Control` client to configure job operations, manifest specifications, job reports, IAM roles, and other job parameters including priority and confirmation requirements.

For examples of how to create S3 Batch Operations jobs with the AWS SDK for Java, see [Create a batch job to copy objects](#) in the *Amazon S3 API Reference*.

Using the REST API

You can use the REST API to create a Batch Operations job. For more information, see [CreateJob](#) in the *Amazon Simple Storage Service API Reference*.

Job responses

If the `CreateJob` request succeeds, Amazon S3 returns a job ID. The job ID is a unique identifier that Amazon S3 generates automatically so that you can identify your Batch Operations job and monitor its status.

When you create a job through the AWS CLI, AWS SDKs, or REST API, you can set S3 Batch Operations to begin processing the job automatically. The job runs as soon as it's ready instead of waiting behind higher-priority jobs.

When you create a job through the Amazon S3 console, you must review the job details and confirm that you want to run the job before Batch Operations can begin to process it. If a job remains in the suspended state for over 30 days, it will fail.

Operations supported by S3 Batch Operations

You can use S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. S3 Batch Operations can perform a single operation on lists of Amazon S3 objects that you specify. A single job can perform a specified operation on billions of objects containing exabytes of data. Amazon S3 tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, and serverless experience. You can use S3 Batch Operations through the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

S3 Batch Operations supports the following operations:

Copy objects

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. The Batch Operations **Copy** operation copies each object that is specified in the manifest. You can copy objects to a bucket in the same AWS Region or to a bucket in a different Region. S3 Batch Operations supports most options available through Amazon S3 for copying objects. These options include setting object metadata, setting permissions, and changing an object's storage class.

You can also use the **Copy** operation to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. For more information, see [Encrypting objects with Amazon S3 Batch Operations](#).

When you copy objects, you can change the checksum algorithm used to calculate the checksum of the object. If objects don't have an additional checksum calculated, you can also add one by specifying the checksum algorithm for Amazon S3 to use. For more information, see [Checking object integrity in Amazon S3](#).

For more information about copying objects in Amazon S3 and the required and optional parameters, see [Copying, moving, and renaming objects](#) in this guide and [CopyObject](#) in the *Amazon Simple Storage Service API Reference*.

Restrictions and limitations

When you're using the Batch Operations **Copy** operation, the following restrictions and limitations apply:

- All source objects must be in one bucket.
- All destination objects must be in one bucket.
- You must have read permissions for the source bucket and write permissions for the destination bucket.
- Objects to be copied can be up to 5 GB in size.
- If you try to copy objects from the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive classes to the S3 Standard storage class, you must first restore these objects. For more information, see [Restoring an archived object](#).
- You must create your Batch Operations **Copy** jobs in the destination Region, which is the Region that you intend to copy the objects to.
- All `CopyObject` options are supported except for conditional checks on entity tags (ETags) and server-side encryption with customer-provided encryption keys (SSE-C).
- If the destination bucket is unversioned, you will overwrite any objects that have the same key names.
- Objects aren't necessarily copied in the same order as they appear in the manifest. For versioned buckets, if preserving the current or noncurrent version order is important, copy all noncurrent versions first. Then, after the first job is complete, copy the current versions in a subsequent job.
- Copying objects to the Reduced Redundancy Storage (RRS) class isn't supported.
- A single Batch Operations Copy job can support a manifest with up to 20 billion objects.

Copying objects using S3 Batch Operations

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. You can use S3 Batch Operations to create a **Copy** (`CopyObject`) job to copy objects within the same account or to a different destination account.

The following examples show how to store and use a manifest that is in a different account. The first example shows how you can use Amazon S3 Inventory to deliver the inventory report to the destination account for use during job creation. The second example shows how to use a comma-separated values (CSV) manifest in the source or destination account. The third example shows how to use the **Copy** operation to enable S3 Bucket Keys for existing objects that have been encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

Using an inventory report to copy objects across AWS accounts

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. You can use S3 Batch Operations to create a **Copy** (CopyObject) job to copy objects within the same account or to a different destination account.

You can use Amazon S3 Inventory to create an inventory report and use the report to create a list (manifest) of objects to copy with S3 Batch Operations. For more information about using a CSV manifest in the source or destination account, see [the section called “Using a CSV manifest to copy objects across AWS accounts”](#).

Amazon S3 Inventory generates inventories of the objects in a bucket. The resulting list is published to an output file. The bucket that is inventoried is called the source bucket, and the bucket where the inventory report file is stored is called the destination bucket.

The Amazon S3 Inventory report can be configured to be delivered to another AWS account. Doing so allows S3 Batch Operations to read the inventory report when the job is created in the destination account.

For more information about Amazon S3 Inventory source and destination buckets, see [Source and destination buckets](#).

The easiest way to set up an inventory is by using the Amazon S3 console, but you can also use the Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

The following console procedure contains the high-level steps for setting up permissions for an S3 Batch Operations job. In this procedure, you copy objects from a source account to a destination account, with the inventory report stored in the destination account.

To set up Amazon S3 Inventory for source and destination buckets owned by different accounts

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.

3. Decide on (or create) a destination manifest bucket to store the inventory report in. In this procedure, the *destination account* is the account that owns both the destination manifest bucket and the bucket that the objects are copied to.
4. Configure an inventory report for a source bucket. For information about how to use the console to configure an inventory or how to encrypt an inventory list file, see [Configuring Amazon S3 Inventory](#).

When you configure the inventory report, you specify the destination bucket where you want the list to be stored. The inventory report for the source bucket is published to the destination bucket. In this procedure, the *source account* is the account that owns the source bucket.

Choose **CSV** for the output format.

When you enter information for the destination bucket, choose **Buckets in another account**. Then enter the name of the destination manifest bucket. Optionally, you can enter the account ID of the destination account.

After the inventory configuration is saved, the console displays a message similar to the following:

Amazon S3 could not create a bucket policy on the destination bucket. Ask the destination bucket owner to add the following bucket policy to allow Amazon S3 to place data in that bucket.

The console then displays a bucket policy that you can use for the destination bucket.

5. Copy the destination bucket policy that appears on the console.
6. In the destination account, add the copied bucket policy to the destination manifest bucket where the inventory report is stored.
7. Create a role in the destination account that is based on the S3 Batch Operations trust policy. For more information about this trust policy, see [Trust policy](#).

For more information about creating a role, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

Enter a name for the role (the following example role uses the name **BatchOperationsDestinationRoleCOPY**). Choose the **S3** service, and then choose the **S3 Batch Operations** use case, which applies the trust policy to the role.

Then choose **Create policy** to attach the following policy to the role. To use this policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowBatchOperationsDestinationObjectCOPY",  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject",

                "s3:GetObjectAcl",  
                "s3:GetObjectTagging",  
                "s3:GetObjectVersionAcl",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/*",  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*",  
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"  
            ]  
        }  
    ]  
}
```

The role uses the policy to grant batchoperations.s3.amazonaws.com permission to read the manifest in the destination bucket. It also grants permissions to GET objects, access control lists (ACLs), tags, and versions in the source object bucket. And it grants permissions to PUT objects, ACLs, tags, and versions into the destination object bucket.

8. In the source account, create a bucket policy for the source bucket that grants the role that you created in the previous step permissions to GET objects, ACLs, tags, and versions in the source

bucket. This step allows S3 Batch Operations to get objects from the source bucket through the trusted role.

The following is an example of the bucket policy for the source account. To use this policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",

        {  
            "Sid": "AllowBatchOperationsSourceObjectCOPY",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS":  
                    "arn:aws:iam::111122223333:role/BatchOperationsDestinationRoleCOPY"  
            },  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:GetObjectAcl",  
                "s3:GetObjectTagging",  
                "s3:GetObjectVersionAcl",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
        }  
    ]  
}
```

- After the inventory report is available, create an S3 Batch Operations **Copy** (CopyObject) job in the destination account, and choose the inventory report from the destination manifest bucket. You need the ARN for the IAM role that you created in the destination account.

For general information about creating a job, see [Creating an S3 Batch Operations job](#).

For information about creating a job by using the console, see [Creating an S3 Batch Operations job](#).

Using a CSV manifest to copy objects across AWS accounts

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. You can use S3 Batch Operations to create a **Copy** (CopyObject) job to copy objects within the same account or to a different destination account.

You can use a CSV manifest that's stored in the source account to copy objects across AWS accounts with S3 Batch Operations. To use an S3 Inventory report as a manifest, see [the section called "Using an inventory report to copy objects across AWS accounts"](#).

For an example of the CSV format for manifest files, see [the section called "Creating a manifest file"](#).

The following procedure shows how to set up permissions when using an S3 Batch Operations job to copy objects from a source account to a destination account with a CSV manifest file that's stored in the source account.

To use a CSV manifest to copy objects across AWS accounts

1. Create an AWS Identity and Access Management (IAM) role in the destination account that's based on the S3 Batch Operations trust policy. In this procedure, the *destination account* is the account that the objects are being copied to.

For more information about the trust policy, see [Trust policy](#).

For more information about creating a role, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

If you create the role by using the console, enter a name for the role (the following example role uses the name *BatchOperationsDestinationRoleCOPY*). Choose the **S3** service, and then choose the **S3 Batch Operations** use case, which applies the trust policy to the role.

Then choose **Create policy** to attach the following policy to the role. To use this policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [
```

```
{  
    "Sid": "AllowBatchOperationsDestinationObjectCOPY",  
    "Effect": "Allow",  
    "Action": [  
        "s3:PutObject",  
        "s3:PutObjectVersionAcl",  
        "s3:PutObjectAcl",  
        "s3:PutObjectVersionTagging",  
        "s3:PutObjectTagging",  
        "s3:GetObject",  
        "s3:GetObjectVersion",  
        "s3:GetObjectAcl",  
        "s3:GetObjectTagging",  
        "s3:GetObjectVersionAcl",  
        "s3:GetObjectVersionTagging"  
    ],  
    "Resource": [  
        "arn:aws:s3:::amzn-s3-demo-destination-bucket/*",  
        "arn:aws:s3:::amzn-s3-demo-source-bucket/*",  
        "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"  
    ]  
}  
]  
}
```

Using the policy, the role grants `batchoperations.s3.amazonaws.com` permission to read the manifest in the source manifest bucket. It grants permissions to GET objects, access control lists (ACLs), tags, and versions in the source object bucket. It also grants permissions to PUT objects, ACLs, tags, and versions into the destination object bucket.

2. In the source account, create a bucket policy for the bucket that contains the manifest to grant the role that you created in the previous step permissions to GET objects and versions in the source manifest bucket.

This step allows S3 Batch Operations to read the manifest by using the trusted role. Apply the bucket policy to the bucket that contains the manifest.

The following is an example of the bucket policy to apply to the source manifest bucket. To use this policy, replace the ***user input placeholders*** with your own information.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowBatchOperationsSourceManifestRead",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/ConsoleUserCreatingJob",  
                    "arn:aws:iam::111122223333:role/BatchOperationsDestinationRoleCOPY"  
                ]  
            },  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"  
        }  
    ]  
}
```

This policy also grants permissions to allow a console user who is creating a job in the destination account the same permissions in the source manifest bucket through the same bucket policy.

3. In the source account, create a bucket policy for the source bucket that grants the role that you created permissions to GET objects, ACLs, tags, and versions in the source object bucket. S3 Batch Operations can then get objects from the source bucket through the trusted role.

The following is an example of the bucket policy for the bucket that contains the source objects. To use this policy, replace the *user input placeholders* with your own information.

JSON

```
{  
    "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Sid": "AllowBatchOperationsSourceObjectCOPY",
        "Effect": "Allow",
        "Principal": {
            "AWS": [
                "arn:aws:iam::111122223333:role/BatchOperationsDestinationRoleCOPY"
            ],
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion",
                "s3:GetObjectAcl",
                "s3:GetObjectTagging",
                "s3:GetObjectVersionAcl",
                "s3:GetObjectVersionTagging"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
        }
    }
]
```

4. Create an S3 Batch Operations job in the destination account. You need the Amazon Resource Name (ARN) for the role that you created in the destination account. For more information about creating a job, see [Creating an S3 Batch Operations job](#).

Using Batch Operations to enable S3 Bucket Keys for SSE-KMS

S3 Bucket Keys reduce the cost of server-side encryption with AWS Key Management Service (AWS KMS) (SSE-KMS) by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#) and [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#). When you perform a CopyObject operation by using the REST API, AWS SDKs, or AWS CLI, you can enable or disable an S3 Bucket Key at the object level by adding the `x-amz-server-side-encryption-bucket-key-enabled` request header with a true or false value.

When you configure an S3 Bucket Key for an object by using a CopyObject operation, Amazon S3 updates only the settings for that object. The S3 Bucket Key settings for the destination bucket don't change. If you submit a CopyObject request for an AWS KMS encrypted object to a bucket that has S3 Bucket Keys enabled, your object level operation will automatically use S3 Bucket Keys unless you disable the keys in the request header. If you don't specify an S3 Bucket Key for your object, Amazon S3 applies the S3 Bucket Key settings for the destination bucket to the object.

To encrypt your existing Amazon S3 objects, you can use S3 Batch Operations. You can use the Batch Operations **Copy** operation to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. For more information, see [Encrypting objects with Amazon S3 Batch Operations](#) on the AWS Storage Blog.

In the following example, you use the Batch Operations **Copy** operation to enable S3 Bucket Keys on existing objects. For more information, see [the section called “Configuring an S3 Bucket Key for an object”](#).

Considerations for using S3 Batch Operations to encrypt objects with S3 Bucket Keys enabled

Consider the following issues when you use S3 Batch Operations to encrypt objects with S3 Bucket Keys enabled:

- You will be charged for S3 Batch Operations jobs, objects, and requests in addition to any charges associated with the operation that S3 Batch Operations performs on your behalf, including data transfers, requests, and other charges. For more information, see [Amazon S3 pricing](#).
- If you use a versioned bucket, each S3 Batch Operations job performed creates new encrypted versions of your objects. It also maintains the previous versions without an S3 Bucket Key configured. To delete the old versions, set up an S3 Lifecycle expiration policy for noncurrent versions as described in [Lifecycle configuration elements](#).
- The copy operation creates new objects with new creation dates, which can affect lifecycle actions like archiving. If you copy all objects in your bucket, all the new copies have identical or similar creation dates. To further identify these objects and create different lifecycle rules for various data subsets, consider using object tags.

Prerequisites

Before you configure your objects to use an S3 Bucket Key, review [Changes to note before enabling an S3 Bucket Key](#).

To use this example, you must have an AWS account and at least one S3 bucket to hold your working files and encrypted results. You might also find much of the existing S3 Batch Operations documentation useful, including the following topics:

Step 1: Get your list of objects using Amazon S3 Inventory

To get started, identify the S3 bucket that contains the objects to encrypt, and get a list of its contents. An Amazon S3 Inventory report is the most convenient and affordable way to do this. The report provides the list of the objects in a bucket along with their associated metadata. In this step, the source bucket is the inventoried bucket, and the destination bucket is the bucket where you store the inventory report file. For more information about Amazon S3 Inventory source and destination buckets, see [Cataloging and analyzing your data with S3 Inventory](#).

The easiest way to set up an inventory is by using the AWS Management Console. But you can also use the REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs. Before following these steps, be sure to sign in to the console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>. If you encounter permission denied errors, add a bucket policy to your destination bucket. For more information, see [Grant permissions for S3 Inventory and S3 analytics](#).

To get a list of objects using S3 Inventory

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**, and choose a bucket that contains objects to encrypt.
3. On the **Management** tab, navigate to the **Inventory configurations** section, and choose **Create inventory configuration**.

4. Give your new inventory a name, enter the name of the destination S3 bucket, and optionally create a destination prefix for Amazon S3 to assign objects in that bucket.
5. For **Output format**, choose **CSV**.
6. (Optional) In the **Additional fields – optional** section, choose **Encryption** and any other report fields that interest you. Set the frequency for report deliveries to **Daily** so that the first report is delivered to your bucket sooner.
7. Choose **Create** to save your configuration.

Amazon S3 can take up to 48 hours to deliver the first report, so check back when the first report arrives. After you receive your first report, proceed to the next step to filter your S3 Inventory report's contents. If you no longer want to receive inventory reports for this bucket, delete your S3 Inventory configuration. Otherwise, Amazon S3 continues to deliver reports on a daily or weekly schedule.

An inventory list isn't a single point-in-time view of all objects. Inventory lists are a rolling snapshot of bucket items, which are eventually consistent (for example, the list might not include recently added or deleted objects). Combining S3 Inventory and S3 Batch Operations works best when you work with static objects, or with an object set that you created two or more days ago. To work with more recent data, use the [ListObjectsV2 \(GET bucket\)](#) API operation to build your list of objects manually. If needed, repeat the process for the next few days or until your inventory report shows the desired status for all objects.

Step 2: Filter your object list with S3 Select

After you receive your S3 Inventory report, you can filter the report's contents to list only the objects that aren't encrypted with S3 Bucket Keys enabled. If you want all your bucket's objects encrypted with S3 Bucket Keys enabled, you can ignore this step. However, filtering your S3 Inventory report at this stage saves you the time and expense of re-encrypting objects that you previously encrypted with S3 Bucket Keys enabled.

Although the following steps show how to filter by using [Amazon S3 Select](#), you can also use [Amazon Athena](#). To decide which tool to use, look at your S3 Inventory report's `manifest.json` file. This file lists the number of data files that are associated with that report. If the number is large, use Amazon Athena because it runs across multiple S3 objects, whereas S3 Select works on one object at a time. For more information about using Amazon S3 and Athena together, see [Querying Amazon S3 Inventory with Amazon Athena](#) and "Using Athena" in the AWS Storage Blog post [Encrypting objects with Amazon S3 Batch Operations](#).

To filter your S3 Inventory report by using S3 Select

1. Open the manifest.json file from your inventory report and look at the fileSchema section of the JSON. This informs the query that you run on the data.

The following JSON is an example manifest.json file for a CSV-formatted inventory on a bucket with versioning enabled. Depending on how you configured your inventory report, your manifest might look different.

```
{  
    "sourceBucket": "batchoperationsdemo",  
    "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
    "version": "2021-05-22",  
    "creationTimestamp": "1558656000000",  
    "fileFormat": "CSV",  
    "fileSchema": "Bucket, Key, VersionId, IsLatest, IsDeleteMarker,  
    BucketKeyStatus",  
    "files": [  
        {  
            "key": "demoinv/batchoperationsdemo/DemoInventory/data/009a40e4-  
f053-4c16-8c75-6100f8892202.csv.gz",  
            "size": 72691,  
            "MD5checksum": "c24c831717a099f0ebe4a9d1c5d3935c"  
        }  
    ]  
}
```

If versioning isn't activated on the bucket, or if you choose to run the report for the latest versions, the fileSchema is Bucket, Key, and BucketKeyStatus.

If versioning *is* activated, depending on how you set up the inventory report, the fileSchema might include the following: Bucket, Key, VersionId, IsLatest, IsDeleteMarker, BucketKeyStatus. So pay attention to columns 1, 2, 3, and 6 when you run your query.

S3 Batch Operations needs the bucket, key, and version ID as inputs to perform the job, in addition to the field to search by, which is BucketKeyStatus. You don't need the VersionID field, but it helps to specify the VersionID field when you operate on a versioned bucket. For more information, see [Working with objects in a versioning-enabled bucket](#).

2. Locate the data files for the inventory report. The manifest.json object lists the data files under **files**.

3. After you locate and select the data file in the S3 console, choose **Actions**, and then choose **Query with S3 Select**.
4. Keep the preset **CSV**, **Comma**, and **GZIP** fields selected, and choose **Next**.
5. To review your inventory report's format before proceeding, choose **Show file preview**.
6. Enter the columns to reference in the SQL expression field, and choose **Run SQL**. The following expression returns columns 1–3 for all objects without an S3 Bucket Key configured.

```
select s._1, s._2, s._3 from s3object s where s._6 = 'DISABLED'
```

The following are example results.

```

```

7. Download the results, save them into a CSV format, and upload them to Amazon S3 as your list of objects for the S3 Batch Operations job.
8. If you have multiple manifest files, run **Query with S3 Select** on those also. Depending on the size of the results, you could combine the lists and run a single S3 Batch Operations job or run each list as a separate job. To decide number of jobs to run, consider the [price](#) of running each S3 Batch Operations job.

Step 3: Set up and run your S3 Batch Operations job

Now that you have your filtered CSV lists of S3 objects, you can begin the S3 Batch Operations job to encrypt the objects with S3 Bucket Keys enabled.

A *job* refers collectively to the list (manifest) of objects provided, the operation performed, and the specified parameters. The easiest way to encrypt this set of objects with S3 Bucket Keys enabled is by using the **Copy** operation and specifying the same destination prefix as the objects listed in the

manifest. In an unversioned bucket, this operation overwrites the existing objects. In a bucket with versioning turned on, this operation creates a newer, encrypted version of the objects.

As part of copying the objects, specify that Amazon S3 should encrypt the objects with SSE-KMS encryption. This job copies the objects, so all of your objects will show an updated creation date upon completion, regardless of when you originally added them to Amazon S3. Also specify the other properties for your set of objects as part of the S3 Batch Operations job, including object tags and storage class.

Substeps

- [Set up your IAM policy](#)
- [Set up your Batch Operations IAM role](#)
- [Enable S3 Bucket Keys for an existing bucket](#)
- [Create your Batch Operations job](#)
- [Run your Batch Operations job](#)

Set up your IAM policy

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policy**, and then choose **Create policy**.
3. Choose the **JSON** tab. Choose **Edit policy** and add the example IAM policy that appears in the following code block.

After copying the policy example into your [IAM Console](#), replace the following:

- a. Replace *amzn-s3-demo-source-bucket* with the name of your source bucket to copy objects from.
- b. Replace *amzn-s3-demo-destination-bucket* with the name of your destination bucket to copy objects to.
- c. Replace *amzn-s3-demo-manifest-bucket/manifest-key* with the name of your manifest object.
- d. Replace *amzn-s3-demo-completion-report-bucket* with the name of the bucket where you want to save your completion reports.

4. Choose **Next: Tags**.
5. Add any tags that you want (optional), and choose **Next: Review**.
6. Add a policy name, optionally add a description, and choose **Create policy**.
7. Choose **Review policy and Save changes**.
8. With your S3 Batch Operations policy now complete, the console returns you to the IAM **Policies** page. Filter on the policy name, choose the button to the left of the policy name, choose **Policy actions**, and choose **Attach**.

To attach the newly created policy to an IAM role, select the appropriate users, groups, or roles in your account and choose **Attach policy**. This takes you back to the IAM console.

Set up your Batch Operations IAM role

1. On the [IAM Console](#), in the navigation pane, choose **Roles**, and then choose **Create role**.
2. Choose **AWS service, S3, and S3 Batch Operations**. Then choose **Next: Permissions**.
3. Start entering the name of the IAM **policy** that you just created. Select the check box by the policy name when it appears, and choose **Next: Tags**.
4. (Optional) Add tags or keep the key and value fields blank for this exercise. Choose **Next: Review**.
5. Enter a role name, and accept the default description or add your own. Choose **Create role**.
6. Ensure that the user creating the job has the permissions in the following example.

Replace **account-id** with your AWS account ID and **IAM-role-name** with the name that you plan to apply to the IAM role that you will create in the Batch Operations job creation step later. For more information, see [Granting permissions for Batch Operations](#).

```

Enable S3 Bucket Keys for an existing bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket that you want to turn on an S3 Bucket Key for.
3. Choose **Properties**.
4. Under **Default encryption**, choose **Edit**.
5. Under **Encryption type**, you can choose between **Amazon S3 managed keys (SSE-S3)** and **AWS Key Management Service key (SSE-KMS)**.
6. If you chose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify the AWS KMS key through one of the following options.
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**. From the list of available keys, choose a symmetric encryption KMS key in the same Region as your bucket. Both the AWS managed key (aws/s3) and your customer managed keys appear in the list.
 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.
7. Under **Bucket Key**, choose **Enable**, and then choose **Save changes**.

Now that an S3 Bucket Key is enabled at the bucket level, objects that are uploaded, modified, or copied into this bucket will inherit this encryption configuration by default. This includes objects that are copied by using Amazon S3 Batch Operations.

Create your Batch Operations job

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Batch Operations**, and then choose **Create Job**.
3. Choose the **Region** where you store your objects, and choose **CSV** as the manifest type.
4. Enter the path or navigate to the CSV manifest file that you created earlier from S3 Select (or Athena) results. If your manifest contains version IDs, select that box. Choose **Next**.

5. Choose the **Copy** operation, and choose the copy destination bucket. You can keep server-side encryption disabled. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies S3 Bucket Keys at the destination bucket.
6. (Optional) Choose a storage class and the other parameters as desired. The parameters that you specify in this step apply to all operations performed on the objects that are listed in the manifest. Choose **Next**.
7. To configure server-side encryption, follow these steps:

- a. Under **Server-side encryption**, choose one of the following:

- To keep the bucket settings for default server-side encryption of objects when storing them in Amazon S3, choose **Do not specify an encryption key**. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies an S3 Bucket Key at the destination bucket.

 **Note**

If the bucket policy for the specified destination requires objects to be encrypted before storing them in Amazon S3, you must specify an encryption key. Otherwise, copying objects to the destination will fail.

- To encrypt objects before storing them in Amazon S3, choose **Specify an encryption key**.
- b. Under **Encryption settings**, if you choose **Specify an encryption key**, you must choose either **Use destination bucket settings for default encryption** or **Override destination bucket settings for default encryption**.
- c. If you choose **Override destination bucket settings for default encryption**, you must configure the following encryption settings.
 - i. Under **Encryption type**, you must choose either **Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**. SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. SSE-KMS provides you with more control over your key. For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#) and [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).
 - ii. If you choose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify your AWS KMS key through one of the following options.

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose a symmetric encryption KMS key in the same Region as your bucket. Both the AWS managed key (aws/s3) and your customer managed keys appear in the list.
 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.
- iii. Under **Bucket Key**, choose **Enable**. The copy operation applies an S3 Bucket Key at the destination bucket.
8. Give your job a description (or keep the default), set its priority level, choose a report type, and specify the **Path to completion report destination**.
9. In the **Permissions** section, be sure to choose the Batch Operations IAM role that you defined earlier. Choose **Next**.
10. Under **Review**, verify the settings. If you want to make changes, choose **Previous**. After confirming the Batch Operations settings, choose **Create job**.

For more information, see [Creating an S3 Batch Operations job](#).

Run your Batch Operations job

The setup wizard automatically returns you to the S3 Batch Operations section of the Amazon S3 console. Your new job transitions from the **New** state to the **Preparing** state as S3 begins the process. During the Preparing state, S3 reads the job's manifest, checks it for errors, and calculates the number of objects.

1. Choose the refresh button in the Amazon S3 console to check progress. Depending on the size of the manifest, reading can take minutes or hours.
2. After S3 finishes reading the job's manifest, the job moves to the **Awaiting your confirmation** state. Choose the option button to the left of the Job ID, and choose **Run job**.
3. Check the settings for the job, and choose **Run job** in the bottom-right corner.

After the job begins running, you can choose the refresh button to check progress through the console dashboard view or by selecting the specific job.

- When the job is complete, you can view the **Successful** and **Failed** object counts to confirm that everything performed as expected. If you enabled job reports, check your job report for the exact cause of any failed operations.

You can also perform these steps by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information about tracking job status and completion reports, see [Tracking job status and completion reports](#).

For examples that show the copy operation with tags using the AWS CLI and AWS SDK for Java, see [Creating a Batch Operations job with job tags used for labeling](#).

Compute checksums

You can use S3 Batch Operations with the **Compute checksum** operation to perform checksum calculations for objects stored in Amazon S3 at rest. The **Compute checksum** operation calculates object checksums which you can use to validate data integrity without downloading or restoring objects for stored data. You can use the **Compute checksum** operation to calculate checksums for both composite and full object checksum types, for all supported checksum algorithms.

With the **Compute checksum** operation, you can process billions of objects through a single job request. This batch operation is compatible with all S3 storage classes, regardless of object size. To create a **Compute checksum** job, use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

When you [enable server access logging](#), you can also receive log entries about your **Compute checksum** job. The **Compute checksum** job operation emits separate server access log events after completing the checksum computations. These log entries follow the standard [S3 server access logging format](#) and include fields such as operation type, timestamp, [error codes](#), and the associated **Compute checksum** job ID. This logging provides an audit trail of checksum verification activities performed on your objects, helping you track and verify data integrity operations.

Note

The **Compute checksum** operation doesn't support server-side encryption with customer-provided encryption keys (SSE-C) encrypted objects. However, you can use the **Compute checksum** operation with objects that are encrypted by using [server-side encryption with S3 managed keys \(SSE-S3\)](#), server-side encryption with AWS Key Management Service

(DSSE-KMS). Make sure that you've [granted the proper AWS KMS permissions](#) to perform the **Compute checksum** operation.

To get started with the **Compute checksum** operation using Batch Operations, you can either:

- Manually create a new manifest file.
- Use an existing manifest.
- Direct Batch Operations to automatically generate a manifest based on object filter criteria that you [specify when you create your job](#).

Then, submit your **Compute checksum** job request and monitor its status. After the **Compute checksum** job finishes, you automatically receive a completion report in the specified destination bucket. This completion report contains checksum information for every object in the bucket, allowing you to verify data consistency. For more information about how to use this report to examine the job, see [Tracking job status and completion reports](#).

For more information about **Compute checksum** capabilities and how to use **Compute checksum** in the console, see [Checking object integrity for data at rest in Amazon S3](#). For information about how to send REST requests to **Compute checksum**, see [DescribeJob](#) and [CreateJob](#) in the *Amazon S3 API Reference*.

The following sections explain how you can get started using the **Compute checksum** operation with S3 Batch Operations.

S3 Batch Operations Compute checksum considerations

Before using the **Compute checksum** operation, review the following list of considerations:

- If your manifest includes a version ID field, you must provide a version ID for all objects in the manifest. If the version ID isn't specified, the **Compute checksum** request performs the operation on the latest version of the object.

- To receive **Compute checksum** operation details in your [server access logs](#), you must first [enable server access logging](#) on the source bucket and specify a destination bucket to store the logs. The destination bucket must also exist in the same AWS Region and AWS account as the source bucket. After configuring server access logging, the **Compute checksum** operation generates [log records](#) that include standard fields such as operation type, HTTP status code, [S3 error codes](#), timestamps, and the associated **Compute checksum** job ID. The **Compute checksum** operation runs asynchronously. As a result, the [log entries](#) use a **Compute checksum** job ID, rather than a request ID, in its log entries.
- The report generation can take up to a few hours for stored objects.
- For the following S3 Glacier storage classes, the **Compute checksum** job can take up to a week to finish:
 - S3 Glacier Flexible Retrieval
 - S3 Glacier Deep Archive
- For buckets where the completion report will be written, you must use the [bucket owner condition](#) when running the **Compute checksum** operation. If the actual bucket owner doesn't match the expected bucket owner for the submitted job request, then the job fails. For a list of S3 operations that don't support bucket owner condition, see [Restrictions and limitations](#).

S3 Batch Operations completion report

When you create a **Compute checksum** job, you can request an S3 Batch Operations completion report. This CSV file shows the objects, success or failure codes, outputs, and descriptions. For more information about job tracking and completion reports, see [Completion reports](#).

Delete all object tags

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. The **Delete all object tags** operation removes all Amazon S3 object tag sets currently associated with the objects that are listed in the manifest. S3 Batch Operations doesn't support deleting tags from objects while keeping other tags in place.

If the objects in your manifest are in a versioned bucket, you can remove the tag sets from a specific version of an object. To do so, you must specify a version ID for every object in the manifest. If you don't include a version ID for an object, S3 Batch Operations removes the tag set from the latest version of every object. For more information about Batch Operations manifests, see [Specifying a manifest](#).

For more details about object tagging, see [Categorizing your objects using tags](#) in this guide, and [PutObjectTagging](#), [GetObjectTagging](#), and [DeleteObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.

Warning

Running this job removes all object tag sets on every object listed in the manifest.

To use the console to create a **Delete all object tags** job, see [Creating an S3 Batch Operations job](#).

Restrictions and limitations

When you're using Batch Operations to delete object tags, the following restrictions and limitations apply:

- The AWS Identity and Access Management (IAM) role that you specify to run the job must have permissions to perform the underlying Amazon S3 DeleteObjectTagging operation. For more information, see [DeleteObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.
- S3 Batch Operations uses the Amazon S3 [DeleteObjectTagging](#) operation to remove the tag sets from every object in the manifest. All restrictions and limitations that apply to the underlying operation also apply to S3 Batch Operations jobs.
- A single delete object tagging job can support a manifest with up to 20 billion objects.

Invoke AWS Lambda function

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. The **Invoke AWS Lambda function** Batch Operations operation initiates AWS Lambda functions to perform custom actions on objects that are listed in a manifest. This section describes how to create a Lambda function to use with S3 Batch Operations and how to create a job to invoke the function. The S3 Batch Operations job uses the LambdaInvoke operation to run a Lambda function on every object listed in a manifest.

You can work with S3 Batch Operations by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. For more information about using Lambda, see [Getting Started with AWS Lambda](#) in the *AWS Lambda Developer Guide*.

The following sections explain how you can get started using S3 Batch Operations with Lambda.

Using Lambda with Batch Operations

When using S3 Batch Operations with AWS Lambda, you must create new Lambda functions specifically for use with S3 Batch Operations. You can't reuse existing Amazon S3 event-based functions with S3 Batch Operations. Event functions can only receive messages; they don't return messages. The Lambda functions that are used with S3 Batch Operations must accept and return messages. For more information about using Lambda with Amazon S3 events, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

You create an S3 Batch Operations job that invokes your Lambda function. The job runs the same Lambda function on all of the objects listed in your manifest. You can control what versions of your Lambda function to use while processing the objects in your manifest. S3 Batch Operations support unqualified Amazon Resource Names (ARNs), aliases, and specific versions. For more information, see [Introduction to AWS Lambda Versioning](#) in the *AWS Lambda Developer Guide*.

If you provide the S3 Batch Operations job with a function ARN that uses an alias or the \$LATEST qualifier, and you update the version that either of those points to, S3 Batch Operations starts calling the new version of your Lambda function. This can be useful when you want to update functionality part of the way through a large job. If you don't want S3 Batch Operations to change the version that's used, provide the specific version in the FunctionARN parameter when you create your job.

A single AWS Lambda job with S3 Batch Operations can support a manifest with up to 20 billion objects.

Using Lambda and Batch Operations with directory buckets

Directory buckets are a type of Amazon S3 bucket that's designed for workloads or performance-critical applications that require consistent single-digit millisecond latency. For more information, see [Directory buckets](#).

There are special requirements for using Batch Operations to invoke Lambda functions that act on directory buckets. For example, you must structure your Lambda request using an updated JSON schema, and specify [InvocationSchemaVersion](#) 2.0 (not 1.0) when you create the job. This updated schema allows you to specify optional key-value pairs for [UserArguments](#), which you can use to modify certain parameters of existing Lambda functions. For more information, see [Automate object processing in Amazon S3 directory buckets with S3 Batch Operations and AWS Lambda](#) in the AWS Storage Blog.

Response and result codes

S3 Batch Operations invokes the Lambda function with one or more keys, each of which has a TaskID associated with it. S3 Batch Operations expects a per-key result code from Lambda functions. Any task IDs sent in the request which aren't returned with a per-key result code will be given the result code from the `treatMissingKeysAs` field. `treatMissingKeysAs` is an optional request field and defaults to `TemporaryFailure`. The following table contains the other possible result codes and values for the `treatMissingKeysAs` field.

Response code	Description
Succeeded	The task completed normally. If you requested a job completion report, the task's result string is included in the report.
TemporaryFailure	The task suffered a temporary failure and will be redriven before the job completes. The result string is ignored. If this is the final redrive, the error message is included in the final report.
PermanentFailure	The task suffered a permanent failure. If you requested a job-completion report, the task is marked as Failed and includes the error message string. Result strings from failed tasks are ignored.

Creating a Lambda function to use with S3 Batch Operations

This section provides example AWS Identity and Access Management (IAM) permissions that you must use with your Lambda function. It also contains an example Lambda function to use with S3 Batch Operations. If you have never created a Lambda function before, see [Tutorial: Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

You must create Lambda functions specifically for use with S3 Batch Operations. You can't reuse existing Amazon S3 event-based Lambda functions because Lambda functions that are used for S3 Batch Operations must accept and return special data fields.

Important

AWS Lambda functions written in Java accept either [RequestHandler](#) or [RequestStreamHandler](#) handler interfaces. However, to support S3 Batch Operations request and response format, AWS Lambda requires the RequestStreamHandler interface for custom serialization and deserialization of a request and response.

This interface allows Lambda to pass an InputStream and OutputStream to the Java handleRequest method.

Be sure to use the RequestStreamHandler interface when using Lambda functions with S3 Batch Operations. If you use a RequestHandler interface, the batch job will fail with "Invalid JSON returned in Lambda payload" in the completion report.

For more information, see [Handler interfaces](#) in the *AWS Lambda User Guide*.

Example IAM permissions

The following are examples of the IAM permissions that are necessary to use a Lambda function with S3 Batch Operations.

Example — S3 Batch Operations trust policy

The following is an example of the trust policy that you can use for the Batch Operations IAM role. This IAM role is specified when you create the job and gives Batch Operations permission to assume the IAM role.

JSON

```
{
```

```
"Version":"2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Service": "batchoperations.s3.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
]
```

Example — Lambda IAM policy

The following is an example of an IAM policy that gives S3 Batch Operations permission to invoke the Lambda function and read the input manifest.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "BatchOperationsLambdaPolicy",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion",
                "s3:PutObject",
                "lambda:InvokeFunction"
            ],
            "Resource": "*"
        }
    ]
}
```

Example request and response

This section provides request and response examples for the Lambda function.

Example Request

The following is a JSON example of a request for the Lambda function.

```
{  
    "invocationSchemaVersion": "1.0",  
    "invocationId": "YXNkbGZqYWRmaiBhc2RmdW9hZHNmZGpmaGFzbGtkaGZza2RmaAo",  
    "job": {  
        "id": "f3cc4f60-61f6-4a2b-8a21-d07600c373ce"  
    },  
    "tasks": [  
        {  
            "taskId": "dGFza2lkZ29lc2h1cmUK",  
            "s3Key": "customerImage1.jpg",  
            "s3VersionId": "1",  
            "s3BucketArn": "arn:aws:s3:us-east-1:0123456788:amzn-s3-demo-bucket1"  
        }  
    ]  
}
```

Example Response

The following is a JSON example of a response for the Lambda function.

```
{  
    "invocationSchemaVersion": "1.0",  
    "treatMissingKeysAs" : "PermanentFailure",  
    "invocationId" : "YXNkbGZqYWRmaiBhc2RmdW9hZHNmZGpmaGFzbGtkaGZza2RmaAo",  
    "results": [  
        {  
            "taskId": "dGFza2lkZ29lc2h1cmUK",  
            "resultCode": "Succeeded",  
            "resultString": "[\"Mary Major\", \"John Stiles\"]"  
        }  
    ]  
}
```

Example Lambda function for S3 Batch Operations

The following example Python Lambda removes a delete marker from a versioned object.

As the example shows, keys from S3 Batch Operations are URL encoded. To use Amazon S3 with other AWS services, it's important that you URL decode the key that is passed from S3 Batch Operations.

```
import logging
from urllib import parse
import boto3
from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
logger.setLevel("INFO")

s3 = boto3.client("s3")

def lambda_handler(event, context):
    """
    Removes a delete marker from the specified versioned object.

    :param event: The S3 batch event that contains the ID of the delete marker
                  to remove.
    :param context: Context about the event.
    :return: A result structure that Amazon S3 uses to interpret the result of the
            operation. When the result code is TemporaryFailure, S3 retries the
            operation.

Creating an S3 Batch Operations job that invokes a Lambda function

When creating an S3 Batch Operations job to invoke a Lambda function, you must provide the following:

- The ARN of your Lambda function (which might include the function alias or a specific version number)
- An IAM role with permission to invoke the function
- The action parameter `LambdaInvokeFunction`

For more information about creating an S3 Batch Operations job, see [Creating an S3 Batch Operations job](#) and [Operations supported by S3 Batch Operations](#).

The following example creates an S3 Batch Operations job that invokes a Lambda function by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3control create-job
  --account-id account-id
  --operation '{"LambdaInvoke": { "FunctionArn": "arn:aws:lambda:region:account-id:function:LambdaFunctionName" } }'
  --manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820","Fields": ["Bucket","Key"]}, "Location":{"ObjectArn":"arn:aws:s3:::amzn-s3-demo-manifest-bucket","ETag":"ManifestETag"}}'
  --report '{"Bucket": "arn:aws:s3:::amzn-s3-demo-bucket", "Format": "Report_CSV_20180820", "Enabled": true, "Prefix": "ReportPrefix", "ReportScope": "All", "Priority": 2}
  --role-arn arn:aws:iam::account-id:role/BatchOperationsRole
  --region region
  --description "Lambda Function"
```

Providing task-level information in Lambda manifests

When you use AWS Lambda functions with S3 Batch Operations, you might want additional data to accompany each task or key that's operated on. For example, you might want to have both a source object key and a new object key provided. Your Lambda function could then copy the source key to a new S3 bucket under a new name. By default, Batch Operations lets you specify only the destination bucket and a list of source keys in the input manifest to your job. The following examples describe how you can include additional data in your manifest so that you can run more complex Lambda functions.

To specify per-key parameters in your S3 Batch Operations manifest to use in your Lambda function's code, use the following URL-encoded JSON format. The key field is passed to your Lambda function as if it were an Amazon S3 object key. But it can be interpreted by the Lambda function to contain other values or multiple keys, as shown in the following examples.

Note

The maximum number of characters for the key field in the manifest is 1,024.

Example — Manifest substituting the "Amazon S3 keys" with JSON strings

The URL-encoded version must be provided to S3 Batch Operations.

```
amzn-s3-demo-bucket, {"origKey": "object1key", "newKey": "newObject1Key"}  
amzn-s3-demo-bucket, {"origKey": "object2key", "newKey": "newObject2Key"}  
amzn-s3-demo-bucket, {"origKey": "object3key", "newKey": "newObject3Key"}
```

Example — Manifest URL-encoded

This URL-encoded version must be provided to S3 Batch Operations. The non-URL-encoded version does not work.

```
amzn-s3-demo-bucket, %7B%22origKey%22%3A%20%22object1key%22%2C%20%22newKey%22%3A  
%20%22newObject1Key%22%7D  
amzn-s3-demo-bucket, %7B%22origKey%22%3A%20%22object2key%22%2C%20%22newKey%22%3A  
%20%22newObject2Key%22%7D  
amzn-s3-demo-bucket, %7B%22origKey%22%3A%20%22object3key%22%2C%20%22newKey%22%3A  
%20%22newObject3Key%22%7D
```

Example — Lambda function with manifest format writing results to the job report

This URL-encoded manifest example contains pipe-delimited object keys for the following Lambda function to parse.

```
amzn-s3-demo-bucket,object1key%7Clower  
amzn-s3-demo-bucket,object2key%7Cupper  
amzn-s3-demo-bucket,object3key%7Creverse  
amzn-s3-demo-bucket,object4key%7Cdelete
```

This Lambda function shows how to parse a pipe-delimited task that's encoded into the S3 Batch Operations manifest. The task indicates which revision operation is applied to the specified object.

```
import logging  
from urllib import parse  
import boto3  
from botocore.exceptions import ClientError  
  
logger = logging.getLogger(__name__)  
logger.setLevel("INFO")  
  
s3 = boto3.resource("s3")
```

```
def lambda_handler(event, context):
    """
    Applies the specified revision to the specified object.

    :param event: The Amazon S3 batch event that contains the ID of the object to
                  revise and the revision type to apply.
    :param context: Context about the event.
    :return: A result structure that Amazon S3 uses to interpret the result of the
            operation.
    """

    obj_key, revision = parse.unquote_plus(task["s3Key"], encoding="utf-8").split("|")

S3 Batch Operations tutorial

The following tutorial presents complete end-to-end procedures for some Batch Operations tasks with Lambda. In this tutorial, you learn how to set up Batch Operations to invoke a Lambda function for batch-transcoding of videos stored in an S3 source bucket. The Lambda function calls AWS Elemental MediaConvert to transcode the videos.

- [Tutorial: Batch-transcoding videos with S3 Batch Operations](#)

Replace all object tags

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. The **Replace all object tags** operation replaces the object tags on every object listed in the manifest. An object tag is a key-value pair of strings that you can use to store metadata about an object.

To create a **Replace all object tags** job, you provide a set of tags that you want to apply. S3 Batch Operations applies the same set of tags to every object. The tag set that you provide replaces whatever tag sets are already associated with the objects in the manifest. S3 Batch Operations doesn't support adding tags to objects while leaving the existing tags in place.

If the objects in your manifest are in a versioned bucket, you can apply the tag set to specific versions of every object. To do so, specify a version ID for every object in the manifest. If you don't include a version ID for any objects, S3 Batch Operations applies the tag set to the latest version of every object. For more information about Batch Operations manifests, see [Specifying a manifest](#).

For more information about object tagging, see [Categorizing your objects using tags](#) in this guide, and see [PutObjectTagging](#), [GetObjectTagging](#), and [DeleteObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.

To use the console to create a **Replace all object tags** job, see [Creating an S3 Batch Operations job](#).

Restrictions and limitations

When you're using Batch Operations to replace object tags, the following restrictions and limitations apply:

- The AWS Identity and Access Management (IAM) role that you specify to run the Batch Operations job must have permissions to perform the underlying PutObjectTagging

operation. For more information about the permissions required, see [PutObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.

- S3 Batch Operations uses the Amazon S3 [PutObjectTagging](#) operation to apply tags to each object in the manifest. All restrictions and limitations that apply to the underlying operation also apply to S3 Batch Operations jobs.
- A single replace all object tags job can support a manifest with up to 20 billion objects.

Replace access control list (ACL)

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. The **Replace access control list (ACL)** operation replaces the access control lists (ACLs) for every object that's listed in the manifest. By using ACLs, you can define who can access an object and what actions they can perform.

Note

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

S3 Batch Operations support custom ACLs that you define and the canned ACLs that Amazon S3 provides with a predefined set of access permissions.

If the objects in your manifest are in a versioned bucket, you can apply the ACLs to specific versions of every object. To do so, specify a version ID for every object in the manifest. If you don't include a version ID for any object, S3 Batch Operations applies the ACL to the latest version of the object.

For more information about ACLs in Amazon S3, see [Access control list \(ACL\) overview](#).

S3 Block Public Access

If you want to limit public access to all objects in a bucket, we recommend using Amazon S3 Block Public Access instead of using S3 Batch Operations to apply ACLs. Block Public Access can limit public access on a per-bucket or account-wide basis with a single, simple operation that takes

effect quickly. This behavior makes Amazon S3 Block Public Access a better choice when your goal is to control public access to all objects in a bucket or account. Use S3 Batch Operations only when you need to apply a customized ACL to every object in the manifest. For more information about S3 Block Public Access, see [Blocking public access to your Amazon S3 storage](#).

S3 Object Ownership

If the objects in the manifest are in a bucket that uses the **Bucket owner enforced** setting for Object Ownership, the **Replace access control list (ACL)** operation can only specify object ACLs that grant full control to the bucket owner. In this case, the **Replace access control list (ACL)** operation can't grant object ACL permissions to other AWS accounts or groups. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Restrictions and limitations

When you're using Batch Operations to replace ACLs, the following restrictions and limitations apply:

- The AWS Identity and Access Management (IAM) role that you specify to run the **Replace access control list (ACL)** job must have permissions to perform the underlying Amazon S3 PutObjectAcl operation. For more information about the permissions required, see [PutObjectAcl](#) in the *Amazon Simple Storage Service API Reference*.
- S3 Batch Operations uses the Amazon S3 PutObjectAcl operation to apply the specified ACL to every object in the manifest. Therefore, all restrictions and limitations that apply to the underlying PutObjectAcl operation also apply to S3 Batch Operations **Replace access control list (ACL)** jobs.
- A single replace access control list job can support a manifest with up to 20 billion objects.

Restore objects with Batch Operations

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. The **Restore** operation initiates restore requests for the archived Amazon S3 objects that are listed in your manifest. The following archived objects must be restored before they can be accessed in real time:

- Objects archived in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes
- Objects archived through the S3 Intelligent-Tiering storage class in the Archive Access or Deep Archive Access tiers

Using a **Restore** ([S3InitiateRestoreObjectOperation](#)) operation in your S3 Batch Operations job results in a `RestoreObject` request for every object that's specified in the manifest.

Important

The **Restore** job only *initiates* the request to restore objects. S3 Batch Operations reports the job as complete for each object after the request is initiated for that object. Amazon S3 doesn't update the job or otherwise notify you when the objects have been restored. However, you can use S3 Event Notifications to receive notifications when the objects are available in Amazon S3. For more information, see [Amazon S3 Event Notifications](#).

When you create a **Restore** job, the following arguments are available:

ExpirationInDays

This argument specifies how long the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive object remains available in Amazon S3. **Restore** jobs that target S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive objects require that you set `ExpirationInDays` to 1 or greater.

Important

Don't set `ExpirationInDays` when creating **Restore** operation jobs that target S3 Intelligent-Tiering Archive Access and Deep Archive Access tier objects. Objects in S3 Intelligent-Tiering archive access tiers aren't subject to restore expiration, so specifying `ExpirationInDays` results in a `RestoreObject` request failure.

GlacierJobTier

Amazon S3 can restore objects by using one of three different retrieval tiers: EXPEDITED, STANDARD, and BULK. However, the S3 Batch Operations feature supports only the STANDARD and BULK retrieval tiers. For more information about the differences between the retrieval tiers, see [Understanding archive retrieval options](#).

For more information about the pricing for each tier, see the **Requests & data retrievals** section on the [Amazon S3 pricing](#) page.

Differences when restoring from S3 Glacier and S3 Intelligent-Tiering

Restoring archived files from the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes differs from restoring files from the S3 Intelligent-Tiering storage class in the Archive Access or Deep Archive Access tiers.

- When you restore from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, a temporary *copy* of the object is created. Amazon S3 deletes this copy after the value that you specified in the `ExpirationInDays` argument has elapsed. After this temporary copy is deleted, you must submit an additional restore request to access the object.
- When restoring archived S3 Intelligent-Tiering objects, do *not* specify the `ExpirationInDays` argument. When you restore an object from the S3 Intelligent-Tiering Archive Access or Deep Archive Access tiers, the object transitions back into the S3 Intelligent-Tiering Frequent Access tier. After a minimum of 90 consecutive days of no access, the object automatically transitions into the Archive Access tier. After a minimum of 180 consecutive days of no access, the object automatically moves into the Deep Archive Access tier.
- Batch Operations jobs can operate either on S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage class objects *or* on S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tier objects. Batch Operations can't operate on both types of archived objects in the same job. To restore objects of both types, you *must* create separate Batch Operations jobs.

Overlapping restores

If your [S3InitiateRestoreObjectOperation](#) job tries to restore an object that's already in the process of being restored, S3 Batch Operations proceeds as follows.

The restore operation succeeds for the object if either of the following conditions is true:

- Compared to the restoration request already in progress, this job's `ExpirationInDays` value is the same and its `GlacierJobTier` value is faster.
- The previous restoration request has already been completed, and the object is currently available. In this case, Batch Operations updates the expiration date of the restored object to match the `ExpirationInDays` value that's specified in the in-progress restoration request.

The restore operation fails for the object if any of the following conditions are true:

- The restoration request already in progress hasn't yet been completed, and the restoration duration for this job (specified by the `ExpirationInDays` value) is different from the restoration duration that's specified in the in-progress restoration request.
- The restoration tier for this job (specified by the `GlacierJobTier` value) is the same or slower than the restoration tier that's specified in the in-progress restoration request.

Limitations

`S3InitiateRestoreObjectOperation` jobs have the following limitations:

- You must create the job in the same Region as the archived objects.
- S3 Batch Operations doesn't support the EXPEDITED retrieval tier.
- A single Batch Operations Restore job can support a manifest with up to 4 billion objects.

For more information about restoring objects, see [Restoring an archived object](#).

S3 Object Lock retention

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. You can use the **Object Lock retention** operation to apply retention dates for your objects by using either *governance* mode or *compliance* mode. These retention modes apply different levels of protection. You can apply either retention mode to any object version. Retention dates, like legal holds, prevent an object from being overwritten or deleted. Amazon S3 stores the *retain until date* specified in the object's metadata and protects the specified version of the object version until the retention period expires.

You can use S3 Batch Operations with Object Lock to manage the retention dates of many Amazon S3 objects at once. You specify the list of target objects in your manifest and submit the manifest to Batch Operations for completion. For more information, see S3 Object Lock [the section called "Retention periods"](#).

Your S3 Batch Operations job with retention dates runs until completion, until cancellation, or until a failure state is reached. We recommend using S3 Batch Operations and S3 Object Lock retention when you want to add, change, or remove the retention date for many objects with a single request.

Batch Operations verifies that Object Lock is enabled on your bucket before processing any keys in the manifest. To perform the operations and validation, Batch Operations needs the

s3:GetBucketObjectLockConfiguration and s3:PutObjectRetention permissions in an AWS Identity and Access Management (IAM) role to allow Batch Operations to call Object Lock on your behalf. For more information, see [the section called "Object Lock considerations"](#).

For information about using this operation with the REST API, see S3PutObjectRetention in the [CreateJob](#) operation in the *Amazon Simple Storage Service API Reference*.

For an AWS Command Line Interface (AWS CLI) example of using this operation, see [the section called "Use Batch Operations with Object Lock retention"](#). For an AWS SDK for Java example, see [the section called "Use Batch Operations with Object Lock retention"](#).

Restrictions and limitations

When you're using Batch Operations to apply Object Lock retention periods, the following restrictions and limitations apply:

- S3 Batch Operations doesn't make any bucket-level changes.
- Versioning and S3 Object Lock must be configured on the bucket where the job is performed.
- All objects listed in the manifest must be in the same bucket.
- The operation works on the latest version of the object unless a version is explicitly specified in the manifest.
- You need s3:PutObjectRetention permission in your IAM role to use an **Object Lock retention** job.
- The s3:GetBucketObjectLockConfiguration IAM permission is required to confirm that Object Lock is enabled for the S3 bucket that you're performing the job on.
- You can only extend the retention period of objects with COMPLIANCE mode retention dates applied, and this retention period can't be shortened.
- A single S3 Object Lock retention job can support a manifest with up to 20 billion objects.

S3 Object Lock legal hold

You can use Amazon S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. You can use the **Object Lock legal hold** operation to place a legal hold on an object version. Like setting a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal hold doesn't have an associated retention period and remains in effect until it's removed.

You can use S3 Batch Operations with Object Lock to add legal holds to many Amazon S3 objects at once. To do so, specify a list of the target objects in your manifest and submit that list to Batch Operations. Your S3 Batch Operations **Object Lock legal hold** job runs until completion, until cancellation, or until a failure state is reached.

S3 Batch Operations verifies that Object Lock is enabled on your S3 bucket before processing any objects in the manifest. To perform the object operations and bucket-level validation, S3 Batch Operations needs the `s3:PutObjectLegalHold` and `s3:GetBucketObjectLockConfiguration` in an AWS Identity and Access Management (IAM) role. These permissions allow S3 Batch Operations to call S3 Object Lock on your behalf.

When you create an S3 Batch Operations job to remove a legal hold, you only need to specify `Off` as the legal hold status. For more information, see [the section called “Object Lock considerations”](#).

For information about how to use this operation with the Amazon S3 REST API, see `S3PutObjectLegalHold` in the [CreateJob](#) operation in the *Amazon Simple Storage Service API Reference*.

For an example of using this operation, see [Using the AWS SDK for Java](#).

Restrictions and limitations

When you're using Batch Operations to apply or remove an Object Lock legal hold, the following restrictions and limitations apply:

- S3 Batch Operations doesn't make any bucket-level changes.
- All objects listed in the manifest must be in the same bucket.
- Versioning and S3 Object Lock must be configured on the bucket where the job is performed.
- The **Object Lock legal hold** operation works on the latest version of the object unless a version is explicitly specified in the manifest.
- The `s3:PutObjectLegalHold` permission is required in your IAM role to add or remove a legal hold from objects.
- The `s3:GetBucketObjectLockConfiguration` IAM permission is required to confirm that S3 Object Lock is enabled for the S3 bucket where the job is performed.
- A single S3 Object Lock legal hold job can support a manifest with up to 20 billion objects.

Managing S3 Batch Operations jobs

Amazon S3 provides a robust set of tools to help you manage your S3 Batch Operations jobs after you create them. This section describes the operations that you can use to manage and track your jobs by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

Topics

- [Using the Amazon S3 console to manage your S3 Batch Operations jobs](#)
- [Listing jobs](#)
- [Viewing job details](#)
- [Assigning job priority](#)

Using the Amazon S3 console to manage your S3 Batch Operations jobs

Using the console, you can manage your S3 Batch Operations jobs. For example, you can:

- View active and queued jobs
- Check the status of a job
- Change a job's priority
- Confirm and run a job
- Clone a job
- Cancel a job

To manage Batch Operations using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose the job that you want to manage.

Listing jobs

You can retrieve a list of your S3 Batch Operations jobs. The list provides information about jobs that haven't yet finished, and jobs that finished within the last 90 days. For each job, the list includes details such as job ID, description, priority, current status, and the number of tasks that have succeeded and failed.

You can filter your job list by status. If you retrieve the list by using the console, you can also search your jobs by description or ID and filter them by AWS Region.

Get a list of Active and Complete jobs

The following AWS CLI example gets a list of Active and Complete jobs. To use this example, replace the *user input placeholders* with your own information.

```
aws s3control list-jobs \
  --region us-west-2 \
  --account-id account-id \
  --job-statuses '["Active", "Complete"]' \
  --max-results 20
```

For more information and examples, see [list-jobs](#) in the *AWS CLI Command Reference*.

Viewing job details

If you want more information about an Amazon S3 Batch Operations job than you can retrieve by listing jobs, you can view all the details for a single job. You can view details for jobs that haven't yet finished, or jobs that finished within the last 90 days. In addition to the information returned in a job list, a single job's details include information such as:

- The operation parameters.
- Details about the manifest.

- Information about the completion report, if you configured one when you created the job.
- The Amazon Resource Name (ARN) of the AWS Identity and Access Management (IAM) role that you assigned to run the job.

By viewing an individual job's details, you can access a job's entire configuration. To view a job's details, you can use the Amazon S3 console or the AWS Command Line Interface (AWS CLI).

Get an S3 Batch Operations job description in the Amazon S3 console

To view a Batch Operations job description by using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose the job ID of the specific job to view its details.

Get an S3 Batch Operations job description in the AWS CLI

The following example gets the description of an S3 Batch Operations job by using the AWS CLI. To use the following example command, replace the *user input placeholders* with your own information.

```
aws s3control describe-job \
--region us-west-2 \
--account-id account-id \
--job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c
```

For more information and examples, see [describe-job](#) in the *AWS CLI Command Reference*.

Assigning job priority

You can assign each Amazon S3 Batch Operations job a numeric priority, which can be any positive integer. S3 Batch Operations prioritizes jobs according to the assigned priority. Jobs with a higher priority (or a higher numeric value for the priority parameter) are evaluated first. Priority is determined in descending order. For example, a job queue with a priority value of 10 is given scheduling preference over a job queue with a priority value of 1.

You can change a job's priority while the job is running. If you submit a new job with a higher priority while a job is running, the lower-priority job can pause to allow the higher-priority job to run.

Changing a job's priority doesn't affect the job's processing speed.

Note

S3 Batch Operations honors job priorities on a best-effort basis. Although jobs with higher priorities generally take precedence over jobs with lower priorities, Amazon S3 doesn't guarantee strict ordering of jobs.

Using the S3 console

How to update job priority in the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Select the specific job that you would like to manage.
4. Choose **Action**. In the dropdown list, choose **Update priority**.

Using the AWS CLI

The following example updates the job priority by using the AWS CLI. A higher number indicates a higher execution priority. To use the following example command, replace the *user input placeholders* with your own information.

```
aws s3control update-job-priority \
--region us-west-2 \
--account-id account-id \
--priority 98 \
--job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c
```

Using the AWS SDK for Java

To update the priority of an S3 Batch Operations job using the AWS SDK for Java, you can use the S3Control client to modify the job's execution priority, which determines the order in which jobs are processed relative to other jobs in the queue.

For more information about job priority, see [Assigning job priority](#).

For examples of how to update job priority with the AWS SDK for Java, see [Update the priority of a batch job](#) in the *Amazon S3 API Reference*.

Tracking job status and completion reports

With S3 Batch Operations, you can view and update job status, add notifications and logging, track job failures, and generate completion reports.

Job statuses

After you create and run a job, it progresses through a series of statuses. The following table describes the statuses and possible transitions between them.

Status	Description	Transitions
New	A job begins in the New state when you create it.	A job automatically moves to the Preparing state when Amazon S3 begins processing the manifest object.

Status	Description	Transitions
Preparing	<p>Amazon S3 is processing the manifest object and other job parameters to set up and run the job.</p>	<p>A job automatically moves to the Ready state after Amazon S3 finishes processing the manifest and other parameters. The job is then ready to begin running the specified operation on the objects listed in the manifest.</p> <p>If the job requires confirmation before running, such as when you create a job using the Amazon S3 console, then the job transitions from Preparing to Suspended. It remains in the Suspended state until you confirm that you want to run it.</p>
Suspended	<p>The job requires confirmation, but you haven't yet confirmed that you want to run it. Only jobs that you create using the Amazon S3 console require confirmation. A job that's created using the console enters the Suspended state immediately after Preparing. After you confirm that you want to run the job and the job becomes Ready, it never returns to the Suspended state.</p>	<p>After you confirm that you want to run the job, its status changes to Ready.</p>

Status	Description	Transitions
Ready	Amazon S3 is ready to begin running the requested object operations.	A job automatically moves to Active when Amazon S3 begins to run it. The amount of time that a job remains in the Ready state depends on whether you have higher-priority jobs running already and how long those jobs take to complete.
Active	Amazon S3 is performing the requested operation on the objects listed in the manifest. While a job is Active, you can monitor its progress using the Amazon S3 console or the <code>DescribeJob</code> operation through the REST API, AWS CLI, or AWS SDKs.	A job moves out of the Active state when the job is no longer running operations on objects. This behavior can happen automatically, such as when a job completes successfully or fails. Or this behavior can occur as a result of user actions, such as canceling a job. The state that the job moves to depends on the reason for the transition.
Pausing	The job is transitioning to Paused from another state.	A job automatically moves to Paused when the Pausing stage is finished.
Paused	A job can become Paused if you submit another job with a higher priority while the current job is running.	A Paused job automatically returns to Active after any higher-priority jobs that are blocking the job's execution complete, fail, or are suspended.

Status	Description	Transitions
Completing	The job is transitioning to Complete from another state.	A job automatically moves to Complete when the Completing stage is finished.
Complete	The job has finished performing the requested operation on all objects in the manifest. The operation might have succeeded or failed for every object. If you configured the job to generate a completion report, the report is available as soon as the job is Complete.	Complete is a terminal state. Once a job reaches Complete, it doesn't transition to any other state.
Cancelling	The job is transitioning to the Cancelled state.	A job automatically moves to Cancelled when the Cancelling stage is finished.
Cancelled	You requested that the job be canceled, and S3 Batch Operations has successfully canceled the job. The job won't submit any new requests to Amazon S3.	Cancelled is a terminal state. After a job reaches Cancelled, the job won't transition to any other state.
Failing	The job is transitioning to the Failed state.	A job automatically moves to Failed once the Failing stage is finished.

Status	Description	Transitions
Failed	The job has failed and is no longer running. For more information about job failures, see Tracking job failures .	Failed is a terminal state. After a job reaches Failed, it won't transition to any other state.

Updating job status

The following AWS CLI and AWS SDK for Java examples update the status of a Batch Operations job. For more information about using the Amazon S3 console to manage Batch Operations jobs, see [Using the Amazon S3 console to manage your S3 Batch Operations jobs](#).

Using the AWS CLI

To use the following example commands, replace the *user input placeholders* with your own information.

- If you didn't specify the `--no-confirmation-required` parameter in your `create-job` command, the job remains in a suspended state until you confirm the job by setting its status to Ready. Amazon S3 then makes the job eligible for execution.

```
aws s3control update-job-status \
  --region us-west-2 \
  --account-id 123456789012 \
  --job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c \
  --requested-job-status 'Ready'
```

- Cancel the job by setting the job status to Cancelled.

```
aws s3control update-job-status \
  --region us-west-2 \
  --account-id 123456789012 \
  --job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c \
  --status-update-reason "No longer needed" \
  --requested-job-status Cancelled
```

Using the AWS SDK for Java

For examples of how to update job status with the AWS SDK for Java, see [Update the status of a batch job](#) in the *Amazon S3 API Reference*.

Notifications and logging

In addition to requesting completion reports, you can also capture, review, and audit Batch Operations activity by using AWS CloudTrail. Because Batch Operations uses existing Amazon S3 API operations to perform tasks, those tasks also emit the same events that they would if you called them directly. Therefore, you can track and record the progress of your job and all of its tasks by using the same notification, logging, and auditing tools and processes that you already use with Amazon S3. For more information, see the examples in the following sections.

Note

Batch Operations generates both management and data events in CloudTrail during job execution. The volume of these events scale with the number of keys in each job's manifest. For more information, see the [CloudTrail pricing](#) page, which includes examples of how pricing changes depending on the number of trails that you have configured in your account. To learn how to configure and log events to fit your needs, see [Create your first trail](#) in the *AWS CloudTrail User Guide*.

For more information about Amazon S3 events, see [Amazon S3 Event Notifications](#).

Tracking job failures

If an S3 Batch Operations job encounters a problem that prevents it from running successfully, such as not being able to read the specified manifest, the job fails. When a job fails, it generates one or more failure codes or failure reasons. S3 Batch Operations stores the failure codes and reasons with the job so that you can view them by requesting the job's details. If you requested a completion report for the job, the failure codes and reasons also appear there.

To prevent jobs from running a large number of unsuccessful operations, Amazon S3 imposes a task-failure threshold on every Batch Operations job. When a job has run at least 1,000 tasks, Amazon S3 monitors the task-failure rate. At any point, if the failure rate (the number of tasks that have failed as a proportion of the total number of tasks that have run) exceeds 50 percent, the job

fails. If your job fails because it exceeded the task-failure threshold, you can identify the cause of the failures. For example, you might have accidentally included some objects in the manifest that don't exist in the specified bucket. After fixing the errors, you can resubmit the job.

Note

S3 Batch Operations operates asynchronously and the tasks don't necessarily run in the order that the objects are listed in the manifest. Therefore, you can't use the manifest ordering to determine which objects' tasks succeeded and which ones failed. Instead, you can examine the job's completion report (if you requested one) or view your AWS CloudTrail event logs to help determine the source of the failures.

Completion reports

When you create a job, you can request a completion report. As long as S3 Batch Operations successfully invokes at least one task, Amazon S3 generates a completion report after the job finishes running tasks, fails, or is canceled. You can configure the completion report to include all tasks or only failed tasks.

The completion report includes the job configuration, status, and information for each task, including the object key and version, status, error codes, and descriptions of any errors. Completion reports provide an easy way to view the results of your tasks in a consolidated format with no additional setup required. Completion reports are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). For an example of a completion report, see [Examples: S3 Batch Operations completion reports](#).

If you don't configure a completion report, you can still monitor and audit your job and its tasks by using CloudTrail and Amazon CloudWatch. For more information, see the following topics:

Topics

- [Examples: Tracking an S3 Batch Operations job in Amazon EventBridge through AWS CloudTrail](#)
- [Examples: S3 Batch Operations completion reports](#)

Examples: Tracking an S3 Batch Operations job in Amazon EventBridge through AWS CloudTrail

Amazon S3 Batch Operations job activity is recorded as events in AWS CloudTrail. You can create a custom rule in Amazon EventBridge and send these events to the target notification resource of your choice, such as Amazon Simple Notification Service (Amazon SNS).

 Note

Amazon EventBridge is the preferred way to manage your events. Amazon CloudWatch Events and EventBridge are the same underlying service and API, but EventBridge provides more features. Changes that you make in either CloudWatch or EventBridge appear in each console. For more information, see the [Amazon EventBridge User Guide](#).

Tracking Examples

- S3 Batch Operations events recorded in CloudTrail
 - EventBridge rule for tracking S3 Batch Operations job events

S3 Batch Operations events recorded in CloudTrail

When a Batch Operations job is created, it is recorded as a JobCreated event in CloudTrail. As the job runs, it changes state during processing, and other JobStatusChanged events are recorded in CloudTrail. You can view these events on the [CloudTrail console](#). For more information about CloudTrail, see the [AWS CloudTrail User Guide](#).

Note

Only S3 Batch Operations job status-change events are recorded in CloudTrail.

Example — S3 Batch Operations job completion event recorded by CloudTrail

```
{  
    "eventVersion": "1.05",  
    "userIdentity": {  
        "accountId": "123456789012",

EventBridge rule for tracking S3 Batch Operations job events

The following example shows how to create a rule in Amazon EventBridge to capture S3 Batch Operations events recorded by AWS CloudTrail to a target of your choice.

To do this, you create a rule by following all the steps in [Creating EventBridge rules that react to events](#). You paste the following S3 Batch Operations custom event pattern policy where applicable, and choose the target service of your choice.

S3 Batch Operations custom event pattern policy

```
{
    "source": [
        "aws.s3"
    ],
    "detail-type": [
        "AWS Service Event via CloudTrail"
    ],
}
```

```
"detail": {  
    "eventSource": [  
        "s3.amazonaws.com"  
    ],  
    "eventName": [  
        "JobCreated",  
        "JobStatusChanged"  
    ]  
}  
}
```

The following examples are two Batch Operations events that were sent to Amazon Simple Queue Service (Amazon SQS) from an EventBridge event rule. A Batch Operations job goes through many different states while processing (New, Preparing, Active, etc.), so you can expect to receive several messages for each job.

Example — JobCreated sample event

Examples: S3 Batch Operations completion reports

When you create an S3 Batch Operations job, you can request a completion report for all tasks or just for failed tasks. As long as at least one task has been invoked successfully, S3 Batch Operations generates a report for jobs that have completed, failed, or been canceled.

The completion report contains additional information for each task, including the object key name and version, status, error codes, and descriptions of any errors. The description of errors for each failed task can be used to diagnose issues that occur during job creation, such as permissions. For **Compute checksum** jobs, the completion report contains checksum values for every object.

 **Note**

Completion reports are always encrypted with Amazon S3 managed keys (SSE-S3).

Example — Top-level manifest result file

The top-level `manifest.json` file contains the locations of each succeeded report and (if the job had any failures) the location of failed reports, as shown in the following example.

```
{
    "Format": "Report_CSV_20180820",
    "ReportCreationDate": "2019-04-05T17:48:39.725Z",
    "Results": [
        {
            "TaskExecutionStatus": "succeeded",

    }
],
"ReportSchema": "Bucket, Key, VersionId, TaskStatus, ErrorCode, HTTPStatusCode,
ResultMessage"
}
```

Succeeded task reports

Succeeded tasks reports contain the following for the *successful* tasks:

- Bucket
- Key
- VersionId
- TaskStatus
- ErrorCode
- HTTPStatusCode
- ResultMessage

Failed task reports

Failed task reports contain the following information for all *failed* tasks:

- Bucket
- Key
- VersionId
- TaskStatus
- ErrorCode
- HTTPStatusCode
- ResultMessage

Example — Lambda function task report

In the following example, the Lambda function successfully copied the Amazon S3 object to another bucket. The returned Amazon S3 response is passed back to S3 Batch Operations and is then written into the final completion report.

Example — Compute checksum task report

In the following example, the **Compute checksum** operation successfully calculated the checksum for the uploaded object while at rest. The returned Amazon S3 response is passed back to S3 Batch Operations, and is then written into the final completion report:

```

Controlling access and labeling jobs using tags

You can label and control access to your S3 Batch Operations jobs by adding *tags*. Tags can be used to identify who is responsible for a Batch Operations job. The presence of job tags can grant or limit a user's ability to cancel a job, activate a job in the confirmation state, or change a job's priority level. You can create jobs with tags attached to them, and you can add tags to jobs after they're created. Each tag is a key-value pair that can be included when you create the job or updated later.

 **Warning**

Make sure that your job tags don't contain any confidential information or personal data.

Consider the following tagging example: Suppose that you want your Finance department to create a Batch Operations job. You could write an AWS Identity and Access Management (IAM) policy that allows a user to invoke CreateJob, provided that the job is created with the Department tag assigned the value Finance. Furthermore, you could attach that policy to all users who are members of the Finance department.

Continuing with this example, you could write a policy that allows a user to update the priority of any job that has the desired tags, or cancel any job that has those tags. For more information, see [the section called "Controlling permissions"](#).

You can add tags to new S3 Batch Operations jobs when you create them, or you can add them to existing jobs.

Note the following tag restrictions:

- You can associate up to 50 tags with a job as long as they have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length.
- The key and values are case sensitive.

For more information about tag restrictions, see [User-Defined Tag Restrictions in the AWS Billing and Cost Management User Guide](#).

API operations related to S3 Batch Operations job tagging

Amazon S3 supports the following API operations that are specific to S3 Batch Operations job tagging:

- [GetJobTagging](#) – Returns the tag set associated with a Batch Operations job.
- [PutJobTagging](#) – Replaces the tag set associated with a job. There are two distinct scenarios for S3 Batch Operations job tag management using this API action:
 - Job has no tags – You can add a set of tags to a job (the job has no prior tags).
 - Job has a set of existing tags – To modify the existing tag set, you can either replace the existing tag set entirely, or make changes within the existing tag set by retrieving the existing tag set using [GetJobTagging](#), modify that tag set, and use this API action to replace the tag set with the one you have modified.

Note

If you send this request with an empty tag set, S3 Batch Operations deletes the existing tag set on the object. If you use this method, you are charged for a Tier 1 Request (PUT). For more information, see [Amazon S3 pricing](#).

To delete existing tags for your Batch Operations job, the `DeleteJobTagging` action is preferred because it achieves the same result without incurring charges.

- [DeleteJobTagging](#) – Deletes the tag set associated with a Batch Operations job.

Creating a Batch Operations job with job tags used for labeling

You can label and control access to your Amazon S3 Batch Operations jobs by adding *tags*. Tags can be used to identify who is responsible for a Batch Operations job. You can create jobs with tags attached to them, and you can add tags to jobs after they are created. For more information, see [the section called “Using tags”](#).

Using the AWS CLI

The following AWS CLI example creates an S3 Batch Operations `S3PutObjectCopy` job using job tags as labels for the job.

1. Select the action or OPERATION that you want the Batch Operations job to perform, and choose your TargetResource.

```
read -d '' OPERATION <<EOF
{
  "S3PutObjectCopy": {
    "TargetResource": "arn:aws:s3:::amzn-s3-demo-destination-bucket"
  }
}
EOF
```

2. Identify the job TAGS that you want for the job. In this case, you apply two tags, department and FiscalYear, with the values Marketing and 2020 respectively.

```
read -d '' TAGS <<EOF
[
  {
    "Key": "department",
    "Value": "Marketing"
  },
  {
    "Key": "FiscalYear",
    "Value": "2020"
  }
]
EOF
```

3. Specify the MANIFEST for the Batch Operations job.

```
read -d '' MANIFEST <<EOF
{
  "Spec": {
    "Format": "EXAMPLE_S3BatchOperations_CSV_20180820",
    "Fields": [
      "Bucket",
      "Key"
    ]
  },
  "Location": {
    "ObjectArn": "arn:aws:s3:::amzn-s3-demo-manifest-bucket/example_manifest.csv",
    "ETag": "example-5dc7a8bfb90808fc5d546218"
  }
}
EOF
```

4. Configure the REPORT for the Batch Operations job.

```
read -d '' REPORT <<EOF
{
    "Bucket": "arn:aws:s3:::amzn-s3-demo-completion-report-bucket",
    "Format": "Example_Report_CSV_20180820",
    "Enabled": true,
    "Prefix": "reports/copy-with-replace-metadata",
    "ReportScope": "AllTasks"
}
EOF
```

5. Run the `create-job` action to create your Batch Operations job with inputs set in the preceding steps.

```
aws \
    s3control create-job \
    --account-id 123456789012 \
    --manifest "${MANIFEST//$/\n}" \
    --operation "${OPERATION//$/\n/}" \
    --report "${REPORT//$/\n}" \
    --priority 10 \
    --role-arn arn:aws:iam::123456789012:role/batch-operations-role \
    --tags "${TAGS//$/\n/}" \
    --client-request-token "$(uuidgen)" \
    --region us-west-2 \
    --description "Copy with Replace Metadata";
```

Using the AWS SDK for Java

To create an S3 Batch Operations job with tags using the AWS SDK for Java, you can use the `S3Control` client to configure job parameters including manifest location, job operations, reporting settings, and tags for organization and tracking purposes.

For examples of how to create S3 Batch Operations jobs with tags using the AWS SDK for Java, see [Create a batch job to copy objects](#) in the *Amazon S3 API Reference*.

Deleting the tags from an S3 Batch Operations job

You can use these examples to delete the tags from an Amazon S3 Batch Operations job.

Using the AWS CLI

The following example deletes the tags from a Batch Operations job using the AWS CLI.

```
aws \
  s3control delete-job-tagging \
  --account-id 123456789012 \
  --job-id Example-e25a-4ed2-8bee-7f8ed7fc2f1c \
  --region us-east-1
```

Delete the job tags of a Batch Operations job

To delete the tags of an S3 Batch Operations job using the AWS SDK for Java, you can use the S3Control client with the job ID to remove all tags associated with the batch operations job.

For examples of how to delete job tags with the AWS SDK for Java, see [Delete tags from a batch job](#) in the *Amazon S3 API Reference*.

Adding job tags to an existing Batch Operations job

You can use the [PutJobTagging](#) API operation to add job tags to your existing Amazon S3 Batch Operations jobs. For more information, see the following examples.

Using the AWS CLI

The following is an example of using `s3control put-job-tagging` to add job tags to your S3 Batch Operations job by using the AWS CLI. To use the examples, replace the *user input placeholders* with your own information.

Note

If you send this request with an empty tag set, Batch Operations deletes the existing tag set on the object. However, if you use this approach, you are charged for a Tier 1 Request (PUT). For more information, see [Amazon S3 pricing](#).

Instead, to delete existing tags for your Batch Operations job, we recommend using the `DeleteJobTagging` operation because it achieves the same result without incurring charges.

1. Identify the job TAGS that you want for the job. In this case, you apply two tags, *department* and *FiscalYear*, with the values *Marketing* and *2020* respectively.

```
read -d '' TAGS <<EOF
[
  {
    "Key": "department",
    "Value": "Marketing"
  },
  {
    "Key": "FiscalYear",
    "Value": "2020"
  }
]
EOF
```

- Run the following put-job-tagging command with the required parameters:

```
aws \
  s3control put-job-tagging \
  --account-id 123456789012 \

Using the AWS SDK for Java

To put tags on an S3 Batch Operations job using the AWS SDK for Java, you can use the `S3Control` client to add or update tags with key-value pairs for organization and tracking purposes.

For examples of how to put job tags with the AWS SDK for Java, see [Add tags to a batch job](#) in the *Amazon S3 API Reference*.

Getting the tags of a S3 Batch Operations job

To retrieve the tags of an Amazon S3 Batch Operations job, you can use the `GetJobTagging` API operation. For more information, see the following examples.

Using the AWS CLI

The following example gets the tags of a Batch Operations job using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws \
```

```
s3control get-job-tagging \
--account-id 123456789012 \
--job-id Example-e25a-4ed2-8bee-7f8ed7fc2f1c \
--region us-east-1
```

Using the AWS SDK for Java

To get the tags of an S3 Batch Operations job using the AWS SDK for Java, you can use the `S3Control` client with the job ID to retrieve all tags associated with the batch operations job and return them as a list.

For examples of how to get job tags with the AWS SDK for Java, see [Get tags from a batch job](#) in the *Amazon S3 API Reference*.

Controlling permissions for Batch Operations using job tags

To help you manage your Amazon S3 Batch Operations jobs, you can add *job tags*. With job tags, you can control access to your Batch Operations jobs and enforce that tags be applied when any job is created.

You can apply up to 50 job tags to each Batch Operations job. By using tags, you can set granular policies to restrict the set of users that can edit the job. Job tags can grant or limit a user's ability to cancel a job, activate a job in the confirmation state, or change a job's priority level. In addition, you can enforce that tags be applied to all new jobs, and specify the allowed key-value pairs for the tags. You can express all of these conditions by using [AWS Identity and Access Management \(IAM\) policy language](#). For more information, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

The following example shows how you can use S3 Batch Operations job tags to grant users permission to create and edit only the jobs that are run within a specific department (for example, the Finance or Compliance department). You can also assign jobs based on the stage of development that they are related to, such as QA or Production.

In this example, you use S3 Batch Operations job tags in IAM policies to grant users permission to create and edit only the jobs that are being run within their department. You assign jobs based on the stage of development that they are related to, such as QA or Production.

The following examples use the following departments, with each department using Batch Operations in different ways:

- Finance
- Compliance
- Business Intelligence
- Engineering

Controlling access by assigning tags to users and resources

In this scenario, the administrators are using [attribute-based access control \(ABAC\)](#). ABAC is an IAM authorization strategy that defines permissions by attaching tags to both users and AWS resources.

Users and jobs are assigned one of the following department tags:

Key : Value

- department : Finance
- department : Compliance
- department : BusinessIntelligence
- department : Engineering

 **Note**

Job tag keys and values are case sensitive.

Using the ABAC access control strategy, you grant a user in the Finance department permission to create and manage S3 Batch Operations jobs within their department by associating the tag department=Finance with their user.

Furthermore, you can attach a managed policy to the IAM user that allows any user in their company to create or modify S3 Batch Operations jobs within their respective departments.

The policy in this example includes three policy statements:

- The first statement in the policy allows the user to create a Batch Operations job provided that the job creation request includes a job tag that matches their respective department. This is expressed using the "\${aws:PrincipalTag/department}" syntax, which is replaced by the user's department tag at policy evaluation time. The condition is satisfied when the value provided for the department tag in the request ("aws:RequestTag/department") matches the user's department.
- The second statement in the policy allows users to change the priority of jobs or update a job's status provided that the job the user is updating matches the user's department.
- The third statement allows a user to update a Batch Operations job's tags at any time via a PutJobTagging request as long as (1) their department tag is preserved and (2) the job they're updating is within their department.

Tagging Batch Operations jobs by stage and enforcing limits on job priority

All S3 Batch Operations jobs have a numeric priority, which Amazon S3 uses to decide in what order to run the jobs. For this example, you restrict the maximum priority that most users can assign to jobs, with higher priority ranges reserved for a limited set of privileged users, as follows:

- QA stage priority range (low): 1-100
- Production stage priority range (high): 1-300

To do this, introduce a new tag set representing the stage of the job:

Key : Value

- stage : QA
- stage : Production

Creating and updating low-priority jobs within a department

This policy introduces two new restrictions on S3 Batch Operations job creation and update, in addition to the department-based restriction:

- It allows users to create or update jobs in their department with a new condition that requires the job to include the tag stage=QA.
- It allows users to create or update a job's priority up to a new maximum priority of 100.

Creating and updating high-priority jobs within a department

A small number of users might require the ability to create high priority jobs in either QA or Production. To support this need, you create a managed policy that's adapted from the low-priority policy in the previous section.

This policy does the following:

- Allows users to create or update jobs in their department with either the tag `stage=QA` or `stage=Production`.
- Allows users to create or update a job's priority up to a maximum of 300.

Managing S3 Object Lock using S3 Batch Operations

You can use S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. S3 Batch Operations can perform a single operation on lists of Amazon S3 objects that you specify. A single job can perform a specified operation on billions of objects containing exabytes of data. Amazon S3 tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, and serverless experience. You can use S3 Batch Operations through the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

With S3 Object Lock, you can place a legal hold on an object version. Like setting a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal hold doesn't have an associated retention period and remains in effect until the legal hold is removed. For more information, see [S3 Object Lock legal hold](#).

To use S3 Batch Operations with Object Lock to add legal holds to many Amazon S3 objects at once, see the following topics.

Topics

- [Enabling S3 Object Lock using S3 Batch Operations](#)
- [Setting Object Lock retention using Batch Operations](#)

Enabling S3 Object Lock using S3 Batch Operations

You can use Amazon S3 Batch Operations with S3 Object Lock to manage retention or enable a legal hold for many Amazon S3 objects at once. You specify the list of target objects in your manifest and submit it to Batch Operations for completion. For more information, see [the section called “Object Lock retention”](#) and [the section called “Object Lock legal hold”](#).

The following examples show how to create an AWS Identity and Access Management (IAM) role with S3 Batch Operations permissions and update the role permissions to create jobs that enable Object Lock. You must also have a CSV manifest that identifies the objects for your S3 Batch Operations job. For more information, see [the section called “Specifying a manifest”](#).

To use the following examples, replace the *user input placeholders* with your own information.

Using the AWS CLI

1. Create an IAM role and assign S3 Batch Operations permissions to run.

This step is required for all S3 Batch Operations jobs.

```
export AWS_PROFILE='aws-user'

read -d '' batch_operations_trust_policy <<EOF
{
    "Version": "2012-10-17" ,           TCX5-2025-waiver;,
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "batchoperations.s3.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
EOF
aws iam create-role --role-name batch_operations-objectlock \
--assume-role-policy-document "${batch_operations_trust_policy}"
```

2. Set up S3 Batch Operations with S3 Object Lock to run.

In this step, you allow the role to do the following:

- Run Object Lock on the S3 bucket that contains the target objects that you want Batch Operations to run on.
- Read the S3 bucket where the manifest CSV file and the objects are located.
- Write the results of the S3 Batch Operations job to the reporting bucket.

```
read -d '' batch_operations_permissions <<EOF
{
    "Version": "2012-10-17" ,           TCX5-2025-waiver;,
    "Statement": [
        {
```

```
        "Effect": "Allow",
        "Action": "s3:GetBucketObjectLockConfiguration",
        "Resource": [
            "arn:aws:s3:::{amzn-s3-demo-manifest-bucket}"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:GetBucketLocation"
        ],
        "Resource": [
            "arn:aws:s3:::{amzn-s3-demo-manifest-bucket}/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:PutObject",
            "s3:GetBucketLocation"
        ],
        "Resource": [
            "arn:aws:s3:::{amzn-s3-demo-completion-report-bucket}/*"
        ]
    }
]
}
EOF

aws iam put-role-policy --role-name batch_operations-objectlock \
--policy-name object-lock-permissions \
--policy-document "${batch_operations_permissions}"
```

Using the AWS SDK for Java

You can create an IAM role with S3 Batch Operations permissions, and update the role permissions to create jobs that enable Object Lock by using the AWS SDK for Java. You must also have a CSV manifest identifying the objects for your S3 Batch Operations job. For more information, see [the section called “Specifying a manifest”](#).

Perform the following steps:

1. Create an IAM role and assign S3 Batch Operations permissions to run. This step is required for all S3 Batch Operations jobs.
2. Set up S3 Batch Operations with S3 Object Lock to run.

You allow the role to do the following:

1. Run Object Lock on the S3 bucket that contains the target objects that you want Batch Operations to run on.
2. Read the S3 bucket where the manifest CSV file and the objects are located.
3. Write the results of the S3 Batch Operations job to the reporting bucket.

For a code example that demonstrates how to create an IAM role for enabling S3 Object Lock using S3 Batch Operations with the AWS SDK for Java, see [CreateObjectLockRole.java](#) in the *AWS SDK for Java 2.x Code Examples*.

Setting Object Lock retention using Batch Operations

You can use Amazon S3 Batch Operations with S3 Object Lock to manage retention for many Amazon S3 objects at once. You specify the list of target objects in your manifest and submit it to Batch Operations for completion. For more information, see [the section called “Object Lock retention”](#) and [the section called “Object Lock legal hold”](#).

The following examples show how to create an AWS Identity and Access Management (IAM) role with S3 Batch Operations permissions and update the role permissions to include the s3:PutObjectRetention permissions so that you can run S3 Object Lock retention on the objects in your manifest bucket. You must also have a CSV manifest that identifies the objects for your S3 Batch Operations job. For more information, see [the section called “Specifying a manifest”](#).

To use the following examples, replace the *user input placeholders* with your own information.

Using the AWS CLI

The following AWS CLI example shows how to use Batch Operations to apply S3 Object Lock retention across multiple objects.

```
export AWS_PROFILE='aws-user'
```

```
read -d '' retention_permissions <<EOF
{
    "Version": "2012-10-17" ,           TCX5-2025-waiver;,
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObjectRetention"
            ],
            "Resource": [
                "arn:aws:s3:::{amzn-s3-demo-manifest-bucket}/*"
            ]
        }
    ]
}
EOF

aws iam put-role-policy --role-name batch_operations-objectlock --policy-name retention-permissions --policy-document "${retention_permissions}"
```

Using the AWS SDK for Java

For examples of how to use Batch Operations to apply S3 Object Lock retention across multiple objects with the AWS SDK for Java, see [Use CreateJob with an AWS SDK or CLI](#) in the *Amazon S3 API Reference*.

Using S3 Batch Operations with S3 Object Lock retention compliance mode

The following example builds on the previous examples of creating a trust policy and setting S3 Batch Operations and S3 Object Lock configuration permissions on your objects. This example sets the retention mode to COMPLIANCE and the retain until date to January 1, 2025. This example creates a job that targets objects in the manifest bucket and reports the results in the reports bucket that you identified.

To use the following examples, replace the *user input placeholders* with your own information.

Using the AWS CLI

The following AWS CLI examples show how to use Batch Operations to apply S3 Object Lock retention compliance mode across multiple objects.

Example — Set S3 Object Lock retention compliance mode across multiple objects

Using the AWS SDK for Java

The following AWS SDK for Java examples show how to use Batch Operations to apply S3 Object Lock retention compliance mode across multiple objects, including setting the retention mode to COMPLIANCE with a retain until date and extending the COMPLIANCE mode retain until date.

For examples of how to use Batch Operations to apply S3 Object Lock retention compliance mode across multiple objects with the AWS SDK for Java, see [Use CreateJob with an AWS SDK or CLI](#) in the [Amazon S3 API Reference](#).

Use S3 Batch Operations with S3 Object Lock retention governance mode

The following example builds on the previous example of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. This example shows how to apply S3 Object Lock retention governance with the `retain until` date of January 30, 2025, across multiple objects. It creates a Batch Operations job that uses the manifest bucket and reports the results in the reports bucket.

To use the following examples, replace the *user input placeholders* with your own information.

Using the AWS CLI

The following AWS CLI examples show how to use Batch Operations to apply S3 Object Lock retention governance mode across multiple objects.

Example — Apply S3 Object Lock retention governance across multiple objects with the retain until date of January 30, 2025

```
export AWS_PROFILE='aws-user'
export AWS_DEFAULT_REGION='us-west-2'
export ACCOUNT_ID=123456789012
export ROLE_ARN='arn:aws:iam::123456789012:role/batch_operations-objectlock'

read -d '' OPERATION <<EOF
{
  "S3PutObjectRetention": {
    "Retention": {
      "RetainUntilDate": "2025-01-30T00:00:00",
      "Mode": "GOVERNANCE"
    }
  }
}
EOF

read -d '' MANIFEST <<EOF
{
  "Spec": {
    "Format": "S3BatchOperations_CSV_20180820",
    "Fields": [
      "Bucket",
      "Key"
    ]
  }
}
EOF
```

```
},
"Location": {
    "ObjectArn": "arn:aws:s3:::amzn-s3-demo-manifest-bucket/governance-objects-

    "ETag": "Your-manifest-ETag"
}
}
EOF

read -d '' REPORT <<EOF
{
    "Bucket": "arn:aws:s3:::amzn-s3-demo-completion-report-bucketT",
    "Format": "Report_CSV_20180820",
    "Enabled": true,
    "Prefix": "reports/governance-objects",
    "ReportScope": "AllTasks"
}
EOF

aws \
    s3control create-job \
    --account-id "${ACCOUNT_ID}" \
    --manifest "${MANIFEST//$/\n}" \
    --operation "${OPERATION//$/\n/}" \
    --report "${REPORT//$/\n}" \

    --role-arn "${ROLE_ARN}" \
    --client-request-token "$(uuidgen)" \
    --region "${AWS_DEFAULT_REGION}" \
    --description "Put governance retention";
```

Example — Bypass retention governance across multiple objects

The following example builds on the previous example of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. It shows how to bypass retention governance across multiple objects and creates a Batch Operations job that uses the manifest bucket and reports the results in the reports bucket.

```
export AWS_PROFILE='aws-user'

read -d '' bypass_governance_permissions <<EOF

  --report "${REPORT//$/\n}" \
  --priority 10 \
  --role-arn "${ROLE_ARN}" \
  --client-request-token "$(uuidgen)" \
  --region "${AWS_DEFAULT_REGION}" \
  --description "Remove governance retention";
```

Using the AWS SDK for Java

The following AWS SDK for Java examples show how to apply S3 Object Lock retention governance with the `retain until` date set to January 30, 2025 across multiple objects, including applying Object Lock retention governance across multiple objects with a retain until date and bypassing retention governance across multiple objects.

For examples of how to use Batch Operations with S3 Object Lock retention governance mode with the AWS SDK for Java, see [Use CreateJob with an AWS SDK or CLI](#) in the *Amazon S3 API Reference*.

Using S3 Batch Operations to turn off S3 Object Lock legal holds

The following example builds on the previous examples of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. This example shows how to disable Object Lock legal hold on objects using Batch Operations.

The example first updates the role to grant s3:PutObjectLegalHold permissions, creates a Batch Operations job that turns off (removes) legal hold from the objects identified in the manifest, and then reports on it.

To use the following examples, replace the *user input placeholders* with your own information.

Using the AWS CLI

The following AWS CLI examples show how to use Batch Operations to turn off S3 Object Lock legal holds across multiple objects.

Example — Updates the role to grant s3:PutObjectLegalHold permissions

```
export AWS_PROFILE='aws-user'

read -d '' legal_hold_permissions <<EOF

            "Effect": "Allow",
            "Action": [
                "s3:PutObjectLegalHold"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
            ]
        }
    ]
}

EOF

aws iam put-role-policy --role-name batch_operations-objectlock --policy-name legal-hold-permissions --policy-document "${legal_hold_permissions}"

Tutorial: Batch-transcoding videos with S3 Batch Operations

Video consumers use devices of all shapes, sizes, and vintages to enjoy media content. This wide array of devices presents a challenge for content creators and distributors. Instead of being in a one-size-fits-all format, videos must be converted so that they can span a broad range of sizes, formats, and bitrates. This conversion task is even more challenging when you have a large number of videos that must be converted.

AWS offers you a method to build a scalable, distributed architecture that does the following:

- Ingests input videos
- Processes the videos for playback on a wide range of devices
- Stores the transcoded media files
- Delivers the output media files to meet demand

When you have extensive video repositories stored in Amazon S3, you can transcode these videos from their source formats into multiple file types in the size, resolution, and format needed by a particular video player or device. Specifically, [S3 Batch Operations](#) provides you with a solution to invoke AWS Lambda functions for existing input videos in an S3 source bucket. Then, the Lambda functions call [AWS Elemental MediaConvert](#) to perform large-scale video transcoding tasks. The converted output media files are stored in an S3 destination bucket.

Objective

In this tutorial, you learn how to set up S3 Batch Operations to invoke a Lambda function for batch-transcoding of videos stored in an S3 source bucket. The Lambda function calls MediaConvert to transcode the videos. The outputs for each video in the S3 source bucket are as follows:

- An [HTTP Live Streaming \(HLS\)](#) adaptive bitrate stream for playback on devices of multiple sizes and varying bandwidths
- An MP4 video file
- Thumbnail images collected at intervals

Topics

- [Prerequisites](#)
- [Step 1: Create an S3 bucket for the output media files](#)
- [Step 2: Create an IAM role for MediaConvert](#)
- [Step 3: Create an IAM role for your Lambda function](#)
- [Step 4: Create a Lambda function for video transcoding](#)
- [Step 5: Configure Amazon S3 Inventory for your S3 source bucket](#)
- [Step 6: Create an IAM role for S3 Batch Operations](#)
- [Step 7: Create and run an S3 Batch Operations job](#)
- [Step 8: Check the output media files from your S3 destination bucket](#)
- [Step 9: Clean up](#)
- [Next steps](#)

Prerequisites

Before you start this tutorial, you must have an Amazon S3 source bucket (for example, *amzn-s3-demo-source-bucket*) with videos to be transcoded already stored in it.

You can give the bucket another name if you want. For more information about bucket names in Amazon S3, see [General purpose bucket naming rules](#).

For the S3 source bucket, keep the settings related to **Block Public Access settings for this bucket** set to the defaults (**Block all public access** is enabled). For more information, see [Creating a general purpose bucket](#).

For more information about uploading videos to the S3 source bucket, see [Uploading objects](#).

If you're uploading many large video files to S3, you might want to use [Amazon S3 Transfer Acceleration](#) to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. For more information, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

Step 1: Create an S3 bucket for the output media files

In this step, you create an S3 destination bucket to store the converted output media files. You also create a Cross Origin Resource Sharing (CORS) configuration to allow cross-origin access to the transcoded media files stored in your S3 destination bucket.

Substeps

- [Create a bucket for the output media files](#)
- [Add a CORS configuration to the S3 output bucket](#)

Create a bucket for the output media files

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. For **Bucket name**, enter a name for your bucket (for example, *amzn-s3-demo-destination-bucket1*).
5. For **Region**, choose the AWS Region where you want the bucket to reside.

6. To ensure public access to your output media files, in **Block Public Access settings for this bucket**, clear **Block all public access**.

 **Warning**

Before you complete this step, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access. When you turn off Block Public Access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

If you don't want to clear the Block Public Access settings, you can use Amazon CloudFront to deliver the transcoded media files to viewers (end users). For more information, see [Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53](#).

7. Select the check box next to **I acknowledge that the current settings might result in this bucket and the objects within becoming public**.
8. Keep the remaining settings set to the defaults.
9. Choose **Create bucket**.

Add a CORS configuration to the S3 output bucket

A JSON CORS configuration defines a way for client web applications (video players in this context) that are loaded in one domain to play transcoded output media files in a different domain.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you created earlier (for example, *amzn-s3-demo-destination-bucket1*).
4. Choose the **Permissions** tab.
5. In the **Cross-origin resource sharing (CORS)** section, choose **Edit**.
6. In the CORS configuration text box, copy and paste the following CORS configuration.

The CORS configuration must be in JSON format. In this example, the `AllowedOrigins` attribute uses the wildcard character (*) to specify all origins. If you know your specific

origin, you can restrict the `AllowedOrigins` attribute to your specific player URL. For more information about configuring this and other attributes, see [Elements of a CORS configuration](#).

```
[  
  {  
    "AllowedOrigins": [  
      "*"  
    ],  
    "AllowedMethods": [  
      "GET"  
    ],  
    "AllowedHeaders": [  
      "*"  
    ],  
    "ExposeHeaders": []  
  }  
]
```

7. Choose **Save changes**.

Step 2: Create an IAM role for MediaConvert

To use AWS Elemental MediaConvert to transcode input videos stored in your S3 bucket, you must have an AWS Identity and Access Management (IAM) service role to grant MediaConvert permissions to read and write video files from and to your S3 source and destination buckets. When you run transcoding jobs, the MediaConvert console uses this role.

To create an IAM role for MediaConvert

1. Create an IAM role with a role name that you choose (for example, **tutorial-mediaconvert-role**). To create this role, follow the steps in [Create your MediaConvert role in IAM \(console\)](#) in the *AWS Elemental MediaConvert User Guide*.
2. After you create the IAM role for MediaConvert, in the list of **Roles**, choose the name of the role for MediaConvert that you created (for example, **tutorial-mediaconvert-role**).
3. On the **Summary** page, copy the **Role ARN** (which starts with `arn:aws:iam::`), and save the ARN for use later.

For more information about ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

Step 3: Create an IAM role for your Lambda function

To batch-transcode videos with MediaConvert and S3 Batch Operations, you use a Lambda function to connect these two services to convert videos. This Lambda function must have an IAM role that grants the Lambda function permissions to access MediaConvert and S3 Batch Operations.

Substeps

- [Create an IAM role for your Lambda function](#)
- [Embed an inline policy for the IAM role of your Lambda function](#)

Create an IAM role for your Lambda function

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**, and then choose **Create role**.
3. Choose the **AWS service** role type, and then under **Common use cases**, choose **Lambda**.
4. Choose **Next: Permissions**.
5. On the **Attach permissions policies** page, enter **AWSLambdaBasicExecutionRole** in the **Filter policies** box. To attach the managed policy **AWSLambdaBasicExecutionRole** to this role to grant write permissions to Amazon CloudWatch Logs, select the check box next to **AWSLambdaBasicExecutionRole**.
6. Choose **Next**.
7. For **Role name**, enter **tutorial-lambda-transcode-role**.
8. (Optional) Add tags to the managed policy.
9. Choose **Create role**.

Embed an inline policy for the IAM role of your Lambda function

To grant permissions to the MediaConvert resource that's needed for the Lambda function to execute, you must use an inline policy.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**.

3. In the **Roles** list, choose the name of the IAM role that you created earlier for your Lambda function (for example, **tutorial-lambda-transcode-role**).
4. Choose the **Permissions** tab.
5. Choose **Add inline policy**.
6. Choose the **JSON** tab, and then copy and paste the following JSON policy.

In the JSON policy, replace the example ARN value of Resource with the role ARN of the IAM role for MediaConvert that you created in [Step 2](#) (for example, **tutorial-mediacconvert-role**).

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "logs:CreateLogGroup",  
                "logs:CreateLogStream",  
                "logs:PutLogEvents"  
            ],  
            "Resource": "*",  
            "Effect": "Allow",  
            "Sid": "Logging"  
        },  
        {  
            "Action": [  
                "iam:PassRole"  
            ],  
            "Resource": [  
                "arn:aws:iam::111122223333:role/tutorial-mediacconvert-role"  
            ],  
            "Effect": "Allow",  
            "Sid": "PassRole"  
        },  
        {  
            "Action": [  
                "mediacconvert:*"  
            ],  
            "Resource": [  
                "*"  
            ]  
        }  
    ]  
}
```

```
        ],
        "Effect": "Allow",
        "Sid": "MediaConvertService"
    },
    {
        "Action": [
            "s3:)"
        ],
        "Resource": [
            "*"
        ],
        "Effect": "Allow",
        "Sid": "S3Service"
    }
]
}
```

7. Choose **Review Policy**.
8. For **Name**, enter **tutorial-lambda-policy**.
9. Choose **Create Policy**.

After you create an inline policy, it is automatically embedded in the IAM role of your Lambda function.

Step 4: Create a Lambda function for video transcoding

In this section of the tutorial, you build a Lambda function using the SDK for Python to integrate with S3 Batch Operations and MediaConvert. To start transcoding the videos already stored in your S3 source bucket, you run an S3 Batch Operations job that directly invokes the Lambda function for each video in the S3 source bucket. Then, the Lambda function submits a transcoding job for each video to MediaConvert.

Substeps

- [Write Lambda function code and create a deployment package](#)
- [Create a Lambda function with an execution role \(console\)](#)
- [Deploy your Lambda function with .zip file archives and configure the Lambda function \(console\)](#)

Write Lambda function code and create a deployment package

1. On your local machine, create a folder named batch-transcode.
2. In the batch-transcode folder, create a file with JSON job settings. For example, you can use the settings provided in this section, and name the file job.json.

A job.json file specifies the following:

- Which files to transcode
- How you want to transcode your input videos
- What output media files you want to create
- What to name the transcoded files
- Where to save the transcoded files
- Which advanced features to apply, and so on

In this tutorial, we use the following job.json file to create the following outputs for each video in the S3 source bucket:

- An HTTP Live Streaming (HLS) adaptive bitrate stream for playback on multiple devices of differing sizes and varying bandwidths
- An MP4 video file
- Thumbnail images collected at intervals

This example job.json file uses Quality-Defined Variable Bitrate (QVBR) to optimize video quality. The HLS output is Apple-compliant (audio unmixed from video, segment duration of 6 seconds, and optimized video quality through auto QVBR).

If you don't want to use the example settings provided here, you can generate a job.json specification based on your use case. To ensure consistency across your outputs, make sure that your input files have similar video and audio configurations. For any input files with different video and audio configurations, create separate automations (unique job.json settings). For more information, see [Example AWS Elemental MediaConvert job settings in JSON](#) in the *AWS Elemental MediaConvert User Guide*.

3. In the batch-transcode folder, create a file with a Lambda function. You can use the following Python example and name the file convert.py.

S3 Batch Operations sends specific task data to a Lambda function and requires result data back. For request and response examples for the Lambda function, information about response and result codes, and example Lambda functions for S3 Batch Operations, see [Invoke AWS Lambda function](#).

4. To create a deployment package with convert.py and job.json as a .zip file named lambda.zip, in your local terminal, open the batch-transcode folder that you created earlier, and run the following command.

For macOS users, run the following command:

```
zip -r lambda.zip convert.py job.json
```

For Windows users, run the following commands:

```
powershell Compress-Archive convert.py lambda.zip
```

```
powershell Compress-Archive -update job.json lambda.zip
```

Create a Lambda function with an execution role (console)

1. Open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. In the left navigation pane, choose **Functions**.
3. Choose **Create function**.
4. Choose **Author from scratch**.
5. Under **Basic information**, do the following:
 - a. For **Function name**, enter **tutorial-lambda-convert**.
 - b. For **Runtime**, choose **Python 3.13**.
6. Choose **Change default execution role**, and under **Execution role**, choose **Use an existing role**.
7. Under **Existing role**, choose the name of the IAM role that you created for your Lambda function in [Step 3](#) (for example, **tutorial-lambda-transcode-role**).
8. For the remaining settings, keep the defaults.
9. Choose **Create function**.

Deploy your Lambda function with .zip file archives and configure the Lambda function (console)

1. In the **Code Source** section of the page for the Lambda function that you created (for example, **tutorial-lambda-convert**), choose **Upload from** and then **.zip file**.
2. Choose **Upload** to select your local .zip file.

3. Choose the `lambda.zip` file that you created earlier, and choose **Open**.
4. Choose **Save**.
5. In the **Runtime settings** section, choose **Edit**.
6. To tell the Lambda runtime which handler method in your Lambda function code to invoke, enter `convert.handler` in the **Handler** field.

When you configure a function in Python, the value of the handler setting is the file name and the name of the handler module, separated by a dot (.). For example, `convert.handler` calls the `handler` method defined in the `convert.py` file.

7. Choose **Save**.
8. On your Lambda function page, choose the **Configuration** tab. In the left navigation pane on the **Configuration** tab, choose **Environment variables**, and then choose **Edit**.
9. Choose **Add environment variable**. Then, enter the specified **Key** and **Value** for each of the following environment variables:

- **Key: DestinationBucket Value: amzn-s3-demo-destination-bucket1**

This value is the S3 bucket for output media files that you created in [Step 1](#).

- **Key: MediaConvertRole Value: arn:aws:iam::111122223333:role/tutorial-mediaconvert-role**

This value is the ARN of the IAM role for MediaConvert that you created in [Step 2](#). Make sure to replace this ARN with the actual ARN of your IAM role.

- **Key: Application Value: Batch-Transcoding**

This value is the name of the application.

10. Choose **Save**.
11. (Optional) On the **Configuration** tab, in the **General configuration** section of the left navigation pane, choose **Edit**. In the **Timeout** field, enter **2 min 0 sec**. Then, choose **Save**.

Timeout is the amount of time that Lambda allows a function to run for an invocation before stopping it. The default is 3 seconds. Pricing is based on the amount of memory configured and the amount of time that your code runs. For more information, see [AWS Lambda pricing](#).

Step 5: Configure Amazon S3 Inventory for your S3 source bucket

After setting up the transcoding Lambda function, create an S3 Batch Operations job to transcode a set of videos. First, you need a list of input video objects that you want S3 Batch Operations to run the specified transcoding action on. To get a list of input video objects, you can generate an S3 Inventory report for your S3 source bucket (for example, [amzn-s3-demo-source-bucket](#)).

Substeps

- [Create and configure a bucket for S3 Inventory reports for input videos](#)
- [Configure Amazon S3 Inventory for your S3 video source bucket](#)
- [Check the inventory report for your S3 video source bucket](#)

Create and configure a bucket for S3 Inventory reports for input videos

To store an S3 Inventory report that lists the objects of the S3 source bucket, create an S3 Inventory destination bucket, and then configure a bucket policy for the bucket to write inventory files to the S3 source bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. For **Bucket name**, enter a name for your bucket (for example, [amzn-s3-demo-destination-bucket2](#)).
5. For **AWS Region**, choose the AWS Region where you want the bucket to reside.

The inventory destination bucket must be in the same AWS Region as the source bucket where you are setting up S3 Inventory. The inventory destination bucket can be in a different AWS account.

6. In **Block Public Access settings for this bucket**, keep the default settings (**Block all public access** is enabled).
7. For the remaining settings, keep the defaults.
8. Choose **Create bucket**.
9. In the **Buckets** list, choose the name of the bucket that you just created (for example, [amzn-s3-demo-destination-bucket2](#)).

10. To grant Amazon S3 permission to write data for the inventory reports to the S3 Inventory destination bucket, choose the **Permissions** tab.
11. Scroll down to the **Bucket policy** section, and choose **Edit**. The **Bucket policy** page opens.
12. To grant permissions for S3 Inventory, in the **Policy** field, paste the following bucket policy.

Replace the three example values with the following values:

- The name of the bucket that you created to store the inventory reports (for example, *amzn-s3-demo-destination-bucket2*).
- The name of the source bucket that stores the input videos (for example, *amzn-s3-demo-source-bucket*).
- The AWS account ID that you used to create the S3 video source bucket (for example, *111122223333*).

                }  
            }  
        }  
    ]  
}
```

13. Choose **Save changes**.

Configure Amazon S3 Inventory for your S3 video source bucket

To generate a flat file list of video objects and metadata, you must configure S3 Inventory for your S3 video source bucket. These scheduled inventory reports can include all the objects in the bucket or objects grouped by a shared prefix. In this tutorial, the S3 Inventory report includes all the video objects in your S3 source bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. To configure an S3 Inventory report of the input videos in your S3 source bucket, in the **Buckets** list, choose the name of the S3 source bucket (for example, *amzn-s3-demo-source-bucket*).
4. Choose the **Management** tab.
5. Scroll down to the **Inventory configurations** section, and choose **Create inventory configuration**.
6. For **Inventory configuration name**, enter a name (for example, **tutorial-inventory-config**).
7. Under **Inventory scope**, choose **Current version only for Object versions** and keep the other **Inventory scope** settings set to the defaults for this tutorial.
8. In the **Report details** section, for **Destination bucket**, choose **This account**.
9. For **Destination**, choose **Browse S3**, and choose the destination bucket that you created earlier to save the inventory reports to (for example, *amzn-s3-demo-destination-bucket2*). Then choose **Choose path**.

The inventory destination bucket must be in the same AWS Region as the source bucket where you are setting up S3 Inventory. The inventory destination bucket can be in a different AWS account.

Under the **Destination** bucket field, the **Destination bucket permission** is added to the inventory destination bucket policy, allowing Amazon S3 to place data in the inventory destination bucket. For more information, see [Creating a destination bucket policy](#).

10. For **Frequency**, choose **Daily**.
11. For **Output format**, choose **CSV**.
12. For **Status**, choose **Enable**.

13. In the **Server-side encryption** section, choose **Disable** for this tutorial.

For more information, see [Configuring inventory by using the S3 console](#) and [Granting Amazon S3 permission to use your customer managed key for encryption](#).

14. In the **Additional fields - optional** section, select **Size**, **Last modified**, and **Storage class**.

15. Choose **Create**.

For more information, see [Configuring inventory by using the S3 console](#).

Check the inventory report for your S3 video source bucket

When an inventory report is published, the manifest files are sent to the S3 Inventory destination bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the video source bucket (for example, *amzn-s3-demo-source-bucket*).
4. Choose **Management**.
5. To see if your S3 Inventory report is ready so that you can create an S3 Batch Operations job in [Step 7](#), under **Inventory configurations**, check whether the **Create job from manifest** button is enabled.

 **Note**

It can take up to 48 hours to deliver the first inventory report. If the **Create job from manifest** button is disabled, the first inventory report has not been delivered. Wait until the first inventory report is delivered and the **Create job from manifest** button is enabled before you create an S3 Batch Operations job in [Step 7](#).

6. To check an S3 Inventory report (`manifest.json`), in the **Destination** column, choose the name of the inventory destination bucket that you created earlier for storing inventory reports (for example, *amzn-s3-demo-destination-bucket2*).
7. On the **Objects** tab, choose the existing folder with the name of your S3 source bucket (for example, *amzn-s3-demo-source-bucket*). Then choose the name that you entered in

Inventory configuration name when you created the inventory configuration earlier (for example, **tutorial-inventory-config**).

You can see a list of folders with the generation dates of the reports as their names.

8. To check the daily S3 Inventory report for a particular date, choose the folder with the corresponding generation date name, and then choose **manifest.json**.
9. To check the details of the inventory report on a specific date, on the **manifest.json** page, choose **Download** or **Open**.

Step 6: Create an IAM role for S3 Batch Operations

To use S3 Batch Operations to do batch-transcoding, you must first create an IAM role to give Amazon S3 permissions to perform S3 Batch Operations.

Substeps

- [Create an IAM policy for S3 Batch Operations](#)
- [Create an S3 Batch Operations IAM role and attach permissions policies](#)

Create an IAM policy for S3 Batch Operations

You must create an IAM policy that gives S3 Batch Operations permission to read the input manifest, invoke the Lambda function, and write the S3 Batch Operations job completion report.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. Choose the **JSON** tab.
5. In the **JSON** text field, paste the following JSON policy.

In the JSON policy, replace the four example values with the following values:

- The name of the source bucket that stores your input videos (for example, *amzn-s3-demo-source-bucket*).
- The name of the inventory destination bucket that you created in [Step 5](#) to store **manifest.json** files (for example, *amzn-s3-demo-destination-bucket2*).

- The name of the bucket that you created in [Step 1](#) to store output media files (for example, **amzn-s3-demo-destination-bucket1**). In this tutorial, we put job completion reports in the destination bucket for output media files.
- The role ARN of the Lambda function that you created in [Step 4](#). To find and copy the role ARN of the Lambda function, do the following:
 - In a new browser tab, open the **Functions** page on the Lambda console at <https://console.aws.amazon.com/lambda/home#/functions>.
 - In **Functions** list, choose the name of the Lambda function that you created in [Step 4](#) (for example, **tutorial-lambda-convert**).
 - Choose **Copy ARN**.

6. Choose **Next: Tags**.
7. Choose **Next: Review**.
8. In the **Name** field, enter **tutorial-s3batch-policy**.
9. Choose **Create policy**.

Create an S3 Batch Operations IAM role and attach permissions policies

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**, and then choose **Create role**.
3. Choose the **AWS service** role type, and then choose the **S3** service.
4. Under **Select your use case**, choose **S3 Batch Operations**.
5. Choose **Next**.
6. Under **Attach permissions**, enter the name of the IAM policy that you created earlier (for example, **tutorial-s3batch-policy**) in the search box to filter the list of policies. Select the check box next to the name of the policy (for example, **tutorial-s3batch-policy**).
7. Choose **Next**.
8. For **Role name**, enter **tutorial-s3batch-role**.
9. Choose **Create role**.

After you create the IAM role for S3 Batch Operations, the following trust policy is automatically attached to the role. This trust policy allows the S3 Batch Operations service principal to assume the IAM role.

JSON

```
{

```
"Version":"2012-10-17",
"Statement": [
    {
        "Effect":"Allow",
        "Principal": {

        },
        "Action":"sts:AssumeRole"
    }
]
```

Step 7: Create and run an S3 Batch Operations job

To create an S3 Batch Operations job to process the input videos in your S3 source bucket, you must specify parameters for this particular job.

Note

Before you start creating an S3 Batch Operations job, make sure that the **Create job from manifest** button is enabled. For more information, see [Check the inventory report for your S3 video source bucket](#). If the **Create job from manifest** button is disabled, the first inventory report has not been delivered and you must wait until the button is enabled. After you configure Amazon S3 Inventory for your S3 source bucket in [Step 5](#), it can take up to 48 hours to deliver the first inventory report.

Substeps

- [Create an S3 Batch Operations job](#)
- [Run the S3 Batch Operations job to invoke your Lambda function](#)
- [\(Optional\) Check your completion report](#)
- [\(Optional\) Monitor each Lambda invocation in the Lambda console](#)
- [\(Optional\) Monitor each MediaConvert video-transcoding job in the MediaConvert console](#)

Create an S3 Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. For **AWS Region**, choose the Region where you want to create your job.

In this tutorial, to use the S3 Batch Operations job to invoke a Lambda function, you must create the job in the same Region as the S3 video source bucket where the objects referenced in the manifest are located.

5. In the **Manifest** section, do the following:
 - a. For **Manifest format**, choose **S3 Inventory report (manifest.json)**.
 - b. For **Manifest object**, choose **Browse S3** to find the bucket that you created in [Step 5](#) for storing inventory reports (for example, *amzn-s3-demo-destination-bucket2*). On the **Manifest object** page, navigate through the object names until you find a `manifest.json` file for a specific date. This file lists the information about all the videos that you want to batch-transcode. When you've found the `manifest.json` file that you want to use, choose the option button next to it. Then choose **Choose path**.
 - c. (Optional) For **Manifest object version ID - optional**, enter the version ID for the manifest object if you want to use a version other than the most recent.
6. Choose **Next**.
7. To use the Lambda function to transcode all the objects listed in the selected `manifest.json` file, under **Operation type**, choose **Invoke AWS Lambda function**.
8. In the **Invoke Lambda function** section, do the following:
 - a. Choose **Choose from functions in your account**.
 - b. For **Lambda function**, choose the Lambda function that you created in [Step 4](#) (for example, **tutorial-lambda-convert**).
 - c. For **Lambda function version**, keep the default value **\$LATEST**.
9. Choose **Next**. The **Configure additional options** page opens.
10. In the **Additional options** section, keep the default settings.

For more information about these options, see [Batch Operations job request elements](#).

11. In the **Completion report** section, for **Path to completion report destination**, choose **Browse S3**. Find the bucket that you created for output media files in [Step 1](#) (for example, *amzn-s3-demo-destination-bucket1*). Choose the option button next to that bucket's name. Then choose **Choose path**.

For the remaining **Completion report** settings, keep the defaults. For more information about completion report settings, see [Batch Operations job request elements](#). A completion report maintains a record of the job's details and the operations performed.

12. In the **Permissions** section, choose **Choose from existing IAM roles**. For **IAM role**, choose the IAM role for your S3 Batch Operations job that you created in [Step 6](#) (for example, **tutorial-s3batch-role**).
13. Choose **Next**.
14. On the **Review** page, review the settings. Then choose **Create job**.

After S3 finishes reading your S3 Batch Operations job's manifest, it sets the **Status** of the job to **Awaiting your confirmation to run**. To see updates to the job's status, refresh the page. You can't run your job until its status is **Awaiting your confirmation to run**.

Run the S3 Batch Operations job to invoke your Lambda function

Run your Batch Operations job to invoke your Lambda function for video transcoding. If your job fails, you can check your completion report to identify the cause.

To run the S3 Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. In the **Jobs** list, choose the **Job ID** of the job on the first row, which is the S3 Batch Operations job that you created earlier.
4. Choose **Run job**.
5. Review your job parameters again, and confirm that the value for **Total objects listed in manifest** is the same as the number of objects in the manifest. Then choose **Run job**.

Your S3 Batch Operations job page opens.

6. After the job starts running, on your job page, under **Status**, check the progress of your S3 Batch Operations job, such as **Status**, **% Complete**, **Total succeeded (rate)**, **Total failed (rate)**, **Date terminated**, and **Reason for termination**.

When the S3 Batch Operations job completes, view the data on your job page to confirm that the job finished as expected.

If more than 50 percent of an S3 Batch Operations job's object operations fail after more than 1,000 operations have been attempted, the job automatically fails. To check your completion report to identify the cause of the failures, use the following optional procedure.

(Optional) Check your completion report

You can use your completion report to determine which objects failed and the cause of the failures.

To check your completion report for details about failed objects

1. On the page of your S3 Batch Operations job, scroll down to the **Completion report** section, and choose the link under **Completion report destination**.

The S3 output destination bucket's page opens.

2. On the **Objects** tab, choose the folder that has a name ending with the job ID of the S3 Batch Operations job that you created earlier.
3. Choose **results/**.
4. Select the check box next to the .csv file.
5. To view the job report, choose **Open** or **Download**.

(Optional) Monitor each Lambda invocation in the Lambda console

After the S3 Batch Operations job starts running, the job invokes the Lambda function for each input video object. S3 writes logs of each Lambda invocation to CloudWatch Logs. You can use the Lambda console's monitoring dashboard to monitor your Lambda function.

1. Open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. In the left navigation pane, choose **Functions**.
3. In the **Functions** list, choose the name of the Lambda function that you created in [Step 4](#) (for example, **tutorial-lambda-convert**).

4. Choose the **Monitor** tab.
5. Under **Metrics**, see the runtime metrics for your Lambda function.
6. Under **Logs**, view log data for each Lambda invocation through CloudWatch Logs Insights.

 **Note**

When you use S3 Batch Operations with a Lambda function, the Lambda function is invoked on each object. If your S3 Batch Operations job is large, it can invoke multiple Lambda functions at the same time, causing a spike in Lambda concurrency.

Each AWS account has a Lambda concurrency quota per Region. For more information, see [AWS Lambda Function Scaling](#) in the *AWS Lambda Developer Guide*. A best practice for using Lambda functions with S3 Batch Operations is to set a concurrency limit on the Lambda function itself. Setting a concurrency limit keeps your job from consuming most of your Lambda concurrency and potentially throttling other functions in your account. For more information, see [Managing Lambda reserved concurrency](#) in the *AWS Lambda Developer Guide*.

(Optional) Monitor each MediaConvert video-transcoding job in the MediaConvert console

A MediaConvert job does the work of transcoding a media file. When your S3 Batch Operations job invokes your Lambda function for each video, each Lambda function invocation creates a MediaConvert transcoding job for each input video.

1. Sign in to the AWS Management Console and open the MediaConvert console at <https://console.aws.amazon.com/mediaconvert/>.
2. If the MediaConvert introductory page appears, choose **Get started**.
3. From the list of **Jobs**, view each row to monitor the transcoding task for each input video.
4. Identify the row of a job that you want to check, and choose the **Job ID** link to open the job details page.
5. On the **Job summary** page, under **Outputs**, choose the link for the HLS, MP4, or Thumbnails output, depending on what is supported by your browser, to go to the S3 destination bucket for the output media files.
6. In the corresponding folder (HLS, MP4, or Thumbnails) of your S3 output destination bucket, choose the name of the output media file object.

The object's detail page opens.

7. On the object's detail page, under **Object overview**, choose the link under **Object URL** to watch the transcoded output media file.

Step 8: Check the output media files from your S3 destination bucket

To check the output media files from your S3 destination bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the S3 destination bucket for output media files that you created in [Step 1](#) (for example, *amzn-s3-demo-destination-bucket1*).
4. On the **Objects** tab, each input video has a folder that has the name of the input video. Each folder contains the transcoded output media files for an input video.

To check the output media files for an input video, do the following:

- a. Choose the folder with the name of the input video that you want to check.
- b. Choose the **Default/** folder.
- c. Choose the folder for a transcoded format (HLS, MP4, or thumbnails in this tutorial).
- d. Choose the name of the output media file.
- e. To watch the transcoded file, on the object's details page, choose the link under **Object URL**.

Output media files in the HLS format are split into short segments. To play these videos, embed the object URL of the .m3u8 file in a compatible player.

Step 9: Clean up

If you transcoded videos using S3 Batch Operations, Lambda, and MediaConvert only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

Substeps

- [Delete the S3 Inventory configuration for your S3 source bucket](#)
- [Delete the Lambda function](#)
- [Delete the CloudWatch log group](#)

- [Delete the IAM roles together with the inline policies for the IAM roles](#)
- [Delete the customer-managed IAM policy](#)
- [Empty the S3 buckets](#)
- [Delete the S3 buckets](#)

Delete the S3 Inventory configuration for your S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of your source bucket (for example, *amzn-s3-demo-source-bucket*).
4. Choose the **Management** tab.
5. In the **Inventory configurations** section, choose the option button next to the inventory configuration that you created in [Step 5](#) (for example, **tutorial-inventory-config**).
6. Choose **Delete**, and then choose **Confirm**.

Delete the Lambda function

1. Open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. In the left navigation pane, choose **Functions**.
3. Select the check box next to the function that you created in [Step 4](#) (for example, **tutorial-lambda-convert**).
4. Choose **Actions**, and then choose **Delete**.
5. In the **Delete function** dialog box, choose **Delete**.

Delete the CloudWatch log group

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the left navigation pane, choose **Logs**, and then choose **Log groups**.
3. Select the check box next to the log group that has a name ending with the Lambda function that you created in [Step 4](#) (for example, **tutorial-lambda-convert**).
4. Choose **Actions**, and then choose **Delete log group(s)**.

5. In the **Delete log group(s)** dialog box, choose **Delete**.

Delete the IAM roles together with the inline policies for the IAM roles

To delete the IAM roles that you created in [Step 2](#), [Step 3](#), and [Step 6](#), do the following:

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**, and then select the check boxes next to the role names that you want to delete.
3. At the top of the page, choose **Delete**.
4. In the confirmation dialog box, enter the required response in the text input field based on the prompt, and choose **Delete**.

Delete the customer-managed IAM policy

To delete the customer-managed IAM policy that you created in [Step 6](#), do the following:

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**.
3. Choose the option button next to the policy that you created in [Step 6](#) (for example, **tutorial-s3batch-policy**). You can use the search box to filter the list of policies.
4. Choose **Actions**, and then choose **Delete**.
5. Confirm that you want to delete this policy by entering its name in the text field, and then choose **Delete**.

Empty the S3 buckets

To empty the S3 buckets that you created in [Prerequisites](#), [Step 1](#), and [Step 5](#), do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the option button next to the name of the bucket that you want to empty, and then choose **Empty**.

4. On the **Empty bucket** page, confirm that you want to empty the bucket by entering **permanently delete** in the text field, and then choose **Empty**.

Delete the S3 buckets

To delete the S3 buckets that you created in [Prerequisites](#), [Step 1](#), and [Step 5](#), do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the option button next to the name of the bucket that you want to delete.
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

Next steps

After completing this tutorial, you can further explore other relevant use cases:

- You can use Amazon CloudFront to stream the transcoded media files to viewers across the globe. For more information, see [Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53](#).
- You can transcode videos at the moment when you upload them to the S3 source bucket. To do so, you can configure an Amazon S3 event trigger that automatically invokes the Lambda function to transcode new objects in S3 with MediaConvert. For more information, see [Tutorial: Using an Amazon S3 trigger to invoke a Lambda function](#) in the *AWS Lambda Developer Guide*.

Troubleshooting S3 Batch Operations

Amazon S3 Batch Operations allows you to perform large-scale operations on Amazon S3 objects. This guide helps you troubleshoot common issues you might encounter.

To troubleshoot issues with S3 Batch Replication, see [Troubleshooting replication](#).

There are two primary types of failures that result in Batch operation errors:

- 1. API Failure** – The requested API (such as `CreateJob`) has failed to execute.
- 2. Job Failure** – The initial API request succeeded but the job failed, for example, due to issues with the manifest or permissions to objects specified in the manifest.

NoSuchJobException

Type: API failure

The `NoSuchJobException` occurs when S3 Batch Operations cannot locate the specified job. This error can happen in several scenarios beyond simple job expiration. Common causes include the following.

- 1. Job expiration** – Jobs are automatically deleted 90 days after reaching a terminal state (`Complete`, `Cancelled`, or `Failed`).
- 2. Incorrect job ID** – The job ID used in `DescribeJob` or `UpdateJobStatus` doesn't match the ID returned by `CreateJob`.
- 3. Wrong region** – Attempting to access a job in a different region than where it was created.
- 4. Wrong account** – Using a job ID from a different AWS account.
- 5. Job ID format errors** – Typos, extra characters, or incorrect formatting in the job ID.
- 6. Timing issues** – Checking job status immediately after creation before the job is fully registered.

Related error messages include the following.

1. No such job
2. The specified job does not exist

Best practices to prevent `NoSuchJobException` API failures

- 1. Store job IDs immediately** – Save the job ID from the `CreateJob` response before making subsequent API calls.
- 2. Implement retry logic** – Add exponential backoff when checking job status immediately after creation.
- 3. Set up monitoring** – Create CloudWatch alarms to track job completion before the 90-day expiration. For details, see [Using CloudWatch alarms](#) in the Amazon CloudWatch User Guide.
- 4. Use consistent regions** – Ensure all job operations use the same region as job creation.

5. Validate input – Check job ID format before making API calls.

When jobs expire

Jobs in terminal states are automatically deleted after 90 days. To avoid losing job information, consider the following.

1. **Download completion reports before expiration** – For instructions on retrieving and storing job results, see

When you create a job, you can request a completion report. As long as S3 Batch Operations successfully invokes at least one task, Amazon S3 generates a completion report after the job finishes running tasks, fails, or is canceled. You can configure the completion report to include all tasks or only failed tasks.

The completion report includes the job configuration, status, and information for each task, including the object key and version, status, error codes, and descriptions of any errors.

Completion reports provide an easy way to view the results of your tasks in a consolidated format with no additional setup required. Completion reports are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). For an example of a completion report, see [Examples: S3 Batch Operations completion reports](#).

If you don't configure a completion report, you can still monitor and audit your job and its tasks by using CloudTrail and Amazon CloudWatch. For more information, see the following topics:

- 2. **Archive job metadata in your own systems** – Store critical job information in your databases or monitoring systems.
- 3. **Set up automated notifications before the 90-day deadline** – Use Amazon EventBridge to create rules that trigger notifications when jobs complete. For more information, see [Amazon S3 Event Notifications](#).

NoSuchJobException troubleshooting

1. Use the following command to verify the job exists in your account and region.

```
aws s3control list-jobs --account-id 111122223333 --region us-east-1
```

2. Use the following command to search across all job statuses. Possible job statuses include Active, Cancelled, Cancelling, Complete, Completing, Failed, Failing, New, Paused, Pausing, Preparing, Ready, and Suspended.

```
aws s3control list-jobs --account-id 111122223333 --job-statuses your-job-status
```

3. Use the following command to check if the job exists in other regions where you commonly create jobs.

```
aws s3control list-jobs --account-id 111122223333 --region job-region-1 aws  
s3control list-jobs --account-id 111122223333 --region job-region-2
```

4. Validate the job ID format. Job IDs typically contain 36 character, such as 12345678-1234-1234-1234-123456789012. Check for extra spaces, missing characters, or case sensitivity issues and verify you're using the complete job ID returned by the CreateJob command.
5. Use the following command to check CloudTrail logs for job creation events.

```
aws logs filter-log-events --log-group-name CloudTrail/S3BatchOperations \ --  
filter-pattern "{ $.eventName = CreateJob }" \ --start-time timestamp
```

AccessDeniedException

Type: API failure

The AccessDeniedException occurs when an S3 Batch Operations request is blocked due to insufficient permissions, unsupported operations, or policy restrictions. This is one of the most common errors in Batch Operations. It has the following common causes:

1. **Missing IAM permissions** – The IAM identity lacks required permissions for Batch Operations APIs.
2. **Insufficient S3 permissions** – Missing permissions to access source or destination buckets and objects.
3. **Job execution role issues** – The job execution role lacks permissions to perform the specified operation.
4. **Unsupported operations** – Attempting to use operations not supported in the current region or bucket type.
5. **Cross-account access issues** – Missing permissions for cross-account bucket or object access.
6. **Resource-based policy restrictions** – Bucket policies or object ACLs blocking the operation.
7. **Service Control Policy (SCP) restrictions** – Organization-level policies preventing the operation.

Related error messages:

1. Access Denied
2. User: arn:aws:iam::account:user/username is not authorized to perform: s3:operation
3. Cross-account pass role is not allowed
4. The bucket policy does not allow the specified operation

Best practices to prevent AccessDeniedException API failures

1. **Use least privilege principle** – Grant only the minimum permissions required for your specific operations.
2. **Test permissions before large jobs** – Run small test jobs to validate permissions before processing thousands of objects.
3. **Use IAM policy simulator** – Test policies before deployment using the IAM policy simulator. For more information, see [IAM policy testing with the IAM policy simulator](#) in the IAM User Guide.
4. **Implement proper cross-account setup** – Check your cross-account access configuration for cross-account job configurations. For more information, see [IAM tutorial: Delegate access across AWS accounts using IAM roles](#) in the IAM User Guide.
5. **Monitor permission changes** – Set up CloudTrail alerts for IAM policy modifications that might affect Batch Operations.

6. **Document role requirements** – Maintain clear documentation of required permissions for each job type.
7. **Use common permission templates** - Use the permission examples and policy templates:
 - a. [Granting permissions for Batch Operations](#)
 - b. [Cross account resources in IAM](#) in the IAM User Guide.
 - c. [Control access to VPC endpoints using endpoint policies](#) in the AWS PrivateLink Guide.

AccessDeniedException troubleshooting

Follow these steps systematically to identify and resolve permission issues.

1. Check [Operations supported by S3 Batch Operations](#) for supported operations by region. Confirm directory bucket operations are only available at Regional and Zonal endpoints. Verify the operation is supported for your bucket's storage class.
2. Use the following command to determine if you can list jobs.

```
aws s3control list-jobs --account-id 111122223333
```

3. Use the following command to check IAM permissions for the requesting identity. The account running the job needs the following permissions: s3:CreateJob, s3:DescribeJob, s3>ListJobs-s3:UpdateJobPriority, s3:UpdateJobStatus-iam:PassRole.

```
aws sts get-caller-identity 111122223333
```

4. Use the following command to check if the role exists and is assumable.

```
aws iam get-role --role-name role-name
```

5. Use the following command to review the role's trust policy. The role running the job must have the following:

1. A trust relationship allowing batchoperations.s3.amazonaws.com to assume the role.

2. The operations the batch operation is performing (such as s3:PutObjectTagging for tagging operations).
3. Access to the source and destination buckets.
4. Permission to read the manifest file.
5. Permission to write completion reports.

```
aws iam get-role --role-name role-name --query 'Role.AssumeRolePolicyDocument'
```

6. Use the following command to rest access to the manifest and source buckets.

```
aws s3 ls s3://bucket-name
```

7. Test the operation being performed by the batch operation. For example, if the batch operation performs tagging, tag a sample object in the source bucket.
8. Review bucket policies for polcies that might deny the operation.
 1. Check object ACLs if working with legacy access controls.
 2. Verify no Service Control Policies (SCPs) are blocking the operation.
 3. Confirm VPC endpoint policies allow Batch Operations if using VPC endpoints.
9. Use the following command to use CloudTrail to identify permission failures.

```
aws logs filter-log-events --log-group-name CloudTrail/S3BatchOperations \
    --filter-pattern "{ $.errorCode = AccessDenied }" \
    --start-time timestamp
```

SlowDownError

Type: API failure

The `SlowDownError` exception occurs when your account has exceeded the request rate limit for S3 Batch Operations APIs. This is a throttling mechanism to protect the service from being overwhelmed by too many requests. It has the following common causes:

1. **High API request frequency** – Making too many API calls in a short time period.
2. **Concurrent job operations** – Multiple applications or users creating/managing jobs simultaneously.
3. **Automated scripts without rate limiting** – Scripts that don't implement proper backoff strategies.
4. **Polling job status too frequently** – Checking job status more often than necessary.
5. **Burst traffic patterns** – Sudden spikes in API usage during peak processing times.
6. **Regional capacity limits** – Exceeding the allocated request capacity for your region.

Related error messages:

1. SlowDown
2. Please reduce your request rate
3. Request rate exceeded

Best practices to prevent `SlowDownError` API failures

1. **Implement client-side rate limiting** – Add delays between API calls in your applications.
2. **Use exponential backoff with jitter** – Randomize retry delays to avoid thundering herd problems.
3. **Set up proper retry logic** – Implement automatic retries with increasing delays for transient errors.
4. **Use event-driven architectures** – Replace polling with EventBridge notifications for job status changes.
5. **Distribute load across time** – Stagger job creation and status checks across different time periods.
6. **Monitor and alert on rate limits** – Set up CloudWatch alarms to detect when you're approaching limits.

Most AWS SDKs include built-in retry logic for rate limiting errors. Configure them as follows:

1. **AWS CLI** – Use `cli-read-timeout` and `cli-connect-timeout` parameters.
2. **AWS SDK for Python (Boto3)** – Configure retry modes and max attempts in your client configuration.
3. **AWS SDK for Java** – Use `RetryPolicy` and `ClientConfiguration` settings.
4. **AWS SDK for JavaScript** – Configure `maxRetries` and `retryDelayOptions`.

For more information about retry patterns and best practices, see [Retry with backoff pattern](#) in the AWS Prescriptive Guidance guide.

SlowDownError troubleshooting

1. In your code, implement exponential backoff immediately.

Example of exponential backoff in bash

```
for attempt in {1..5}; do
    if aws s3control describe-job --account-id 111122223333 --job-id job-id; then
        break
    else
        wait_time=$((2**attempt)) echo "Rate limited, waiting ${wait_time} seconds..." sleep $wait_time
    fi
done
```

2. Use CloudTrail to identify the source of high request volume.

```
aws logs filter-log-events \
--log-group-name CloudTrail/S3BatchOperations \
--filter-pattern "{ $.eventName = CreateJob || $.eventName = DescribeJob }" \
--start-time timestamp \
--query 'events[*].[eventTime,sourceIPAddress,userIdentity.type,eventName]'
```

3. Review polling frequency.

1. Avoid checking job status more than once every 30 seconds for active jobs.
2. Use job completion notifications instead of polling when possible.

3. Implement jitter in your polling intervals to avoid synchronized requests.
4. Optimize your API usage patterns.
 1. Batch multiple operations when possible.
 2. Use `ListJobs` to get status of multiple jobs in one call.
 3. Cache job information to reduce redundant API calls.
 4. Spread job creation across time rather than creating many jobs simultaneously.
5. Use CloudWatch metrics for API calls to monitor your request patterns.

```
aws logs put-metric-filter \
    --log-group-name CloudTrail/S3BatchOperations \
    --filter-name S3BatchOpsAPICallCount \
    --filter-pattern "{ $.eventSource = s3.amazonaws.com && $.eventName = CreateJob }" \
    --metric-transformations \
        metricName=S3BatchOpsAPICalls,metricNamespace=Custom/
S3BatchOps,metricValue=1
```

InvalidManifestContent

Type: Job failure

The `InvalidManifestContent` exception occurs when there are issues with the manifest file format, content, or structure that prevent S3 Batch Operations from processing the job. It has the following common causes:

1. **Format violations** – Missing required columns, incorrect delimiters, or malformed CSV structure.
2. **Content encoding issues** – Incorrect character encoding, BOM markers, or non-UTF-8 characters.
3. **Object key problems** – Invalid characters, improper URL encoding, or keys exceeding length limits.
4. **Size limitations** – Manifest contains more objects than the operation supports.
5. **Version ID format errors** – Malformed or invalid version IDs for versioned objects.
6. **ETag format issues** – Incorrect ETag format or missing quotes for operations that require ETags.
7. **Inconsistent data** – Mixed formats within the same manifest or inconsistent column counts.

Related error messages:

1. Required fields are missing in the schema: + missingFields
2. Invalid Manifest Content
3. The S3 Batch Operations job failed because it contains more keys than the maximum allowed in a single job
4. Invalid object key format
5. Manifest file is not properly formatted
6. Invalid version ID format
7. ETag format is invalid

Best practices to prevent InvalidManifestContent job failures

1. **Validate before upload** – Test manifest format with small jobs before processing large datasets.
2. **Use consistent encoding** – Always use UTF-8 encoding without BOM for manifest files.
3. **Implement manifest generation standards** – Create templates and validation procedures for manifest creation.
4. **Handle special characters properly** – URL encode object keys that contain special characters.
5. **Monitor object counts** – Track manifest size and split large jobs proactively.
6. **Validate object existence** – Verify objects exist before including them in manifests.
7. **Use AWS tools for manifest generation** – Leverage AWS CLI `s3api list-objects-v2` to generate properly formatted object lists.

Common manifest issues and solutions:

1. **Missing required columns** – Ensure your manifest includes all required columns for your operation type. The most common missing columns are Bucket and Key.
2. **Incorrect CSV format** – Use comma delimiters, ensure consistent column counts across all rows, and avoid embedded line breaks within fields.
3. **Special characters in object keys** – URL encode object keys that contain spaces, Unicode characters, or XML special characters (<, >, &, ", ').
4. **Large manifest files** – Split manifests with more than the operation limit into multiple smaller manifests and create separate jobs.

5. **Invalid version IDs** – Ensure version IDs are properly formatted alphanumeric strings. Remove version ID column if not needed.
6. **Encoding issues** – Save manifest files as UTF-8 without BOM. Avoid copying manifests through systems that might alter encoding.

For detailed manifest format specifications and examples, see the following:

1. [Specify a manifest](#)
2. [Operations supported by S3 Batch Operations](#)
3. [Naming Amazon S3 objects](#)

InvalidManifestContent troubleshooting

1. Download and inspect the manifest file. Manually verify the manifest meets format requirements:
 1. CSV format with comma delimiters.
 2. UTF-8 encoding without BOM.
 3. Consistent number of columns across all rows.
 4. No empty lines or trailing spaces.
 5. Object keys properly URL encoded if they contain special characters.

Use the following command to download the manifest file.

```
aws s3 cp s3://amzn-s3-demo-bucket1/manifest-key ./manifest.csv
```

2. Check required columns for your operation:
 1. All operations: Bucket, Key
 2. Copy operations: VersionId (optional)
 3. Restore operations: VersionId (optional)
 4. Replace tag operations: No additional columns required.
 5. Replace ACL operations: No additional columns required.

6. Initiate restore: VersionId (optional)
3. Check object count limits:
 1. Copy: 1 billion objects maximum.
 2. Delete: 1 billion objects maximum.
 3. Restore: 1 billion objects maximum.
 4. Tagging: 1 billion objects maximum.
 5. ACL: 1 billion objects maximum.
4. Create a test manifest with a few objects from your original manifest.
5. Use the following command to check if a sample of objects from the manifest exist.

```
aws s3 ls s3://amzn-s3-demo-bucket1/object-key
```

6. Check job failure details and review the failure reason and any specific error details in the job description.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id
```

Querying data in place with Amazon S3 Select

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

With Amazon S3 Select, you can use structured query language (SQL) statements to filter the contents of an Amazon S3 object and retrieve only the subset of data that you need. By using Amazon S3 Select to filter this data, you can reduce the amount of data that Amazon S3 transfers, which reduces the cost and latency to retrieve this data.

Amazon S3 Select only allows you to query one object at a time. It works on an object stored in CSV, JSON, or Apache Parquet format. It also works with an object that is compressed with GZIP or BZIP2 (for CSV and JSON objects only), and a server-side encrypted object. You can specify the format of the results as either CSV or JSON, and you can determine how the records in the result are delimited.

You pass SQL expressions to Amazon S3 in the request. Amazon S3 Select supports a subset of SQL. For more information about the SQL elements that are supported by Amazon S3 Select, see [SQL reference for Amazon S3 Select](#).

You can perform SQL queries by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the `SelectObjectContent` REST API operation, or the AWS SDKs.

 **Note**

The Amazon S3 console limits the amount of data returned to 40 MB. To retrieve more data, use the AWS CLI or the API.

Requirements and limits

The following are requirements for using Amazon S3 Select:

- You must have `s3:GetObject` permission for the object you are querying.
- If the object you are querying is encrypted with server-side encryption with customer-provided keys (SSE-C), you must use `https`, and you must provide the encryption key in the request.

The following limits apply when using Amazon S3 Select:

- S3 Select can query only one object per request.
- S3 Select supports querying files up to 5 TB in size.
- The maximum length of a SQL expression is 256 KB.
- The maximum length of a record in the input or result is 1 MB.
- Amazon S3 Select can only emit nested data by using the JSON output format.
- You cannot query an object stored in the S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or Reduced Redundancy Storage (RRS) storage classes. You also cannot query an object stored

in the S3 Intelligent-Tiering Archive Access tier or the S3 Intelligent-Tiering Deep Archive Access tier. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

Additional limitations apply when using Amazon S3 Select with a Parquet object:

- Amazon S3 Select supports only columnar compression using GZIP or Snappy. Amazon S3 Select doesn't support whole-object compression for a Parquet object.
- Amazon S3 Select doesn't support Parquet output. You must specify the output format as CSV or JSON.
- The maximum uncompressed row group size is 512 MB.
- You must use the data types that are specified in the object's schema.
- Selecting on a repeated field returns only the last value.

Constructing a request

When you construct a request, you provide details of the object that is being queried by using an `InputSerialization` object. You provide details of how the results are to be returned by using an `OutputSerialization` object. You also include the SQL expression that Amazon S3 uses to filter the request.

For more information about constructing an Amazon S3 Select request, see [SelectObjectContent](#) in the *Amazon Simple Storage Service API Reference*. You can also see one of the SDK code examples in the following sections.

Requests using scan ranges

With Amazon S3 Select, you can scan a subset of an object by specifying a range of bytes to query. This capability lets you parallelize scanning the whole object by splitting the work into separate Amazon S3 Select requests for a series of non-overlapping scan ranges.

Scan ranges don't need to be aligned with record boundaries. An Amazon S3 Select scan range request runs across the byte range that you specify. A record that starts within the specified scan range but extends beyond that scan range will be processed by the query. For example, the following shows an Amazon S3 object that contains a series of records in a line-delimited CSV format:

A,B
C,D
D,E
E,F
G,H
I,J

Suppose that you're using the Amazon S3 Select ScanRange parameter and *Start at (Byte) 1* and *End at (Byte) 4*. So the scan range would start at "," and scan until the end of the record starting at C. Your scan range request will return the result C, D because that is the end of the record.

Amazon S3 Select scan range requests support Parquet, CSV (without quoted delimiters), or JSON objects (in LINES mode only). CSV and JSON objects must be uncompressed. For line-based CSV and JSON objects, when a scan range is specified as part of the Amazon S3 Select request, all records that start within the scan range are processed. For Parquet objects, all of the row groups that start within the scan range requested are processed.

Amazon S3 Select scan range requests are available to use with the AWS CLI, Amazon S3 API, and AWS SDKs. You can use the ScanRange parameter in the Amazon S3 Select request for this feature. For more information, see [SelectObjectContent](#) in the *Amazon Simple Storage Service API Reference*.

Errors

Amazon S3 Select returns an error code and associated error message when an issue is encountered while attempting to run a query. For a list of error codes and descriptions, see the [List of SELECT Object Content Error Codes](#) section of the *Error Responses* page in the *Amazon Simple Storage Service API Reference*.

Examples of using Amazon S3 Select on an object

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

You can use S3 Select to select content from one object by using the Amazon S3 console, the REST API, and the AWS SDKs.

For more information about supported SQL functions for S3 Select, see [SQL functions](#).

Using the S3 console

To select content from an object in the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose the bucket that contains the object that you want to select content from, and then choose the name of the object.
4. Choose **Object actions**, and choose **Query with S3 Select**.
5. Configure **Input settings**, based on the format of your input data.
6. Configure **Output settings**, based on the format of the output that you want to receive.
7. To extract records from the chosen object, under **SQL query**, enter the SELECT SQL commands. For more information on how to write SQL commands, see [SQL reference for Amazon S3 Select](#).
8. After you enter SQL queries, choose **Run SQL query**. Then, under **Query results**, you can see the results of your SQL queries.

Using the REST API

You can use the AWS SDKs to select content from an object. However, if your application requires it, you can send REST requests directly. For more information about the request and response format, see [SelectObjectContent](#).

Using the AWS SDKs

You can use Amazon S3 Select to select some of the content of an object by using the `selectObjectContent` method. If this method is successful, it returns the results of the SQL expression.

Java

To use Amazon S3 Select with the AWS SDK for Java, you can return the value of the first column for each record that is stored in an object that contains data stored in CSV format. You can also request Progress and Stats messages to be returned. You must provide a valid bucket name and an object that contains data in CSV format.

SELECT command

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports only the SELECT SQL command. The following ANSI standard clauses are supported for SELECT:

- SELECT list
- FROM clause
- WHERE clause
- LIMIT clause

Note

Amazon S3 Select queries currently do not support subqueries or joins.

SELECT list

The SELECT list names the columns, functions, and expressions that you want the query to return. The list represents the output of the query.

```
SELECT *
SELECT projection1 AS column_alias_1, projection2 AS column_alias_2
```

The first form of SELECT with the * (asterisk) returns every row that passed the WHERE clause, as-is. The second form of SELECT creates a row with user-defined output scalar expressions *projection1* and *projection2* for each column.

FROM clause

Amazon S3 Select supports the following forms of the FROM clause:

```
FROM table_name
FROM table_name alias
FROM table_name AS alias
```

In each form of the FROM clause, *table_name* is the S3Object that's being queried. Users coming from traditional relational databases can think of this as a database schema that contains multiple views over a table.

Following standard SQL, the FROM clause creates rows that are filtered in the WHERE clause and projected in the SELECT list.

For JSON objects that are stored in Amazon S3 Select, you can also use the following forms of the FROM clause:

```
FROM S3Object[*].path
FROM S3Object[*].path alias
FROM S3Object[*].path AS alias
```

Using this form of the FROM clause, you can select from arrays or objects within a JSON object. You can specify path by using one of the following forms:

- By name (in an object): `.name` or `['name']`
- By index (in an array): `[index]`
- By wildcard character (in an object): `.*`
- By wildcard character (in an array): `[*]`

Note

- This form of the FROM clause works only with JSON objects.
- Wildcard characters always emit at least one record. If no record matches, then Amazon S3 Select emits the value MISSING. During output serialization (after the query finishes running), Amazon S3 Select replaces MISSING values with empty records.
- Aggregate functions (AVG, COUNT, MAX, MIN, and SUM) skip MISSING values.
- If you don't provide an alias when using a wildcard character, you can refer to the row by using the last element in the path. For example, you could select all prices from a list of books by using the query `SELECT price FROM S3Object[*].books[*].price`. If the path ends in a wildcard character instead of a name, then you can use the value `_1` to refer to the row. For example, instead of `SELECT price FROM S3Object[*].books[*].price`, you could use the query `SELECT _1.price FROM S3Object[*].books[*]`.
- Amazon S3 Select always treats a JSON document as an array of root-level values. Thus, even if the JSON object that you are querying has only one root element, the FROM clause must begin with `S3Object[*]`. However, for compatibility reasons, Amazon S3 Select allows you to omit the wildcard character if you don't include a path. Thus, the complete clause `FROM S3Object` is equivalent to `FROM S3Object[*] as S3Object`. If you include a path, you must also use the wildcard character. So, `FROM S3Object` and `FROM S3Object[*].path` are both valid clauses, but `FROM S3Object.path` is not.

Example

Examples:

Example #1

This example shows results when using the following dataset and query:

```
{ "Rules": [ {"id": "1"}, {"expr": "y > x"}, {"id": "2", "expr": "z = DEBUG"} ]}  
 { "created": "June 27", "modified": "July 6" }
```

```
SELECT id FROM S3Object[*].Rules[*].id
```

```
{"id":"1"}
```

```
{}
{"id":"2"}
{}
```

Amazon S3 Select produces each result for the following reasons:

- {"id":"id-1"} – S3Object[0].Rules[0].id produced a match.
- {} – S3Object[0].Rules[1].id did not match a record, so Amazon S3 Select emitted MISSING, which was then changed to an empty record during output serialization and returned.
- {"id":"id-2"} – S3Object[0].Rules[2].id produced a match.
- {} – S3Object[1] did not match on Rules, so Amazon S3 Select emitted MISSING, which was then changed to an empty record during output serialization and returned.

If you don't want Amazon S3 Select to return empty records when it doesn't find a match, you can test for the value MISSING. The following query returns the same results as the previous query, but with the empty values omitted:

```
SELECT id FROM S3Object[*].Rules[*].id WHERE id IS NOT MISSING
```

```
{"id":"1"}
{"id":"2"}
```

Example #2

This example shows results when using the following dataset and queries:

```
{ "created": "936864000", "dir_name": "important_docs", "files": [ { "name": "." },
{ "name": ".." }, { "name": ".aws" }, { "name": "downloads" } ], "owner": "Amazon
S3" }
{ "created": "936864000", "dir_name": "other_docs", "files": [ { "name": "." },
{ "name": ".." }, { "name": "my stuff" }, { "name": "backup" } ], "owner": "User" }
```

```
SELECT d.dir_name, d.files FROM S3Object[*] d
```

```
{"dir_name":"important_docs","files":[{"name":".","name":".."}, {"name":".aws"}, {"name":"downloads"}]}
```

```
{"dir_name": "other_docs", "files": [{"name": "."}, {"name": ".."}, {"name": "my stuff"}, {"name": "backup"}]}
```

```
SELECT _1.dir_name, _1.owner FROM S3Object[*]
```

```
{"dir_name": "important_docs", "owner": "Amazon S3"}  
{"dir_name": "other_docs", "owner": "User"}
```

WHERE clause

The WHERE clause follows this syntax:

```
WHERE condition
```

The WHERE clause filters rows based on the *condition*. A condition is an expression that has a Boolean result. Only rows for which the condition evaluates to TRUE are returned in the result.

LIMIT clause

The LIMIT clause follows this syntax:

```
LIMIT number
```

The LIMIT clause limits the number of records that you want the query to return based on *number*.

Attribute access

The SELECT and WHERE clauses can refer to record data by using one of the methods in the following sections, depending on whether the file that is being queried is in CSV or JSON format.

CSV

- **Column Numbers** – You can refer to the *Nth* column of a row with the column name *_N*, where *N* is the column position. The position count starts at 1. For example, the first column is named *_1* and the second column is named *_2*.

You can refer to a column as *_N* or *alias._N*. For example, *_2* and *myAlias._2* are both valid ways to refer to a column in the SELECT list and WHERE clause.

- **Column Headers** – For objects in CSV format that have a header row, the headers are available to the SELECT list and WHERE clause. In particular, as in traditional SQL, within SELECT and WHERE clause expressions, you can refer to the columns by *alias.column_name* or *column_name*.

JSON

- **Document** – You can access JSON document fields as *alias.name*. You can also access nested fields, for example, *alias.name1.name2.name3*.
- **List** – You can access elements in a JSON list by using zero-based indexes with the [] operator. For example, you can access the second element of a list as *alias[1]*. You can combine accessing list elements with fields, for example, *alias.name1.name2[1].name3*.
- **Examples:** Consider this JSON object as a sample dataset:

```
{"name": "Susan Smith",
"org": "engineering",
"projects":
  [
    {"project_name": "project1", "completed": false},
    {"project_name": "project2", "completed": true}
  ]
}
```

Example #1

The following query returns these results:

```
Select s.name from S3Object s
```

```
{"name": "Susan Smith"}
```

Example #2

The following query returns these results:

```
Select s.projects[0].project_name from S3Object s
```

```
{"project_name": "project1"}
```

Case sensitivity of header and attribute names

With Amazon S3 Select, you can use double quotation marks to indicate that column headers (for CSV objects) and attributes (for JSON objects) are case sensitive. Without double quotation marks, object headers and attributes are case insensitive. An error is thrown in cases of ambiguity.

The following examples are either 1) Amazon S3 objects in CSV format with the specified column headers, and with `FileHeaderInfo` set to "Use" for the query request; or 2) Amazon S3 objects in JSON format with the specified attributes.

Example #1: The object being queried has the header or attribute NAME.

- The following expression successfully returns values from the object. Because there are no quotation marks, the query is case insensitive.

```
SELECT s.name from S3Object s
```

- The following expression results in a 400 error `MissingHeaderName`. Because there are quotation marks, the query is case sensitive.

```
SELECT s."name" from S3Object s
```

Example #2: The Amazon S3 object being queried has one header or attribute with NAME and another header or attribute with name.

- The following expression results in a 400 error `AmbiguousFieldName`. Because there are no quotation marks, the query is case insensitive, but there are two matches, so the error is thrown.

```
SELECT s.name from S3Object s
```

- The following expression successfully returns values from the object. Because there are quotation marks, the query is case sensitive, so there is no ambiguity.

```
SELECT s."NAME" from S3Object s
```

Using reserved keywords as user-defined terms

Amazon S3 Select has a set of reserved keywords that are needed to run the SQL expressions used to query object content. Reserved keywords include function names, data types, operators, and

so on. In some cases, user-defined terms, such as the column headers (for CSV files) or attributes (for JSON objects), might clash with a reserved keyword. When this happens, you must use double quotation marks to indicate that you are intentionally using a user-defined term that clashes with a reserved keyword. Otherwise a 400 parse error will result.

For the full list of reserved keywords, see [Reserved keywords](#).

The following example is either 1) an Amazon S3 object in CSV format with the specified column headers, with `FileInfo` set to "Use" for the query request, or 2) an Amazon S3 object in JSON format with the specified attributes.

Example: The object being queried has a header or attribute named `CAST`, which is a reserved keyword.

- The following expression successfully returns values from the object. Because quotation marks are used in the query, S3 Select uses the user-defined header or attribute.

```
SELECT s."CAST" from S3Object s
```

- The following expression results in a 400 parse error. Because no quotation marks are used in the query, `CAST` clashes with a reserved keyword.

```
SELECT s.CAST from S3Object s
```

Scalar expressions

Within the `WHERE` clause and the `SELECT` list, you can have SQL *scalar expressions*, which are expressions that return scalar values. They have the following form:

- **literal**

An SQL literal.

- **column_reference**

A reference to a column in the form `column_name` or `alias.column_name`.

- **unary_op expression**

In this case, **unary_op** is an SQL unary operator.

- **expression binary_op expression**

In this case, ***binary_op*** is an SQL binary operator.

- ***func_name***

In this case, ***func_name*** is the name of the scalar function to invoke.

- ***expression* [NOT] BETWEEN *expression* AND *expression***
- ***expression* LIKE *expression* [ESCAPE *expression*]**

Data types

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports several primitive data types.

Data type conversions

The general rule is to follow the CAST function if it's defined. If CAST is not defined, then all input data is treated as a string. In that case, you must cast your input data into the relevant data types when necessary.

For more information about the CAST function, see [CAST](#).

Supported data types

Amazon S3 Select supports the following set of primitive data types.

Name	Description	Examples
bool	A Boolean value, either TRUE or FALSE.	FALSE
int, integer	An 8-byte signed integer in the range -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807.	100000
string	A UTF8-encoded variable-length string. The default limit is 1 character. The maximum character limit is 2,147,483,647.	'xyz'

Name	Description	Examples
float	An 8-byte floating point number.	CAST(0.456 AS FLOAT)
decimal, numeric	A base-10 number, with a maximum precision of 38 (that is, the maximum number of significant digits), and with a scale within the range of -2^{31} to $2^{31}-1$ (that is, the base-10 exponent).	123.456
timestamp	<p>Timestamps represent a specific moment in time, always include a local offset, and are capable of arbitrary precision .</p> <p>In the text format, timestamps follow the W3C note on date and time formats, but they must end with the literal T if the timestamps are not at least whole-day precision. Fractional seconds are allowed, with at least one digit of precision, and an unlimited maximum. Local-time offsets can be represented as either hour:minute offsets from UTC, or as the literal Z to denote a local time of UTC. Local-time offsets are required on timestamps with time and are not allowed on date values.</p>	CAST('2007-04-05T14:30Z' AS TIMESTAMP)

Supported Parquet types

Amazon S3 Select supports the following Parquet types.

- DATE
- DECIMAL

- ENUM
- INT(8)
- INT(16)
- INT(32)
- INT(64)
- LIST

 **Note**

For LIST Parquet type output, Amazon S3 Select supports only JSON format. However, if the query limits the data to simple values, the LIST Parquet type can also be queried in CSV format.

- STRING
- TIMESTAMP supported precision (MILLIS/MICROS/NANOS)

 **Note**

Timestamps saved as an INT(96) are unsupported.

Because of the range of the INT(64) type, timestamps that are using the NANOS unit can represent only values between 1677-09-21 00:12:43 and 2262-04-11 23:47:16. Values outside of this range cannot be represented with the NANOS unit.

Mapping of Parquet types to supported data types in Amazon S3 Select

Parquet types	Supported data types
DATE	timestamp
DECIMAL	decimal, numeric
ENUM	string

Parquet types	Supported data types
INT(8)	int, integer
INT(16)	int, integer
INT(32)	int, integer
INT(64)	decimal, numeric
LIST	Each Parquet type in list is mapped to the corresponding data type.
STRING	string
TIMESTAMP	timestamp

Operators

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports the following operators.

Logical operators

- AND
- NOT
- OR

Comparison operators

- <
- >
- <=
- >=
- =
- <>
- !=
- BETWEEN
- IN – For example: IN ('a', 'b', 'c')

Pattern-matching operators

- LIKE
- _ (Matches any character)
- % (Matches any sequence of characters)

Unitary operators

- IS NULL
- IS NOT NULL

Math operators

Addition, subtraction, multiplication, division, and modulo are supported, as follows:

- +
- -
- *
- /
- %

Operator precedence

The following table shows the operators' precedence in decreasing order.

Operator or element	Associativity	Required
-	right	unary minus
*, /, %	left	multiplication, division, modulo
+, -	left	addition, subtraction
IN		set membership
BETWEEN		range containment
LIKE		string pattern matching
<>		less than, greater than
=	right	equality, assignment
NOT	right	logical negation
AND	left	logical conjunction
OR	left	logical disjunction

SQL functions

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports the following SQL functions.

Topics

- [Aggregate functions](#)
- [Conditional functions](#)
- [Conversion functions](#)
- [Date functions](#)
- [String functions](#)

Aggregate functions

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports the following aggregate functions.

Function	Argument type	Return type
AVG(<i>expression</i>)	INT, FLOAT, DECIMAL	DECIMAL for an INT argument, FLOAT for a floating-point argument; otherwise the same as the

Function	Argument type	Return type
		argument data type.
COUNT	-	INT
MAX(<i>expressic</i> <i>n</i>)	INT, DECIMAL	Same as the argument type.
MIN(<i>expressic</i> <i>n</i>)	INT, DECIMAL	Same as the argument type.
SUM(<i>expressic</i> <i>n</i>)	INT, FLOAT, DOUBLE, DECIMAL	INT for an INT argument, FLOAT for a floating-point argument; otherwise, the same as the argument data type.

SUM example

To aggregate the total object sizes of a folder in an [S3 Inventory report](#), use a SUM expression.

The following S3 Inventory report is a CSV file that's compressed with GZIP. There are three columns.

- The first column is the name of the S3 bucket ([DOC-EXAMPLE-BUCKET](#)) that the S3 Inventory report is for.
- The second column is the object key name that uniquely identifies the object in the bucket.

The *example-folder/* value in the first row is for the folder *example-folder*. In Amazon S3, when you create a folder in your bucket, S3 creates a 0-byte object with a key that's set to the folder name that you provided.

The *example-folder/object1* value in the second row is for the object *object1* in the folder *example-folder*.

The *example-folder/object2* value in the third row is for the object *object2* in the folder *example-folder*.

For more information about S3 folders, see [Organizing objects in the Amazon S3 console by using folders](#).

- The third column is the object size in bytes.

```
"DOC-EXAMPLE-BUCKET","example-folder/", "0"  
"DOC-EXAMPLE-BUCKET","example-folder/object1", "2011267"  
"DOC-EXAMPLE-BUCKET","example-folder/object2", "1570024"
```

To use a SUM expression to calculate the total size of the folder *example-folder*, run the SQL query with Amazon S3 Select.

```
SELECT SUM(CAST(_3 as INT)) FROM s3object s WHERE _2 LIKE '%example-folder/%' AND _2 != 'example-folder/' ;
```

Query Result:

```
3581291
```

Conditional functions

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports the following conditional functions.

Topics

- [CASE](#)
- [COALESCE](#)

- [NULLIF](#)

CASE

The CASE expression is a conditional expression, similar to `if/then/else` statements found in other languages. CASE is used to specify a result when there are multiple conditions. There are two types of CASE expressions: simple and searched.

In simple CASE expressions, an expression is compared with a value. When a match is found, the specified action in the `THEN` clause is applied. If no match is found, the action in the `ELSE` clause is applied.

In searched CASE expressions, each CASE is evaluated based on a Boolean expression, and the CASE statement returns the first matching CASE. If no matching CASE is found among the `WHEN` clauses, the action in the `ELSE` clause is returned.

Syntax

Note

Currently, Amazon S3 Select doesn't support `ORDER BY` or queries that contain new lines. Make sure that you use queries with no line breaks.

The following is a simple CASE statement that's used to match conditions:

```
CASE expression WHEN value THEN result [WHEN...] [ELSE result] END
```

The following is a searched CASE statement that's used to evaluate each condition:

```
CASE WHEN boolean condition THEN result [WHEN ...] [ELSE result] END
```

Examples

Note

If you use the Amazon S3 console to run the following examples and your CSV file contains a header row, choose **Exclude the first line of CSV data**.

Example 1: Use a simple CASE expression to replace New York City with Big Apple in a query. Replace all other city names with other.

```
SELECT venuecity, CASE venuecity WHEN 'New York City' THEN 'Big Apple' ELSE 'other' END  
FROM S3object;
```

Query result:

venuecity	case
Los Angeles	other
New York City	Big Apple
San Francisco	other
Baltimore	other
...	

Example 2: Use a searched CASE expression to assign group numbers based on the pricepaid value for individual ticket sales:

```
SELECT pricepaid, CASE WHEN CAST(pricepaid as FLOAT) < 10000 THEN 'group 1' WHEN  
CAST(pricepaid as FLOAT) > 10000 THEN 'group 2' ELSE 'group 3' END FROM S3object;
```

Query result:

pricepaid	case
12624.00	group 2
10000.00	group 3
10000.00	group 3
9996.00	group 1
9988.00	group 1
...	

COALESCE

COALESCE evaluates the arguments in order and returns the first non-unknown value, that is, the first non-null or non-missing value. This function does not propagate null and missing values.

Syntax

```
COALESCE ( expression, expression, ... )
```

Parameters

expression

The target expression that the function operates on.

Examples

```
COALESCE(1)          -- 1
COALESCE(null)        -- null
COALESCE(null, null)  -- null
COALESCE(missing)     -- null
COALESCE(missing, missing) -- null
COALESCE(1, null)      -- 1
COALESCE(null, null, 1) -- 1
COALESCE(null, 'string') -- 'string'
COALESCE(missing, 1)    -- 1
```

NULLIF

Given two expressions, NULLIF returns NULL if the two expressions evaluate to the same value; otherwise, NULLIF returns the result of evaluating the first expression.

Syntax

```
NULLIF ( expression1, expression2 )
```

Parameters

expression1, *expression2*

The target expressions that the function operates on.

Examples

```
NULLIF(1, 1)          -- null
NULLIF(1, 2)          -- 1
NULLIF(1.0, 1)         -- null
NULLIF(1, '1')         -- 1
NULLIF([1], [1])       -- null
NULLIF(1, NULL)        -- 1
```

```
NULLIF(NULL, 1)          -- null
NULLIF(null, null)       -- null
NULLIF(missing, null)    -- null
NULLIF(missing, missing) -- null
```

Conversion functions

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports the following conversion function.

Topics

- [CAST](#)

CAST

The CAST function converts an entity, such as an expression that evaluates to a single value, from one type to another.

Syntax

```
CAST ( expression AS data_type )
```

Parameters

expression

A combination of one or more values, operators, and SQL functions that evaluate to a value.

data_type

The target data type, such as INT, to cast the expression to. For a list of supported data types, see [Data types](#).

Examples

```
CAST('2007-04-05T14:30Z' AS TIMESTAMP)
```

```
CAST(0.456 AS FLOAT)
```

Date functions

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports the following date functions.

Topics

- [DATE_ADD](#)
- [DATE_DIFF](#)
- [EXTRACT](#)
- [TO_STRING](#)
- [TO_TIMESTAMP](#)
- [UTCNOW](#)

DATE_ADD

Given a date part, a quantity, and a timestamp, DATE_ADD returns an updated timestamp by altering the date part by the quantity.

Syntax

```
DATE_ADD( date_part, quantity, timestamp )
```

Parameters

date_part

Specifies which part of the date to modify. This can be one of the following:

- year
- month

- day
- hour
- minute
- second

quantity

The value to apply to the updated timestamp. Positive values for *quantity* add to the timestamp's date_part, and negative values subtract.

timestamp

The target timestamp that the function operates on.

Examples

```
DATE_ADD(year, 5, `2010-01-01T`)  
    -- 2015-01-01 (equivalent to  
    -- 2015-01-01T)  
DATE_ADD(month, 1, `2010T`)  
    -- 2010-02T (result will add precision  
    as necessary)  
DATE_ADD(month, 13, `2010T`)  
    -- 2011-02T  
DATE_ADD(day, -1, `2017-01-10T`)  
    -- 2017-01-09 (equivalent to  
    -- 2017-01-09T)  
DATE_ADD(hour, 1, `2017T`)  
    -- 2017-01-01T01:00-00:00  
DATE_ADD(hour, 1, `2017-01-02T03:04Z`)  
    -- 2017-01-02T04:04Z  
DATE_ADD(minute, 1, `2017-01-02T03:04:05.006Z`)  
    -- 2017-01-02T03:05:05.006Z  
DATE_ADD(second, 1, `2017-01-02T03:04:05.006Z`)  
    -- 2017-01-02T03:04:06.006Z
```

DATE_DIFF

Given a date part and two valid timestamps, DATE_DIFF returns the difference in date parts. The return value is a negative integer when the *date_part* value of *timestamp1* is greater than the *date_part* value of *timestamp2*. The return value is a positive integer when the *date_part* value of *timestamp1* is less than the *date_part* value of *timestamp2*.

Syntax

```
DATE_DIFF( date_part, timestamp1, timestamp2 )
```

Parameters

date_part

Specifies which part of the timestamps to compare. For the definition of date_part, see [DATE_ADD](#).

timestamp1

The first timestamp to compare.

timestamp2

The second timestamp to compare.

Examples

```
DATE_DIFF(year, `2010-01-01T`, `2011-01-01T`)          -- 1
DATE_DIFF(year, `2010T`, `2010-05T`)                   -- 4 (2010T is equivalent to
2010-01-01T00:00:00.000Z)
DATE_DIFF(month, `2010T`, `2011T`)                    -- 12
DATE_DIFF(month, `2011T`, `2010T`)                    -- -12
DATE_DIFF(day, `2010-01-01T23:00`, `2010-01-02T01:00`) -- 0 (need to be at least 24h
apart to be 1 day apart)
```

EXTRACT

Given a date part and a timestamp, EXTRACT returns the timestamp's date part value.

Syntax

```
EXTRACT( date_part FROM timestamp )
```

Parameters

date_part

Specifies which part of the timestamps to extract. This can be one of the following:

- YEAR
- MONTH
- DAY

- HOUR
- MINUTE
- SECOND
- TIMEZONE_HOUR
- TIMEZONE_MINUTE

timestamp

The target timestamp that the function operates on.

Examples

```
EXTRACT(YEAR FROM `2010-01-01T` )                                -- 2010
EXTRACT(MONTH FROM `2010T` )                                         -- 1 (equivalent to
2010-01-01T00:00:00.000Z)
EXTRACT(MONTH FROM `2010-10T` )                                     -- 10
EXTRACT(HOUR FROM `2017-01-02T03:04:05+07:08` )                   -- 3
EXTRACT(MINUTE FROM `2017-01-02T03:04:05+07:08` )                 -- 4
EXTRACT(TIMEZONE_HOUR FROM `2017-01-02T03:04:05+07:08` )           -- 7
EXTRACT(TIMEZONE_MINUTE FROM `2017-01-02T03:04:05+07:08` )          -- 8
```

TO_STRING

Given a timestamp and a format pattern, TO_STRING returns a string representation of the timestamp in the given format.

Syntax

```
TO_STRING ( timestamp time_format_pattern )
```

Parameters

timestamp

The target timestamp that the function operates on.

time_format_pattern

A string that has the following special character interpretations:

Format	Example	Description
yy	69	2-digit year
y	1969	4-digit year
yyyy	1969	Zero-padded 4-digit year
M	1	Month of year
MM	01	Zero-padded month of year
MMM	Jan	Abbreviated month year name
MMMM	January	Full month of year name
MMMMM	J	Month of year first letter (NOTE: This format is not valid for use with the TO_TIMESTAMP function.)
d	2	Day of month (1-31)
dd	02	Zero-padded day of month (01-31)

Format	Example	Description
a	AM	AM or PM of day
h	3	Hour of day (1-12)
hh	03	Zero-padded hour of day (0 1-12)
H	3	Hour of day (0-23)
HH	03	Zero-padded hour of day (0 0-23)
m	4	Minute of hour (0-59)
mm	04	Zero-padded minute of hour (00-59)
s	5	Second of minute (0-59)
ss	05	Zero-padded second of minute (00-59)
S	0	Fraction of a second (precision: 0.1, range: 0.0-0.9)

Format	Example	Description
SS	6	Fraction of a second (precision: 0.01, range: 0.0-0.99)
SSS	60	Fraction of a second (precision: 0.001, range: 0.0-0.999)
...
SSSSSSSS	60000000	Fraction of a second (maximum precision: 1 nanosecond, range: 0.0-0.999999999)
n	60000000	Nano of a second
X	+07 or Z	Offset in hours, or Z if the offset is 0
XX or XXXX	+0700 or Z	Offset in hours and minutes, or Z if the offset is 0

Format	Example	Description
XXX or XXXXX	+07:00 or Z	Offset in hours and minutes, or Z if the offset is 0
x	7	Offset in hours
xx or xxxx	700	Offset in hours and minutes
xxx or xxxxx	+07:00	Offset in hours and minutes

Examples

```

TO_STRING(`1969-07-20T20:18Z`, 'MMMM d, y')          -- "July 20, 1969"
TO_STRING(`1969-07-20T20:18Z`, 'MMM d, yyyy')        -- "Jul 20, 1969"
TO_STRING(`1969-07-20T20:18Z`, 'M-d-yy')             -- "7-20-69"
TO_STRING(`1969-07-20T20:18Z`, 'MM-d-y')             -- "07-20-1969"
TO_STRING(`1969-07-20T20:18Z`, 'MMMM d, y h:m a')    -- "July 20, 1969 8:18 PM"
TO_STRING(`1969-07-20T20:18Z`, 'y-MM-dd''T''H:m:ssX') -- "1969-07-20T20:18:00Z"
TO_STRING(`1969-07-20T20:18+08:00Z`, 'y-MM-dd''T''H:m:ssX') -- "1969-07-20T20:18:00Z"
TO_STRING(`1969-07-20T20:18+08:00`, 'y-MM-dd''T''H:m:ssXXXX') -- "1969-07-20T20:18:00+0800"
TO_STRING(`1969-07-20T20:18+08:00`, 'y-MM-dd''T''H:m:ssXXXX') -- "1969-07-20T20:18:00+08:00"

```

TO_TIMESTAMP

Given a string, TO_TIMESTAMP converts it to a timestamp. TO_TIMESTAMP is the inverse operation of TO_STRING.

Syntax

```
TO_TIMESTAMP ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
TO_TIMESTAMP('2007T')          -- `2007T'  
TO_TIMESTAMP('2007-02-23T12:14:33.079-08:00') -- `2007-02-23T12:14:33.079-08:00`
```

UTCNOW

UTCNOW returns the current time in UTC as a timestamp.

Syntax

```
UTCNOW()
```

Parameters

UTCNOW takes no parameters.

Examples

```
UTCNOW() -- 2017-10-13T16:02:11.123Z
```

String functions

Important

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#)

Amazon S3 Select supports the following string functions.

Topics

- [CHAR_LENGTH, CHARACTER_LENGTH](#)
- [LOWER](#)
- [SUBSTRING](#)
- [TRIM](#)
- [UPPER](#)

CHAR_LENGTH, CHARACTER_LENGTH

CHAR_LENGTH (or CHARACTER_LENGTH) counts the number of characters in the specified string.

Note

CHAR_LENGTH and CHARACTER_LENGTH are synonyms.

Syntax

```
CHAR_LENGTH ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
CHAR_LENGTH('')          -- 0  
CHAR_LENGTH('abcdefg')  -- 7
```

LOWER

Given a string, LOWER converts all uppercase characters to lowercase characters. Any non-upercased characters remain unchanged.

Syntax

```
LOWER ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
LOWER('AbCdEfG!@#$') -- 'abcdefg!@#$'
```

SUBSTRING

Given a string, a start index, and optionally a length, SUBSTRING returns the substring from the start index up to the end of the string, or up to the length provided.

Note

The first character of the input string has an index position of 1.

- If `start` is < 1, with no length specified, then the index position is set to 1.
- If `start` is < 1, with a length specified, then the index position is set to `start` + `length` - 1.
- If `start` + `length` - 1 < 0, then an empty string is returned.
- If `start` + `length` - 1 >= 0, then the substring starting at index position 1 with the length `start` + `length` - 1 is returned.

Syntax

```
SUBSTRING( string FROM start [ FOR length ] )
```

Parameters

string

The target string that the function operates on.

start

The start position of the string.

length

The length of the substring to return. If not present, proceed to the end of the string.

Examples

```
SUBSTRING("123456789", 0)      -- "123456789"  
SUBSTRING("123456789", 1)      -- "123456789"  
SUBSTRING("123456789", 2)      -- "23456789"  
SUBSTRING("123456789", -4)     -- "123456789"  
SUBSTRING("123456789", 0, 999)  -- "123456789"  
SUBSTRING("123456789", 1, 5)    -- "12345"
```

TRIM

Trims leading or trailing characters from a string. The default character to remove is a space (' ').

Syntax

```
TRIM ( [[LEADING | TRAILING | BOTH remove_chars] FROM] string )
```

Parameters

string

The target string that the function operates on.

LEADING | TRAILING | BOTH

This parameter indicates whether to trim leading or trailing characters, or both leading and trailing characters.

remove_chars

The set of characters to remove. *remove_chars* can be a string with a length > 1. This function returns the string with any character from *remove_chars* found at the beginning or end of the string that was removed.

Examples

```
TRIM('      foobar      ')          -- 'foobar'  
TRIM('  \tfoobar\t  ')           -- '\tfoobar\t'  
TRIM(LEADING FROM '      foobar      ') -- 'foobar      '  
TRIM(TRAILING FROM '      foobar      ') -- '      foobar'  
TRIM(BOTH FROM '      foobar      ') -- 'foobar'  
TRIM(BOTH '12' FROM '1112211foobar2221122') -- 'foobar'
```

UPPER

Given a string, UPPER converts all lowercase characters to uppercase characters. Any non-lowercased characters remain unchanged.

Syntax

```
UPPER ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
UPPER('AbCdEfG!@#$') -- 'ABCDEFG!@#$'
```

Working with directory buckets

Directory buckets organize data hierarchically into directories as opposed to the flat storage structure of general purpose buckets. There aren't prefix limits for directory buckets, and individual directories can scale horizontally.

You can create up to 100 directory buckets in each of your AWS accounts, with no limit on the number of objects that you can store in a bucket. Your bucket quota is applied to each Region in your AWS account. If your application requires increasing this limit, contact Support.

Important

Directory buckets in Availability Zones that have no request activity for a period of at least 90 days transition to an inactive state. While in an inactive state, a directory bucket is temporarily inaccessible for reads and writes. Inactive buckets retain all storage, object metadata, and bucket metadata. Existing storage charges apply to inactive buckets. If you make an access request to an inactive bucket, the bucket transitions to an active state, typically within a few minutes. During this transition period, reads and writes return an HTTP 503 (Service Unavailable) error code. This doesn't apply to buckets in Local Zones.

There are several types of Amazon S3 buckets. Before creating a bucket, make sure that you choose the bucket type that best fits your application and performance requirements. For more information about the various bucket types and the appropriate use cases for each, see [Buckets](#).

The following topics provide information about directory buckets. For more information about general purpose buckets, see [General purpose buckets overview](#).

For more information about directory buckets, see the following topics.

- [Directory bucket names](#)
- [Directories](#)
- [Key names](#)
- [Access management](#)

Directory bucket names

A directory bucket name consists of a base name that you provide and a suffix that contains the ID of the Zone (Availability Zone or Local Zone) that your bucket is located in. Directory bucket names must use the following format and follow the naming rules for directory buckets:

bucket-base-name--zone-id--x-s3

For example, the following directory bucket name contains the Availability Zone ID usw2-az1:

bucket-base-name--usw2-az1--x-s3

For more information, see [Directory bucket naming rules](#).

Directories

Directory buckets organize data hierarchically into directories as opposed to the flat sorting structure of general purpose buckets.

With a hierarchical namespace, the delimiter in the object key is important. The only supported delimiter is a forward slash (/). Directories are determined by delimiter boundaries. For example, the object key dir1/dir2/file1.txt results in the directories dir1/ and dir2/ being automatically created, and the object file1.txt being added to the /dir2 directory in the path dir1/dir2/file1.txt.

The directory bucket indexing model returns unsorted results for the `ListObjectsV2` API operation. If you need to limit your results to a subsection of your bucket, you can specify a subdirectory path in the `prefix` parameter, for example, `prefix=dir1/`.

Key names

For directory buckets, subdirectories that are common to multiple object keys are created with the first object key. Additional object keys for the same subdirectory use the previously created subdirectory. This model gives you flexibility in choosing object keys that are best suited to the application, with equal support for sparse and dense directories.

Access management

Directory buckets have all S3 Block Public Access settings enabled by default at the bucket level. S3 Object Ownership is set to bucket owner enforced and access control lists (ACLs) are disabled. These settings can't be modified.

By default, users don't have permissions for directory buckets. To grant access permissions for directory buckets, you can use IAM to create users, groups, or roles and attach permissions to those identities. For more information, see [Authorizing Regional endpoint API operations with IAM](#).

You can also control access to directory buckets through access points. Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are unique hostnames you create to enforce distinct permissions and network controls for all requests made through an access point. For more information, see [Managing access to shared datasets in directory buckets with access points](#).

Directory buckets quotas

Quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. The following are the quotas for directory buckets. For more information on quotas in Amazon S3, see [Amazon S3 quotas](#).

Name	Default	Adjustable	Description
Directory buckets	Each Account: 100	Yes	The number of Amazon S3 directory buckets that you can create in an account.
Read TPS per directory bucket	Each directory bucket: up to 200,000 read TPS	To request a quota increase, contact Support .	The number of GET/HEAD requests per second per directory bucket.
Write TPS per directory bucket	Each directory bucket: up to 100,000 write TPS	To request a quota increase, contact Support .	The number of PUT/DELETE requests per second per directory bucket.

Use cases for directory buckets

Directory buckets support bucket creation in the following bucket location types: Availability Zone or Local Zone.

For low latency use cases, you can create a directory bucket in a single Availability Zone to store data. Directory buckets in Availability Zones support the S3 Express One Zone storage class. S3 Express One Zone storage class is recommended if your application is performance sensitive and benefits from single-digit millisecond PUT and GET latencies. To learn more about creating directory buckets in Availability Zones, see [High performance workloads](#).

For data residency use cases, you can create a directory bucket in a single AWS Dedicated Local Zone (DLZ) to store data. Directory buckets in Local Zones support the S3 One Zone-Infrequent Access (S3 One Zone-IA; Z-IA) storage class. To learn more about creating directory buckets in Local Zones, see [Data residency workloads](#).

- [High performance workloads](#)
- [Data residency workloads](#)

High performance workloads

S3 Express One Zone

You can use Amazon S3 Express One Zone for high-performance workloads. S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources which provides the highest possible access speed. Objects in S3 Express One Zone are stored in directory buckets located in Availability Zones. For more information on directory buckets, see [Directory buckets](#).

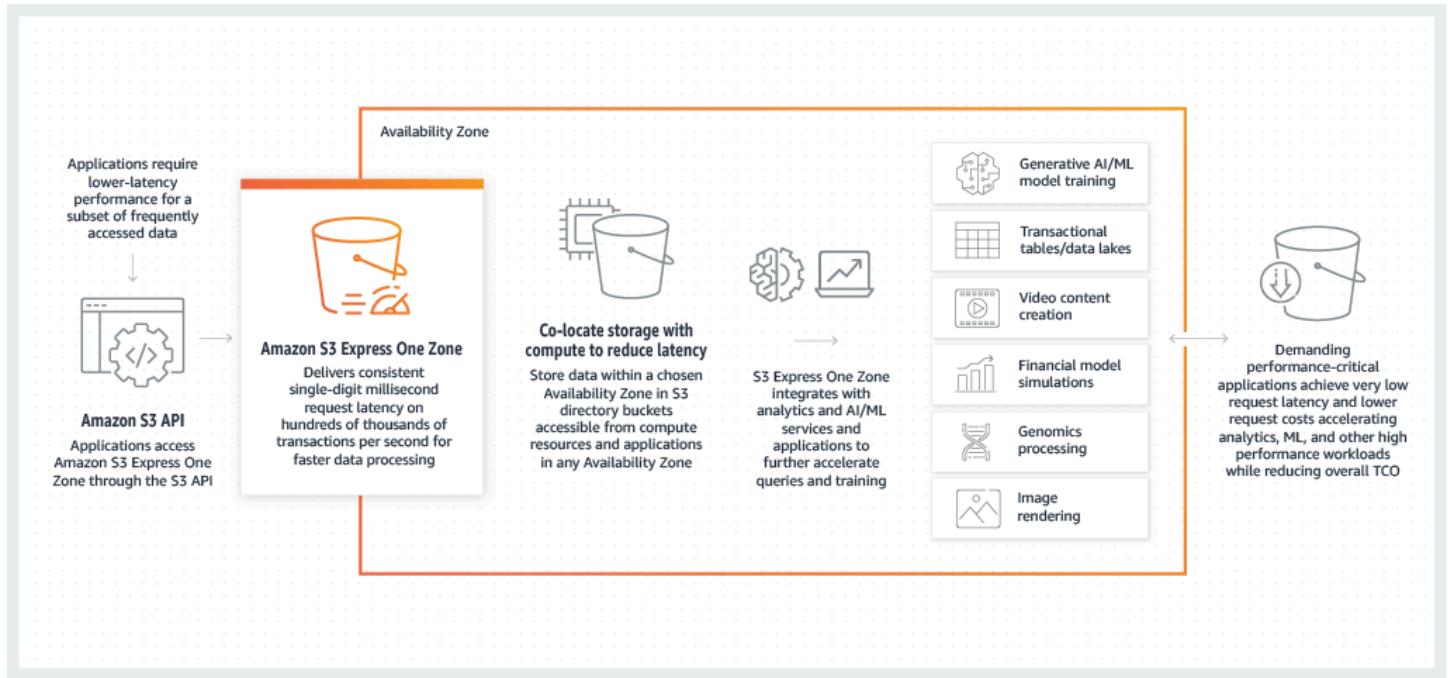

Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud-object storage class available today, with data access speeds up to 10x faster and with request costs 50 percent lower than S3 Standard. Applications can benefit immediately from requests being completed up to an order of magnitude faster. S3 Express One Zone provides similar performance elasticity as other S3 storage classes. S3 Express One Zone is used for workloads or performance-critical applications that require consistent single-digit millisecond latency.

As with other Amazon S3 storage classes, you don't need to plan or provision capacity or throughput requirements in advance. You can scale your storage up or down, based on need, and access your data through the Amazon S3 API.

The Amazon S3 Express One Zone storage class is designed for 99.95 percent availability within a single Availability Zone and is backed by the [Amazon S3 Service Level Agreement](#). With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy. If the existing device encounters a failure, S3 Express One Zone

automatically shifts requests to new devices within an Availability Zone. This redundancy helps ensure uninterrupted access to your data within an Availability Zone.

S3 Express One Zone is ideal for any application where it's important to minimize the latency required to access an object. Such applications can be human-interactive workflows, like video editing, where creative professionals need responsive access to content from their user interfaces. S3 Express One Zone also benefits analytics and machine learning workloads that have similar responsiveness requirements from their data, especially workloads with lots of smaller accesses or large numbers of random accesses. S3 Express One Zone can be used with other AWS services to support analytics and artificial intelligence and machine learning (AI/ML) workloads, such as Amazon EMR, Amazon SageMaker AI, and Amazon Athena.

For the directory buckets that use the S3 Express One Zone storage class, data is stored across multiple devices within a single Availability Zone but doesn't store data redundantly across Availability Zones. When you create a directory bucket to use the S3 Express One Zone storage class, we recommend that you specify an AWS Region and an Availability Zone that's local to your Amazon EC2, Amazon Elastic Kubernetes Service, or Amazon Elastic Container Service (Amazon ECS) compute instances to optimize performance.

When using S3 Express One Zone, you can interact with your directory bucket in a virtual private cloud (VPC) by using a gateway VPC endpoint. With a gateway endpoint, you can access S3 Express One Zone directory buckets from your VPC without an internet gateway or NAT device for your VPC, and at no additional cost.

You can use many of the same Amazon S3 API operations and features with directory buckets that you use with general purpose buckets and other storage classes. These include Mountpoint for Amazon S3, server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), S3 Batch Operations, and S3 Block Public Access. You can access S3 Express One Zone by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, and the Amazon S3 REST API.

Overview

To optimize performance and reduce latency, S3 Express One Zone introduces the following new concepts.

Availability Zones

The Amazon S3 Express One Zone storage class is designed for 99.95 percent availability within a single Availability Zone and is backed by the [Amazon S3 Service Level Agreement](#). With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy. If the existing device encounters a failure, S3 Express One Zone automatically shifts requests to new devices within an Availability Zone. This redundancy helps ensure uninterrupted access to your data within an Availability Zone.

An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. When you create a directory bucket, you choose the Availability Zone and AWS Region where your bucket will be located.

Single Availability Zone

When you create a directory bucket, you choose the Availability Zone and AWS Region.

Directory buckets use the S3 Express One Zone storage class, which is built to be used by performance-sensitive applications. S3 Express One Zone is the first S3 storage class where you can

select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed.

With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed for 99.95 percent availability within a single Availability Zone and is backed by the [Amazon S3 Service Level Agreement](#). For more information, see [Availability Zones](#)

Endpoints and gateway VPC endpoints

Bucket-management API operations for directory buckets are available through a Regional endpoint and are referred to as Regional endpoint API operations. Examples of Regional endpoint API operations are `CreateBucket` and `DeleteBucket`. After you create a directory bucket, you can use Zonal endpoint API operations to upload and manage the objects in your directory bucket. Zonal endpoint API operations are available through a Zonal endpoint. Examples of Zonal endpoint API operations are `PutObject` and `CopyObject`.

You can access S3 Express One Zone from your VPC by using gateway VPC endpoints. After you create a gateway endpoint, you can add it as a target in your route table for traffic destined from your VPC to S3 Express One Zone. As with Amazon S3, there is no additional charge for using gateway endpoints. For more information about how to configure gateway VPC endpoints, see [Networking for directory buckets](#)

Session-based authorization

With S3 Express One Zone, you authenticate and authorize requests through a new session-based mechanism that is optimized to provide the lowest latency. You can use `CreateSession` to request temporary credentials that provide low-latency access to your bucket. These temporary credentials are scoped to a specific S3 directory bucket. Session tokens are used only with Zonal (object-level) operations (with the exception of [CopyObject](#)). For more information, see [Authorizing Zonal endpoint API operations with CreateSession](#).

The [supported AWS SDKs for S3 Express One Zone](#) handle session establishment and refreshment on your behalf. To protect your sessions, temporary security credentials expire after 5 minutes. After you download and install the AWS SDKs and configure the necessary AWS Identity and Access Management (IAM) permissions, you can immediately start using API operations.

Features of S3 Express One Zone

The following S3 features are available for S3 Express One Zone. For a complete list of supported API operations and unsupported features, see [Differences for directory buckets](#).

Access management and security

You can use the following features to audit and manage access. By default, directory buckets are private and can be accessed only by users who are explicitly granted access. Unlike general purpose buckets, which can set the access control boundary at the bucket, prefix, or object tag level, the access control boundary for directory buckets is set only at the bucket level. For more information, see [Authorizing Regional endpoint API operations with IAM](#).

- [S3 Block Public Access](#) – All S3 Block Public Access settings are enabled by default at the bucket level. This default setting can't be modified.
- [S3 Object Ownership](#) (bucket owner enforced by default) – Access control lists (ACLs) are not supported for directory buckets. Directory buckets automatically use the bucket owner enforced setting for S3 Object Ownership. Bucket owner enforced means that ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. This default setting can't be modified.
- [AWS Identity and Access Management \(IAM\)](#) – IAM helps you securely control access to your directory buckets. You can use IAM to grant access to bucket management (Regional) API operations and object management (Zonal) API operations through the `s3express:CreateSession` action. For more information, see [Authorizing Regional endpoint API operations with IAM](#). Unlike object-management actions, bucket management actions cannot be cross-account. Only the bucket owner can perform those actions.
- [Bucket policies](#) – Use IAM-based policy language to configure resource-based permissions for your directory buckets. You can also use IAM to control access to the `CreateSession` API operation, which allows you to use the Zonal, or object management, API operations. You can grant same-account or cross-account access to Zonal API operations. For more information about S3 Express One Zone permissions and policies, see [Authorizing Regional endpoint API operations with IAM](#).
- [IAM Access Analyzer for S3](#) – Evaluate and monitor your access policies to make sure that the policies provide only the intended access to your S3 resources.

Logging and monitoring

S3 Express One Zone uses the following S3 logging and monitoring tools that you can use to monitor and control how your resources are being used:

- [Amazon CloudWatch metrics](#) – Monitor your AWS resources and applications by using CloudWatch to collect and track metrics. S3 Express One Zone uses the same CloudWatch

namespace as other Amazon S3 storage classes (AWS/S3) and supports daily storage metrics for directory buckets: `BucketSizeBytes` and `NumberOfObjects`. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

- [AWS CloudTrail logs](#) – AWS CloudTrail is an AWS service that helps you implement operational and risk auditing, governance, and compliance of your AWS account by recording the actions taken by a user, role, or an AWS service. For S3 Express One Zone, CloudTrail captures Regional endpoint API operations (for example, `CreateBucket` and `PutBucketPolicy`) as management events and Zonal API operations (for example, `GetObject` and `PutObject`) as data events. These events include actions taken in the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, and AWS API operations. For more information, see [Logging with AWS CloudTrail for S3 Express One Zone](#).

 **Note**

Amazon S3 server access logs aren't supported with S3 Express One Zone.

Object management

You can manage your object storage by using the Amazon S3 console, AWS SDKs, and AWS CLI. The following features are available for object management with S3 Express One Zone:

- [S3 Batch Operations](#) – Use Batch Operations to perform bulk operations on objects in directory buckets, for example, **Copy** and **Invoke AWS Lambda function**. For example, you can use Batch Operations to copy objects between directory buckets and general purpose buckets. With Batch Operations, you can manage billions of objects at scale with a single S3 request by using the AWS SDKs or AWS CLI or a few clicks in the Amazon S3 console.
- [Import](#) – After you create a directory bucket, you can populate your bucket with objects by using the import feature in the Amazon S3 console. Import is a streamlined method for creating Batch Operations jobs to copy objects from general purpose buckets to directory buckets.

AWS SDKs and client libraries

You can manage your object storage by using the AWS SDKs and client libraries.

- [Mountpoint for Amazon S3](#) – Mountpoint for Amazon S3 is an open source file client that delivers high-throughput access, lowering compute costs for data lakes on Amazon S3.

Mountpoint for Amazon S3 translates local file system API calls to S3 object API calls like GET and LIST. It is ideal for read-heavy data lake workloads that process petabytes of data and need the high elastic throughput provided by Amazon S3 to scale up and down across thousands of instances.

- [S3A](#) – S3A is a recommended Hadoop-compatible interface for accessing data stores in Amazon S3. S3A replaces the S3N Hadoop file system client.
- [PyTorch on AWS](#) – PyTorch on AWS is an open source deep-learning framework that makes it easier to develop machine learning models and deploy them to production.
- [AWS SDKs](#) – You can use the AWS SDKs when developing applications with Amazon S3. The AWS SDKs simplify your programming tasks by wrapping the underlying Amazon S3 REST API. For more information about using the AWS SDKs with S3 Express One Zone, see [the section called "AWS SDKs"](#).

Encryption and data protection

Objects in S3 Express One Zone are automatically encrypted by server-side encryption with Amazon S3 managed keys (SSE-S3). S3 Express One Zone also supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). S3 Express One Zone doesn't support server-side encryption with customer-provided encryption keys (SSE-C), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information, see [Data protection and encryption](#).

S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32C, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.

For more information, see [S3 additional checksum best practices](#).

AWS Signature Version 4 (SigV4)

S3 Express One Zone uses AWS Signature Version 4 (SigV4). SigV4 is a signing protocol used to authenticate requests to Amazon S3 over HTTPS. S3 Express One Zone signs requests by using AWS Sigv4. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the [Amazon Simple Storage Service API Reference](#).

Strong consistency

S3 Express One Zone provides strong read-after-write consistency for PUT and DELETE requests of objects in your directory buckets in all AWS Regions. For more information, see [Amazon S3 data consistency model](#).

Related services

You can use the following AWS services with the S3 Express One Zone storage class to support your specific low-latency use case.

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) – Amazon EC2 provides secure and scalable computing capacity in the AWS Cloud. Using Amazon EC2 lessens your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.
- [AWS Lambda](#) – Lambda is a compute service that lets you run code without provisioning or managing servers. You configure notification settings on a bucket, and grant Amazon S3 permission to invoke a function on the function's resource-based permissions policy.
- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) – Amazon EKS is a managed service that eliminates the need to install, operate, and maintain your own Kubernetes control plane on AWS. [Kubernetes](#) is an open source system that automates the management, scaling, and deployment of containerized applications.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) – Amazon ECS is a fully managed container orchestration service that helps you easily deploy, manage, and scale containerized applications.
- [AWS Key Management Service \(AWS KMS\)](#) – AWS Key Management Service (AWS KMS) is an AWS managed service that makes it easy for you to create and control the encryption keys that are used to encrypt your data. The AWS KMS keys that you create in AWS KMS are protected by FIPS 140-2 validated hardware security modules (HSM). To use or manage your KMS keys, you interact with AWS KMS.
- [Amazon Athena](#) – Athena is an interactive query service that makes it easy to analyze data directly in Amazon S3 by using standard [SQL](#). You can also use Athena to interactively run data analytics by using Apache Spark without having to plan for, configure, or manage resources. When you run Apache Spark applications on Athena, you submit Spark code for processing and receive the results directly.

- [Amazon SageMaker Training](#) – Review the options for training models with Amazon SageMaker, including built-in algorithms, custom algorithms, libraries, and models from the AWS Marketplace.
- [AWS Glue](#) – AWS Glue is a serverless data-integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use AWS Glue for analytics, machine learning, and application development. AWS Glue also includes additional productivity and data-ops tooling for authoring, running jobs, and implementing business workflows.
- [Amazon EMR](#) – Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data.
- [AWS CloudTrail](#) – AWS CloudTrail is an AWS service that helps you enable operational and risk auditing, governance, and compliance of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail. Events include actions taken in the AWS Management Console, AWS Command Line Interface, and AWS SDKs and APIs.
- [AWS CloudFormation](#) – is a service that helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS. You create a template that describes all the AWS resources that you want (like Amazon EC2 instances or Amazon RDS DB instances), and CloudFormation takes care of provisioning and configuring those resources for you. You don't need to individually create and configure AWS resources and figure out what's dependent on what; CloudFormation handles that.

Next steps

For more information about working with the S3 Express One Zone storage class and directory buckets, see the following topics:

- [Tutorial: Getting started with S3 Express One Zone](#)
- [S3 Express One Zone Availability Zones and Regions](#)

Tutorial: Getting started with S3 Express One Zone

Amazon S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources which provides the highest possible access speed. Data in S3 Express One Zone is stored in directory buckets located in Availability Zones. For more information on directory buckets, see [Directory buckets](#).

S3 Express One Zone is ideal for any application where it's critical to minimize request latency. Such applications can be human-interactive workflows, like video editing, where creative professionals need responsive access to content from their user interfaces. S3 Express One Zone also benefits analytics and machine learning workloads that have similar responsiveness requirements from their data, especially workloads with a lot of smaller accesses or a large numbers of random accesses. S3 Express One Zone can be used with other AWS services such as Amazon EMR, Amazon Athena, AWS Glue Data Catalog and Amazon SageMaker Model Training to support analytics, artificial intelligence and machine learning (AI/ML) workloads,. You can work with the S3 Express One Zone storage class and directory buckets by using the Amazon S3 console, AWS SDKs, AWS Command Line Interface (AWS CLI), and Amazon S3 REST API. For more information, see [What is S3 Express One Zone?](#) and [How is S3 Express One Zone different?](#).

This is an S3 Express One Zone workflow diagram.

Objective

In this tutorial, you will learn how to create a gateway endpoint, create and attach an IAM policy, create a directory bucket and then use the Import action to populate your directory bucket with objects currently stored in your general purpose bucket. Alternatively, you can manually upload objects to your directory bucket.

Topics

- [Prerequisites](#)
- [Step 1: Configure a gateway VPC endpoint to reach S3 Express One Zone directory buckets](#)
- [Step 2: Create a S3 Express One Zone directory bucket](#)
- [Step 3: Importing data into a S3 Express One Zone directory bucket](#)
- [Step 4: Manually upload objects to your S3 Express One Zone directory bucket](#)
- [Step 5: Empty your S3 Express One Zone directory bucket](#)
- [Step 6: Delete your S3 Express One Zone directory bucket](#)
- [Next steps](#)

Prerequisites

Before you start this tutorial, you must have an AWS account that you can sign in to as an AWS Identity and Access Management (IAM) user with correct permissions.

Substeps

- [Create an AWS account](#)
- [Create an IAM user in your AWS account \(console\)](#)
- [Create an IAM policy and attach it to an IAM user or role \(console\)](#)

Create an AWS account

To complete this tutorial, you need an AWS account. When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon S3. You are charged only for the services that you use. For more information about pricing, see [S3 pricing](#).

Create an IAM user in your AWS account (console)

AWS Identity and Access Management (IAM) is an AWS service that helps administrators securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to access objects and use directory buckets in S3 Express One Zone. You can use IAM for no additional charge.

By default, users don't have permissions to access directory buckets and perform S3 Express One Zone operations. To grant access permissions for directory buckets and S3 Express One Zone operations, you can use IAM to create users or roles and attach permissions to those identities. For more information about how to create an IAM user, see [Creating IAM users \(console\)](#) in the *IAM User Guide*. For more information about how to create an IAM role, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

For simplicity, this tutorial creates and uses an IAM user. After completing this tutorial, remember to [Delete the IAM user](#). For production use, we recommend that you follow the [Security best practices in IAM](#) in the *IAM User Guide*. A best practice requires human users to use federation with an identity provider to access AWS with temporary credentials. Another best practice is to require workloads to use temporary credentials with IAM roles to access AWS. To learn more about using AWS IAM Identity Center to create users with temporary credentials, see [Getting started](#) in the *AWS IAM Identity Center User Guide*.

Warning

IAM users have long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

Create an IAM policy and attach it to an IAM user or role (console)

By default, users don't have permissions for directory buckets and S3 Express One Zone operations. To grant access permissions for directory buckets, you can use IAM to create users, groups, or roles and attach permissions to those identities. Directory buckets are the only resource that you can include in bucket policies or IAM identity policies for S3 Express One Zone access.

To use Regional endpoint API operations (bucket-level or control plane operations) with S3 Express One Zone, you use the IAM authorization model, which doesn't involve session management. Permissions are granted for actions individually. To use Zonal endpoint API operations (object-level or data plane operations), you use [CreateSession](#) to create and manage sessions that are optimized for low-latency authorization of data requests. To retrieve and use a session token, you must allow the `s3express:CreateSession` action for your directory bucket in an identity-based policy or a bucket policy. If you're accessing S3 Express One Zone in the Amazon S3 console, through the AWS Command Line Interface (AWS CLI), or by using the AWS SDKs, S3 Express One Zone creates a session on your behalf. For more information, see [CreateSession authorization](#) and [AWS Identity and Access Management \(IAM\) for S3 Express One Zone](#).

To create an IAM policy and attach the policy to an IAM user (or role)

1. Sign in to the AWS Management Console and open the IAM Management Console.
2. In the navigation pane, choose **Policies**.
3. Choose **Create Policy**.
4. Select **JSON**.
5. Copy the policy below into the **Policy editor** window. Before you can create directory buckets or use S3 Express One Zone, you must grant the necessary permissions to your AWS Identity and Access Management (IAM) role or users. This example policy allows access to the `CreateSession` API operation (for use with other Zonal or object-level API operations) and all of the Regional endpoint (bucket-level) API operations. This policy allows the `CreateSession` API operation for use with all directory buckets, but the Regional

endpoint API operations are allowed only for use with the specified directory bucket. To use this example policy, replace the *user input placeholders* with your own information.

        }  
    ]  
}
```

6. Choose **Next**.
7. Name the policy.

 **Note**

Bucket tags are not supported for S3 Express One Zone.

8. Select **Create policy**.

9. Now that you've created an IAM policy, you can attach it to an IAM user. In the navigation pane, choose **Policies**.
10. In the **search bar**, enter the name of your policy.
11. From the **Actions** menu, select **Attach**.
12. Under **Filter by Entity Type**, select **IAM users or Roles**.
13. In the **search field**, type the name of the user or role you wish to use.
14. Choose **Attach Policy**.

Step 1: Configure a gateway VPC endpoint to reach S3 Express One Zone directory buckets

You can access both Zonal and Regional API operations through gateway virtual private cloud (VPC) endpoints. Gateway endpoints can allow traffic to reach S3 Express One Zone without traversing a NAT Gateway. We strongly recommend using gateway endpoints as they provide the most optimal networking path when working with S3 Express One Zone. You can access S3 Express One Zone directory buckets from your VPC without an internet gateway or NAT device for your VPC, and at no additional cost. Use the following procedure to configure a gateway endpoint that connects to S3 Express One Zone storage class objects and directory buckets.

To access S3 Express One Zone, you use Regional and Zonal endpoints that are different from standard Amazon S3 endpoints. Depending on the Amazon S3 API operation that you use, either a Zonal or Regional endpoint is required. For a complete list of supported API operations by endpoint type, see [API operations supported by S3 Express One Zone](#). You must access both Zonal and Regional endpoints through a gateway virtual private cloud (VPC) endpoint.

Use the following procedure to create a gateway endpoint that connects to S3 Express One Zone storage class objects and directory buckets.

To configure a gateway VPC endpoint

1. Open the Amazon VPC Console at <https://console.aws.amazon.com/vpc/>.
2. In the side navigation pane under **Virtual private cloud**, choose **Endpoints**.
3. Choose **Create endpoint**.
4. Create a name for your endpoint.
5. For **Service category**, choose **AWS services**.
6. Under **Services**, search using the filter **Type=Gateway** and then choose the option button next to **com.amazonaws.*region*.s3express**.

7. For **VPC**, choose the VPC in which to create the endpoint.
8. For **Route tables**, choose the route table on your Local Zone to be used by the endpoint. After the endpoint is created, a route record will be added to the route table that you select in this step.
9. For **Policy**, choose **Full access** to allow all operations by all principals on all resources over the VPC endpoint. Otherwise, choose **Custom** to attach a VPC endpoint policy that controls the principals' permissions to perform actions on resources over the VPC endpoint.
10. For **IP address type**, choose from the following options:
 - **IPv4** – Assign IPv4 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have IPv4 address ranges and the service accepts IPv4 requests.
 - **IPv6** – Assign IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets are IPv6 only subnets and the service accepts IPv6 requests.
 - **Dualstack** – Assign both IPv4 and IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have both IPv4 and IPv6 address ranges and the service accepts both IPv4 and IPv6 requests.
11. (Optional) To add a tag, choose **Add new tag**, and enter the tag key and the tag value.
12. Choose **Create endpoint**.

After creating a gateway endpoint, you can use Regional API endpoints and Zonal API endpoints to access Amazon S3 Express One Zone storage class objects and directory buckets.

Step 2: Create a S3 Express One Zone directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **Directory buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. Under **General configuration**, view the AWS Region where your bucket will be created.

Under **Bucket type**, choose **Directory**.

 **Note**

- If you've chosen a Region that doesn't support directory buckets, the **Bucket type** option disappears, and the bucket type defaults to a general purpose bucket. To create a directory bucket, you must choose a supported Region. For a list of Regions that support directory buckets and the Amazon S3 Express One Zone storage class, see [the section called "S3 Express One Zone Availability Zones and Regions"](#).
- After you create the bucket, you can't change the bucket type.

 **Note**

The Availability Zone can't be changed after the bucket is created.

6. For **Availability Zone**, choose a Availability Zone local to your compute services. For a list of Availability Zones that support directory buckets and the S3 Express One Zone storage class, see [the section called "S3 Express One Zone Availability Zones and Regions"](#).

Under **Availability Zone**, select the check box to acknowledge that in the event of an Availability Zone outage, your data might be unavailable or lost.

 **Important**

Although directory buckets are stored across multiple devices within a single Availability Zone, directory buckets don't store data redundantly across Availability Zones.

7. For **Bucket name**, enter a name for your directory bucket.

The following naming rules apply for directory buckets.

- Be unique within the chosen Zone (AWS Availability Zone or AWS Local Zone).

- Name must be between 3 (min) and 63 (max) characters long, including the suffix.
- Consists only of lowercase letters, numbers and hyphens (-).
- Begin and end with a letter or number.
- Must include the following suffix: --*zone-id*--x-s3.
- Bucket names must not start with the prefix xn--.
- Bucket names must not start with the prefix sthree-.
- Bucket names must not start with the prefix sthree-configurator.
- Bucket names must not start with the prefix amzn-s3-demo-.
- Bucket names must not end with the suffix -s3alias. This suffix is reserved for access point alias names. For more information, see [Access point aliases](#).
- Bucket names must not end with the suffix --ol-s3. This suffix is reserved for Object Lambda Access Point alias names. For more information, see [How to use a bucket-style alias for your S3 bucket Object Lambda Access Point](#).
- Bucket names must not end with the suffix .mrap. This suffix is reserved for Multi-Region Access Point names. For more information, see [Rules for naming Amazon S3 Multi-Region Access Points](#).

A suffix is automatically added to the base name that you provide when you create a directory bucket using the console. This suffix includes the Availability Zone ID of the Availability Zone that you chose.

After you create the bucket, you can't change its name. For more information about naming buckets, see [General purpose bucket naming rules](#).

 **Important**

Do not include sensitive information, such as account numbers, in the bucket name.
The bucket name is visible in the URLs that point to the objects in the bucket.

8. Under **Object Ownership**, the **Bucket owner enforced** setting is automatically enabled, and all access control lists (ACLs) are disabled. For directory buckets, ACLs can't be enabled.

Bucket owner enforced (default) – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the general purpose bucket. ACLs no longer

- affect access permissions to data in the S3 general purpose bucket. The bucket uses policies exclusively to define access control.
9. Under **Block Public Access settings for this bucket**, all Block Public Access settings for your directory bucket are automatically enabled. These settings can't be modified for directory buckets. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).
 10. To configure default encryption, under **Encryption type**, choose one of the following:
 - **Server-side encryption with Amazon S3 managed key (SSE-S3)**
 - **Server-side encryption with AWS Key Management Service key (SSE-KMS)**

For more information about using Amazon S3 server-side encryption to encrypt your data, see [Data protection and encryption](#).

 **Important**

If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

When you enable default encryption, you might need to update your bucket policy. For more information, see [Using SSE-KMS encryption for cross-account operations](#).

11. If you chose **Server-side encryption with Amazon S3 managed keys (SSE-S3)**, under **Bucket Key, Enabled** appears. S3 Bucket Keys are always enabled when you configure your directory bucket to use default encryption with SSE-S3. S3 Bucket Keys are always enabled for GET and PUT operations in a directory bucket and can't be disabled. S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [CopyObject](#), [UploadPartCopy](#), [the Copy operation in Batch Operations](#), or [the import jobs](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object.

S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

12. If you chose **Server-side encryption with AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, specify your AWS Key Management Service key in one of the following ways or create a new key.

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from **Available AWS KMS keys**.

Only your customer managed keys appear in this list. The AWS managed key (aws/s3) isn't supported in directory buckets. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN or alias, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN or alias in **AWS KMS key ARN**.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

Important

- Your SSE-KMS configuration can only support 1 [customer managed key](#) per directory bucket for the lifetime of the bucket. The [AWS managed key](#) (aws/s3) isn't supported. Also, after you specify a customer managed key for SSE-KMS, you can't override the customer managed key for the bucket's SSE-KMS configuration.

You can identify the customer managed key you specified for the bucket's SSE-KMS configuration, in the following way:

- You make a HeadObject API operation request to find the value of `x-amz-server-side-encryption-aws-kms-key-id` in your response.

To use a new customer managed key for your data, we recommend copying your existing objects to a new directory bucket with a new customer managed key.

- You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN. For more information on cross account permissions for KMS keys, see [Creating KMS keys that](#)

[other accounts can use](#) in the *AWS Key Management Service Developer Guide*. For more information on SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\) for new object uploads in directory buckets](#).

- When you use an AWS KMS key for server-side encryption in directory buckets, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

For more information about using AWS KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in directory buckets](#).

13. Choose **Create bucket**. After creating the bucket, you can add files and folders to the bucket. For more information, see [the section called “Working with objects in a directory bucket”](#).

Step 3: Importing data into a S3 Express One Zone directory bucket

To complete this step, you must have a general purpose bucket that contains objects and is located in the same AWS Region as your directory bucket.

After you create a directory bucket in Amazon S3, you can populate the new bucket with data by using the Import action in the Amazon S3 console. Import simplifies copying data into directory buckets by letting you choose a prefix or a general purpose bucket to Import data from without having to specify all of the objects to copy individually. Import uses S3 Batch Operations which copies the objects in the selected prefix or general purpose bucket. You can monitor the progress of the Import copy job through the S3 Batch Operations job details page.

To use the Import action

- Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
- In the left navigation pane, choose **Directory buckets**.
- Choose the option button next to the name of the bucket that you want to import objects into.

5. Choose **Import**.
6. For **Source**, enter the general purpose bucket (or bucket path including prefix) that contains the objects that you want to import. To choose an existing general purpose bucket from a list, choose **Browse S3**.
7. In the **Permissions** section, you can choose to have an IAM role auto-generated. Alternatively, you can select an IAM role from a list, or directly enter an IAM role ARN.
 - To allow Amazon S3 to create a new IAM role on your behalf, choose **Create new IAM role**.

 **Note**

If your source objects are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), don't choose the **Create new IAM role** option. Instead, specify an existing IAM role that has the `kms:Decrypt` permission.

Amazon S3 will use this permission to decrypt your objects. During the import process, Amazon S3 will then re-encrypt those objects by using server-side encryption with Amazon S3 managed keys (SSE-S3).

- To choose an existing IAM role from a list, choose **Choose from existing IAM roles**.
 - To specify an existing IAM role by entering its Amazon Resource Name (ARN), choose **Enter IAM role ARN**, then enter the ARN in the corresponding field.
8. Review the information that's displayed in the **Destination** and **Copied object settings** sections. If the information in the **Destination** section is correct, choose **Import** to start the copy job.

The Amazon S3 console displays the status of your new job on the **Batch Operations** page. For more information about the job, choose the option button next to the job name, and then on the **Actions** menu, choose **View details**. To open the directory bucket that the objects will be imported into, choose **View import destination**.

Step 4: Manually upload objects to your S3 Express One Zone directory bucket

You can also manually upload objects to your directory bucket.

To manually upload objects

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the upper right corner of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
3. In the left navigation pane, choose **Directory buckets**.
4. Choose the name of the bucket that you want to upload your folders or files to.

 **Note**

If you chose the same directory bucket that you used in previous steps of this tutorial, your directory bucket will contain the objects that were uploaded from the Import tool. Notice that these objects are now stored in the S3 Express One Zone storage class.

5. In the **Objects** list, choose **Upload**.
6. On the **Upload** page, do one of the following:
 - Drag and drop files and folders to the dotted upload area.
 - Choose **Add files** or **Add folder**, choose the files or folders to upload, and then choose **Open** or **Upload**.
7. Under **Checksums**, choose the **Checksum function** that you want to use.

 **Note**

We recommend using CRC32 and CRC32C for the best performance with the S3 Express One Zone storage class. For more information, see [S3 additional checksum best practices](#).

(Optional) If you're uploading a single object that's less than 16 MB in size, you can also specify a pre-calculated checksum value. When you provide a pre-calculated value, Amazon S3 compares it with the value that it calculates by using the selected checksum function. If the values don't match, the upload won't start.

8. The options in the **Permissions** and **Properties** sections are automatically set to default settings and can't be modified. Block Public Access is automatically enabled, and S3 Versioning and S3 Object Lock can't be enabled for directory buckets.

(Optional) If you want to add metadata in key-value pairs to your objects, expand the **Properties** section, and then in the **Metadata** section, choose **Add metadata**.

9. To upload the listed files and folders, choose **Upload**.

Amazon S3 uploads your objects and folders. When the upload is finished, you see a success message on the **Upload: status** page.

You have successfully created a directory bucket and uploaded objects to your bucket.

Step 5: Empty your S3 Express One Zone directory bucket

You can empty your Amazon S3 directory bucket by using the Amazon S3 console.

To empty a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the upper right corner of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
3. In the left navigation pane, choose **Directory buckets**.
4. Choose the option button next to the name of the bucket that you want to empty, and then choose **Empty**.
5. On the **Empty bucket** page, confirm that you want to empty the bucket by entering **permanently delete** in the text field, and then choose **Empty**.
6. Monitor the progress of the bucket emptying process on the **Empty bucket: status** page.

Step 6: Delete your S3 Express One Zone directory bucket

After you empty your directory bucket and abort all in-progress multipart uploads, you can delete your bucket by using the Amazon S3 console.

To delete a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the upper right corner of the page, choose the name of the currently displayed AWS Region. Next, choose the Region associated with the Availability Zone in which your directory bucket is located.
3. In the left navigation pane, choose **Directory buckets**.
4. In the **Directory buckets** list, choose the option button next to the bucket that you want to delete.
5. Choose **Delete**.
6. On the **Delete bucket** page, enter the name of the bucket in the text field to confirm the deletion of your bucket.

 **Important**

Deleting a directory bucket can't be undone.

7. To delete your directory bucket, choose **Delete bucket**.

Next steps

In this tutorial, you have learned how to create a directory bucket and use the S3 Express One Zone storage class. After completing this tutorial, you can explore related AWS services to use with the S3 Express One Zone storage class.

You can use the following AWS services with the S3 Express One Zone storage class to support your specific low-latency use case.

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) – Amazon EC2 provides secure and scalable computing capacity in the AWS Cloud. Using Amazon EC2 lessens your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.
- [AWS Lambda](#) – Lambda is a compute service that lets you run code without provisioning or managing servers. You configure notification settings on a bucket, and grant Amazon S3 permission to invoke a function on the function's resource-based permissions policy.

- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#) – Amazon EKS is a managed service that eliminates the need to install, operate, and maintain your own Kubernetes control plane on AWS. [Kubernetes](#) is an open-source system that automates the management, scaling, and deployment of containerized applications.
- [Amazon Elastic Container Service \(Amazon ECS\)](#) – Amazon ECS is a fully managed container orchestration service that helps you easily deploy, manage, and scale containerized applications.
- [Amazon EMR](#) – Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark on AWS to process and analyze vast amounts of data.
- [Amazon Athena](#) – Athena is an interactive query service that makes it easy to analyze data directly in Amazon S3 by using standard [SQL](#). You can also use Athena to interactively run data analytics by using Apache Spark without having to plan for, configure, or manage resources. When you run Apache Spark applications on Athena, you submit Spark code for processing and receive the results directly.
- [AWS Glue Data Catalog](#) – AWS Glue is a serverless data-integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use AWS Glue for analytics, machine learning, and application development. AWS Glue Data Catalog is a centralized repository that stores metadata about your organization's data sets. It acts as an index to the location, schema, and run-time metrics of your data sources.
- [Amazon SageMaker Runtime Model Training](#) – Amazon SageMaker Runtime is a fully managed machine learning service. With SageMaker Runtime, data scientists and developers can quickly and easily build and train machine learning models, and then directly deploy them into a production-ready hosted environment.

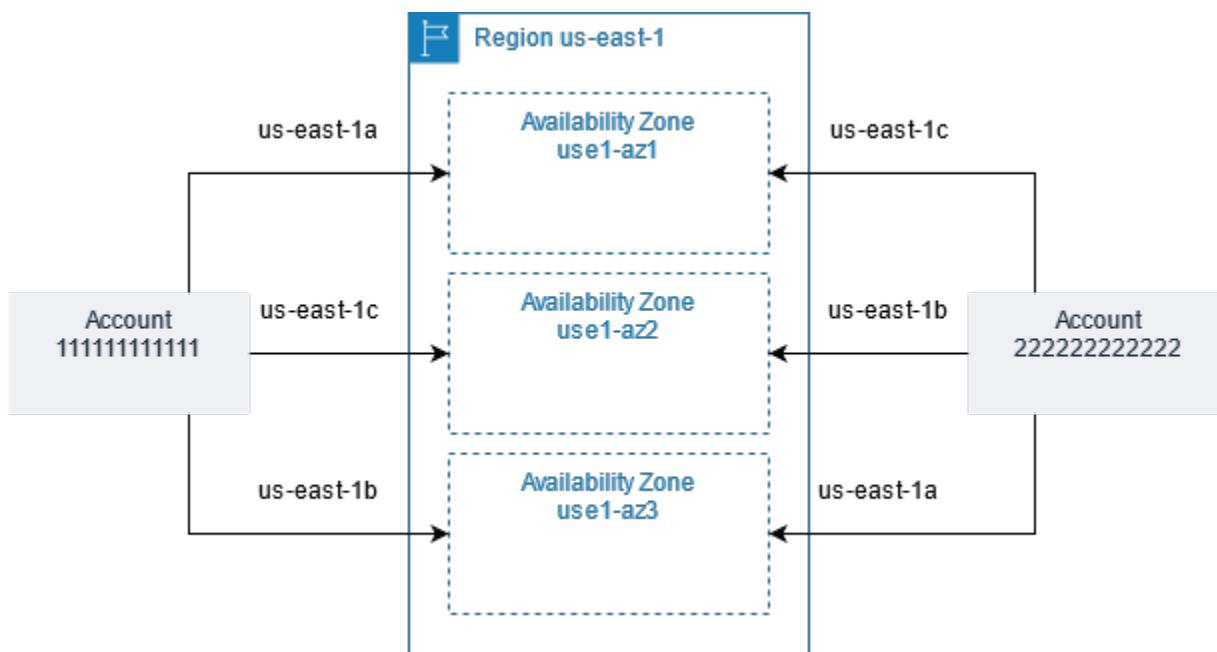

For more information on S3 Express One Zone, see [What is S3 Express One Zone?](#) and [How is S3 Express One Zone different?](#).

S3 Express One Zone Availability Zones and Regions

An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. To optimize low-latency retrievals, objects in the Amazon S3 Express One Zone storage class are redundantly stored in S3 directory buckets in a single Availability Zone that's local to your compute workload. When you create a directory bucket, you choose the Availability Zone and AWS Region where your bucket will be located.

AWS maps the physical Availability Zones randomly to the Availability Zone names for each AWS account. This approach helps to distribute resources across the Availability Zones in an AWS Region, instead of resources likely being concentrated in the first Availability Zone for each Region. As a result, the Availability Zone `us-east-1a` for your AWS account might not represent the same physical location as `us-east-1a` for a different AWS account. For more information, see [Regions and Availability Zones](#) in the *Amazon EC2 User Guide*.

To coordinate Availability Zones across accounts, you must use the *AZ ID*, which is a unique and consistent identifier for an Availability Zone. For example, `use1-az1` is an AZ ID for the `us-east-1` Region and it has the same physical location in every AWS account. The following illustration shows how the AZ IDs are the same for every account, even though the Availability Zone names might be mapped differently for each account.

With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed for 99.95 percent availability within a single Availability Zone and is backed by the [Amazon S3 Service Level Agreement](#). For more information, see [Availability Zones](#)

The following table shows the S3 Express One Zone supported Regions and Availability Zones.

Region name	Region code	Availability Zone ID			
US East (N. Virginia)	<code>us-east-1</code>	<code>use1-az4</code>			

Region name	Region code	Availability Zone ID				
		use1-az5				
		use1-az6				
US East (Ohio)	us-east-2	use2-az1				
		use2-az2				
US West (Oregon)	us-west-2	usw2-az1				
		usw2-az3				
		usw2-az4				
Asia Pacific (Mumbai)	ap-south-1	aps1-az1				
		aps1-az3				
Asia Pacific (Tokyo)	ap-northeast-1	apne1-az1				
		apne1-az4				
Europe (Ireland)	eu-west-1	euw1-az1				
		euw1-az3				
Europe (Stockholm)	eu-north-1	eun1-az1				
		eun1-az2				
		eun1-az3				

Networking for directory buckets in an Availability Zone

To reduce the amount of time your packets spend on the network, configure your virtual private cloud (VPC) with a gateway endpoint to access directory buckets in Availability Zones while keeping traffic within the AWS network, and at no additional cost.

Topics

- [Endpoints for directory buckets in Availability Zones](#)
- [Configuring VPC gateway endpoints](#)

Endpoints for directory buckets in Availability Zones

The following table shows the Regional and Zonal API endpoints that are available for each Region and Availability Zone.

Configuring VPC gateway endpoints

Use the following procedure to create a gateway endpoint that connects to Amazon S3 Express One Zone storage class objects and directory buckets.

To configure a gateway VPC endpoint

1. Open the [Amazon VPC Console](#).
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**.
4. Create a name for your endpoint.
5. For **Service category**, choose **AWS services**.
6. For **Services**, add the filter **Type=Gateway** and then choose the option button next to **com.amazonaws.*region*.s3express**.
7. For **VPC**, choose the VPC in which to create the endpoint.
8. For **Route tables**, choose the route table in your VPC to be used by the endpoint. After the endpoint is created, a route record will be added to the route table that you select in this step.
9. For **Policy**, choose **Full access** to allow all operations by all principals on all resources over the VPC endpoint. Otherwise, choose **Custom** to attach a VPC endpoint policy that controls the principals' permissions to perform actions on resources over the VPC endpoint.
10. For **IP address type**, choose from the following options:
 - **IPv4** – Assign IPv4 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have IPv4 address ranges and the service accepts IPv4 requests.
 - **IPv6** – Assign IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets are IPv6 only subnets and the service accepts IPv6 requests.

- **Dualstack** – Assign both IPv4 and IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have both IPv4 and IPv6 address ranges and the service accepts both IPv4 and IPv6 requests.
11. (Optional) To add a tag, choose **Add new tag**, and enter the tag key and the tag value.
12. Choose **Create endpoint**.

After creating a gateway endpoint, you can use Regional API endpoints and Zonal API endpoints to access Amazon S3 Express One Zone storage class objects and directory buckets.

To learn more about gateway VPC endpoints, see [Gateway endpoints](#) in the *AWS PrivateLink Guide*. For the data residency use cases, we recommend enabling access to your buckets only from your VPC using gateway VPC endpoints. When access is restricted to a VPC or a VPC endpoint, you can access the objects through the AWS Management Console, the REST API, AWS CLI, and AWS SDKs.

 **Note**

To restrict access to a VPC or a VPC endpoint using the AWS Management Console, you must use the AWS Management Console Private Access. For more information, see [AWS Management Console Private Access](#) in the *AWS Management Console guide* AWS Management Console guide.

Creating directory buckets in an Availability Zone

To start using the Amazon S3 Express One Zone storage class, you create a directory bucket. The S3 Express One Zone storage class can be used only with directory buckets. The S3 Express One Zone storage class supports low-latency use cases and provides faster data processing within a single Availability Zone. If your application is performance sensitive and benefits from single-digit millisecond PUT and GET latencies, we recommend creating a directory bucket so that you can use the S3 Express One Zone storage class.

There are two types of Amazon S3 buckets, general purpose buckets and directory buckets. You should choose the bucket type that best fits your application and performance requirements. General purpose buckets are the original S3 bucket type. General purpose buckets are recommended for most use cases and access patterns and allow objects stored across all storage classes, except S3 Express One Zone. For more information about general purpose buckets, see [General purpose buckets overview](#).

Directory buckets use the S3 Express One Zone storage class, which is designed to be used for workloads or performance-critical applications that require consistent single-digit millisecond latency. S3 Express One Zone is the first S3 storage class where you can select a single Availability Zone with the option to co-locate your object storage with your compute resources, which provides the highest possible access speed. When you create a directory bucket, you can optionally specify an AWS Region and an Availability Zone that's local to your Amazon EC2, Amazon Elastic Kubernetes Service, or Amazon Elastic Container Service (Amazon ECS) compute instances to optimize performance.

With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. S3 Express One Zone is designed for 99.95 percent availability within a single Availability Zone and is backed by the [Amazon S3 Service Level Agreement](#). For more information, see [Availability Zones](#)

Directory buckets organize data hierarchically into directories, as opposed to the flat storage structure of general purpose buckets. There aren't prefix limits for directory buckets, and individual directories can scale horizontally.

For more information about directory buckets, see [Working with directory buckets](#).

Directory bucket names

Directory bucket names must follow this format and comply with the rules for directory bucket naming:

bucket-base-name--zone-id--x-s3

For example, the following directory bucket name contains the Availability Zone ID usw2-az1:

bucket-base-name--usw2-az1--x-s3

For more information about directory bucket naming rules, see [Directory bucket naming rules](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **Directory buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. Under **General configuration**, view the AWS Region where your bucket will be created.

Under **Bucket type**, choose **Directory**.

Note

- If you've chosen a Region that doesn't support directory buckets, the **Bucket type** option disappears, and the bucket type defaults to a general purpose bucket. To create a directory bucket, you must choose a supported Region. For a list of Regions that support directory buckets and the Amazon S3 Express One Zone storage class, see [the section called "S3 Express One Zone Availability Zones and Regions"](#).
- After you create the bucket, you can't change the bucket type.

Note

The Availability Zone can't be changed after the bucket is created.

6. For **Availability Zone**, choose a Availability Zone local to your compute services. For a list of Availability Zones that support directory buckets and the S3 Express One Zone storage class, see [the section called "S3 Express One Zone Availability Zones and Regions"](#).

Under **Availability Zone**, select the check box to acknowledge that in the event of an Availability Zone outage, your data might be unavailable or lost.

⚠️ Important

Although directory buckets are stored across multiple devices within a single Availability Zone, directory buckets don't store data redundantly across Availability Zones.

7. For **Bucket name**, enter a name for your directory bucket.

The following naming rules apply for directory buckets.

- Be unique within the chosen Zone (AWS Availability Zone or AWS Local Zone).
- Name must be between 3 (min) and 63 (max) characters long, including the suffix.
- Consists only of lowercase letters, numbers and hyphens (-).
- Begin and end with a letter or number.
- Must include the following suffix: --*zone-id*--x-s3.
- Bucket names must not start with the prefix xn--.
- Bucket names must not start with the prefix sthree-.
- Bucket names must not start with the prefix sthree-configurator.
- Bucket names must not start with the prefix amzn-s3-demo-.
- Bucket names must not end with the suffix -s3alias. This suffix is reserved for access point alias names. For more information, see [Access point aliases](#).
- Bucket names must not end with the suffix --ol-s3. This suffix is reserved for Object Lambda Access Point alias names. For more information, see [How to use a bucket-style alias for your S3 bucket Object Lambda Access Point](#).
- Bucket names must not end with the suffix .mrapp. This suffix is reserved for Multi-Region Access Point names. For more information, see [Rules for naming Amazon S3 Multi-Region Access Points](#).

A suffix is automatically added to the base name that you provide when you create a directory bucket using the console. This suffix includes the Availability Zone ID of the Availability Zone that you chose.

After you create the bucket, you can't change its name. For more information about naming buckets, see [General purpose bucket naming rules](#).

⚠️ Important

Do not include sensitive information, such as account numbers, in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

8. Under **Object Ownership**, the **Bucket owner enforced** setting is automatically enabled, and all access control lists (ACLs) are disabled. For directory buckets, ACLs can't be enabled.

Bucket owner enforced (default) – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the general purpose bucket. ACLs no longer affect access permissions to data in the S3 general purpose bucket. The bucket uses policies exclusively to define access control.

9. Under **Block Public Access settings for this bucket**, all Block Public Access settings for your directory bucket are automatically enabled. These settings can't be modified for directory buckets. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).
10. To configure default encryption, under **Encryption type**, choose one of the following:

- **Server-side encryption with Amazon S3 managed key (SSE-S3)**
- **Server-side encryption with AWS Key Management Service key (SSE-KMS)**

For more information about using Amazon S3 server-side encryption to encrypt your data, see [Data protection and encryption](#).

⚠️ Important

If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

When you enable default encryption, you might need to update your bucket policy. For more information, see [Using SSE-KMS encryption for cross-account operations](#).

11. If you chose **Server-side encryption with Amazon S3 managed keys (SSE-S3)**, under **Bucket Key, Enabled** appears. S3 Bucket Keys are always enabled when you configure your directory bucket to use default encryption with SSE-S3. S3 Bucket Keys are always enabled for GET and

PUT operations in a directory bucket and can't be disabled. S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [CopyObject](#), [UploadPartCopy](#), [the Copy operation in Batch Operations](#), or [the import jobs](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object.

S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

12. If you chose **Server-side encryption with AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, specify your AWS Key Management Service key in one of the following ways or create a new key.

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from **Available AWS KMS keys**.

Only your customer managed keys appear in this list. The AWS managed key (aws/s3) isn't supported in directory buckets. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN or alias, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN or alias in **AWS KMS key ARN**.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

Important

- Your SSE-KMS configuration can only support 1 [customer managed key](#) per directory bucket for the lifetime of the bucket. The [AWS managed key](#) (aws/s3) isn't supported. Also, after you specify a customer managed key for SSE-KMS, you can't override the customer managed key for the bucket's SSE-KMS configuration.

You can identify the customer managed key you specified for the bucket's SSE-KMS configuration, in the following way:

- You make a HeadObject API operation request to find the value of x-amz-server-side-encryption-aws-kms-key-id in your response.

To use a new customer managed key for your data, we recommend copying your existing objects to a new directory bucket with a new customer managed key.

- You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN. For more information on cross account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*. For more information on SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\) for new object uploads in directory buckets](#).
- When you use an AWS KMS key for server-side encryption in directory buckets, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

For more information about using AWS KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in directory buckets](#).

13. Choose **Create bucket**. After creating the bucket, you can add files and folders to the bucket. For more information, see [the section called “Working with objects in a directory bucket”](#).

Using the AWS SDKs

SDK for Go

This example shows how to create a directory bucket by using the AWS SDK for Go.

Example

```
var bucket = "..."

func runCreateBucket(c *s3.Client) {
    resp, err := c.CreateBucket(context.Background(), &s3.CreateBucketInput{
```

```
Bucket: &bucket,
CreateBucketConfiguration: &types.CreateBucketConfiguration{
    Location: &types.LocationInfo{
        Name: aws.String("usw2-az1"),
        Type: types.LocationTypeAvailabilityZone,
    },
    Bucket: &types.BucketInfo{
        DataRedundancy: types.DataRedundancySingleAvailabilityZone,
        Type:           types.BucketTypeDirectory,
    },
},
})
var terr *types.BucketAlreadyOwnedByYou
if errors.As(err, &terr) {
    fmt.Printf("BucketAlreadyOwnedByYou: %s\n", aws.ToString(terr.Message))
    fmt.Printf("noop...\n")
    return
}
if err != nil {
    log.Fatal(err)
}

fmt.Printf("bucket created at %s\n", aws.ToString(resp.Location))
}
```

SDK for Java 2.x

This example shows how to create an directory bucket by using the AWS SDK for Java 2.x.

Example

```
public static void createBucket(S3Client s3Client, String bucketName) {

    //Bucket name format is {base-bucket-name}-{az-id}-x-s3
    //example: doc-example-bucket--usw2-az1--x-s3 is a valid name for a directory
    bucket created in
    //Region us-west-2, Availability Zone 2

    CreateBucketConfiguration bucketConfiguration =
    CreateBucketConfiguration.builder()
        .location(LocationInfo.builder()
            .type(LocationType.AVAILABILITY_ZONE)
            .name("usw2-az1").build()) //this must match the Region and
    Availability Zone in your bucket name
```

```
.bucket(BucketInfo.builder()
    .type(BucketType DIRECTORY)
    .dataRedundancy(DataRedundancy SINGLE_AVAILABILITY_ZONE)
    .build()).build();

try {

    CreateBucketRequest bucketRequest =
CreateBucketRequest.builder().bucket(bucketName).createBucketConfiguration(bucketConfigurat
    CreateBucketResponse response = s3Client.createBucket(bucketRequest);
    System.out.println(response);
}

catch (S3Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

AWS SDK for JavaScript

This example shows how to create a directory bucket by using the AWS SDK for JavaScript.

Example

```
// file.mjs, run with Node.js v16 or higher
// To use with the preview build, place this in a folder
// inside the preview build directory, such as /aws-sdk-js-v3/workspace/

import { S3 } from "@aws-sdk/client-s3";

const region = "us-east-1";
const zone = "use1-az4";
const suffix = `${zone}--x-s3`;

const s3 = new S3({ region });

const bucketName = `....-${suffix}`;

const createResponse = await s3.createBucket(
  { Bucket: bucketName,
    CreateBucketConfiguration: {Location: {Type: "AvailabilityZone", Name: zone},
```

```

SDK for .NET

This example shows how to create a directory bucket by using the SDK for .NET.

Example

```
using (var amazonS3Client = new AmazonS3Client())  
{  
    var putBucketResponse = await amazonS3Client.PutBucketAsync(new PutBucketRequest  
    {  
  
        BucketName = "DOC-EXAMPLE-BUCKET--usw2-az1--x-s3",  
        PutBucketConfiguration = new PutBucketConfiguration  
        {  
            BucketInfo = new BucketInfo { DataRedundancy =  
                DataRedundancy.SingleAvailabilityZone, Type = BucketType.Directory },  
            Location = new LocationInfo { Name = "usw2-az1", Type =  
                LocationType.AvailabilityZone }  
        }  
    }).ConfigureAwait(false);  
}
```

SDK for PHP

This example shows how to create a directory bucket by using the AWS SDK for PHP.

Example

```
require 'vendor/autoload.php';  
  
$s3Client = new S3Client([  
  
    'region'      => 'us-east-1',  
]);  
  
$result = $s3Client->createBucket([
```

```
'Bucket' => 'doc-example-bucket--use1-az4--x-s3',
'CreateBucketConfiguration' => [
    'Location' => ['Name'=> 'use1-az4', 'Type'=> 'AvailabilityZone'],
    'Bucket' => ["DataRedundancy" => "SingleAvailabilityZone" , "Type" =>
    "Directory"] ],
]);
```

SDK for Python

This example shows how to create a directory bucket by using the AWS SDK for Python (Boto3).

Example

```
import logging
import boto3
from botocore.exceptions import ClientError

def create_bucket(s3_client, bucket_name, availability_zone):
    """
    Create a directory bucket in a specified Availability Zone

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket to create; for example, 'doc-example-bucket--usw2-az1--x-s3'
    :param availability_zone: String; Availability Zone ID to create the bucket in,
    for example, 'usw2-az1'
    :return: True if bucket is created, else False
    """

    try:
        bucket_config = {
            'Location': {
                'Type': 'AvailabilityZone',
                'Name': availability_zone
            },
            'Bucket': {
                'Type': 'Directory',
                'DataRedundancy': 'SingleAvailabilityZone'
            }
        }
        s3_client.create_bucket(
            Bucket = bucket_name,
            CreateBucketConfiguration = bucket_config
    
```

```
)  
except ClientError as e:  
    logging.error(e)  
    return False  
return True  
  
if __name__ == '__main__':  
    bucket_name = 'BUCKET_NAME'  
    region = 'us-west-2'  
    availability_zone = 'usw2-az1'  
    s3_client = boto3.client('s3', region_name = region)  
    create_bucket(s3_client, bucket_name, availability_zone)
```

SDK for Ruby

This example shows how to create an directory bucket by using the AWS SDK for Ruby.

Example

```
s3 = Aws::S3::Client.new(region:'us-west-2')  
s3.create_bucket(  
    bucket: "bucket_base_name--az_id--x-s3",  
    create_bucket_configuration: {  
        location: { name: 'usw2-az1', type: 'AvailabilityZone' },  
        bucket: { data_redundancy: 'SingleAvailabilityZone', type: 'Directory' }  
    }  
)
```

Using the AWS CLI

This example shows how to create a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create a directory bucket you must provide configuration details and use the following naming convention: *bucket-base-name--zone-id--x-s3*

```
aws s3api create-bucket  
--bucket bucket-base-name--zone-id--x-s3  
--create-bucket-configuration 'Location={Type=AvailabilityZone,Name=usw2-  
az1},Bucket={DataRedundancy=SingleAvailabilityZone,Type=Directory}'
```

```
--region us-west-2
```

Regional and Zonal endpoints for directory buckets in an Availability Zone

To access your objects and directory buckets stored in S3 Express One Zone, you use gateway VPC endpoints. Directory buckets use Regional and Zonal API endpoints. Depending on the Amazon S3 API operation that you use, either a Regional or Zonal endpoint is required. There is no additional charge for using gateway endpoints.

Bucket-level (or control plane) API operations are available through Regional endpoints and are referred to as Regional endpoint API operations. Examples of Regional endpoint API operations are `CreateBucket` and `DeleteBucket`.

When you create directory buckets that are stored in S3 Express One Zone, you choose the Availability Zone where your bucket will be located. You can use Zonal endpoint API operations to upload and manage the objects in your directory bucket.

Object-level (or data plane) API operations are available through Zonal endpoints and are referred to as Zonal endpoint API operations. Examples of Zonal endpoint API operations are `CreateSession` and `PutObject`.

Optimizing S3 Express One Zone performance

Amazon S3 Express One Zone is a high-performance, single Availability Zone (AZ) S3 storage class that's purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the first S3 storage class that gives you the option to co-locate high-performance object storage and AWS compute resources, such as Amazon Elastic Compute Cloud, Amazon Elastic Kubernetes Service, and Amazon Elastic Container Service, within a single Availability Zone. Co-locating your storage and compute resources optimizes compute performance and costs and provides increased data-processing speed.

S3 Express One Zone provides similar performance elasticity to other S3 storage classes, but with consistent single-digit millisecond first-byte read and write request latencies—up to 10x faster than S3 Standard. S3 Express One Zone is designed from the ground up to support burst throughput up to very high aggregate levels. The S3 Express One Zone storage class uses a custom-built architecture to optimize for performance and deliver consistently low request latency by storing data on high-performance hardware. The object protocol for S3 Express One Zone has been enhanced to streamline authentication and metadata overhead.

To further reduce latency and support up to 2 million reads and up to 200,000 writes per second, S3 Express One Zone stores data in an Amazon S3 directory bucket. By default, each directory bucket supports up to 200,000 reads and up to 100,000 writes per second. If your workload requires higher than the default TPS limits, you can request an increase through [AWS Support](#).

The combination of high-performance, purpose-built hardware and software that delivers single-digit millisecond data access speed and directory buckets that scale for large numbers of transactions per second makes S3 Express One Zone the best Amazon S3 storage class for request-intensive operations or performance-critical applications.

The following topics describe best practice guidelines and design patterns for optimizing performance with applications that use the S3 Express One Zone storage class.

Topics

- [Best practices to optimize S3 Express One Zone performance](#)

Best practices to optimize S3 Express One Zone performance

When building applications that upload and retrieve objects from Amazon S3 Express One Zone, follow our best practice guidelines to optimize performance. To use the S3 Express One Zone storage class, you must create an S3 directory bucket. The S3 Express One Zone storage class isn't supported for use with S3 general purpose buckets.

For performance guidelines for all other Amazon S3 storage classes and S3 general purpose buckets, see [Best practices design patterns: optimizing Amazon S3 performance](#).

For optimal performance and scalability with S3 Express One Zone storage class and directory buckets in high-scale workloads, it's important to understand how directory buckets work differently from general purpose buckets. Then, we provide best practices to align your applications with the way directory buckets work.

How directory buckets work

Amazon S3 Express One Zone storage class can support workloads with up to 2,000,000 GET and up to 200,000 PUT transactions per second (TPS) per directory bucket. With S3 Express One Zone, data is stored in S3 directory buckets in Availability Zones. Objects in directory buckets are accessible within a hierarchical namespace, similar to a file system and in contrast to S3 general purpose buckets that have a flat namespace. Unlike general purpose buckets, directory buckets organize keys hierarchically into directories instead of prefixes. A prefix is a string of characters at

the beginning of the object key name. You can use prefixes to organize your data and manage a flat object storage architecture in general purpose buckets. For more information, see [Organizing objects using prefixes](#).

In directory buckets, objects are organized in a hierarchical namespace using forward slash (/) as the only supported delimiter. When you upload an object with a key like dir1/dir2/file1.txt, the directories dir1/ and dir2/ are automatically created and managed by Amazon S3. Directories are created during PutObject or CreateMultiPartUpload operations and automatically removed when they become empty after DeleteObject or AbortMultiPartUpload operations. There is no upper limit to the number of objects and subdirectories in a directory.

The directories that are created when objects are uploaded to directory buckets can scale instantaneously to reduce the chance of HTTP 503 (Slow Down) errors. This automatic scaling allows your applications to parallelize read and write requests within and across directories as needed. For S3 Express One Zone, individual directories are designed to support the maximum request rate of a directory bucket. There is no need to randomize key prefixes to achieve optimal performance as the system automatically distributes objects for even load distribution, but as a result, keys are not stored lexicographically in directory buckets. This is in contrast to S3 general purpose buckets where keys that are lexicographically closer are more likely to be co-located on the same server.

For more information about examples of directory bucket operations and directory interactions, see [Directory bucket operation and directory interaction examples](#).

Best practices

Follow the best practices to optimize your directory bucket performance and help your workloads scale over time.

Use directories that contain many entries (objects or subdirectories)

Directory buckets deliver high performance by default for all workloads. For even greater performance optimization with certain operations, consolidating more entries (which are objects or subdirectories) into directories will lead to lower latency and higher request rate:

- Mutating API operations, such as PutObject, DeleteObject, CreateMultiPartUpload and AbortMultiPartUpload, achieve optimal performance when implemented with fewer, denser directories containing thousands of entries, rather than with a large number of smaller directories.

- ListObjectsV2 operations perform better when fewer directories need to be traversed to populate a page of results.

Don't use entropy in prefixes

In Amazon S3 operations, entropy refers to the randomness in prefix naming that helps distribute workloads evenly across storage partitions. However, since directory buckets internally manage load distribution, it's not recommended to use entropy in prefixes for the best performance. This is because for directory buckets, entropy can cause requests to be slower by not reusing the directories that have already been created.

A key pattern such as \$HASH/directory/object could end up creating many intermediate directories. In the following example, all the job-1 s are different directories since their parents are different. Directories will be sparse and mutation and list requests will be slower. In this example there are 12 intermediate Directories that all have a single entry.

```
s3://my-bucket/0cc175b9c0f1b6a831c399e269772661/job-1/file1  
s3://my-bucket/92eb5ffee6ae2fec3ad71c777531578f/job-1/file2  
s3://my-bucket/4a8a08f09d37b73795649038408b5f33/job-1/file3  
s3://my-bucket/8277e0910d750195b448797616e091ad/job-1/file4  
s3://my-bucket/e1671797c52e15f763380b45e841ec32/job-1/file5  
s3://my-bucket/8fa14cdd754f91cc6554c9e71929cce7/job-1/file6
```

Instead, for better performance, we can remove the \$HASH component and allow job-1 to become a single directory, improving the density of a directory. In the following example, the single intermediate directory that has 6 entries can lead to better performance, compared with the previous example.

```
s3://my-bucket/job-1/file1  
s3://my-bucket/job-1/file2  
s3://my-bucket/job-1/file3  
s3://my-bucket/job-1/file4
```

```
s3://my-bucket/job-1/file5
```

```
s3://my-bucket/job-1/file6
```

This performance advantage occurs because when an object key is initially created and its key name includes a directory, the directory is automatically created for the object. Subsequent object uploads to that same directory do not require the directory to be created, which reduces latency on object uploads to existing directories.

Use a separator other than the delimiter / to separate parts of your key if you don't need the ability to logically group objects during ListObjectsV2 calls

Since the / delimiter is treated specially for directory buckets, it should be used with intention. While directory buckets do not lexicographically order objects, objects within a directory are still grouped together in ListObjectsV2 outputs. If you don't need this functionality, you can replace / with another character as a separator to not cause the creation of intermediate directories.

For example, assume the following keys are in a YYYY/MM/DD/HH/ prefix pattern

```
s3://my-bucket/2024/04/00/01/file1
```

```
s3://my-bucket/2024/04/00/02/file2
```

```
s3://my-bucket/2024/04/00/03/file3
```

```
s3://my-bucket/2024/04/01/01/file4
```

```
s3://my-bucket/2024/04/01/02/file5
```

```
s3://my-bucket/2024/04/01/03/file6
```

If you don't have the need to group objects by hour or day in ListObjectsV2 results, but you need to group objects by month, the following key pattern of YYYY/MM/DD-HH- will lead to significantly fewer directories and better performance for the ListObjectsV2 operation.

```
s3://my-bucket/2024/04/00-01-file1
```

```
s3://my-bucket/2024/04/00-01-file2
```

```
s3://my-bucket/2024/04/00-01-file3  
s3://my-bucket/2024/04/01-02-file4  
s3://my-bucket/2024/04/01-02-file5  
s3://my-bucket/2024/04/01-02-file6
```

Use delimited list operations where possible

A `ListObjectsV2` request without a delimiter performs depth-first recursive traversal of all directories. A `ListObjectsV2` request with a delimiter retrieves only entries in the directory specified by the `prefix` parameter, reducing request latency and increasing aggregate keys per second. For directory buckets, use delimited list operations where possible. Delimited lists result in directories being visited fewer times, which leads to more keys per second and lower request latency.

For example, for the following directories and objects in your directory bucket:

```
s3://my-bucket/2024/04/12-01-file1  
s3://my-bucket/2024/04/12-01-file2  
...  
s3://my-bucket/2024/05/12-01-file1  
s3://my-bucket/2024/05/12-01-file2  
...  
s3://my-bucket/2024/06/12-01-file1  
s3://my-bucket/2024/06/12-01-file2  
...  
s3://my-bucket/2024/07/12-01-file1  
s3://my-bucket/2024/07/12-01-file2  
...
```

For better `ListObjectsV2` performance, use a delimited list to list your subdirectories and objects, if your application's logic allows for it. For example, you can run the following command for the delimited list operation,

```
aws s3api list-objects-v2 --bucket my-bucket --prefix '2024/' --delimiter '/'
```

The output is the list of subdirectories.

```
{
  "CommonPrefixes": [
    {
      "Prefix": "2024/04/"
    },
    {
      "Prefix": "2024/05/"
    },
    {
      "Prefix": "2024/06/"
    },
    {
      "Prefix": "2024/07/"
    }
  ]
}
```

To list each subdirectory with better performance, you can run a command like the following example:

Command:

```
aws s3api list-objects-v2 --bucket my-bucket --prefix '2024/04' --delimiter '/'
```

Output:

```
{
  "Contents": [
    {
      "Key": "2024/04/12-01-file1"
    },
    {
      "Key": "2024/04/12-01-file2"
    }
  ]
}
```

```
    }  
]  
}
```

Co-locate S3 Express One Zone storage with your compute resources

With S3 Express One Zone, each directory bucket is located in a single Availability Zone that you select when you create the bucket. You can get started by creating a new directory bucket in an Availability Zone local to your compute workloads or resources. You can then immediately begin very low-latency reads and writes. Directory buckets are a type of S3 buckets where you can choose the Availability Zone in an AWS Region to reduce latency between compute and storage.

If you access directory buckets across Availability Zones, you may experience slightly increased latency. To optimize performance, we recommend that you access a directory bucket from Amazon Elastic Container Service, Amazon Elastic Kubernetes Service, and Amazon Elastic Compute Cloud instances that are located in the same Availability Zone when possible.

Use concurrent connections to achieve high throughput with objects over 1MB

You can achieve the best performance by issuing multiple concurrent requests to directory buckets to spread your requests over separate connections to maximize the accessible bandwidth. Like general purpose buckets, S3 Express One Zone doesn't have any limits for the number of connections made to your directory bucket. Individual directories can scale performance horizontally and automatically when large numbers of concurrent writes to the same directory are happening.

Individual TCP connections to directory buckets have a fixed upper bound on the number of bytes that can be uploaded or downloaded per second. When objects get larger, request times become dominated by byte streaming rather than transaction processing. To use multiple connections to parallelize the upload or download of larger objects, you can reduce end-to-end latency. If using the Java 2.x SDK, you should consider using the [S3 Transfer Manager](#) which will take advantage of performance improvements such as the [multipart upload API operations](#) and byte-range fetches to access data in parallel.

Use Gateway VPC endpoints

Gateway endpoints provide a direct connection from your VPC to directory buckets, without requiring an internet gateway or a NAT device for your VPC. To reduce the amount of time your packets spend on the network, you should configure your VPC with a gateway VPC endpoint for directory buckets. For more information, see [Networking for directory buckets](#).

Use session authentication and reuse session tokens while they're valid

Directory buckets provide a session token authentication mechanism to reduce latency on performance-sensitive API operations. You can make a single call to `CreateSession` to get a session token which is then valid for all requests in the following 5 minutes. To get the lowest latency in your API calls, make sure to acquire a session token and reuse it for the entire lifetime of that token before refreshing it.

If you use AWS SDKs, SDKs handle the session token refreshes automatically to avoid service interruptions when a session expires. We recommend that you use the AWS SDKs to initiate and manage requests to the `CreateSession` API operation.

For more information about `CreateSession`, see [Authorizing Zonal endpoint API operations with `CreateSession`](#).

Use a CRT-based client

The AWS Common Runtime (CRT) is a set of modular, performant, and efficient libraries written in C and meant to act as the base of the AWS SDKs. The CRT provides improved throughput, enhanced connection management, and faster startup times. The CRT is available through all the AWS SDKs except Go.

For more information on how to configure the CRT for the SDK you use, see [AWS Common Runtime \(CRT\) libraries](#), [Accelerate Amazon S3 throughput with the AWS Common Runtime](#), [Introducing CRT-based S3 client and the S3 Transfer Manager in the AWS SDK for Java 2.x](#), [Using S3CrtClient for Amazon S3 operations](#), and [Configure AWS CRT-based HTTP clients](#).

Use the latest version of the AWS SDKs

The AWS SDKs provide built-in support for many of the recommended guidelines for optimizing Amazon S3 performance. The SDKs offer a simpler API for taking advantage of Amazon S3 from within an application and are regularly updated to follow the latest best practices. For example, the SDKs automatically retry requests after HTTP 503 errors and handle slow connections responses.

If using the Java 2.x SDK, you should consider using the [S3 Transfer Manager](#), which automatically scales connections horizontally to achieve thousands of requests per second using byte-range requests when appropriate. Byte-range requests can improve performance because you can use concurrent connections to S3 to fetch different byte ranges from within the same object. This helps you achieve higher aggregate throughput versus a single whole-object request. So it's important to use the latest version of the AWS SDKs to obtain the latest performance optimization features.

Performance troubleshooting

Are you setting retry requests for latency-sensitive applications?

S3 Express One Zone is purpose-built to deliver consistent levels of high-performance without additional tuning. However, setting aggressive timeout values and retries can further help drive consistent latency and performance. The AWS SDKs have configurable timeout and retry values that you can tune to the tolerances of your specific application.

Are you using AWS Common Runtime (CRT) libraries and optimal Amazon EC2 instance types?

Applications that perform a large number of read and write operations likely need more memory or computing capacity than applications that don't. When launching your Amazon Elastic Compute Cloud (Amazon EC2) instances for your performance-demanding workload, choose instance types that have the amount of these resources that your application needs. S3 Express One Zone high-performance storage is ideally paired with larger and newer instance types with larger amounts of system memory and more powerful CPUs and GPUs that can take advantage of higher-performance storage. We also recommend using the latest versions of the CRT-enabled AWS SDKs, which can better accelerate read and write requests in parallel.

Are you using AWS SDKs for session-based authentication?

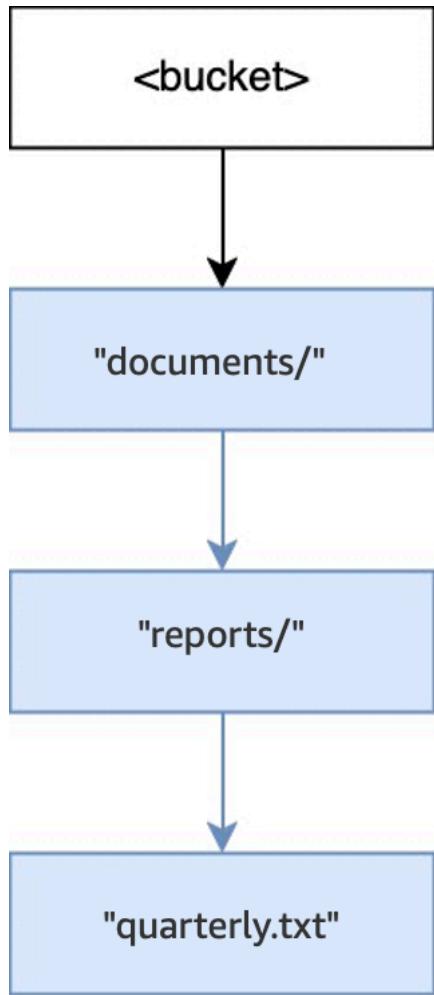

With Amazon S3, you can also optimize performance when you're using HTTP REST API requests by following the same best practices that are part of the AWS SDKs. However, with the session-based authorization and authentication mechanism that's used by S3 Express One Zone, we strongly recommend that you use the AWS SDKs to manage `CreateSession` and its managed session token. The AWS SDKs automatically create and refresh tokens on your behalf by using the `CreateSession` API operation. Using `CreateSession` saves on per-request round-trip latency to AWS Identity and Access Management (IAM) to authorize each request.

Directory bucket operation and directory interaction examples

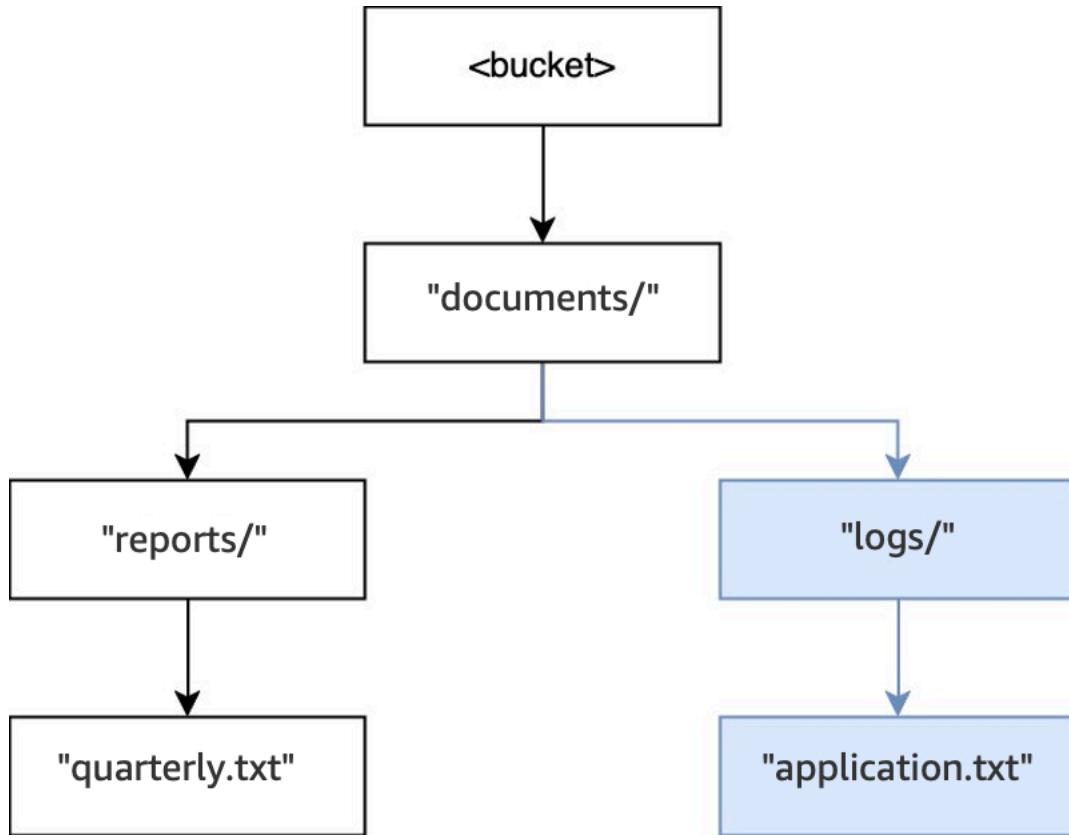

The following shows three examples about how directory buckets work.

Example 1: How S3 PutObject requests to a directory bucket interact with directories

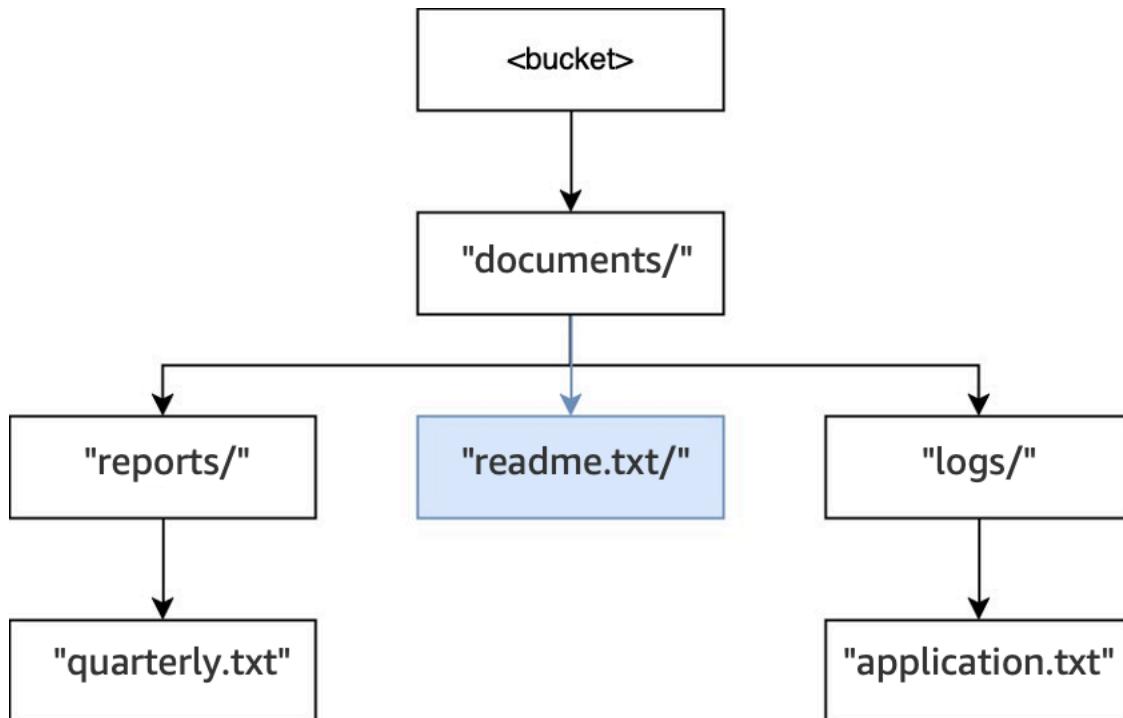

1. When the operation `PUT(<bucket>, "documents/reports/quarterly.txt")` is executed in an empty bucket, the directory `documents/` within the root of the bucket is created, the directory `reports/` within `documents/` is created, and the object `quarterly.txt` within `reports/` is created. For this operation, two directories were created in addition to the object.

2. Then, when another operation `PUT(<bucket>, "documents/logs/application.txt")` is executed, the directory `documents/` already exists, the directory `logs/` within `documents/` doesn't exist and is created, and the object `application.txt` within `logs/` is created. For this operation, only one directory was created in addition to the object.

3. Lastly, when a `PUT(<bucket>, "documents/readme.txt")` operation is executed, the directory `documents/` within the root already exists and the object `readme.txt` is created. For this operation, no directories are created.

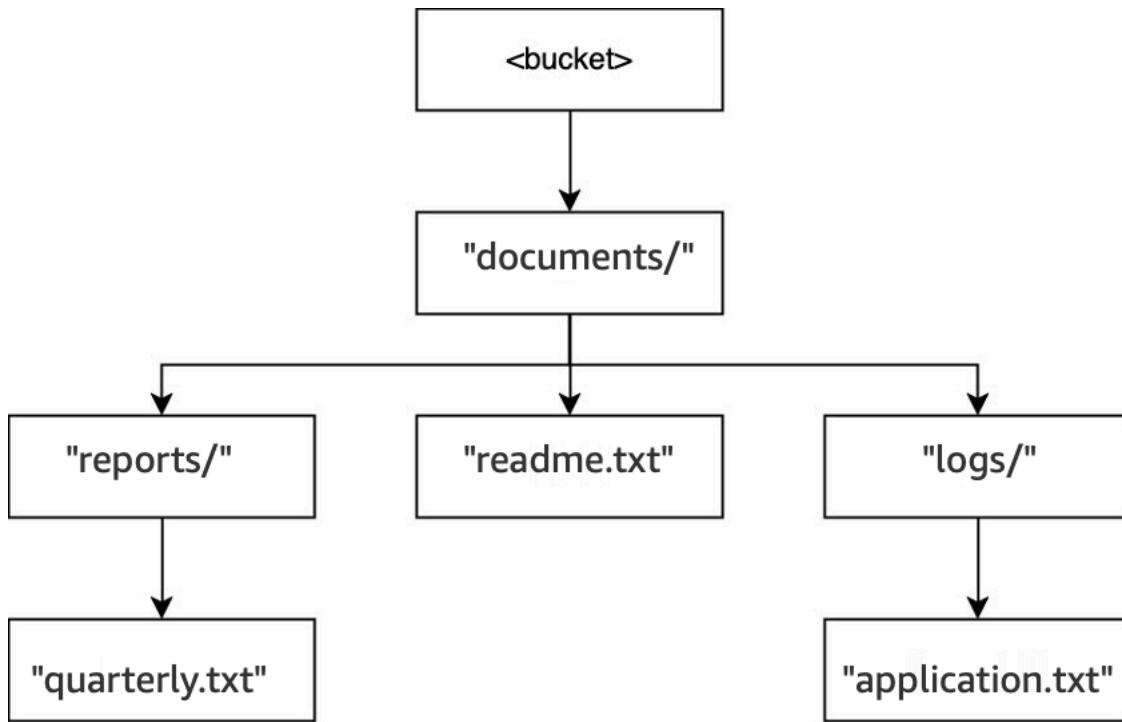

Example 2: How S3 ListObjectsV2 requests to a directory bucket interact with directories

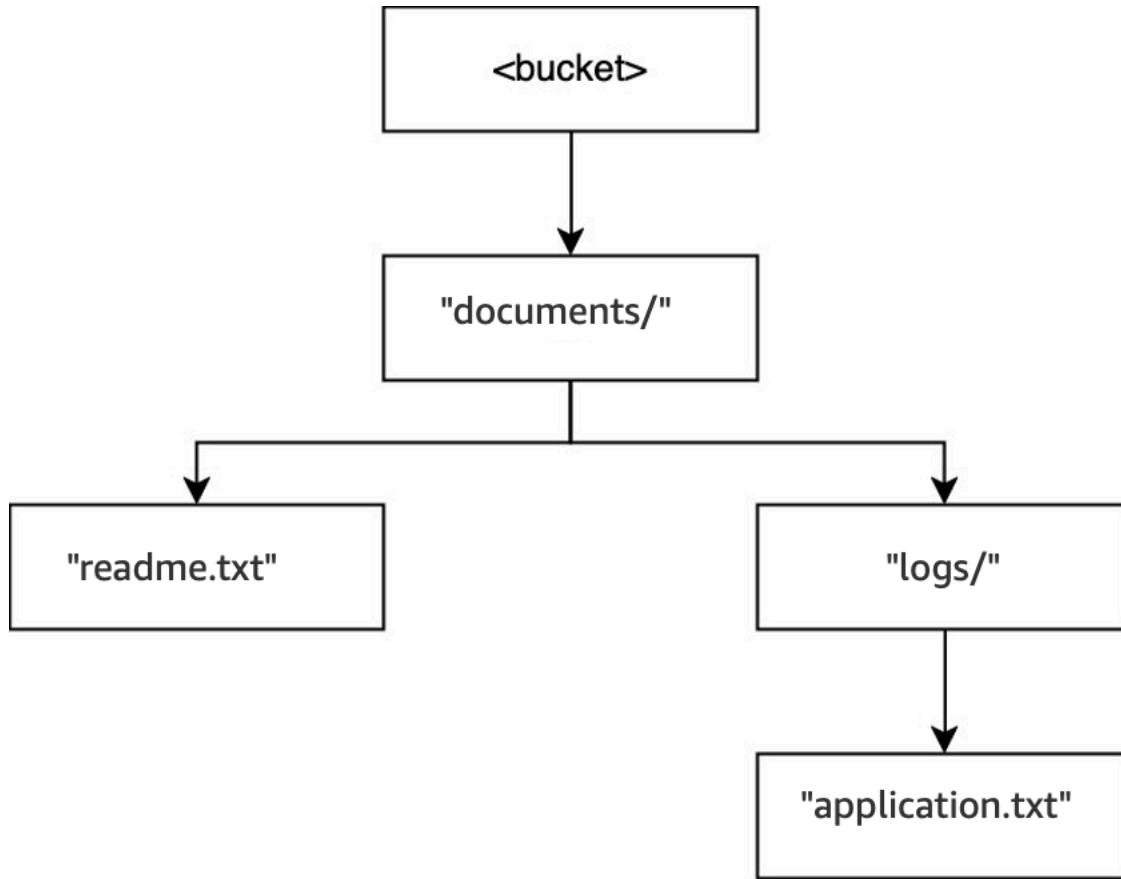

For the S3 ListObjectsV2 requests without specifying a delimiter, a bucket is traversed in a depth-first manner. The outputs are returned in a consistent order. However, while this order remains the same between requests, the order is not lexicographic. For the bucket and directories created in the previous example:

1. When a LIST(<bucket>) is executed, the directory documents/ is entered and the traversing begins.
2. The subdirectory logs/ is entered and the traversing begins.
3. The object application.txt is found within logs/.
4. No more entries exist within logs/. The List operation exits from logs/ and enters documents/ again.
5. The documents/ directory continues being traversed and the object readme.txt is found.
6. The documents/ directory continues being traversed and the subdirectory reports/ is entered and the traversing begins.
7. The object quarterly.txt is found within reports/.
8. No more entries exist within reports/. The List exits from reports/ and enters documents/ again.
9. No more entries exist within documents/ and the List returns.

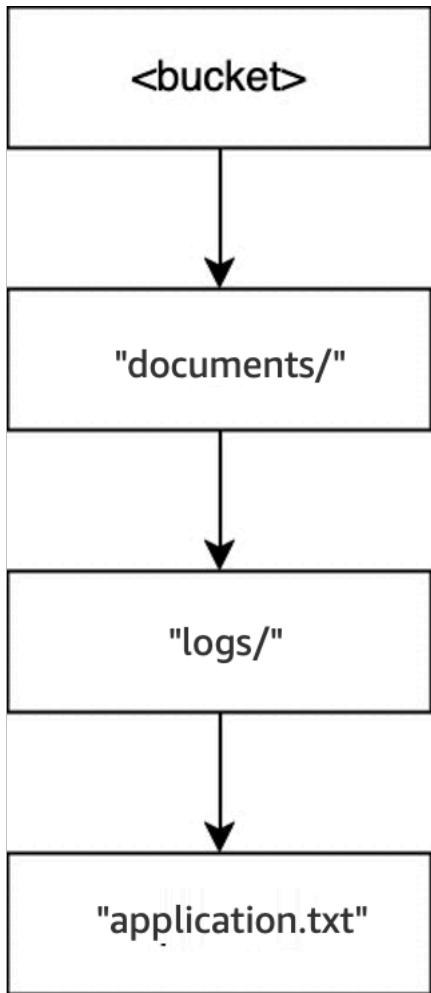

In this example, logs/ is ordered before readme.txt and readme.txt is ordered before reports/.

Example 3: How S3 DeleteObject requests to a directory bucket interact with directories

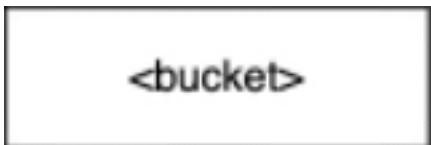

1. In that same bucket, when the operation `DELETE(<bucket>, "documents/reports/quarterly.txt")` is executed, the object `quarterly.txt` is deleted, leaving the directory `reports/` empty and causing it to be deleted immediately. The `documents/` directory is not empty because it has both the directory `logs/` and the object `readme.txt` within it, so it's not deleted. For this operation, only one object and one directory were deleted.

2. When the operation `DELETE(<bucket>, "documents/readme.txt")` is executed, the object `readme.txt` is deleted. `documents/` is still not empty because it contains the directory `logs/`, so it's not deleted. For this operation, no directories are deleted and only the object is deleted.

3. Lastly, when the operation `DELETE(<bucket>, "documents/logs/application.txt")` is executed, `application.txt` is deleted, leaving `logs/` empty and causing it to be deleted immediately. This then leaves `documents/` empty and causing it to also be deleted immediately. For this operation, two directories and one object are deleted. The bucket is now empty.

Data residency workloads

AWS Dedicated Local Zones (Dedicated Local Zones) are a type of AWS Infrastructure that are fully managed by AWS, built for exclusive use by you or your community, and placed in a location or data center specified by you to help comply with regulatory requirements. Dedicated Local Zones

are a type of AWS Local Zones (Local Zones) offering. For more information, see [AWS Dedicated Local Zones](#).

In Dedicated Local Zones, you can create S3 directory buckets to store data in a specific data perimeter, which helps support data residency and isolation use cases. Directory buckets in Dedicated Local Zones can support the S3 Express One Zone and S3 One Zone-Infrequent Access (S3 One Zone-IA; Z-IA) storage classes. Directory buckets are not currently available in other [AWS Local Zones locations](#).

You can use the AWS Management Console, REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs in Dedicated Local Zones.

For more information about working with the directory buckets in Local Zones, see the following topics:

Concepts for directory buckets in Local Zones

Before creating a directory bucket in a Local Zone, you must have the Local Zone ID where you want to create a bucket. You can find all Local Zone information by using the [DescribeAvailabilityZones](#) API operation. This API operation lists information about Local Zones, including their Local Zone IDs, parent Region names, network border groups, and opt-in status. After you have your Local Zone ID and you are opted in, you can create a directory bucket in the Local Zone. A directory bucket name consists of a base name that you provide and a suffix that contains the Zone ID of your bucket location, followed by --x-s3.

A Local Zone is connected to the **parent Region** using the Amazon redundant and very high-bandwidth private network. This gives applications running in the Local Zone fast, secure, and seamless access to the rest of the AWS services in the parent Region. **Parent Zone ID** is the ID of the zone that handles the Local Zone control plane operations. **Network Border Group** is a unique

group from which AWS advertises public IP addresses. For more information about Local Zones, parent Region, and parent Zone ID, see [AWS Local Zones concepts](#) in the AWS Local Zones *User Guide*.

All directory buckets use the s3express namespace, which is separate from the s3 namespace for general purpose buckets. For directory buckets, requests are routed to either a **Regional endpoint** or a **Zonal endpoint**. The routing is handled automatically for you if you use the AWS Management Console, AWS CLI, or AWS SDKs.

Most bucket-level API operations (such as CreateBucket and DeleteBucket) are routed to Regional endpoints, and are referred to as Regional endpoint API operations. Regional endpoints are in the format of s3express-control.ParentRegionCode.amazonaws.com. All object-level API operations (such as PutObject) and two bucket-level API operations (CreateSession and HeadBucket) are routed to Zonal endpoints, and are referred to as Zonal endpoint API operations. Zonal endpoints are in the format of s3express-LocalZoneID.ParentRegionCode.amazonaws.com. For a complete list of API operations by endpoint type, see [Directory bucket API operations](#).

S3 is available in the Beijing Local Zone:

Local Zone ID: cnn1-pkx1-az1

Parent Region Name: China (Beijing)

Parent Region Code: cn-north-1

Parent Zone IDs: cnn1-az1

Local Zone Name: China (Beijing)

Local Zone Code: cnn1-pkx1-az1

Network Border Group: cn-north-1-pkx-1

Example bucket ARN: arn:aws-cn:s3express:cn-north-1:[123456789012](#):bucket/[amzn-s3-demo-bucket](#)--cnn1-pkx1-az1--x-s3

Regional endpoint: s3express-control.cn-north-1.amazonaws.com.cn

Zonal endpoint: s3express-cnn1-pkx1-az1.cn-north-1.amazonaws.com.cn

Storage class: S3 One Zone-Infrequent Access (S3 One Zone-IA; Z-IA)

To access directory buckets in Local Zones from your virtual private cloud (VPC), you can use gateway VPC endpoints. There is no additional charge for using gateway endpoints. To configure gateway VPC endpoints to access directory buckets and objects in Local Zones, see [Private connectivity from your VPC](#).

Enable accounts for Local Zones

The following topic describes how accounts are enabled for Dedicated Local Zones.

For all the services in AWS Dedicated Local Zones (Dedicated Local Zones), including Amazon S3, your administrator must enable your AWS account before you can create or access any resource in the Dedicated Local Zone. You can use the [DescribeAvailabilityZones](#) API operation to confirm your account ID access to a Local Zone.

To further protect your data in Amazon S3, by default, you only have access to the S3 resources that you create. Buckets in Local Zones have all S3 Block Public Access settings enabled by default and S3 Object Ownership is set to bucket owner enforced. These settings can't be modified. Optionally, to restrict access to only within the Local Zone network border groups, you can use the condition key `s3express:AllAccessRestrictedToLocalZoneGroup` in your IAM policies. For more information, see [Authenticating and authorizing for directory buckets in Local Zones](#).

Private connectivity from your VPC

To reduce the amount of time your packets spend on the network, configure your virtual private cloud (VPC) with a gateway endpoint to access directory buckets in Availability Zones while keeping traffic within the AWS network, and at no additional cost.

To configure a gateway VPC endpoint

1. Open the [Amazon VPC Console](#).
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**.
4. Create a name for your endpoint.
5. For **Service category**, choose **AWS services**.
6. For **Services**, add the filter **Type=Gateway** and then choose the option button next to **com.amazonaws.*region*.s3express**.

7. For **VPC**, choose the VPC in which to create the endpoint.
8. For **Route tables**, choose the route table in your VPC to be used by the endpoint. After the endpoint is created, a route record will be added to the route table that you select in this step.
9. For **Policy**, choose **Full access** to allow all operations by all principals on all resources over the VPC endpoint. Otherwise, choose **Custom** to attach a VPC endpoint policy that controls the principals' permissions to perform actions on resources over the VPC endpoint.
10. For **IP address type**, choose from the following options:
 - **IPv4** – Assign IPv4 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have IPv4 address ranges and the service accepts IPv4 requests.
 - **IPv6** – Assign IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets are IPv6 only subnets and the service accepts IPv6 requests.
 - **Dualstack** – Assign both IPv4 and IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have both IPv4 and IPv6 address ranges and the service accepts both IPv4 and IPv6 requests.
11. (Optional) To add a tag, choose **Add new tag**, and enter the tag key and the tag value.
12. Choose **Create endpoint**.

To learn more about gateway VPC endpoints, see [Gateway endpoints](#) in the *AWS PrivateLink Guide*. For the data residency use cases, we recommend enabling access to your buckets only from your VPC using gateway VPC endpoints. When access is restricted to a VPC or a VPC endpoint, you can access the objects through the AWS Management Console, the REST API, AWS CLI, and AWS SDKs.

 **Note**

To restrict access to a VPC or a VPC endpoint using the AWS Management Console, you must use the AWS Management Console Private Access. For more information, see [AWS Management Console Private Access](#) in the *AWS Management Console guide*.

Creating a directory bucket in a Local Zone

In Dedicated Local Zones, you can create directory buckets to store and retrieve objects in a specific data perimeter to help meet your data residency and data isolation use cases. S3 directory buckets are the only supported bucket type in Local Zones, and contain a bucket location type called `LocalZone`. A directory bucket name consists of a base name that you provide and a suffix that

contains the Zone ID of your bucket location and --x-s3. You can obtain a list of Local Zone IDs by using the [DescribeAvailabilityZones](#) API operation. For more information, see [Directory bucket naming rules](#).

Note

- For all the services in AWS Dedicated Local Zones (Dedicated Local Zones), including S3, your administrator must enable your AWS account before you can create or access any resource in the Dedicated Local Zone. For more information, see [Enable accounts for Local Zones](#).
- For the data residency requirements, we recommend enabling access to your buckets only from gateway VPC endpoints. For more information, see [Private connectivity from your VPC](#).
- To restrict access to only within the Local Zone network border groups, you can use the condition key s3express:AllAccessRestrictedToLocalZoneGroup in your IAM policies. For more information, see [Authenticating and authorizing for directory buckets in Local Zones](#).

The following describes ways to create a directory bucket in a single Local Zone with the AWS Management Console, AWS CLI, and AWS SDKs.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the parent Region of a Local Zone in which you want to create a directory bucket.

Note

For more information about the parent Regions, see [Concepts for directory buckets in Local Zones](#).

3. In the left navigation pane, choose **Buckets**.
4. Choose **Create bucket**.

- The **Create bucket** page opens.
5. Under **General configuration**, view the AWS Region where your bucket will be created.
 6. Under **Bucket type**, choose **Directory**.

 **Note**

- If you've chosen a Region that doesn't support directory buckets, the bucket type defaults to a general purpose bucket. To create a directory bucket, you must choose a supported Region. For a list of Regions that support directory buckets, see [the section called "Regional and Zonal endpoints for directory buckets"](#).
- After you create the bucket, you can't change the bucket type.

7. Under **Bucket location**, choose a Local Zone that you want to use.

 **Note**

The Local Zone can't be changed after the bucket is created.

8. Under **Bucket location**, select the checkbox to acknowledge that in the event of a Local Zone outage, your data might be unavailable or lost.

 **Important**

Although directory buckets are stored across multiple devices within a single Local Zone, directory buckets don't store data redundantly across Local Zones.

9. For **Bucket name**, enter a name for your directory bucket.

For more information about the naming rules for directory buckets, see [General purpose bucket naming rules](#). A suffix is automatically added to the base name that you provide when you create a directory bucket using the console. This suffix includes the Zone ID of the Local Zone that you chose.

After you create the bucket, you can't change its name.

⚠️ Important

Don't include sensitive information, such as account numbers, in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

10. Under **Object Ownership**, the **Bucket owner enforced** setting is automatically enabled, and all access control lists (ACLs) are disabled. For directory buckets, ACLs are disabled and can't be enabled.

With the **Bucket owner enforced** setting enabled, the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect access permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

11. Under **Block Public Access settings for this bucket**, all Block Public Access settings for your directory bucket are automatically enabled. These settings can't be modified for directory buckets. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).
12. Under **Default encryption**, directory buckets use **Server-side encryption with Amazon S3 managed keys (SSE-S3)** to encrypt data by default. You also have the option to encrypt data in directory buckets with **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**.
13. Choose **Create bucket**.

After creating the bucket, you can add files and folders to the bucket. For more information, see [the section called "Working with objects in a directory bucket"](#).

Using the AWS CLI

This example shows how to create a directory bucket in a Local Zone by using the AWS CLI. To use the command, replace the *user input placeholders* with your own information.

When you create a directory bucket, you must provide configuration details and use the following naming convention: *bucket-base-name--zone-id--x-s3*.

```
aws s3api create-bucket  
--bucket bucket-base-name--zone-id--x-s3
```

```
--create-bucket-configuration 'Location={Type=LocalZone,Name=local-zone-id},Bucket={DataRedundancy=SingleLocalZone,Type=Directory}'  
--region parent-region-code
```

For more information about Local Zone ID and Parent Region Code, see [Concepts for directory buckets in Local Zones](#). For more information about the AWS CLI command, see [create-bucket](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

SDK for Go

This example shows how to create a directory bucket in a Local Zone by using the AWS SDK for Go.

Example

```
var bucket = "bucket-base-name--zone-id--x-s3" // The full directory bucket name

func runCreateBucket(c *s3.Client) {
    resp, err := c.CreateBucket(context.Background(), &s3.CreateBucketInput{
        Bucket: &bucket,
        CreateBucketConfiguration: &types.CreateBucketConfiguration{
            Location: &types.LocationInfo{
                Name: aws.String("local-zone-id"),
                Type: types.LocationTypeLocalZone,
            },
            Bucket: &types.BucketInfo{
                DataRedundancy: types.DataRedundancySingleLocalZone,
                Type:          types.BucketTypeDirectory,
            },
        },
    })
    var terr *types.BucketAlreadyOwnedByYou
    if errors.As(err, &terr) {
        fmt.Printf("BucketAlreadyOwnedByYou: %s\n", aws.ToString(terr.Message))
        fmt.Printf("noop...\n") // No operation performed, just printing a message
        return
    }
    if err != nil {
        log.Fatal(err)
    }
}
```

```
    fmt.Sprintf("bucket created at %s\n", aws.ToString(resp.Location))
}
```

SDK for Java 2.x

This example shows how to create a directory bucket in a Local Zone by using the AWS SDK for Java 2.x.

Example

```
public static void createBucket(S3Client s3Client, String bucketName) {

    //Bucket name format is {base-bucket-name}--{local-zone-id}--x-s3
    //example: doc-example-bucket--local-zone-id--x-s3 is a valid name for a
    //directory bucket created in a Local Zone.

    CreateBucketConfiguration bucketConfiguration =
CreateBucketConfiguration.builder()
        .location(LocationInfo.builder()
            .type(LocationType.LOCAL_ZONE)
            .name("local-zone-id").build()) //this must match the Local
Zone ID in your bucket name
        .bucket(BucketInfo.builder()
            .type(BucketType.DIRECTORY)
            .dataRedundancy(DataRedundancy.SINGLE_LOCAL_ZONE)
            .build()).build();

    try {

        CreateBucketRequest bucketRequest =
CreateBucketRequest.builder().bucket(bucketName).createBucketConfiguration(bucketConfigurat
            CreateBucketResponse response = s3Client.createBucket(bucketRequest);
            System.out.println(response);
    }

    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

AWS SDK for JavaScript

This example shows how to create a directory bucket in a Local Zone by using the AWS SDK for JavaScript.

Example

```
// file.mjs, run with Node.js v16 or higher
// To use with the preview build, place this in a folder
// inside the preview build directory, such as /aws-sdk-js-v3/workspace/

import { S3 } from "@aws-sdk/client-s3";

const region = "parent-region-code";
const zone = "local-zone-id";
const suffix = `${zone}--x-s3`;

const s3 = new S3({ region });

const bucketName = `"bucket-base-name--${suffix}`; // Full directory bucket name

const createResponse = await s3.createBucket(
  { Bucket: bucketName,
    CreateBucketConfiguration: {Location: {Type: "LocalZone", Name: "local-zone-id"}, Bucket: { Type: "Directory", DataRedundancy: "SingleLocalZone" }}
  }
);
```

SDK for .NET

This example shows how to create a directory bucket in a Local Zone by using the SDK for .NET.

Example

```
using (var amazonS3Client = new AmazonS3Client())
{
    var putBucketResponse = await amazonS3Client.PutBucketAsync(new PutBucketRequest
    {

        BucketName = "bucket-base-name--local-zone-id--x-s3",
        PutBucketConfiguration = new PutBucketConfiguration
        {
```

```
        BucketInfo = new BucketInfo { DataRedundancy =
DataRedundancy.SingleLocalZone, Type = BucketType.Directory },
        Location = new LocationInfo { Name = "local-zone-id", Type =
LocationType.LocalZone }
    }
}).ConfigureAwait(false);
}
```

SDK for PHP

This example shows how to create a directory bucket in a Local Zone by using the AWS SDK for PHP.

Example

```
require 'vendor/autoload.php';

$s3Client = new S3Client([
    'region'      => 'parent-region-code',
]);

$result = $s3Client->createBucket([
    'Bucket' => 'bucket-base-name--local-zone-id--x-s3',
    'CreateBucketConfiguration' => [
        'Location' => ['Name'=> 'local-zone-id', 'Type'=> 'LocalZone'],
        'Bucket' => ["DataRedundancy" => "SingleLocalZone" , "Type" => "Directory"]
    ],
]);
```

SDK for Python

This example shows how to create a directory bucket in a Local Zone by using the AWS SDK for Python (Boto3).

Example

```
import logging
import boto3
from botocore.exceptions import ClientError
```

```
def create_bucket(s3_client, bucket_name, local_zone):
    """
    Create a directory bucket in a specified Local Zone

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket to create; for example, 'bucket-base-name--local-zone-id--x-s3'
    :param local_zone: String; Local Zone ID to create the bucket in
    :return: True if bucket is created, else False
    """

    try:
        bucket_config = {
            'Location': {
                'Type': 'LocalZone',
                'Name': local_zone
            },
            'Bucket': {
                'Type': 'Directory',
                'DataRedundancy': 'SingleLocalZone'
            }
        }
        s3_client.create_bucket(
            Bucket = bucket_name,
            CreateBucketConfiguration = bucket_config
        )
    except ClientError as e:
        logging.error(e)
        return False
    return True

if __name__ == '__main__':
    bucket_name = 'BUCKET_NAME'
    region = 'parent-region-code'
    local_zone = 'local-zone-id'
    s3_client = boto3.client('s3', region_name = region)
    create_bucket(s3_client, bucket_name, local_zone)
```

SDK for Ruby

This example shows how to create an directory bucket in a Local Zone by using the AWS SDK for Ruby.

Example

```
s3 = Aws::S3::Client.new(region:'parent-region-code')
s3.create_bucket(
  bucket: "bucket-base-name--local-zone-id--x-s3",
  create_bucket_configuration: {
    location: { name: 'local-zone-id', type: 'LocalZone' },
    bucket: { data_redundancy: 'SingleLocalZone', type: 'Directory' }
  }
)
```

Authenticating and authorizing for directory buckets in Local Zones

Directory buckets in Local Zones support both AWS Identity and Access Management (IAM) authorization and session-based authorization. For more information about authentication and authorization for directory buckets, see [Authenticating and authorizing requests](#).

Resources

Amazon Resource Names (ARNs) for directory buckets contain the s3express namespace, the AWS parent Region, the AWS account ID, and the directory bucket name which includes the Zone ID. To access and perform actions on your directory bucket, you must use the following ARN format:

```
arn:aws:s3express:region-code:account-id:bucket/bucket-base-name--ZoneID--x-s3
```

For directory buckets in a Local Zone, the Zone ID is the ID of the Local Zone. For more information about directory buckets in Local Zones, see [Concepts for directory buckets in Local Zones](#). For more information about ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *IAM User Guide*. For more information about resources, see [IAM JSON Policy Elements: Resource](#) in the *IAM User Guide*.

Condition keys for directory buckets in Local Zones

In Local Zones, you can use all of these [condition keys](#) in your IAM policies. Additionally, to create a data perimeter around your Local Zone network border groups, you can use the condition key s3express:AllAccessRestrictedToLocalZoneGroup to deny all requests from outside the groups.

The following condition key can be used to further refine the conditions under which an IAM policy statement applies. For a complete list of API operations, policy actions, and condition keys that are supported by directory buckets, see [Policy actions for directory buckets](#).

Note

The following condition key only applies to Local Zones and isn't supported in Availability Zones and AWS Regions.

API operations	Policy actions	Description	Condition key	Description	Type
<u>Zonal endpoint API operations</u>	s3express:CreateSession	Grants permission to create a session token, which is used for granting access to all Zonal endpoint API operations, such as <code>CreateSession</code> , <code>HeadBucket</code> , <code>CopyObject</code> , <code>PutObject</code> , and <code>GetObject</code> .	s3express:AllAccess, sRestrictToLocalZoneGroup	Filters all access to the bucket unless the request originates from the AWS Local Zone network border groups provided in this condition key. Values: Local Zone network border group value	String

Example policies

To restrict object access to requests from within a data residency boundary that you define (specifically, a Local Zone Group which is a set of Local Zones parented to the same AWS Region), you can set any of the following policies:

- The service control policy (SCP). For information about SCPs, see [Service control policies \(SCPs\)](#) in the *AWS Organizations User Guide*.
- The IAM identity-based policy for the IAM role.

- The VPC endpoint policy. For more information about the VPC endpoint policies, see [Control access to VPC endpoints using endpoint policies](#) in the *AWS PrivateLink Guide*.
- The S3 bucket policy.

 **Note**

The condition key `s3express:AllAccessRestrictedToLocalZoneGroup` doesn't support access from an on-premises environment. To support the access from an on-premises environment, you must add the source IP to the policies. For more information, see [aws:SourceIp](#) in the IAM User Guide.

Differences for directory buckets

When using Amazon S3, you can choose the bucket type that best fits your application and performance requirements. A directory bucket is a type of bucket that is best used for low latency or data residency use cases. To learn more about directory buckets, see [Working with directory buckets](#).

For more information about how directory buckets are different, see the following topics.

Topics

- [Differences for directory buckets](#)
- [API operations supported for directory buckets](#)
- [Amazon S3 features not supported by directory buckets](#)

Differences for directory buckets

- **Directory bucket names**
 - A directory bucket name consists of a base name that you provide and a suffix that contains the ID of the AWS Zone (an Availability Zone or Local Zone) that your bucket is located in, followed by --x-s. For a list of rules and examples of directory bucket names, see [Directory bucket naming rules](#).
- **ListObjectsV2 behavior**
 - For directory buckets, ListObjectsV2 does not return objects in lexicographical (alphabetical) order. Additionally, prefixes must end in a delimiter and only "/" can be specified as the delimiter.
 - For directory buckets, ListObjectsV2 response includes the prefixes that are related only to in-progress multipart uploads.
- **Deletion behavior** – When you delete an object in a directory bucket, Amazon S3 recursively deletes any empty directories in the object path. For example, if you delete the object key dir1/dir2/file1.txt, Amazon S3 deletes file1.txt. If the dir1/ and dir2/ directories are empty and contain no other objects, Amazon S3 also deletes those directories.
- **ETags and checksums** – Entity tags (ETags) for directory buckets are random alphanumeric strings unique to the object and not MD5 checksums. For more information about using additional checksums with directory buckets, see [S3 additional checksum best practices](#).
- **Object keys in DeleteObjects requests**
 - Object keys in DeleteObjects requests must contain at least one non-white space character. Strings of all white space characters aren't supported in DeleteObjects requests.
 - Object keys in DeleteObjects requests cannot contain Unicode control characters, except for the newline (\n), tab (\t), and carriage return (\r) characters.
- **Regional and Zonal endpoints** – Bucket-management API operations for directory buckets are available through a Regional endpoint and are referred to as Regional endpoint API operations.

Examples of Regional endpoint API operations are `CreateBucket` and `DeleteBucket`. After you create a directory bucket, you can use Zonal endpoint API operations to upload and manage the objects in your directory bucket. Zonal endpoint API operations are available through a Zonal endpoint. Examples of Zonal endpoint API operations are `PutObject` and `CopyObject`. When using directory buckets, you must specify the Region in all requests. For Regional endpoints, you specify the Region, for example, `s3express-control.us-west-2.amazonaws.com`. For Zonal endpoints, you specify both the Region and the Availability Zone, for example, `s3express-usw2-az1.us-west-2.amazonaws.com`. For more information, see [Regional and Zonal endpoints for directory buckets](#).

- **Multipart uploads** – You can upload and copy large objects that are stored in directory buckets by using the multipart upload process. However, the following are some differences when using the multipart upload process with objects stored in directory buckets. For more information, see [the section called “Using multipart uploads with directory buckets”](#).
 - The object creation date is the completion date of the multipart upload.
 - Multipart part numbers must use consecutive part numbers. If you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates an HTTP 400 (Bad Request) error.
 - The initiator of a multipart upload can abort the multipart upload request only if they have been granted explicit allow access to `AbortMultipartUpload` through the `s3express:CreateSession` permission. For more information, see [Authorizing Regional endpoint API operations with IAM](#).
- **Emptying a directory bucket** – The `s3 rm` command through the AWS Command Line Interface (CLI), the `delete` operation through Mountpoint, and the **Empty** bucket option button through the AWS Management Console are unable to delete in-progress multipart uploads in a directory bucket. To delete these in-progress multipart uploads, use the `ListMultipartUploads` operation to list the in-progress multipart uploads in the bucket and use the `AbortMultipartUpload` operation to abort all the in-progress multipart uploads.
- **AWS Local Zones** – Local Zones are only supported for directory buckets not general purpose buckets.
 - Appending data to existing objects isn't supported for directory buckets that reside in Local Zones. You can only append data to existing objects in directory buckets that reside in Availability Zones.

API operations supported for directory buckets

The directory buckets support both Regional (bucket level, or control plane) and Zonal (object level, or data plane) endpoint API operations. For more information, see [Networking for directory buckets](#) and [Endpoints and gateway VPC endpoints](#). For a list of supported API operations see [Directory bucket API operations](#).

Amazon S3 features not supported by directory buckets

The following Amazon S3 features are not supported by directory buckets:

- AWS managed policies
- AWS PrivateLink for S3
- MD5 checksums
- Multi-factor authentication (MFA) delete
- S3 Object Lock
- Requester Pays
- S3 Access Grants
- Amazon CloudWatch request metrics
- S3 Event Notifications
- S3 Lifecycle transition actions
- S3 Multi-Region Access Points
- S3 Object Lambda Access Points
- S3 Versioning
- S3 Inventory
- S3 Replication
- Object tags
- S3 Select
- Server access logs
- Static website hosting
- S3 Storage Lens
- S3 Storage Lens groups
- S3 Transfer Acceleration

- Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)
- The option to copy an existing bucket's settings when creating a new bucket in the Amazon S3 console
- Enhanced access denied (HTTP 403 Forbidden) error messages

Networking for directory buckets

To access directory buckets and objects inside, you use Regional and Zonal API endpoints that are different from the standard Amazon S3 endpoints. Depending on the S3 API operation that you use, either a Zonal or Regional endpoint is required. For a complete list of API operations by endpoint type, see [Differences for directory buckets](#).

You can access both Zonal and Regional API operations through gateway virtual private cloud (VPC) endpoints.

The following topics describe the networking requirements for accessing S3 Express One Zone by using a gateway VPC endpoint.

Topics

- [Endpoints](#)
- [Configuring VPC gateway endpoints](#)

Endpoints

You can access directory buckets and objects inside from your VPC by using gateway VPC endpoints. Directory buckets use Regional and Zonal API endpoints. Depending on the Amazon S3 API operation that you use, either a Regional or Zonal endpoint is required. There is no additional charge for using gateway endpoints.

Bucket-level (or control plane) API operations are available through Regional endpoints and are referred to as Regional endpoint API operations. Examples of Regional endpoint API operations are `CreateBucket` and `DeleteBucket`. When you create a directory bucket, you choose a single Zone (Availability Zone or Local Zone) where your directory bucket will be created. After you create a directory bucket, you can use Zonal endpoint API operations to upload and manage the objects in your directory bucket.

Object-level (or data plane) API operations are available through Zonal endpoints and are referred to as Zonal endpoint API operations. Examples of Zonal endpoint API operations are `CreateSession` and `PutObject`.

For more information about the endpoints and the locations that support directory buckets in Availability Zones, see [Endpoints for directory buckets in Availability Zones](#).

For more information about the endpoints and the locations that support directory buckets in Local Zones, see [Enable accounts for Local Zones](#).

Configuring VPC gateway endpoints

To configure gateway VPC endpoints for access directory buckets in Availability Zones, see [the section called “Configuring VPC gateway endpoints”](#).

To configure gateway VPC endpoints for access directory buckets in Local Zones, see [Private connectivity from your VPC](#).

Directory bucket naming rules

When you create a directory bucket in Amazon S3, the following bucket naming rules apply. For general purpose bucket naming rules, see [General purpose bucket naming rules](#).

A directory bucket name consists of a base name that you provide, and a suffix that contains the ID of the AWS Zone (an Availability Zone or a Local Zone) that your bucket is located in and `--x-s3`. The `zone-id` can be the ID of an Availability Zone or a Local Zone.

`base-name--zoneid--x-s3`

For example, the following directory bucket name contains the Availability Zone ID `usw2-az1`:

`bucket-base-name--usw2-az1--x-s3`

Note

When you create a directory bucket by using the console, a suffix is automatically added to the base name that you provide. This suffix includes the Zone ID of the Zone (Availability Zone or Local Zone) that you chose.

When you create a directory bucket by using an API, you must provide the full suffix, including the Zone ID, in your request. For a list of Zone IDs, see [Endpoints](#).

The following naming rules apply for directory buckets.

- Be unique within the chosen Zone (AWS Availability Zone or AWS Local Zone).
- Name must be between 3 (min) and 63 (max) characters long, including the suffix.
- Consists only of lowercase letters, numbers and hyphens (-).
- Begin and end with a letter or number.
- Must include the following suffix: --**zone-id**--x-s3.
- Bucket names must not start with the prefix xn--.
- Bucket names must not start with the prefix sthree-.
- Bucket names must not start with the prefix sthree-configurator.
- Bucket names must not start with the prefix amzn-s3-demo-.
- Bucket names must not end with the suffix -s3alias. This suffix is reserved for access point alias names. For more information, see [Access point aliases](#).
- Bucket names must not end with the suffix --ol-s3. This suffix is reserved for Object Lambda Access Point alias names. For more information, see [How to use a bucket-style alias for your S3 bucket Object Lambda Access Point](#).
- Bucket names must not end with the suffix .mrap. This suffix is reserved for Multi-Region Access Point names. For more information, see [Rules for naming Amazon S3 Multi-Region Access Points](#).

Viewing directory bucket properties

You can view and configure the properties for an Amazon S3 directory bucket by using the Amazon S3 console. For more information, see [Working with directory buckets](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Directory buckets**.

3. In the **Directory buckets** list, choose the name of the bucket that you want to view the properties for.
4. Choose the **Properties** tab.
5. On the **Properties** tab, you can view the following properties for the bucket:
 - **Directory bucket overview** – You can see the AWS Region, Zone (Availability Zone or Local Zone), Amazon Resource Name (ARN), and creation date for the bucket.
 - **Server-side encryption settings** – Amazon S3 applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for all S3 buckets. Amazon S3 encrypts an object before saving it to a disk and decrypts the object when you download it. For more information, see [Setting and monitoring default encryption for directory buckets](#).

For more information about supported features for directory buckets, see [Creating and using directory buckets](#).

Managing directory bucket policies

You can add, delete, update, and view bucket policies for Amazon S3 directory buckets by using the Amazon S3 console, the AWS SDKs and the AWS CLI. For more information, see the following topics. For more information about supported AWS Identity and Access Management (IAM) actions, see [Authorizing Regional endpoint API operations with IAM](#). For example bucket policies for directory buckets, see [Example bucket policies for directory buckets](#).

Topics

- [Adding a bucket policy](#)
- [Viewing a bucket policy](#)
- [Deleting a bucket policy](#)

Adding a bucket policy

To add a bucket policy to a directory bucket, you can use the Amazon S3 console, the AWS SDKs, or the AWS CLI.

Using the S3 console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Directory buckets**.
3. In the **Directory buckets** list, choose the name of the bucket that you want to add a policy to.
4. Choose the **Permissions** tab.
5. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.
6. To generate a policy automatically, choose **Policy generator**.

If you choose **Policy generator**, the AWS Policy Generator opens in a new window.

If you don't want to use the AWS Policy Generator, you can add or edit JSON statements in the **Policy** section.

- a. On the **AWS Policy Generator** page, for **Select Type of Policy**, choose **S3 Bucket Policy**.
- b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat this step for as many statements as you want to add. For more information about these fields, see the [IAM JSON policy elements reference](#) in the *IAM User Guide*.

 **Note**

For your convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

- c. After you finish adding statements, choose **Generate Policy**.
 - d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.
7. In the **Policy** box, edit the existing policy or paste the bucket policy from the AWS Policy Generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

Note

Bucket policies are limited to 20 KB in size.

8. Choose **Save changes**, which returns you to the **Permissions** tab.

Using the AWS SDKs

SDK for Java 2.x

Example

PutBucketPolicy AWS SDK for Java 2.x

```
public static void setBucketPolicy(S3Client s3Client, String bucketName, String policyText) {

    //sample policy text
    /**
     * policy_statement = {
     *     'Version': '2012-10-17',
     *     'Statement': [
     *         {
     *             'Sid': 'AdminPolicy',
     *             'Effect': 'Allow',
     *             'Principal': {
     *                 "AWS": "111122223333"
     *             },
     *             'Action': 's3express:*',
     *             'Resource':
     *                 'arn:aws:s3express:region:111122223333:bucket/bucket-base-name--zone-id--x-s3'
     *             }
     *         ]
     *     }
     */
    System.out.println("Setting policy:");
    System.out.println("----");
    System.out.println(policyText);
    System.out.println("----");
    System.out.format("On Amazon S3 bucket: \"%s\"\n", bucketName);

    try {
```

```
PutBucketPolicyRequest policyReq = PutBucketPolicyRequest.builder()
    .bucket(bucketName)
    .policy(policyText)
    .build();
s3Client.putBucketPolicy(policyReq);
System.out.println("Done!");
}

catch (S3Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

Using the AWS CLI

This example shows how to add a bucket policy to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api put-bucket-policy --bucket bucket-base-name--zone-id--x-s3 --policy file:///  
bucket_policy.json
```

bucket_policy.json:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AdminPolicy",
            "Effect": "Allow",
            "Principal": {
                "AWS": "111122223333"
            },
            "Action": "s3express*",
            "Resource": "arn:aws:s3express:us-west-2:111122223333:bucket/amzn-s3-  
demo-bucket--usw2-az1--x-s3"
        }
    ]
}
```

```
}
```

For more information, see [put-bucket-policy](#) in the AWS Command Line Interface.

Viewing a bucket policy

To view a bucket policy for a directory bucket, use the following examples.

Using the AWS CLI

This example shows how to view the bucket policy attached to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api get-bucket-policy --bucket bucket-base-name--zone-id--x-s3
```

For more information, see [get-bucket-policy](#) in the AWS Command Line Interface.

Deleting a bucket policy

To delete a bucket policy for a directory bucket, use the following examples.

Using the AWS SDKs

SDK for Java 2.x

Example

DeleteBucketPolicy AWS SDK for Java 2.x

```
public static void deleteBucketPolicy(S3Client s3Client, String bucketName) {
    try {
        DeleteBucketPolicyRequest deleteBucketPolicyRequest =
DeleteBucketPolicyRequest
            .builder()
            .bucket(bucketName)
            .build()
        s3Client.deleteBucketPolicy(deleteBucketPolicyRequest);
        System.out.println("Successfully deleted bucket policy");
    }

    catch (S3Exception e) {
```

```
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
```

Using the AWS CLI

This example shows how to delete a bucket policy for a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api delete-bucket-policy --bucket bucket-base-name--zone-id--x-s3
```

For more information, see [delete-bucket-policy](#) in the AWS Command Line Interface.

Emptying a directory bucket

You can empty an Amazon S3 directory bucket by using the Amazon S3 console. For more information about directory buckets, see [Working with directory buckets](#).

Before you empty a directory bucket, note the following:

- When you empty a directory bucket, you delete all the objects, but you keep the directory bucket.
- After you empty a directory bucket, the empty action can't be undone.
- Objects that are added to the directory bucket while the empty bucket action is in progress might be deleted.

If you also want to delete the bucket, note the following:

- All objects in the directory bucket must be deleted before the bucket itself can be deleted.
- In-progress multipart uploads in the directory bucket must be aborted before the bucket itself can be deleted.

Note

The `s3 rm` command through the AWS Command Line Interface (CLI), the `delete` operation through Mountpoint, and the **Empty** bucket option button through the AWS Management Console are unable to delete in-progress multipart uploads in a directory bucket. To delete these in-progress multipart uploads, use the `ListMultipartUploads`

operation to list the in-progress multipart uploads in the bucket and use the AbortMultipartUpload operation to abort all the in-progress multipart uploads.

To delete a directory bucket, see [Deleting a directory bucket](#). To abort an in-progress multipart upload, see [the section called “Aborting a multipart upload”](#).

To empty a general purpose bucket, see [Emptying a general purpose bucket](#).

Using the S3 console

To empty a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Directory buckets**.
3. Choose the option button next to the name of the bucket that you want to empty, and then choose **Empty**.
4. On the **Empty bucket** page, confirm that you want to empty the bucket by entering **permanently delete** in the text field, and then choose **Empty**.
5. Monitor the progress of the bucket emptying process on the **Empty bucket: status** page.

Deleting a directory bucket

You can delete only empty Amazon S3 directory buckets. Before you delete your directory bucket, you must delete all objects in the bucket and abort all in-progress multipart uploads.

If the directory bucket is attached to an access point, you must delete the access point first. For more information, see [Delete your access point for directory buckets](#).

To empty a directory bucket, see [Emptying a directory bucket](#). To abort an in-progress multipart upload, see [the section called “Aborting a multipart upload”](#).

To delete a general purpose bucket, see [Deleting a general purpose bucket](#).

Using the S3 console

After you empty your directory bucket and abort all in-progress multipart uploads, you can delete your bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Directory buckets**.
3. In the **Directory buckets** list, choose the option button next to the bucket that you want to delete.
4. Choose **Delete**.
5. On the **Delete bucket** page, enter the name of the bucket in the text field to confirm the deletion of your bucket.

⚠ Important

Deleting a directory bucket can't be undone.

6. To delete your directory bucket, choose **Delete bucket**.

Using the AWS SDKs

The following examples delete a directory bucket by using the AWS SDK for Java 2.x and AWS SDK for Python (Boto3).

SDK for Java 2.x

Example

```
public static void deleteBucket(S3Client s3Client, String bucketName) {  
  
    try {  
        DeleteBucketRequest del = DeleteBucketRequest.builder()  
            .bucket(bucketName)  
            .build();  
        s3Client.deleteBucket(del);  
        System.out.println("Bucket " + bucketName + " has been deleted");  
    }  
    catch (S3Exception e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

SDK for Python

Example

```
import logging
import boto3
from botocore.exceptions import ClientError

def delete_bucket(s3_client, bucket_name):
    """
    Delete a directory bucket in a specified Region

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket to delete; for example, 'doc-example-bucket--usw2-az1--x-s3'
    :return: True if bucket is deleted, else False
    """

    try:
        s3_client.delete_bucket(Bucket = bucket_name)
    except ClientError as e:
        logging.error(e)
        return False
    return True

if __name__ == '__main__':
    bucket_name = 'BUCKET_NAME'
    region = 'us-west-2'
    s3_client = boto3.client('s3', region_name = region)
```

Using the AWS CLI

This example shows how to delete a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3api delete-bucket --bucket bucket-base-name--zone-id--x-s3 --region us-west-2
```

For more information, see [delete-bucket](#) in the AWS Command Line Interface.

Listing directory buckets

The following examples show how to list directory buckets by using the AWS Management Console, AWS SDKs, and AWS CLI.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to view a list of your directory buckets.
3. In the left navigation pane, choose **Directory buckets**. A list of directory buckets appears. To view the objects in the bucket, bucket properties, bucket permissions, metrics, access points associated with the bucket, or to manage the bucket, choose the bucket name.

Using the AWS SDKs

SDK for Java 2.x

Example

The following example lists directory buckets by using the AWS SDK for Java 2.x.

```
public static void listBuckets(S3Client s3Client) {
    try {
        ListDirectoryBucketsRequest listDirectoryBucketsRequest =
ListDirectoryBucketsRequest.builder().build();
        ListDirectoryBucketsResponse response =
s3Client.listDirectoryBuckets(listDirectoryBucketsRequest);
        if (response.hasBuckets()) {
            for (Bucket bucket: response.buckets()) {
                System.out.println(bucket.name());
                System.out.println(bucket.creationDate());
            }
        }
    }

    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
}
```

```
        System.exit(1);
    }
}
```

SDK for Python

Example

The following example lists directory buckets by using the AWS SDK for Python (Boto3).

```
import logging
import boto3
from botocore.exceptions import ClientError

def list_directory_buckets(s3_client):
    """
    Prints a list of all directory buckets in a Region

    :param s3_client: boto3 S3 client
    :return: True if there are buckets in the Region, else False
    """

    try:
        response = s3_client.list_directory_buckets()
        for bucket in response['Buckets']:
            print(bucket['Name'])
    except ClientError as e:
        logging.error(e)
        return False
    return True

if __name__ == '__main__':
    region = 'us-east-1'
    s3_client = boto3.client('s3', region_name = region)
    list_directory_buckets(s3_client)
```

SDK for .NET

Example

The following example lists directory buckets by using the AWS SDK for .NET.

```
var listDirectoryBuckets = await amazonS3Client.ListDirectoryBucketsAsync(new  
    ListDirectoryBucketsRequest  
{  
    MaxDirectoryBuckets = 10  
}).ConfigureAwait(false);
```

SDK for PHP

Example

The following example lists directory buckets by using the AWS SDK for PHP.

```
require 'vendor/autoload.php';  
  
$s3Client = new S3Client([  
    'region'      => 'us-east-1',  
]);  
$result = $s3Client->listDirectoryBuckets();
```

SDK for Ruby

Example

The following example lists directory buckets by using the AWS SDK for Ruby.

```
s3 = Aws::S3::Client.new(region:'us-west-1')  
s3.list_directory_buckets
```

Using the AWS CLI

The following `list-directory-buckets` example command shows how you can use the AWS CLI to list your directory buckets in the `us-east-1` region. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api list-directory-buckets --region us-east-1
```

For more information, see [list-directory-buckets](#) in the *AWS CLI Command Reference*.

Determining whether you can access a directory bucket

The following AWS SDK examples show how to use the HeadBucket API operation to determine if an Amazon S3 directory bucket exists and if you have permission to access it.

Using the AWS SDKs

The following AWS SDK for Java 2.x example shows how to determine if a bucket exists and if you have permission to access it.

SDK for Java 2.x

Example

AWS SDK for Java 2.x

```
public static void headBucket(S3Client s3Client, String bucketName) {  
    try {  
        HeadBucketRequest headBucketRequest = HeadBucketRequest  
            .builder()  
            .bucket(bucketName)  
            .build();  
        s3Client.headBucket(headBucketRequest);  
        System.out.format("Amazon S3 bucket: \"%s\" found.", bucketName);  
    }  
  
    catch (S3Exception e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

Using the AWS CLI

The following head-bucket example command shows how you can use the AWS CLI to determine if a directory bucket exists and if you have permission to access it. To run this command, replace the user input placeholders with your own information.

```
aws s3api head-bucket --bucket bucket-base-name--zone-id--x-s3
```

For more information, see [head-bucket](#) in the *AWS CLI Command Reference*.

Working with objects in a directory bucket

After you create an Amazon S3 directory bucket, you can work with objects by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and the AWS SDKs.

For more information about performing bulk operations, importing, uploading, copying, deleting, and downloading objects in directory buckets, see the following topics.

Importing objects into a directory bucket

After you create a directory bucket in Amazon S3, you can populate the new bucket with data by using the import action. Import is a streamlined method for creating S3 Batch Operations jobs to copy objects from general purpose buckets to directory buckets.

Note

The following limitations apply to import jobs:

- The source bucket and the destination bucket must be in the same AWS Region and account.
- The source bucket cannot be a directory bucket.
- Objects larger than 5GB are not supported and will be omitted from the copy operation.
- Objects in the Glacier Flexible Retrieval, Glacier Deep Archive, Intelligent-Tiering Archive Access tier, and Intelligent-Tiering Deep Archive tier storage classes must be restored before they can be imported.
- Imported objects with MD5 checksum algorithms are converted to use CRC32 checksums.
- Imported objects use the Express One Zone storage class, which has a different pricing structure than the storage classes used by general purpose buckets. Consider this difference in cost when importing large numbers of objects.

When you configure an import job, you specify the source bucket or prefix where the existing objects will be copied from. You also provide an AWS Identity and Access Management (IAM) role that has permissions to access the source objects. Amazon S3 then starts a Batch Operations job that copies the objects and automatically applies appropriate storage class and checksum settings.

To configure import jobs, you use the Amazon S3 console.

Using the Amazon S3 console

To import objects into a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**, and then choose the **Directory** buckets tab. Choose the option button next to the directory bucket that you want to import objects into.
3. Choose **Import**.
4. For **Source**, enter the general purpose bucket (or bucket path including prefix) that contains the objects that you want to import. To choose an existing general purpose bucket from a list, choose **Browse S3**.
5. For **Permission to access and copy source objects**, do one of the following to specify an IAM role with the permissions necessary to import your source objects:
 - To allow Amazon S3 to create a new IAM role on your behalf, choose **Create new IAM role**.

- To choose an existing IAM role from a list, choose **Choose from existing IAM roles**.
 - To specify an existing IAM role by entering its Amazon Resource Name (ARN), choose **Enter IAM role ARN**, then enter the ARN in the corresponding field.
6. Review the information that's displayed in the **Destination** and **Copied object settings** sections. If the information in the **Destination** section is correct, choose **Import** to start the copy job.

The Amazon S3 console displays the status of your new job on the **Batch Operations** page. For more information about the job, choose the option button next to the job name, and then on the **Actions** menu, choose **View details**. To open the directory bucket that the objects will be imported into, choose **View import destination**.

Working with S3 Lifecycle for directory buckets

S3 Lifecycle helps you store objects in S3 Express One Zone in directory buckets cost effectively by deleting expired objects on your behalf. To manage the lifecycle of your objects, create an S3 Lifecycle configuration for your directory bucket. An S3 Lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. You can set an Amazon S3 Lifecycle configuration on a directory bucket by using the AWS Command Line Interface (AWS CLI), the AWS SDKs, the Amazon S3 REST API and AWS CloudFormation.

In your lifecycle configuration, you use rules to define actions that you want Amazon S3 to take on your objects. For objects stored in directory buckets, you can create lifecycle rules to expire objects as they age. You can also create lifecycle rules to delete incomplete multipart uploads in directory buckets at a daily frequency.

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation, S3 will queue for removal any existing objects that are more than 30 days old and that have the specified prefix.

How S3 Lifecycle for directory buckets is different

For objects in directory buckets, you can create lifecycle rules to expire objects and delete incomplete multipart uploads. However, S3 Lifecycle for directory buckets doesn't support transition actions between storage classes.

CreateSession

Lifecycle uses public DeleteObject and DeleteObjects API operations to expire objects in directory buckets. To use these API operations, S3 Lifecycle will use the CreateSession API to establish temporary security credentials to access the objects in the directory buckets. For more information, see [CreateSessionin the Amazon S3 API Reference](#).

If you have an active policy that denies delete permissions to the lifecycle principal, this will prevent you from allowing S3 Lifecycle to delete objects on your behalf.

Using a bucket policy to Grant permissions to the S3 Lifecycle service principal

The following bucket policy grants permission to allow CreateSession calls with the default ReadWrite session and allows the lifecycle service principal.

Example – Bucket policy to allow CreateSession calls with the default ReadWrite session

```
{  
    "Version": "2008-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "lifecycle.s3.amazonaws.com"  
            },  
            "Action": "s3express>CreateSession",  
            "Condition": {  
                "StringEquals": {  
                    "s3express:SessionMode": "ReadWrite"  
                }  
            },  
            "Resource": "arn:aws:s3express:us-east-2:412345678921:bucket/amzn-s3-demo-  
bucket--use2-az2--x-s3"  
        }  
    ]  
}
```

Monitoring lifecycle rules

For objects stored in directory buckets, S3 Lifecycle generates AWS CloudTrail management and data event logs. For more information, see [CloudTrail log file examples for S3 Express One Zone](#).

For more information about creating lifecycle configurations and troubleshooting S3 Lifecycle related issues, see the following topics:

Creating and managing a Lifecycle configuration for your directory bucket

You can create a lifecycle configuration for directory buckets by using the AWS Command Line Interface (AWS CLI), AWS SDKs and REST APIs.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Lifecycle configurations:

- `put-bucket-lifecycle-configuration`
- `get-bucket-lifecycle-configuration`
- `delete-bucket-lifecycle`

For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the [Amazon S3 API Reference](#).

The Amazon S3 Lifecycle configuration is an XML file. But when you're using the AWS CLI, you cannot specify the XML format. You must specify the JSON format instead. The following are example XML lifecycle configurations and the equivalent JSON configurations that you can specify in an AWS CLI command.

The following AWS CLI example puts a lifecycle configuration policy on a directory bucket. This policy specifies that all objects that have the flagged prefix (`myprefix`) and are the defined object size expire after 7 days. To use this example, replace each ***user input placeholder*** with your own information.

Save the lifecycle configuration policy to a JSON file. In this example, the file is named `lifecycle1.json`.

Example

JSON

```
{  
    "Rules": [  
        {  
            "Expiration": {  
                "Days": 7  
            },  
            "ID": "Lifecycle expiration rule",  
            "Filter": {  
                "And": {  
                    "Prefix": "myprefix/",  
                    "ObjectSizeGreaterThan": 500,  
                    "ObjectSizeLessThan": 64000  
                }  
            },  
            "Status": "Enabled"  
        }  
    ]  
}
```

Submit the JSON file as part of the `put-bucket-lifecycle-configuration` CLI command. To use this command, replace each *user input placeholder* with your own information.

```
aws s3api put-bucket-lifecycle-configuration --region us-west-2 --profile default  
--bucket amzn-s3-demo-bucket--usw2-az1--x-s3 --lifecycle-configuration file://lc-policy.json --checksum-algorithm crc32
```

Example

XML

```
<LifecycleConfiguration>  
    <Rule>  
        <ID>Lifecycle expiration rule</ID>  
        <Filter>  
            <And>  
                <Prefix>myprefix/</Prefix>  
                <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
```

```
<ObjectSizeLessThan>64000</ObjectSizeLessThan>
</And>
</Filter>
<Status>Enabled</Status>
<Expiration>
<Days>7</Days>
</Expiration>
</Rule>
</LifecycleConfiguration>
```

Troubleshooting S3 Lifecycle issues for directory buckets

I set up my lifecycle configuration but objects in my directory bucket are not expiring

S3 Lifecycle for directory buckets utilizes public APIs to delete objects in S3 Express One Zone. To use object level public APIs, you must grant permission to `CreateSession` and allow S3 Lifecycle permission to delete your objects. If you have an active policy that denies deletes, this will prevent you from allowing S3 Lifecycle to delete objects on your behalf.

It's important to configure your bucket policies correctly to ensure that the objects that you want to delete are eligible for expiration. You can check your AWS CloudTrail logs for `AccessDenied` Trails for `CreateSession` API invocations in CloudTrail to verify if access has been denied. Checking your CloudTrail logs can assist you in troubleshooting access issues and identifying the root cause of access denied errors. You can then fix your incorrect access controls by updating the relevant policies.

If you confirm that your bucket policies are set correctly and you are still experiencing issues, we recommend that you review the lifecycle rules to ensure that they are applied to the right subset of objects.

How do I monitor the actions taken by my lifecycle rules?

You can use AWS CloudTrail data event logs to monitor actions taken by S3 Lifecycle in directory buckets. For more information, see [CloudTrail log file examples](#).

Using Batch Operations with directory buckets

You can use Amazon S3 Batch Operations to perform operations on objects stored in S3 buckets. To learn more about S3 Batch Operations, see [Performing large-scale batch operations on Amazon S3 objects](#).

The following topics discuss performing batch operations on objects stored in the S3 Express One Zone storage class in directory buckets.

Topics

- [Using Batch Operations with directory buckets](#)
- [Key differences](#)

Using Batch Operations with directory buckets

You can perform the **Copy** operation and the **Invoke AWS Lambda function** operations on objects that are stored in directory buckets. With **Copy**, you can copy objects between buckets of the same type (for example, from a directory bucket to a directory bucket). You can also copy between general purpose buckets and directory buckets. With **Invoke AWS Lambda function**, you can use a Lambda function to perform actions on objects in your directory bucket with code that you define.

Copying objects

You can copy between the same bucket type or between directory buckets and general purpose buckets. When you copy to a directory bucket, you must use the correct Amazon Resource Name (ARN) format for this bucket type. The ARN format for a directory bucket is `arn:aws:s3express:region:account-id:bucket/bucket-base-name--x-s3`.

Note

Copying objects across different AWS Regions isn't supported when the source or destination bucket is in an AWS Local Zone. The source and destination buckets must have the same parent AWS Region. The source and destination buckets can be different bucket location types (Availability Zone or Local Zone).

You can also populate your directory bucket with data by using the **Import** action in the S3 console. **Import** is a streamlined method for creating Batch Operations jobs to copy objects from general purpose buckets to directory buckets. For **Import** copy jobs from general purpose buckets to directory buckets, S3 automatically generates a manifest. For more information, see [Importing objects to a directory bucket](#) and [Specifying a manifest](#).

Invoking Lambda functions (LambdaInvoke)

There are special requirements for using Batch Operations to invoke Lambda functions that act on directory buckets. For example, you must structure your Lambda request by using a v2 JSON invocation schema, and specify InvocationSchemaVersion 2.0 when you create the job. For more information, see [Invoke AWS Lambda function](#).

Key differences

The following is a list of key differences when you're using Batch Operations to perform bulk operations on objects that are stored in directory buckets with the S3 Express One Zone storage class:

- For directory buckets, SSE-S3 and server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) are supported. If you make a CopyObject request that specifies to use server-side encryption with customer-provided keys (SSE-C) on a directory bucket (source or destination), the response returns an HTTP 400 (Bad Request) error.

We recommend that the bucket's default encryption uses the desired encryption configuration and you don't override the bucket default encryption in your CreateSession requests or PUT object requests. Then, new objects are automatically encrypted with the desired encryption settings. For more information about the encryption overriding behaviors in directory buckets and how to encrypt new object copies in a directory bucket with SSE-KMS, see [Specifying server-side encryption with AWS KMS for new object uploads](#).

S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [the Copy operation in Batch Operations](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object. For more information about using SSE-KMS on directory buckets, see [Setting and monitoring default encryption for directory buckets](#) and [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in directory buckets](#).

- Objects in directory buckets can't be tagged. You can only specify an empty tag set. By default, Batch Operations copies tags. If you copy an object that has tags between general purpose buckets and directory buckets, you receive a 501 (Not Implemented) response.
- S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during uploads or downloads. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.
- By default, all Amazon S3 buckets set the S3 Object Ownership setting to bucket owner enforced and access control lists (ACLs) are disabled. For directory buckets, this setting can't be modified. You can copy an object from general purpose buckets to directory buckets. However, you can't overwrite the default ACL when you copy to or from a directory bucket.
- Regardless of how you specify your manifest, the list itself must be stored in a general purpose bucket. Batch Operations can't import existing manifests from (or save generated manifests to) directory buckets. However, objects described within the manifest can be stored in directory buckets.
- Batch Operations can't specify a directory bucket as a location in an S3 Inventory report. Inventory reports don't support directory buckets. You can create a manifest file for objects within a directory bucket by using the `ListObjectsV2` API operation to list the objects. You can then insert the list in a CSV file.

Granting access

To perform copy jobs, you must have the following permissions:

- To copy objects from one directory bucket to another directory bucket, you must have the `s3express:CreateSession` permission.
- To copy objects from directory buckets to general purpose buckets, you must have the `s3express:CreateSession` permission and the `s3:PutObject` permission to write the object copy to the destination bucket.
- To copy objects from general purpose buckets to directory buckets, you must have the `s3express:CreateSession` permission and the `s3:GetObject` permission to read the source object that is being copied.

For more information, see [CopyObject](#) in the *Amazon Simple Storage Service API Reference*.

- To invoke a Lambda function, you must grant permissions to your resource based on your Lambda function. To determine which permissions are required, check the corresponding API operations.

Appending data to objects in directory buckets

You can add data to the end of existing objects stored in the S3 Express One Zone storage class in directory buckets. We recommend that you use the ability to append data to an object if the data is written continuously over a period of time or if you need to read the object while you are writing to the object. Appending data to objects is common for use-cases such as adding new log entries to log files or adding new video segments to video files as they are transcoded then streamed. By appending data to objects, you can simplify applications that previously combined data in local storage before copying the final object to Amazon S3.

There is no minimum size requirement for the data you can append to an object. However, the maximum size of the data that you can append to an object in a single request is 5GB. This is the same limit as the largest request size when uploading data using any Amazon S3 API.

With each successful append operation, you create a part of the object and each object can have up to 10,000 parts. This means you can append data to an object up to 10,000 times. If an object is created using S3 multipart upload, each uploaded part is counted towards the total maximum of 10,000 parts. For example, you can append up to 9,000 times to an object created by multipart upload comprising of 1,000 parts.

Note

If you hit the limit of parts, you will receive a [TooManyParts](#) error. You can use the `CopyObject` API to reset the count.

If you want to upload parts to an object in parallel and you don't need to read the parts while the parts are being uploaded, we recommend that you use Amazon S3 multipart upload. For more information, see [Using multipart upload](#).

Appending data to objects is only supported for objects in directory buckets that are stored in the S3 Express One Zone storage class. For more information on S3 Express One Zone Zone, see [Getting started with S3 Express One Zone](#).

To get started appending data to objects in your directory buckets, you can use the AWS SDKs, AWS CLI, and the PutObject API. When you make a PutObject request, you set the `x-amz-write-offset-bytes` header to the size of the object that you are appending to. To use the PutObject API operation, you must use the CreateSession API to establish temporary security credentials to access the objects in your directory buckets. For more information, see [PutObject](#) and [CreateSession](#) in the *Amazon S3 API Reference*.

Each successful append operation is billed as a PutObject request. To learn more about pricing, see [Amazon S3 pricing](#).

Note

Starting with the 1.12 release, Mountpoint for Amazon S3 supports appending data to objects stored in S3 Express One Zone. To get started, you must opt-in by setting the `--incremental-upload` flag. For more information on Mountpoint, see [Working with Mountpoint](#).

If you use a CRC (Cyclic Redundancy Check) algorithm while uploading the appended data, you can retrieve full object CRC-based checksums using the HeadObject or GetObject request. If you use the SHA-1 or SHA-256 algorithm while uploading your appended data, you can retrieve a checksum of the appended parts and verify their integrity using the SHA checksums returned on prior PutObject responses. For more information, see [Data protection and encryption](#).

Appending data to your objects by using the AWS CLI, AWS SDKs and the REST API

You can append data to your objects by using the AWS Command Line Interface (AWS CLI), AWS SDKs and REST API.

Using the AWS CLI

The following put-object example command shows how you can use the AWS CLI to append data to an object. To run this command, replace the *user input placeholders* with your own information

```
aws s3api put-object --bucket amzn-s3-demo-bucket--azid--x-s3 --key sampleinput/file001.bin --body bucket-seed/file001.bin --write-offset-bytes size-of-sampleinput/file001.bin
```

Using the AWS SDKs

SDK for Java

You can use the AWS SDK for Java to append data to your objects.

```
var putObjectRequestBuilder = PutObjectRequest.builder()
    .key(key)
    .bucket(bucketName)
    .writeOffsetBytes(9);
var response = s3Client.putObject(putObjectRequestBuilder.build());
```

SDK for Python

```
s3.put_object(Bucket='amzn-s3-demo-bucket--use2-az2--x-s3', Key='2024-11-05-sdk-test', Body=b'123456789', WriteOffsetBytes=9)
```

Using the REST API

You can send REST requests to append data to an object. For more information, see [PutObject](#).

Renaming objects in directory buckets

Using the RenameObject operation, you can atomically rename an existing object in a directory bucket that uses the S3 Express One Zone storage class, without any data movement. You can rename an object by specifying the existing object's name as the source and the new name of the object as the destination within the same directory bucket. The RenameObject API operation will not succeed on objects that end with the slash (/) delimiter character. For more information, see [Naming Amazon S3 objects](#).

The RenameObject operation is typically completed in milliseconds regardless of the size of the object. This capability accelerates applications like log file management, media processing, and data analytics. Additionally, RenameObject preserves all object metadata properties, including the storage class, encryption type, creation date, last modified date, and checksum properties.

Note

RenameObject is only supported for objects stored in the S3 Express One Zone storage class.

To grant access to the `RenameObject` operation, we recommend that you use the `CreateSession` operation for session-based authorization. Specifically, you grant the `s3express:CreateSession` permission to the directory bucket in a bucket policy or an identity-based policy. Then, you make the `CreateSession` API call on the directory bucket to obtain a session token. With the session token in your request header, you can make API requests to this operation. After the session token expires, you make another `CreateSession` API call to generate a new session token for use. The AWS CLI and AWS SDKs will create and manage your session including refreshing the session token automatically to avoid service interruptions when a session expires. For more information about authorization, see [CreateSession](#) in the *Amazon S3 API Reference*. To learn more about Zonal endpoint API operations, see [Authorizing Zonal endpoint API operations with CreateSession](#).

If you don't want to overwrite an existing object, you can add the `If-None-Match` conditional header with the value `'*''` in the `RenameObject` request. Amazon S3 returns a `412 Precondition Failed` error if the object name already exists. For more information, see [RenameObject](#) in the *Amazon S3 API Reference*.

`RenameObject` is a Zonal endpoint API operation (object-level or data plane operation) that is logged to AWS CloudTrail. You can use CloudTrail to gather information on the `RenameObject` operation performed on your objects in directory buckets. For more information, see [Logging with AWS CloudTrail for directory buckets](#) and [CloudTrail log file examples for directory buckets](#).

S3 Express One Zone is the only storage class that supports `RenameObject`, which is priced the same as `PUT`, `COPY`, `POST`, and `LIST` requests (per 1,000 requests) in S3 Express One Zone. For more information, see [Amazon S3 pricing](#).

Renaming an object

To rename an object in your directory bucket, you can use the Amazon S3 console, AWS CLI, AWS SDKs, the REST API or Mountpoint for Amazon S3 (version 1.19.0 or higher).

Using the S3 console

To rename an object in a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the **Directory buckets** tab. Navigate to the Amazon S3 directory bucket that contains the object that you want to rename.

3. Select the check box for the object that you want to rename.
4. On the **Actions** menu, choose **Rename object**.
5. In the **New object name** box, enter the new name for the object.

 **Note**

If you specify the same object name as an existing object, the operation will fail and Amazon S3 returns a 412 Precondition Failed error. The object key name length can't exceed 1,024 bytes. Prefixes included in the object name count toward the total length.

6. Choose **Rename object**. Amazon S3 renames your object.

Using the AWS CLI

The `rename-object` examples show how you can use the AWS CLI to rename an object. To run these commands, replace the *user input placeholders* with your own information

The following example shows how to rename an object with a conditional check on the source object's ETag.

```
aws s3api rename-object \  
  --bucket amzn-s3-demo-bucket--usw2-az1--x-s3 \  
  --key new-file.txt \  
  --rename-source original-file.txt \  
  --source-if-match "\"a1b7c3d2e5f6\""
```

This command does the following:

- Renames an object from *original-file.txt* to *new-file.txt* in the *amzn-s3-demo-bucket--usw2-az1--x-s3* directory bucket.
- Only performs the rename if the source object's ETag matches "*a1b7c3d2e5f6*".

If the ETag doesn't match, the operation will fail with a 412 Precondition Failed error.

The following example shows how to rename an object with a conditional check on the new specified object name.

```
aws s3api rename-object \
--bucket amzn-s3-demo-bucket--usw2-az1--x-s3 \
--key new-file.txt \
--rename-source amzn-s3-demo-bucket--usw2-az1--x-s3/original-file.txt \
--destination-if-none-match "\"e5f3g7h8i9j0\""
```

This command does the following:

- Renames an object from *original-file.txt* to *new-file.txt* in the *amzn-s3-demo-bucket--usw2-az1--x-s3* directory bucket.
- Only performs the rename operation if the object exists and the object's ETag doesn't match "*e5f3g7h8i9j0*".

If an object already exists with the new specified name and the matching ETag, the operation will fail with a 412 Precondition Failed error.

Using the AWS SDKs

SDK for Java

You can use the AWS SDK for Java to rename your objects. To use these examples, replace the *user input placeholders* with your own information

The following example demonstrates how to create a RenameObjectRequest using the AWS SDK for Java

```
String key = "key";
String newKey = "new-key";
String expectedETag = "e5f3g7h8i9j0";
RenameObjectRequest renameRequest = RenameObjectRequest.builder()
    .bucket(amzn-s3-demo-bucket--usw2-az1--x-s3)
    .key(newKey)
    .renameSource(key)
    .destinationIfMatch(e5f3g7h8i9j0)
    .build();
```

This code does the following:

- Create a request to rename an object from "*key*" to "*new-key*" in the *amzn-s3-demo-bucket--usw2-az1--x-s3* directory bucket.

- Includes a condition that the rename will only occur if the object's ETag matches "*e5f3g7h8i9j0*".
- If the ETag doesn't match or the object doesn't exist, the operation will fail.

The following example shows how to create a `RenameObjectRequest` with a none-match condition using the AWS SDK for Java.

```
String key = "key";
String newKey = "new-key";
String noneMatchETag = "e5f3g7h8i9j0";
RenameObjectRequest renameRequest = RenameObjectRequest.builder()
    .bucket(amzn-s3-demo-bucket--usw2-az1--x-s3)
    .key(newKey)
    .renameSource(key)
    .destinationIfNoneMatch(noneMatchETag)
    .build();
```

This code does the following:

- Creates a request to rename an object from "key" to "new-key" in the `amzn-s3-demo-bucket--usw2-az1--x-s3` directory bucket.
- Includes a condition using `.destinationIfNoneMatch(noneMatchETag)` that ensures the rename will only occur if the destination object's ETag doesn't match "*e5f3g7h8i9j0*".

The operation will fail with a `412 Precondition Failed` error if an object exists with the new specified name and has the specified ETag.

SDK for Python

You can use the SDK for Python to rename your objects. To use these examples, replace the *user input placeholders* with your own information.

The following example demonstrates how to rename an object using the AWS SDK for Python (Boto3).

```
def basic_rename(bucket, source_key, destination_key):
    try:
        s3.rename_object(
            Bucket=amzn-s3-demo-bucket--usw2-az1--x-s3,
```

```
        Key=destination_key,  
        RenameSource=f"{source_key}"  
    )  
    print(f"Successfully renamed {source_key} to {destination_key}")  
except ClientError as e:  
    print(f"Error renaming object: {e}")
```

This code does the following:

- Renames an object from *source_key* to *destination_key* in the *amzn-s3-demo-bucket--usw2-az1--x-s3* directory bucket.
- Prints a success message if the renaming of your object is successful or prints an error message if it fails.

The following example demonstrate how to rename an object with the SourceIfMatch and DestinationIfNoneMatch conditions using the AWS SDK for Python (Boto3).

```
def rename_with_conditions(bucket, source_key, destination_key, source_etag,  
dest_etag):  
    try:  
        s3.rename_object(  
            Bucket=amzn-s3-demo-bucket--usw2-az1--x-s3,  
            Key=destination_key,  
            RenameSource=f"amzn-s3-demo-bucket--usw2-az1--x-s3/{source_key}",  
            SourceIfMatch=source_ETag,  
            DestinationIfNoneMatch=dest_ETag  
        )  
        print(f"Successfully renamed {source_key} to {destination_key} with  
conditions")  
    except ClientError as e:  
        print(f"Error renaming object: {e}")
```

This code does the following:

- Performs a conditional rename operation and applies two conditions, SourceIfMatch and DestinationIfNoneMatch. The combination of these conditions ensures that the object hasn't been modified and that an object doesn't already exist with the new specified name.
- Renames an object from *source_key* to *destination_key* in the *amzn-s3-demo-bucket--usw2-az1--x-s3* directory bucket.

- Prints a success message if the renaming of your object is successful, or prints an error message if it fails or if conditions aren't met.

SDK for Rust

You can use the SDK for Rust to rename your objects. To use these examples, replace the *user input placeholders* with your own information.

The following example demonstrates how to rename an object in the *amzn-s3-demo-bucket--usw2-az1--x-s3* directory bucket using the SDK for Rust.

```
async fn basic_rename_example(client: &Client) -> Result<(), Box<dyn Error>> {  
    let response = client  
        .rename_object()  
        .bucket(" amzn-s3-demo-bucket--usw2-az1--x-s3")  
        .key("new-name.txt") // New name/path for the object  
        .rename_source("old-name.txt") // Original object name/path  
        .send()  
        .await?;  
    Ok(())  
}
```

This code does the following:

- Creates a request to rename an object from "*old-name.tx*" to "*new-name.txt*" in the *amzn-s3-demo-bucket--usw2-az1--x-s3* directory bucket.
- Returns a Result type to handle potential errors.

Using the REST API

You can send REST requests to rename an object. For more information, see [RenameObject](#) in the *Amazon S3 API Reference*.

Using Mountpoint for Amazon S3

Starting with the 1.19.0 version or higher, Mountpoint for Amazon S3 supports renaming objects in S3 Express One Zone. For more information on Mountpoint, see [Working with Mountpoint](#).

Uploading objects to a directory bucket

After you create an Amazon S3 directory bucket, you can upload objects to it. The following examples show how to upload an object to a directory bucket by using the S3 console and the AWS SDKs. For information about bulk object upload operations with S3 Express One Zone, see [Object management](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Directory buckets**.
3. Choose the name of the bucket that you want to upload your folders or files to.
4. In the **Objects** list, choose **Upload**.
5. On the **Upload** page, do one of the following:
 - Drag and drop files and folders to the dotted upload area.
 - Choose **Add files** or **Add folder**, choose the files or folders to upload, and then choose **Open** or **Upload**.

6. Under **Checksums**, choose the **Checksum function** that you want to use.

(Optional) If you're uploading a single object that's less than 16 MB in size, you can also specify a precalculated checksum value. When you provide a precalculated value, Amazon S3 compares it with the value that it calculates by using the selected checksum function. If the values don't match, the upload won't start.

7. The options in the **Permissions** and **Properties** sections are automatically set to default settings and can't be modified. Block Public Access is automatically enabled, and S3 Versioning and S3 Object Lock can't be enabled for directory buckets.

(Optional) If you want to add metadata in key-value pairs to your objects, expand the **Properties** section, and then in the **Metadata** section, choose **Add metadata**.

8. To upload the listed files and folders, choose **Upload**.

Amazon S3 uploads your objects and folders. When the upload is finished, you see a success message on the **Upload: status** page.

Using the AWS SDKs

SDK for Java 2.x

Example

```
public static void putObject(S3Client s3Client, String bucketName, String objectKey,
Path filePath) {
    //Using File Path to avoid loading the whole file into memory
    try {
        PutObjectRequest putObj = PutObjectRequest.builder()
            .bucket(bucketName)
            .key(objectKey)
            //.metadata(metadata)
            .build();
        s3Client.putObject(putObj, filePath);
        System.out.println("Successfully placed " + objectKey + " into bucket
" + bucketName);

    }

    catch (S3Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

SDK for Python

Example

```
import boto3
import botocore
from botocore.exceptions import ClientError

def put_object(s3_client, bucket_name, key_name, object_bytes):
    """
    Upload data to a directory bucket.
    :param s3_client: The boto3 S3 client
    :param bucket_name: The bucket that will contain the object
    :param key_name: The key of the object to be uploaded
    :param object_bytes: The data to upload
    """
```

```
"""
try:
    response = s3_client.put_object(Bucket=bucket_name, Key=key_name,
                                    Body=object_bytes)
    print(f"Upload object '{key_name}' to bucket '{bucket_name}'.")
    return response
except ClientError:
    print(f"Couldn't upload object '{key_name}' to bucket '{bucket_name}'.")
    raise

def main():
    # Share the client session with functions and objects to benefit from S3 Express
    # One Zone auth key
    s3_client = boto3.client('s3')
    # Directory bucket name must end with --zone-id--x-s3
    resp = put_object(s3_client, 'doc-bucket-example--use1-az5--x-s3', 'sample.txt',
b'Hello, World!')
    print(resp)

if __name__ == "__main__":
    main()
```

Using the AWS CLI

The following `put-object` example command shows how you can use the AWS CLI to upload an object from Amazon S3. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api put-object --bucket bucket-base-name--zone-id--x-s3 --key sampleinut/file001.bin --body bucket-seed/file001.bin
```

For more information, see [put-object](#) in the *AWS CLI Command Reference*.

- [Using multipart uploads with directory buckets](#)

Using multipart uploads with directory buckets

You can use the multipart upload process to upload a single object as a set of parts. Each part is a contiguous portion of the object's data. You can upload these object parts independently and

in any order. If transmission of any part fails, you can retransmit that part without affecting other parts. After all parts of your object are uploaded, Amazon S3 assembles these parts and creates the object. In general, when your object size reaches 100 MB, you should consider using multipart uploads instead of uploading the object in a single operation.

Using multipart upload provides the following advantages:

- **Improved throughput** – You can upload parts in parallel to improve throughput.
- **Quick recovery from any network issues** – Smaller part sizes minimize the impact of restarting a failed upload because of a network error.
- **Pause and resume object uploads** – You can upload object parts over time. After you initiate a multipart upload, there is no expiration date. You must explicitly complete or abort the multipart upload.
- **Begin an upload before you know the final object size** – You can upload an object as you are creating it.

We recommend that you use multipart uploads in the following ways:

- If you're uploading large objects over a stable high-bandwidth network, use multipart uploads to maximize the use of your available bandwidth by uploading object parts in parallel for multi-threaded performance.
- If you're uploading over a spotty network, use multipart uploads to increase resiliency to network errors by avoiding upload restarts. When using multipart uploads, you need to retry uploading only the parts that are interrupted during the upload. You don't need to restart uploading your object from the beginning.

When you're using multipart uploads to upload objects to the Amazon S3 Express One Zone storage class in directory buckets, the multipart upload process is similar to the process of using multipart upload to upload objects to general purpose buckets. However, there are some notable differences.

For more information about using multipart uploads to upload objects to S3 Express One Zone, see the following topics.

Topics

- [The multipart upload process](#)
- [Checksums with multipart upload operations](#)

- [Concurrent multipart upload operations](#)
- [Multipart uploads and pricing](#)
- [Multipart upload API operations and permissions](#)
- [Examples](#)

The multipart upload process

A multipart upload is a three-step process:

- You initiate the upload.
- You upload the object parts.
- After you have uploaded all of the parts, you complete the multipart upload.

Upon receiving the complete multipart upload request, Amazon S3 constructs the object from the uploaded parts, and you can then access the object as you would any other object in your bucket.

Multipart upload initiation

When you send a request to initiate a multipart upload, Amazon S3 returns a response with an upload ID, which is a unique identifier for your multipart upload. You must include this upload ID whenever you upload parts, list the parts, complete an upload, or abort an upload.

Parts upload

When uploading a part, in addition to the upload ID, you must specify a part number. When you're using a multipart upload with S3 Express One Zone, the multipart part numbers must be consecutive part numbers. If you try to complete a multipart upload request with nonconsecutive part numbers, an `HTTP 400 Bad Request (Invalid Part Order)` error is generated.

A part number uniquely identifies a part and its position in the object that you are uploading. If you upload a new part by using the same part number as a previously uploaded part, the previously uploaded part is overwritten.

Whenever you upload a part, Amazon S3 returns an entity tag (ETag) header in its response. For each part upload, you must record the part number and the ETag value. The ETag values for all object part uploads will remain the same, but each part will be assigned a different part number. You must include these values in the subsequent request to complete the multipart upload.

Amazon S3 automatically encrypts all new objects that are uploaded to an S3 bucket. When doing a multipart upload, if you don't specify encryption information in your request, the encryption setting of the uploaded parts is set to the default encryption configuration of the destination bucket. The default encryption configuration of an Amazon S3 bucket is always enabled and is at a minimum set to server-side encryption with Amazon S3 managed keys (SSE-S3). For directory buckets, SSE-S3 and server-side encryption with AWS KMS keys (SSE-KMS) are supported. For more information, see [Data protection and encryption](#).

Multipart upload completion

When you complete a multipart upload, Amazon S3 creates the object by concatenating the parts in ascending order based on the part number. After a successful *complete* request, the parts no longer exist.

Your *complete multipart upload* request must include the upload ID and a list of both part numbers and their corresponding ETag values. The Amazon S3 response includes an ETag that uniquely identifies the combined object data. This ETag is not an MD5 hash of the object data.

Multipart upload listings

You can list the parts of a specific multipart upload or all in-progress multipart uploads. The list parts operation returns the parts information that you have uploaded for a specific multipart upload. For each list parts request, Amazon S3 returns the parts information for the specified multipart upload, up to a maximum of 1,000 parts. If there are more than 1,000 parts in the multipart upload, you must use pagination to retrieve all the parts.

The returned list of parts doesn't include parts that haven't finished uploading. Using the *list multipart uploads* operation, you can obtain a list of multipart uploads that are in progress.

An in-progress multipart upload is an upload that you have initiated, but have not yet completed or aborted. Each request returns at most 1,000 multipart uploads. If there are more than 1,000 multipart uploads in progress, you must send additional requests to retrieve the remaining multipart uploads. Use the returned listing only for verification. Do not use the result of this listing when sending a *complete multipart upload* request. Instead, maintain your own list of the part numbers that you specified when uploading parts and the corresponding ETag values that Amazon S3 returns.

For more information about multipart upload listings, see [ListParts](#) in the *Amazon Simple Storage Service API Reference*.

Checksums with multipart upload operations

When you upload an object to, you can specify a checksum algorithm to check object integrity. MD5 is not supported for directory buckets. You can specify one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms:

- CRC32
- CRC32C
- SHA-1
- SHA-256

You can use the Amazon S3 REST API or the AWS SDKs to retrieve the checksum value for individual parts by using `GetObject` or `HeadObject`. If you want to retrieve the checksum values for individual parts of multipart uploads still in process, you can use `ListParts`.

Important

When using the preceding checksum algorithms, the multipart part numbers must use consecutive part numbers. If you try to complete a multipart upload request with nonconsecutive part numbers, Amazon S3 generates an `HTTP 400 Bad Request (Invalid Part Order)` error.

For more information about how checksums work with multipart upload objects, see [Checking object integrity in Amazon S3](#).

Concurrent multipart upload operations

In a distributed development environment, your application can initiate several updates on the same object at the same time. For example, your application might initiate several multipart uploads by using the same object key. For each of these uploads, your application can then upload parts and send a complete upload request to Amazon S3 to create the object. For S3 Express One Zone, the object creation time is the completion date of the multipart upload.

Important

Versioning isn't supported for objects that are stored in directory buckets.

Multipart uploads and pricing

After you initiate a multipart upload, Amazon S3 retains all the parts until you either complete or abort the upload. Throughout its lifetime, you are billed for all storage, bandwidth, and requests for this multipart upload and its associated parts. If you abort the multipart upload, Amazon S3 deletes the upload artifacts and any parts that you have uploaded, and you are no longer billed for them. There are no early delete charges for deleting incomplete multipart uploads, regardless of the storage class specified. For more information about pricing, see [Amazon S3 pricing](#).

Important

If the complete multipart upload request isn't sent successfully, the object parts aren't assembled and an object isn't created. You are billed for all storage associated with uploaded parts. It's important that you either complete the multipart upload to have the object created or abort the multipart upload to remove any uploaded parts.

Before you can delete a directory bucket, you must complete or abort all in-progress multipart uploads. Directory buckets don't support S3 Lifecycle configurations. If needed, you can list your active multipart uploads, then abort the uploads, and then delete your bucket.

Multipart upload API operations and permissions

To allow access to object management API operations on a directory bucket, you grant the `s3express:CreateSession` permission in a bucket policy or an AWS Identity and Access Management (IAM) identity-based policy.

You must have the necessary permissions to use the multipart upload operations. You can use bucket policies or IAM identity-based policies to grant IAM principals permissions to perform these operations. The following table lists the required permissions for various multipart upload operations.

You can identify the initiator of a multipart upload through the `Initiator` element. If the initiator is an AWS account, this element provides the same information as the `Owner` element. If the initiator is an IAM user, this element provides the user ARN and display name.

Action	Required permissions
Create a multipart upload	To create the multipart upload, you must be allowed to perform the <code>s3express:CreateSession</code> action on the directory bucket.

Creating a multipart upload

Note

For directory buckets, when you perform a `CreateMultipartUpload` operation and an `UploadPartCopy` operation, the bucket's default encryption must use the desired encryption configuration, and the request headers you provide in the `CreateMultipartUpload` request must match the default encryption configuration of the destination bucket.

The following examples show how to create a multipart upload.

Using the AWS SDKs

SDK for Java 2.x

Example

```
/**  
 * This method creates a multipart upload request that generates a unique upload ID  
 * that is used to track  
 * all the upload parts  
 *  
 * @param s3  
 * @param bucketName - for example, 'doc-example-bucket--use1-az4--x-s3'  
 * @param key  
 * @return  
 */  
private static String createMultipartUpload(S3Client s3, String bucketName, String  
key) {  
  
    CreateMultipartUploadRequest createMultipartUploadRequest =  
CreateMultipartUploadRequest.builder()  
        .bucket(bucketName)  
        .key(key)  
        .build();  
  
    String uploadId = null;  
  
    try {
```

```
        CreateMultipartUploadResponse response =
s3.createMultipartUpload(createMultipartUploadRequest);
    uploadId = response.uploadId();
}
catch (S3Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
return uploadId;
```

SDK for Python

Example

```
def create_multipart_upload(s3_client, bucket_name, key_name):
    """
    Create a multipart upload to a directory bucket

    :param s3_client: boto3 S3 client
    :param bucket_name: The destination bucket for the multipart upload
    :param key_name: The key name for the object to be uploaded
    :return: The UploadId for the multipart upload if created successfully, else None
    """

    try:
        mpu = s3_client.create_multipart_upload(Bucket = bucket_name, Key =
key_name)
        return mpu['UploadId']
    except ClientError as e:
        logging.error(e)
        return None
```

Using the AWS CLI

This example shows how to create a multipart upload to a directory bucket by using the AWS CLI. This command starts a multipart upload to the directory bucket **bucket-base-name--zone-id--x-s3** for the object **KEY_NAME**. To use the command replace the *user input placeholders* with your own information.

```
aws s3api create-multipart-upload --bucket bucket-base-name--zone-id--x-s3 --
key KEY_NAME
```

"AS_mgt9RaQE9GEaifATue15dAAAAAAAAAEMAAAAAAAADQwNzI4MDU0MjUyMBYAAAAAAA0AAAAAAA0H2AFYA
--multipart-upload file://parts.json
```

This example takes a JSON structure that describes the parts of the multipart upload that should be reassembled into the complete file. In this example, the `file://` prefix is used to load the JSON structure from a file in the local folder named `parts`.

`parts.json`:

```
parts.json
{
    "Parts": [
        {
            "PartNumber": 1,
            "ETag": "e3774444444444444444444444444444",
            "LastModified": "2016-03-01T12:00:00Z"
        }
    ]
}
```

```
        "ETag": "6b78c4a64dd641a58dac8d9258b88147",
        "PartNumber": 1
    }

Creating a multipart upload copy operation

Note

- To encrypt new object part copies in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). The [AWS managed key](#) (aws/s3) isn't supported. Your SSE-KMS configuration can only support 1 [customer managed key](#) per directory bucket for the lifetime of the bucket. After you specify a customer managed key for SSE-KMS, you can't override the customer managed key for the bucket's SSE-KMS configuration. You can't specify server-side encryption settings for new object part copies with SSE-KMS in the [UploadPartCopy](#) request headers. Also, the request headers you provide in the CreateMultipartUpload request must match the default encryption configuration of the destination bucket.
- S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose

buckets, or between directory buckets, through [UploadPartCopy](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object.

The following examples show how to copy objects from one bucket to another using a multipart upload.

Listing in-progress multipart uploads

To list in-progress multipart uploads to a directory bucket, you can use the AWS SDKs, or the AWS CLI.

Using the AWS SDKs

SDK for Java 2.x

The following examples show how to list in-progress (incomplete) multipart uploads by using the SDK for Java 2.x.

Example

```
public static void listMultiPartUploads( S3Client s3, String bucketName) {  
    try {  
        ListMultipartUploadsRequest listMultipartUploadsRequest =  
ListMultipartUploadsRequest.builder()  
            .bucket(bucketName)  
            .build();  
  
        ListMultipartUploadsResponse response =  
s3.listMultipartUploads(listMultipartUploadsRequest);
```

```
        List MultipartUpload uploads = response/uploads();
        for (MultipartUpload upload: uploads) {
            System.out.println("Upload in progress: Key = \\" + upload.key() +
"\\", id = " + upload.uploadId());
        }
    }
    catch (S3Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

SDK for Python

The following examples show how to list in-progress (incomplete) multipart uploads by using the SDK for Python.

Example

```
import logging
import boto3
from botocore.exceptions import ClientError

def list_multipart_uploads(s3_client, bucket_name):
    """

Copying objects from or to a directory bucket

The copy operation creates a copy of an object that is already stored in Amazon S3. You can copy objects between directory buckets and general purpose buckets. You can also copy objects within a bucket and across buckets of the same type, for example, from directory bucket to directory bucket.

Note

Copying objects across different AWS Regions isn't supported when the source or destination bucket is in an AWS Local Zone. The source and destination buckets must have the same parent AWS Region. The source and destination buckets can be different bucket location types (Availability Zone or Local Zone).

You can create a copy of object up to 5 GB in a single atomic operation. However, to copy an object that is greater than 5 GB, you must use the multipart upload API operations. For more information, see [Using multipart uploads with directory buckets](#).

Permissions

To copy objects, you must have the following permissions:

- To copy objects from one directory bucket to another directory bucket, you must have the `s3express:CreateSession` permission.
- To copy objects from directory buckets to general purpose buckets, you must have the `s3express:CreateSession` permission and the `s3:PutObject` permission to write the object copy to the destination bucket.

- To copy objects from general purpose buckets to directory buckets, you must have the `s3express:CreateSession` permission and `s3:GetObject` permission to read the source object that is being copied.

For more information, see [CopyObject](#) in the *Amazon Simple Storage Service API Reference*.

Encryption

Amazon S3 automatically encrypts all new objects that are uploaded to an S3 bucket. The default encryption configuration of an S3 bucket is always enabled and is at a minimum set to server-side encryption with Amazon S3 managed keys (SSE-S3).

For directory buckets, SSE-S3 and server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) are supported. When the destination bucket is a directory bucket, we recommend that the destination bucket's default encryption uses the desired encryption configuration and you don't override the bucket default encryption. Then, new objects are automatically encrypted with the desired encryption settings. Also, S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [CopyObject](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object. For more information about the encryption overriding behaviors in directory buckets, see [Specifying server-side encryption with AWS KMS for new object uploads](#).

For general purpose buckets, you can use SSE-S3 (the default), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C).

If you make a copy request that specifies to use DSSE-KMS or SSE-C for a directory bucket (either the source or destination bucket), the response returns an error.

Tags

Directory buckets don't support tags. If you copy an object that has tags from a general purpose bucket to a directory bucket, you receive an HTTP 501 (Not Implemented) response. For more information, see [CopyObject](#) in the *Amazon Simple Storage Service API Reference*.

ETags

Entity tags (ETags) for S3 Express One Zone are random alphanumeric strings and are not MD5 checksums. To help ensure object integrity, use additional checksums.

Additional checksums

S3 Express One Zone offers you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32C, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.

For more information, see [S3 additional checksum best practices](#).

Supported features

For more information about which Amazon S3 features are supported for S3 Express One Zone, see [Differences for directory buckets](#).

Using the S3 console (copy to a directory bucket)

Note

The restrictions and limitations when you copy an object to a directory bucket with the console are as follows:

- The Copy action applies to all objects within the specified folders (prefixes). Objects added to these folders while the action is in progress might be affected.
- Objects encrypted with customer-provided encryption keys (SSE-C) cannot be copied by using the S3 console. To copy objects encrypted with SSE-C, use the AWS CLI, AWS SDK, or the Amazon S3 REST API.
- Copied objects will not retain the Object Lock settings from the original objects.
- If the bucket you are copying objects from uses the bucket owner enforced setting for S3 Object Ownership, object ACLs will not be copied to the specified destination.
- If you want to copy objects to a bucket that uses the bucket owner enforced setting for S3 Object Ownership, make sure that the source bucket also uses the bucket owner enforced setting, or remove any object ACL grants to other AWS accounts and groups.
- Objects copied from a general purpose bucket to a directory bucket will not retain object tags, ACLs, or Etag values. Checksum values can be copied, but are not equivalent to an Etag. The checksum value may change compared to when it was added.
- All objects copied to a directory bucket will be with the bucket owner enforced setting for S3 Object Ownership.

To copy an object from a general purpose bucket or a directory bucket to a directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, the bucket type that you want to copy objects from:
 - To copy from a general purpose bucket, choose the **General purpose buckets** tab.
 - To copy from a directory bucket, choose the **Directory buckets** tab.
3. Choose the general purpose bucket or directory bucket that contains the objects that you want to copy.
4. Choose the **Objects** tab. On the **Objects** page, select the check box to the left of the names of the objects that you want to copy.
5. On the **Actions** menu, choose **Copy**.

The **Copy** page appears.

6. Under **Destination**, choose **Directory bucket** for your destination type. To specify the destination path, choose **Browse S3**, navigate to the destination, and then choose the option button to the left of the destination. Choose **Choose destination** in the lower-right corner.

Alternatively, enter the destination path.

7. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for server-side encryption, checksums, and metadata.
8. Choose **Copy** in the bottom-right corner. Amazon S3 copies your objects to the destination.

Using the S3 console (copy to a general purpose bucket)

Note

The restrictions and limitations when you copy an object to a general purpose bucket with the console are as follows:

- The Copy action applies to all objects within the specified folders (prefixes). Objects added to these folders while the action is in progress might be affected.

- Objects encrypted with customer-provided encryption keys (SSE-C) cannot be copied by using the S3 console. To copy objects encrypted with SSE-C, use the AWS CLI, AWS SDK, or the Amazon S3 REST API.
- Copied objects will not retain the Object Lock settings from the original objects.
- If the bucket you are copying objects from uses the bucket owner enforced setting for S3 Object Ownership, object ACLs will not be copied to the specified destination.
- If you want to copy objects to a bucket that uses the bucket owner enforced setting for S3 Object Ownership, make sure that the source bucket also uses the bucket owner enforced setting, or remove any object ACL grants to other AWS accounts and groups.

To copy an object from a directory bucket to a general purpose bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose the **Directory buckets** tab.
4. Choose the directory bucket that contains the objects that you want to copy.
5. Choose the **Objects** tab. On the **Objects** page, select the check box to the left of the names of the objects that you want to copy.
6. On the **Actions** menu, choose **Copy**.
7. Under **Destination**, choose **General purpose bucket** for your destination type. To specify the destination path, choose **Browse S3**, navigate to the destination, and choose the option button to the left of the destination. Choose **Choose destination** in the lower-right corner.
Alternatively, enter the destination path.
8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Copy** in the bottom-right corner. Amazon S3 copies your objects to the destination.

Using the AWS SDKs

SDK for Java 2.x

Example

```
public static void copyBucketObject (S3Client s3, String sourceBucket, String
objectKey, String targetBucket) {
    CopyObjectRequest copyReq = CopyObjectRequest.builder()
        .sourceBucket(sourceBucket)
        .sourceKey(objectKey)
        .destinationBucket(targetBucket)
        .destinationKey(objectKey)
        .build();
    String temp = "";

    try {
        CopyObjectResponse copyRes = s3.copyObject(copyReq);
        System.out.println("Successfully copied " + objectKey +" from bucket " +
sourceBucket +" into bucket "+targetBucket);
    }

    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Using the AWS CLI

The following copy-object example command shows how you can use the AWS CLI to copy an object from one bucket to another bucket. You can copy objects between bucket types. To run this command, replace the user input placeholders with your own information.

```
aws s3api copy-object --copy-source SOURCE_BUCKET/SOURCE_KEY_NAME --key TARGET_KEY_NAME
--bucket TARGET_BUCKET_NAME
```

For more information, see [copy-object](#) in the *AWS CLI Command Reference*.

Deleting objects from a directory bucket

You can delete objects from an Amazon S3 directory bucket by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), or AWS SDKs. For more information, see [Working with directory buckets](#) and [S3 Express One Zone](#).

Warning

- Deleting an object can't be undone.
- This action deletes all specified objects. When deleting folders, wait for the delete action to finish before adding new objects to the folder. Otherwise, new objects might be deleted as well.

Note

When you programmatically delete multiple objects from a directory bucket, note the following:

- Object keys in `DeleteObjects` requests must contain at least one non-white space character. Strings of all white space characters are not supported.
- Object keys in `DeleteObjects` requests cannot contain Unicode control characters, except for newline (\n), tab (\t), and carriage return (\r).

Using the S3 console

To delete objects

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Directory buckets**.
3. Choose the directory bucket that contains the objects that you want to delete.
4. Choose the **Objects** tab. In the **Objects** list, select the check box to the left of the object or objects that you want to delete.
5. Choose **Delete**.

6. On the **Delete objects** page, enter **permanently delete** in the text box.
7. Choose **Delete objects**.

Using the AWS SDKs

SDK for Java 2.x

Example

The following example deletes objects in a directory bucket by using the AWS SDK for Java 2.x.

```
static void deleteObject(S3Client s3Client, String bucketName, String objectKey) {  
  
    try {  
  
        DeleteObjectRequest del = DeleteObjectRequest.builder()  
            .bucket(bucketName)  
            .key(objectKey)  
            .build();  
  
        s3Client.deleteObject(del);  
  
        System.out.println("Object " + objectKey + " has been deleted");  
  
    } catch (S3Exception e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

SDK for Python

Example

The following example deletes objects in a directory bucket by using the AWS SDK for Python (Boto3).

```
import logging
```

```
import boto3
from botocore.exceptions import ClientError

def delete_objects(s3_client, bucket_name, objects):
    """
    Delete a list of objects in a directory bucket

    :param s3_client: boto3 S3 client
    :param bucket_name: Bucket that contains objects to be deleted; for example,
    'doc-example-bucket--usw2-az1--x-s3'
    :param objects: List of dictionaries that specify the key names to delete
    :return: Response output, else False
    """

    try:
        response = s3_client.delete_objects(
            Bucket = bucket_name,
            Delete = {
                'Objects': objects
            }
        )
        return response
    except ClientError as e:
        logging.error(e)
        return False

if __name__ == '__main__':
    region = 'us-west-2'
    bucket_name = 'BUCKET_NAME'
    objects = [
        {
            'Key': '0.txt'
        },
        {
            'Key': '1.txt'
        },
        {
            'Key': '2.txt'
        },
        {
            'Key': '3.txt'
        },
        {
    ]
```

```
        'Key': '4.txt'
    }
]

s3_client = boto3.client('s3', region_name = region)
results = delete_objects(s3_client, bucket_name, objects)
if results is not None:
    if 'Deleted' in results:
        print (f'Deleted {len(results["Deleted"])} objects from {bucket_name}')
    if 'Errors' in results:
        print (f'Failed to delete {len(results["Errors"])} objects from
{bucket_name}'')
```

Using the AWS CLI

The following delete-object example command shows how you can use the AWS CLI to delete an object from a directory bucket. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api delete-object --bucket bucket-base-name--zone-id--x-s3 --key KEY_NAME
```

For more information, see [delete-object](#) in the *AWS CLI Command Reference*.

The following delete-objects example command shows how you can use the AWS CLI to delete objects from a directory bucket. To run this command, replace the *user input placeholders* with your own information.

The delete.json file is as follows:

```
{
  "Objects": [
    {
      "Key": "0.txt"
    },
    {
      "Key": "1.txt"
    },
    {
      "Key": "2.txt"
    },
  ]}
```

```
{  
    "Key": "3.txt"  
}  
]  
}
```

The delete-objects example command is as follows:

```
aws s3api delete-objects --bucket bucket-base-name--zone-id--x-s3 --delete  
file://delete.json
```

For more information, see [delete-objects](#) in the *AWS CLI Command Reference*.

Downloading an object from a directory bucket

The following code examples show how to read data from (download) an object in an Amazon S3 directory bucket by using the GetObject API operation.

Using the AWS SDKs

SDK for Java 2.x

Example

The following code example shows how to read data from an object in a directory bucket by using the AWS SDK for Java 2.x.

```
public static void get0bject(S3Client s3Client, String bucketName, String objectKey)  
{  
    try {  
        GetObjectRequest objectRequest = GetObjectRequest  
            .builder()  
            .key(objectKey)  
            .bucket(bucketName)  
            .build();  
  
        ResponseBytes<GetObjectResponse> objectBytes =  
s3Client.getObjectAsBytes(objectRequest);  
        byte[] data = objectBytes.asByteArray();  
  
        //Print object contents to console  
    }  
}
```

```
        String s = new String(data, StandardCharsets.UTF_8);
        System.out.println(s);
    }

    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

SDK for Python

Example

The following code example shows how to read data from an object in a directory bucket by using the AWS SDK for Python (Boto3).

```
import boto3
from botocore.exceptions import ClientError
from botocore.response import StreamingBody

def get_object(s3_client: boto3.client, bucket_name: str, key_name: str) ->
    StreamingBody:
    """
    Gets the object.
    :param s3_client:
    :param bucket_name: The bucket that contains the object.
    :param key_name: The key of the object to be downloaded.
    :return: The object data in bytes.
    """
    try:
        response = s3_client.get_object(Bucket=bucket_name, Key=key_name)
        body = response['Body'].read()
        print(f"Got object '{key_name}' from bucket '{bucket_name}'.")
    except ClientError:
        print(f"Couldn't get object '{key_name}' from bucket '{bucket_name}'.")
        raise
    else:
        return body

def main():
    s3_client = boto3.client('s3')
    resp = get_object(s3_client, 'doc-example-bucket--use1-az4--x-s3', 'sample.txt')
```

```
print(resp)

if __name__ == "__main__":
    main()
```

Using the AWS CLI

The following get-object example command shows how you can use the AWS CLI to download an object from Amazon S3. This command gets the object *KEY_NAME* from the directory bucket *bucket-base-name--zone-id--x-s3*. The object will be downloaded to a file named *LOCAL_FILE_NAME*. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket bucket-base-name--zone-id--x-s3 --
key KEY_NAME LOCAL_FILE_NAME
```

For more information, see [get-object](#) in the *AWS CLI Command Reference*.

Generating presigned URLs to share objects directory bucket

The following code examples show how to generate presigned URLs to share objects from an Amazon S3 directory bucket.

Using the AWS CLI

The following example command shows how you can use the AWS CLI to generate a presigned URL for an object from Amazon S3. This command generates a presigned URL for an object *KEY_NAME* from the directory bucket *bucket-base-name--zone-id--x-s3*. To run this command, replace the *user input placeholders* with your own information.

```
aws s3 presign s3://bucket-base-name--zone-id--x-s3/KEY_NAME --expires-in 7200
```

For more information, see [presign](#) in the *AWS CLI Command Reference*.

Retrieving object metadata from directory buckets

The following AWS SDK and AWS CLI examples show how to use the HeadObject and GetObjectAttributes API operation to retrieve metadata from an object in an Amazon S3 directory bucket without returning the object itself.

Using the AWS SDKs

SDK for Java 2.x

Example

```
public static void headObject(S3Client s3Client, String bucketName, String objectKey) {
    try {
        HeadObjectRequest headObjectRequest = HeadObjectRequest
            .builder()
            .bucket(bucketName)
            .key(objectKey)
            .build();
        HeadObjectResponse response = s3Client.headObject(headObjectRequest);
        System.out.format("Amazon S3 object: \"%s\" found in bucket: \"%s\" with
ETag: \"%s\"", objectKey, bucketName, response.eTag());
    }
    catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
}
```

Using the AWS CLI

The following head-object example command shows how you can use the AWS CLI to retrieve metadata from an object. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api head-object --bucket bucket-base-name--zone-id--x-s3 --key KEY_NAME
```

For more information, see [head-object](#) in the *AWS CLI Command Reference*.

The following get-object-attributes example command shows how you can use the AWS CLI to retrieve metadata from an object. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api get-object-attributes --bucket bucket-base-name--zone-id--x-s3 --key KEY_NAME
--object-attributes "StorageClass" "ETag" "ObjectSize"
```

For more information, see [get-object-attributes](#) in the *AWS CLI Command Reference*.

Listing objects from a directory bucket

The following code examples show how to list objects in an Amazon S3 directory bucket by using the `ListObjectsV2` API operation.

Using the AWS CLI

The following `list-objects-v2` example command shows how you can use the AWS CLI to list objects from Amazon S3. This command lists objects from the directory bucket `bucket-base-name--zone-id--x-s3`. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api list-objects-v2 --bucket bucket-base-name--zone-id--x-s3
```

For more information, see [list-objects-v2](#) in the *AWS CLI Command Reference*.

Security for directory buckets

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations. Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS Compliance Programs](#).

To learn about the compliance programs, see [AWS services in Scope by Compliance Program](#).

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors, including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation will help you understand how to apply the shared responsibility model when using directory buckets. The following topics show you how to configure directory buckets to meet your security and compliance objectives. You will also learn how to use other AWS services that can help you monitor and secure your objects in directory buckets.

Data protection and encryption

For more information about how you can configure encryption for directory buckets, see the following topics.

Topics

- [Server-side encryption](#)
- [Setting and monitoring default encryption for directory buckets](#)
- [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in directory buckets](#)
- [Encryption in transit](#)
- [Data deletion](#)

Server-side encryption

All directory buckets have encryption configured by default, and all new objects that are uploaded to directory buckets are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every directory bucket. If you want to specify a different encryption type, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), by setting the default encryption configuration of the bucket. For more information about SSE-KMS in directory buckets, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in directory buckets](#).

We recommend that the bucket's default encryption uses the desired encryption configuration and you don't override the bucket default encryption in your CreateSession requests or PUT object requests. Then, new objects are automatically encrypted with the desired encryption settings. For more information about the encryption overriding behaviors in directory buckets, see [Specifying server-side encryption with AWS KMS for new object uploads](#).

SSE-KMS with directory buckets differs from SSE-KMS in general purpose buckets in the following aspects.

- Your SSE-KMS configuration can only support 1 [customer managed key](#) per directory bucket for the lifetime of the bucket. The [AWS managed key](#) (aws/s3) isn't supported. Also, after you specify a customer managed key for SSE-KMS, you can't override the customer managed key for the bucket's SSE-KMS configuration.

You can identify the customer managed key you specified for the bucket's SSE-KMS configuration, in the following way:

- You make a HeadObject API operation request to find the value of `x-amz-server-side-encryption-aws-kms-key-id` in your response.

To use a new customer managed key for your data, we recommend copying your existing objects to a new directory bucket with a new customer managed key.

- For [Zonal endpoint \(object-level\) API operations](#) except [CopyObject](#) and [UploadPartCopy](#), you authenticate and authorize requests through [CreateSession](#) for low latency. We recommend that the bucket's default encryption uses the desired encryption configuration and you don't override the bucket default encryption in your CreateSession requests or PUT object requests. Then, new objects are automatically encrypted with the desired encryption settings. To encrypt new objects in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). Then, when a session is created for Zonal endpoint API operations, new objects are automatically encrypted and decrypted with SSE-KMS and S3 Bucket Keys during the session. For more information about the encryption overriding behaviors in directory buckets, see [Specifying server-side encryption with AWS KMS for new object uploads](#).

In the Zonal endpoint API calls (except [CopyObject](#) and [UploadPartCopy](#)), you can't override the values of the encryption settings (`x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, `x-amz-server-side-encryption-context`, and `x-amz-server-side-encryption-bucket-key-enabled`) from the CreateSession request. You don't need to explicitly specify these encryption settings values in Zonal endpoint API calls, and Amazon S3 will use the encryption settings values from the CreateSession request to protect new objects in the directory bucket.

Note

When you use the AWS CLI or the AWS SDKs, for CreateSession, the session token refreshes automatically to avoid service interruptions when a session expires. The AWS CLI or the AWS SDKs use the bucket's default encryption configuration for the CreateSession request. It's not supported to override the encryption settings values in the CreateSession request. Also, in the Zonal endpoint API calls (except [CopyObject](#) and [UploadPartCopy](#)), it's not supported override the values of the encryption settings from the CreateSession request.

- For [CopyObject](#), to encrypt new object copies in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). Then, when you specify server-side encryption settings for new object copies with SSE-KMS, you must make sure the encryption key is the same customer managed key that you specified for the directory bucket's default encryption configuration. For [UploadPartCopy](#), to encrypt new object part copies in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). You can't specify server-side encryption settings for new object part copies with SSE-KMS in the [UploadPartCopy](#) request headers. Also, the encryption settings that you provide in the [CreateMultipartUpload](#) request must match the default encryption configuration of the destination bucket.
- S3 Bucket Keys are always enabled for GET and PUT operations in a directory bucket and can't be disabled. S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [CopyObject](#), [UploadPartCopy](#), [the Copy operation in Batch Operations](#), or [the import jobs](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object.
- When you specify an [AWS KMS customer managed key](#) for encryption in your directory bucket, only use the key ID or key ARN. The key alias format of the KMS key isn't supported.

Directory buckets don't support dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS), or server-side encryption with customer-provided encryption keys (SSE-C).

Setting and monitoring default encryption for directory buckets

Amazon S3 buckets have bucket encryption enabled by default, and new objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption applies to all new objects in your Amazon S3 buckets, and comes at no cost to you.

If you need more control over your encryption keys, such as managing key rotation and access policy grants, you can elect to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

Note

- We recommend that the bucket's default encryption uses the desired encryption configuration and you don't override the bucket default encryption in your `CreateSession` requests or `PUT` object requests. Then, new objects are automatically encrypted with the desired encryption settings. For more information about the encryption overriding behaviors in directory buckets, see [Specifying server-side encryption with AWS KMS for new object uploads](#).
- To encrypt new objects in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a customer managed key). Then, when a session is created for Zonal endpoint API operations, new objects are automatically encrypted and decrypted with SSE-KMS and S3 Bucket Keys during the session.
- When you set default bucket encryption to SSE-KMS, S3 Bucket Keys are always enabled for GET and PUT operations in a directory bucket and can't be disabled. S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [CopyObject](#), [UploadPartCopy](#), [the Copy operation in Batch Operations](#), or [the import jobs](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object. For more information about how S3 Bucket Keys reduce your AWS KMS request costs, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).
- When you specify an [AWS KMS customer managed key](#) for encryption in your directory bucket, only use the key ID or key ARN. The key alias format of the KMS key isn't supported.
- Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) and server-side encryption with customer-provided keys (SSE-C) aren't supported for default encryption in directory buckets.

For more information about configuring default encryption, see [Configuring default encryption](#).

For more information about the permissions required for default encryption, see [PutBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

You can configure Amazon S3 default encryption for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

Using the S3 console

To configure default encryption on an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want.
4. Choose the **Properties** tab.
5. Under **Server-side encryption settings**, directory buckets use Server-side encryption with **Amazon S3 managed keys (SSE-S3)**.
6. Choose **Save changes**.

Using the AWS CLI

These examples show you how to configure default encryption by using SSE-S3 or by using SSE-KMS with an S3 Bucket Key.

For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about using the AWS CLI to configure default encryption, see [put-bucket-encryption](#).

Example – Default encryption with SSE-S3

This example configures default bucket encryption with Amazon S3 managed keys. To use the command, replace the *user input placeholders* with your own information.

```
aws s3api put-bucket-encryption --bucket bucket-base-name--zone-id--x-s3 --server-side-  
encryption-configuration '{  
    "Rules": [  
        {  
            "ApplyServerSideEncryptionByDefault": {  
                "SSEAlgorithm": "AES256"  
            }  
        }  
    ]  
}'
```

```
]  
}'
```

Example – Default encryption with SSE-KMS using an S3 Bucket Key

This example configures default bucket encryption with SSE-KMS using an S3 Bucket Key. To use the command, replace the *user input placeholders* with your own information.

```
aws s3api put-bucket-encryption --bucket bucket-base-name--zone-id--x-s3 --server-side-  
encryption-configuration '{  
    "Rules": [  
        {  
            "ApplyServerSideEncryptionByDefault": {  
                "SSEAlgorithm": "aws:kms",  
                "KMSMasterKeyID": "KMS-Key-ARN"  
            },  
            "BucketKeyEnabled": true  
        }  
    ]  
}'
```

Using the REST API

Use the REST API PutBucketEncryption operation to set default encryption with a type of server-side encryption to use — SSE-S3, or SSE-KMS.

For more information, see [PutBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use AWS KMS keys for server-side encryption. The following AWS SDKs for Java and .NET examples configure default encryption configuration for a directory bucket with SSE-KMS and an S3 Bucket Key. For information about other SDKs, see [Sample code and libraries](#) on the AWS Developer Center.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS

keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the [AWS Key Management Service Developer Guide](#).

Java

With the AWS SDK for Java 2.x, you can request Amazon S3 to use an AWS KMS key by using the `applyServerSideEncryptionByDefault` method to specify the default encryption configuration of your directory bucket for data encryption with SSE-KMS. You create a symmetric encryption KMS key and specify that in the request.

```
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.PutBucketEncryptionRequest;
import software.amazon.awssdk.services.s3.model.ServerSideEncryption;
import software.amazon.awssdk.services.s3.model.ServerSideEncryptionByDefault;
import software.amazon.awssdk.services.s3.model.ServerSideEncryptionConfiguration;
import software.amazon.awssdk.services.s3.model.ServerSideEncryptionRule;

public class Main {
    public static void main(String[] args) {
        S3Client s3 = S3Client.create();
        String bucketName = "bucket-base-name--zoneid--x-s3";
        String kmsKeyId = "your-kms-customer-managed-key-id";

        // AWS managed KMS keys aren't supported. Only customer-managed keys are
        // supported.
        ServerSideEncryptionByDefault serverSideEncryptionByDefault =
        ServerSideEncryptionByDefault.builder()
            .sseAlgorithm(ServerSideEncryption.AWS_KMS)
            .kmsMasterKeyID(kmsKeyId)
            .build();

        // The bucketKeyEnabled field is enforced to be true.
        ServerSideEncryptionRule rule = ServerSideEncryptionRule.builder()
            .bucketKeyEnabled(true)
            .applyServerSideEncryptionByDefault(serverSideEncryptionByDefault)
            .build();

        ServerSideEncryptionConfiguration serverSideEncryptionConfiguration =
        ServerSideEncryptionConfiguration.builder()
            .rules(rule)
```

```
        .build();

    PutBucketEncryptionRequest putRequest = PutBucketEncryptionRequest.builder()
        .bucket(bucketName)

    .serverSideEncryptionConfiguration(serverSideEncryptionConfiguration)
        .build();

    s3.putBucketEncryption(putRequest);

}
```

For more information about creating customer managed keys, see [Programming the AWS KMS API](#) in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see [Uploading objects to a directory bucket](#).
- For multipart upload API operations, see [Using multipart uploads with directory buckets](#).

.NET

With the AWS SDK for .NET, you can request Amazon S3 to use an AWS KMS key by using the `ServerSideEncryptionByDefault` property to specify the default encryption configuration of your directory bucket for data encryption with SSE-KMS. You create a symmetric encryption customer managed key and specify that in the request.

```
// Set the bucket server side encryption to use AWSKMS with a customer-managed
key id.
// bucketName: Name of the directory bucket. "bucket-base-name--zonsid--x-s3"
// kmsKeyId: The Id of the customer managed KMS Key. "your-kms-customer-managed-
key-id"
// Returns True if successful.
public static async Task<bool> SetBucketServerSideEncryption(string bucketName,
string kmsKeyId)
```

```
{  
    var serverSideEncryptionByDefault = new ServerSideEncryptionConfiguration  
    {  
        ServerSideEncryptionRules = new List<ServerSideEncryptionRule>  
        {  
            new ServerSideEncryptionRule  
            {  
                ServerSideEncryptionByDefault = new  
ServerSideEncryptionByDefault  
                {  
                    ServerSideEncryptionAlgorithm =  
ServerSideEncryptionMethod.AWSKMS,  
                    ServerSideEncryptionKeyManagementServiceKeyId = kmsKeyId  
                }  
            }  
        }  
    };  
    try  
    {

For more information about creating customer managed keys, see [Programming the AWS KMS API](#) in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see [Uploading objects to a directory bucket](#).
- For multipart upload API operations, see [Using multipart uploads with directory buckets](#).

Monitoring default encryption for directory buckets with AWS CloudTrail

You can track default encryption configuration requests for Amazon S3 directory buckets by using AWS CloudTrail events. The following API event names are used in CloudTrail logs:

- PutBucketEncryption
- GetBucketEncryption
- DeleteBucketEncryption

Note

- EventBridge isn't supported in directory buckets.
- Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) or server-side encryption with customer-provided encryption keys (SSE-C) aren't supported in directory buckets.

For more information about monitoring default encryption with AWS CloudTrail, see [Monitoring default encryption with AWS CloudTrail and Amazon EventBridge](#).

Using server-side encryption with AWS KMS keys (SSE-KMS) in directory buckets

The security controls in AWS KMS can help you meet encryption-related compliance requirements. You can choose to configure directory buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) and use these KMS keys to protect your data in Amazon S3 directory buckets. For more information about SSE-KMS, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

Permissions

To upload or download an object encrypted with an AWS KMS key to or from Amazon S3, you need kms:GenerateDataKey and kms:Decrypt permissions on the key. For more information, see [Allow key users to use a KMS key for cryptographic operations](#) in the *AWS Key Management Service Developer Guide*. For information about the AWS KMS permissions that are required for multipart uploads, see [Multipart upload API and permissions](#).

For more information about KMS keys for SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#).

AWS KMS keys

Your SSE-KMS configuration can only support 1 [customer managed key](#) per directory bucket for the lifetime of the bucket. The [AWS managed key](#) (aws/s3) isn't supported. Also, after you specify a customer managed key for SSE-KMS, you can't override the customer managed key for the bucket's SSE-KMS configuration.

You can identify the customer managed key you specified for the bucket's SSE-KMS configuration, in the following way:

- You make a HeadObject API operation request to find the value of x-amz-server-side-encryption-aws-kms-key-id in your response.

To use a new customer managed key for your data, we recommend copying your existing objects to a new directory bucket with a new customer managed key.

When you specify an [AWS KMS customer managed key](#) for encryption in your directory bucket, only use the key ID or key ARN. The key alias format of the KMS key isn't supported.

For more information about KMS keys for SSE-KMS, see [AWS KMS keys](#).

Using SSE-KMS for cross-account operations

When using encryption for cross-account operations in directory buckets, be aware of the following:

- If you want to grant cross-account access to your S3 objects, configure a policy of a customer managed key to allow access from another account.
- To specify a customer managed key, you must use a fully qualified KMS key ARN.

Amazon S3 Bucket Keys

S3 Bucket Keys are always enabled for GET and PUT operations in a directory bucket and can't be disabled. S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [CopyObject](#), [UploadPartCopy](#), [the Copy operation in Batch Operations](#), or [the import jobs](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object.

For [Zonal endpoint \(object-level\) API operations](#) except [CopyObject](#) and [UploadPartCopy](#), you authenticate and authorize requests through [CreateSession](#) for low latency. We recommend that the bucket's default encryption uses the desired encryption configuration and you don't override the bucket default encryption in your CreateSession requests or PUT object requests. Then, new objects are automatically encrypted with the desired encryption settings. To encrypt new objects in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with an KMS key (specifically, a [customer managed key](#)). Then, when a session is created for Zonal endpoint API operations, new objects are automatically encrypted and decrypted with SSE-KMS and S3 Bucket Keys during the session. For more information about the encryption overriding behaviors in directory buckets, see [Specifying server-side encryption with AWS KMS for new object uploads](#).

S3 Bucket Keys are used for a time-limited period within Amazon S3, further reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations. For more information about using S3 Bucket Keys, see [Amazon S3 Bucket Keys](#) and [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

Requiring SSE-KMS

To require SSE-KMS of all objects in a particular directory bucket, you can use a bucket policy. For example, when you use the `CreateSession` API operation to grant permission to upload a new object (`PutObject`, `CopyObject`, and `CreateMultipartUpload`), the following bucket policy denies the upload object permission (`s3express:CreateSession`) to everyone if the `CreateSession` request doesn't include an `x-amz-server-side-encryption-aws-kms-key-id` header that requests SSE-KMS.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "UploadObjectPolicy",  
    "Statement": [  
        {  
            "Sid": "DenyObjectsThatAreNotSSEKMS",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3express:CreateSession",  
            "Resource": "arn:aws:s3express:us-east-1:111122223333:bucket/amzn-s3-demo-bucket--usw2-az1--x-s3",  
            "Condition": {  
                "Null": {  
                    "s3express:x-amz-server-side-encryption-aws-kms-key-id": "true"  
                }  
            }  
        }  
    ]  
}
```

To require that a particular AWS KMS key be used to encrypt the objects in a bucket, you can use the `s3express:x-amz-server-side-encryption-aws-kms-key-id` condition key. To specify the KMS key, you must use a key Amazon Resource Name (ARN) that is in the `arn:aws:kms:region:acct-id:key/key-id` format. AWS Identity and Access Management does not validate if the string for `s3express:x-amz-server-side-encryption-aws-kms-key-id` exists. The AWS KMS key ID that Amazon S3 uses for object encryption must match the AWS KMS key ID in the policy, otherwise Amazon S3 denies the request.

For more information about how to use SSE-KMS for new object uploads, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\) for new object uploads in directory buckets](#).

For a complete list of specific condition keys for directory buckets, see [Authorizing Regional endpoint API operations with IAM](#).

Encryption context

For directory buckets, an *encryption context* is a set of key-value pairs that contains contextual information about the data. An additional encryption context value is not supported. For more information about the encryption context, see [Encryption context](#).

By default, if you use SSE-KMS on a directory bucket, Amazon S3 uses the bucket Amazon Resource Name (ARN) as the encryption context pair:

```
arn:aws:s3express:region:account-id:bucket/bucket-base-name--zone-id--x-s3
```

Make sure your IAM policies or AWS KMS key policies use your bucket ARN as the encryption context.

You can optionally provide an explicit encryption context pair by using the `x-amz-server-side-encryption-context` header in a Zonal endpoint API request, such as [CreateSession](#). The value of this header is a Base64-encoded string of a UTF-8 encoded JSON, which contains the encryption context as key-value pairs. For directory buckets, the encryption context must match the default encryption context – the bucket Amazon Resource Name (ARN). Also, because the encryption context is not encrypted, make sure it does not include sensitive information.

You can use the encryption context to identify and categorize your cryptographic operations. You can also use the default encryption context ARN value to track relevant requests in AWS CloudTrail by viewing which directory bucket ARN was used with which encryption key.

In the `requestParameters` field of a CloudTrail log file, if you use SSE-KMS on a directory bucket, the encryption context value is the ARN of the bucket.

```
"encryptionContext": {  
    "aws:s3express:arn": "arn:aws:s3:::arn:aws:s3express:region:account-id:bucket/bucket-base-name--zone-id--x-s3"  
}
```

Also, for object encryption with SSE-KMS in a directory bucket, your AWS KMS CloudTrail events log your bucket ARN instead of your object ARN.

Sending requests for AWS KMS encrypted objects

Directory buckets can only be accessed through HTTPS (TLS). Also, directory buckets sign requests by using AWS Signature Version 4 (SigV4). For more information about sending requests for AWS KMS encrypted objects, see [Sending requests for AWS KMS encrypted objects](#).

If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests. Otherwise, you'll get an HTTP 400 Bad Request error.

Auditing SSE-KMS encryption in directory buckets

To audit the usage of your AWS KMS keys for your SSE-KMS encrypted data, you can use AWS CloudTrail logs. You can get insight into your [cryptographic operations](#), such as [GenerateDataKey](#) and [Decrypt](#). CloudTrail supports numerous [attribute values](#) for filtering your search, including event name, user name, and event source.

Specifying server-side encryption with AWS KMS (SSE-KMS) for new object uploads in directory buckets

For directory buckets, to encrypt your data with server-side encryption, you can use either server-side encryption with Amazon S3 managed keys (SSE-S3) (the default) or server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). We recommend that the bucket's default encryption uses the desired encryption configuration and you don't override the bucket default encryption in your CreateSession requests or PUT object requests. Then, new objects are automatically encrypted with the desired encryption settings. For more information about the encryption overriding behaviors in directory buckets, see [Specifying server-side encryption with AWS KMS for new object uploads](#).

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. If you want to specify a different encryption type for a directory bucket, you can use server-

side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). To encrypt new objects in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). The [AWS managed key](#) (aws/s3) isn't supported. Your SSE-KMS configuration can only support 1 [customer managed key](#) per directory bucket for the lifetime of the bucket. After you specify a customer managed key for SSE-KMS, you can't override the customer managed key for the bucket's SSE-KMS configuration. Then, when you specify server-side encryption settings for new objects with SSE-KMS, you must make sure the encryption key is the same customer managed key that you specified for the directory bucket's default encryption configuration. To use a new customer managed key for your data, we recommend copying your existing objects to a new directory bucket with a new customer managed key.

You can apply encryption when you are either uploading a new object or copying an existing object. If you change an object's encryption, a new object is created to replace the old one.

You can specify SSE-KMS by using the REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI).

Note

- For directory buckets, the encryption overriding behaviors are as follows:
 - When you use [CreateSession](#) with the REST API to authenticate and authorize Zonal endpoint API requests except [CopyObject](#) and [UploadPartCopy](#), you can override the encryption settings to SSE-S3 or to SSE-KMS only if you specified the bucket's default encryption with SSE-KMS previously.
 - When you use [CreateSession](#) with the AWS CLI or the AWS SDKs to authenticate and authorize Zonal endpoint API requests except [CopyObject](#) and [UploadPartCopy](#), you can't override the encryption settings at all.
 - When you make [CopyObject](#) requests, you can override the encryption settings to SSE-S3 or to SSE-KMS only if you specified the bucket's default encryption with SSE-KMS previously. When you make [UploadPartCopy](#) requests, you can't override the encryption settings.
- You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in [AWS Key Management Service Developer Guide](#).

- If you want to use a KMS key that's owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

Using the REST API

Note

Only 1 [customer managed key](#) is supported per directory bucket for the lifetime of the bucket. The [AWS managed key](#) (aws/s3) isn't supported. After you specify SSE-KMS as your bucket's default encryption configuration with a customer managed key, you can't change the customer managed key for the bucket's SSE-KMS configuration.

For [Zonal endpoint \(object-level\) API operations](#) except [CopyObject](#) and [UploadPartCopy](#), you authenticate and authorize requests through [CreateSession](#) for low latency. We recommend that the bucket's default encryption uses the desired encryption configurations and you don't override the bucket default encryption in your [CreateSession](#) requests or PUT object requests. Then, new objects are automatically encrypted with the desired encryption settings. To encrypt new objects in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). Then, when a session is created for Zonal endpoint API operations, new objects are automatically encrypted and decrypted with SSE-KMS and S3 Bucket Keys during the session. For more information about the encryption overriding behaviors in directory buckets, see [Specifying server-side encryption with AWS KMS for new object uploads](#).

In the Zonal endpoint API calls (except [CopyObject](#) and [UploadPartCopy](#)) using the REST API, you can't override the values of the encryption settings (x-amz-server-side-encryption, x-amz-server-side-encryption-aws-kms-key-id, x-amz-server-side-encryption-context, and x-amz-server-side-encryption-bucket-key-enabled) from the [CreateSession](#) request. You don't need to explicitly specify these encryption settings values in Zonal endpoint API calls, and Amazon S3 will use the encryption settings values from the [CreateSession](#) request to protect new objects in the directory bucket.

Note

When you use the AWS CLI or the AWS SDKs, for `CreateSession`, the session token refreshes automatically to avoid service interruptions when a session expires. The AWS CLI or the AWS SDKs use the bucket's default encryption configuration for the `CreateSession` request. It's not supported to override the encryption settings values in the `CreateSession` request. Also, in the Zonal endpoint API calls (except [CopyObject](#) and [UploadPartCopy](#)), it's not supported to override the values of the encryption settings from the `CreateSession` request.

For [CopyObject](#), to encrypt new object copies in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). Then, when you specify server-side encryption settings for new object copies with SSE-KMS, you must make sure the encryption key is the same customer managed key that you specified for the directory bucket's default encryption configuration. For [UploadPartCopy](#), to encrypt new object part copies in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a [customer managed key](#)). You can't specify server-side encryption settings for new object part copies with SSE-KMS in the [UploadPartCopy](#) request headers. Also, the encryption settings that you provide in the [CreateMultipartUpload](#) request must match the default encryption configuration of the destination bucket.

Amazon S3 REST API operations that support SSE-KMS

The following object-level REST API operations in directory buckets accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- [CreateSession](#) – When you use Zonal endpoint (object-level) API operations (except CopyObject and UploadPartCopy), you can specify these request headers.
- [PutObject](#) – When you upload data by using the PUT API operation, you can specify these request headers.
- [CopyObject](#) – When you copy an object, you have both a source object and a target object. When you pass SSE-KMS headers with the CopyObject operation, they're applied only to the target object.
- [CreateMultipartUpload](#) – When you upload large objects by using the multipart upload API operation, you can specify these headers. You specify these headers in the CreateMultipartUpload request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored by using server-side encryption.

- [CreateSession](#)
- [PutObject](#)
- [CopyObject](#)
- [POST Object](#)
- [CreateMultipartUpload](#)
- [UploadPart](#)
- [UploadPartCopy](#)
- [CompleteMultipartUpload](#)
- [GetObject](#)
- [HeadObject](#)

 **Important**

- All GET and PUT requests for an object protected by AWS KMS fail if you don't make these requests by using Transport Layer Security (TLS), or Signature Version 4.
- If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 BadRequest error.

Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms`, the Amazon S3 API supports you to optionally provide an explicit encryption context with the `x-amz-server-side-encryption-context` header. For directory buckets, an encryption context is a set of key-value pairs that contain contextual information about the data. The value must match the default encryption context — the bucket Amazon Resource Name (ARN). An additional encryption context value is not supported.

For information about the encryption context in directory buckets, see [Encryption context](#). For general information about the encryption context, see [AWS Key Management Service Concepts - Encryption context](#) in the *AWS Key Management Service Developer Guide*.

AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data.

Your SSE-KMS configuration can only support 1 [customer managed key](#) per directory bucket for the lifetime of the bucket. The [AWS managed key](#) (aws/s3) isn't supported. Also, after you specify a customer managed key for SSE-KMS, you can't override the customer managed key for the bucket's SSE-KMS configuration.

You can identify the customer managed key you specified for the bucket's SSE-KMS configuration, in the following way:

- You make a HeadObject API operation request to find the value of `x-amz-server-side-encryption-aws-kms-key-id` in your response.

To use a new customer managed key for your data, we recommend copying your existing objects to a new directory bucket with a new customer managed key.

For information about the encryption context in directory buckets, see [AWS KMS keys](#).

S3 Bucket Keys (`x-amz-server-side-encryption-aws-bucket-key-enabled`)

S3 Bucket Keys are always enabled for GET and PUT operations in a directory bucket and can't be disabled. S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets,

or between directory buckets, through [CopyObject](#), [UploadPartCopy](#), [the Copy operation in Batch Operations](#), or [the import jobs](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object. For information about the S3 Bucket Keys in directory buckets, see [Encryption context](#).

Using the AWS CLI

Note

When you use the AWS CLI, for `CreateSession`, the session token refreshes automatically to avoid service interruptions when a session expires. It's not supported to override the encryption settings values for the `CreateSession` request. Also, in the Zonal endpoint API calls (except [CopyObject](#) and [UploadPartCopy](#)), it's not supported to override the values of the encryption settings from the `CreateSession` request.

To encrypt new objects in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a customer managed key). Then, when a session is created for Zonal endpoint API operations, new objects are automatically encrypted and decrypted with SSE-KMS and S3 Bucket Keys during the session.

To use the following example AWS CLI commands, replace the *user input placeholders* with your own information.

When you upload a new object or copy an existing object, you can specify the use of server-side encryption with AWS KMS keys to encrypt your data. To do this, use the `put-bucket-encryption` command to set the directory bucket's default encryption configuration as SSE-KMS (`aws:kms`). Specifically, add the `--server-side-encryption aws:kms` header to the request. Use the `--ssekmss-key-id` *example-key-id* to add your [customer managed AWS KMS key](#) that you created. If you specify `--server-side-encryption aws:kms`, you must provide an AWS KMS key ID of your customer managed key. Directory buckets don't use an AWS managed key. For an example command, see [Using the AWS CLI](#).

Then, when you upload a new object with the following command, Amazon S3 uses the bucket settings for default encryption to encrypt the object by default.

```
aws s3api put-object --bucket bucket-base-name--zone-id--x-s3 --key example-object-key --body filepath
```

You don't need to add -\bucket-key-enabled explicitly in your Zonal endpoint API operations commands. S3 Bucket Keys are always enabled for GET and PUT operations in a directory bucket and can't be disabled. S3 Bucket Keys aren't supported, when you copy SSE-KMS encrypted objects from general purpose buckets to directory buckets, from directory buckets to general purpose buckets, or between directory buckets, through [CopyObject](#), [UploadPartCopy](#), [the Copy operation in Batch Operations](#), or [the import jobs](#). In this case, Amazon S3 makes a call to AWS KMS every time a copy request is made for a KMS-encrypted object.

You can copy an object from a source bucket (for example, a general purpose bucket) to a new bucket (for example, a directory bucket) and use SSE-KMS encryption for the destination objects. To do this, use the put-bucket-encryption command to set the default encryption configuration of the destination bucket (for example, a directory bucket) as SSE-KMS (aws:kms). For an example command, see [Using the AWS CLI](#). Then, when you copy an object with the following command, Amazon S3 uses the bucket settings for default encryption to encrypt the object by default.

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket/example-object-key --  
bucket bucket-base-name--zone-id--x-s3 --key example-object-key
```

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use AWS KMS keys for server-side encryption. The following examples show how to use SSE-KMS with the AWS SDKs for Java and .NET. For information about other SDKs, see [Sample code and libraries](#) on the AWS Developer Center.

Note

When you use the AWS SDKs, for CreateSession, the session token refreshes automatically to avoid service interruptions when a session expires. It's not supported to override the encryption settings values for the CreateSession request. Also, in the Zonal endpoint API calls (except [CopyObject](#) and [UploadPartCopy](#)), it's not supported to override the values of the encryption settings from the CreateSession request.

To encrypt new objects in a directory bucket with SSE-KMS, you must specify SSE-KMS as the directory bucket's default encryption configuration with a KMS key (specifically, a customer managed key). Then, when a session is created for Zonal endpoint API operations, new objects are automatically encrypted and decrypted with SSE-KMS and S3 Bucket Keys during the session.

For more information about using AWS SDKs to set the default encryption configuration of a directory bucket as SSE-KMS, see [Using the AWS SDKs](#).

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the [AWS Key Management Service Developer Guide](#).

For more information about creating customer managed keys, see [Programming the AWS KMS API](#) in the [AWS Key Management Service Developer Guide](#).

Encryption in transit

Directory buckets use Regional and Zonal API endpoints. Depending on the Amazon S3 API operation that you use, either a Regional or Zonal endpoint is required. You can access Zonal and Regional endpoints through a gateway virtual private cloud (VPC) endpoint. There is no additional charge for using gateway endpoints. To learn more about Regional and Zonal API endpoints, see [Networking for directory buckets](#).

Data deletion

You can delete one or more objects directly from your directory buckets by using the Amazon S3 console, AWS SDKs, AWS Command Line Interface (AWS CLI), or Amazon S3 REST API. Because all objects in your directory buckets incur storage costs, we recommend deleting objects that you no longer need.

Deleting an object that's stored in a directory bucket also recursively deletes any parent directories, if those parent directories don't contain any objects other than the object that's being deleted.

Note

Multi-factor authentication (MFA) delete and S3 Versioning are not supported for S3 Express One Zone.

Authenticating and authorizing requests

By default, directory buckets are private and can be accessed only by users who are explicitly granted access. The access control boundary for directory buckets is set only at the bucket level. In contrast, the access control boundary for general purpose buckets can be set at the bucket, prefix, or object tag level. This difference means that directory buckets are the only resource that you can include in bucket policies or IAM identity policies for S3 Express One Zone access.

Amazon S3 Express One Zone supports both AWS Identity and Access Management (AWS IAM) authorization and session-based authorization:

- To use Regional endpoint API operations (bucket-level, or control plane, operations) with S3 Express One Zone, you use the IAM authorization model, which doesn't involve session management. Permissions are granted for actions individually. For more information, see [Authorizing Regional endpoint API operations with IAM](#).
- To use Zonal endpoint API operations (object-level, or data plane, operations), except for CopyObject and HeadBucket, you use the CreateSession API operation to create and manage sessions that are optimized for low-latency authorization of data requests. To retrieve and use a session token, you must allow the s3express:CreateSession action for your directory bucket in an identity-based policy or a bucket policy. For more information, see [Authorizing Regional endpoint API operations with IAM](#). If you're accessing S3 Express One Zone in the Amazon S3 console, through the AWS Command Line Interface (AWS CLI), or by using the AWS SDKs, S3 Express One Zone creates a session on your behalf.

With the CreateSession API operation, you authenticate and authorize requests through a new session-based mechanism. You can use CreateSession to request temporary credentials that provide low-latency access to your bucket. These temporary credentials are scoped to a specific directory bucket.

To work with CreateSession, we recommend using the latest version of the AWS SDKs or using the AWS Command Line Interface (AWS CLI). The supported AWS SDKs and the AWS CLI handle session establishment, refreshment, and termination on your behalf.

You use session tokens with only Zonal (object-level) operations (except for CopyObject and HeadBucket) to distribute the latency that's associated with authorization over a number of requests in a session. For Regional endpoint API operations (bucket-level operations), you use IAM authorization, which doesn't involve managing a session. For more information, see [Authorizing](#)

[Regional endpoint API operations with IAM](#) and [Authorizing Zonal endpoint API operations with CreateSession](#).

How API operations are authenticated and authorized

The following table lists authentication and authorization information for directory bucket API operations. For each API operation, the table shows the API operation name, IAM policy action, endpoint type (Regional or Zonal), and authorization mechanism (IAM or session-based). This table also indicates whether cross-account access is supported. Access to bucket-level actions can be granted only in IAM identity-based policies (user or role), not bucket policies.

API	Endpoint type	IAM action	Cross-account access
CreateBucket	Regional	s3express:CreateBucket	No
DeleteBucket	Regional	s3express:DeleteBucket	No

Authorizing Regional endpoint API operations with IAM

AWS Identity and Access Management (IAM) is an AWS service that helps administrators securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon S3 resources in directory buckets and S3 Express One Zone operations. You can use IAM for no additional charge.

By default, users don't have permissions for directory buckets. To grant access permissions for directory buckets, you can use IAM to create users, groups, or roles and attach permissions to those identities. For more information about IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

To provide access, you can add permissions to your users, groups, or roles through the following means:

- **Users and groups in AWS IAM Identity Center** – Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.
- **Users managed in IAM through an identity provider** – Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- **IAM roles and users** – Create a role that your user can assume. Follow the instructions in [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

For more information about IAM for S3 Express One Zone, see the following topics.

Topics

- [Principals](#)
- [Resources](#)
- [Actions for directory buckets](#)
- [IAM identity-based policies for directory buckets](#)
- [Example bucket policies for directory buckets](#)

Principals

When you create a resource-based policy to grant access to your buckets, you must use the Principal element to specify the person or application that can make a request for an action or operation on that resource. For directory bucket policies, you can use the following principals:

- An AWS account
- An IAM user
- An IAM role
- A federated user

For more information, see [Principal](#) in the *IAM User Guide*.

Resources

Amazon Resource Names (ARNs) for directory buckets contain the s3express namespace, the AWS Region, the AWS account ID, and the directory bucket name, which includes the AWS Zone ID. (an Availability Zone or Local Zone ID).

To access and perform actions on your directory bucket, you must use the following ARN format:

```
arn:aws:s3express:region:account-id:bucket/base-bucket-name--zone-id--x-s3
```

To access and perform actions on your access point for a directory bucket, you must use the following ARN format:

arn:aws::s3express:*region*:*account-id*:accesspoint/*accesspoint-basename--zone-id--xa-s3*

For more information about ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *IAM User Guide*. For more information about resources, see [IAM JSON Policy Elements: Resource](#) in the *IAM User Guide*.

Actions for directory buckets

In an IAM identity-based policy or resource-based policy, you define which S3 actions are allowed or denied. Actions correspond to specific API operations. With directory buckets, you must use the S3 Express One Zone namespace to grant permissions, called s3express.

When you allow the s3express:CreateSession permission, the CreateSession API operation retrieves a temporary session token for all Zonal endpoint API (object level) operations. The session token returns credentials that are used for all other Zonal endpoint API operations. As a result, you don't grant access permissions to Zonal API operations with IAM policies. Instead, CreateSession enables access for all object level operations. For the list of Zonal API operations and permissions, see [Authenticating and authorizing requests](#).

To learn more about the CreateSession API operation, see [CreateSession](#) in the *Amazon Simple Storage Service API Reference*.

You can specify the following actions in the Action element of an IAM policy statement. Use policies to grant permissions to perform an operation in AWS. When you use an action in a policy, you usually allow or deny access to the API operation with the same name. However, in some cases, a single action controls access to more than one API operation. Access to bucket-level actions can be granted in only IAM identity-based policies (user or role) and not bucket policies.

For more information about how to configure access point policies, see [Configuring IAM policies for using access points for directory buckets](#).

For more information, see [Actions, resources, and condition keys for Amazon S3 Express](#).

IAM identity-based policies for directory buckets

Before you can create directory buckets, you must grant the necessary permissions to your AWS Identity and Access Management (IAM) role or users. This example policy allows access to the CreateSession API operation (for use with Zonal endpoint [object level] API operations) and all of the Regional endpoint (bucket-level) API operations. This policy allows the CreateSession API operation for use with all directory buckets, but the Regional endpoint API operations are

allowed only for use with the specified directory bucket. To use this example policy, replace the *user input placeholders* with your own information.

Example bucket policies for directory buckets

This section provides example directory bucket policies. To use these policies, replace the *user input placeholders* with your own information.

The following example bucket policy allows AWS account ID **111122223333** to use the CreateSession API operation with the default ReadWrite session for the specified directory bucket. This policy grants access to the Zonal endpoint (object level) API operations.

Example – Bucket policy to allow CreateSession calls with the default ReadWrite session

```

Example – Bucket policy to allow CreateSession calls with a ReadOnly session

The following example bucket policy allows AWS account ID **111122223333** to use the CreateSession API operation. This policy uses the s3express:SessionMode condition key with the ReadOnly value to set a read-only session.

}
```

Example – Bucket policy to allow cross-account access for CreateSession calls

The following example bucket policy allows AWS account ID **111122223333** to use the CreateSession API operation for the specified directory bucket that's owned by AWS account ID **444455556666**.

JSON

Authorizing Zonal endpoint API operations with CreateSession

To use Zonal endpoint API operations (object-level, or data plane operations), except for CopyObject and HeadBucket, you use the CreateSession API operation to create and manage sessions that are optimized for low-latency authorization of data requests. To retrieve and use a session token, you must allow the s3express:CreateSession action for your directory bucket in an identity-based policy or a bucket policy. For more information, see [Authorizing Regional endpoint API operations with IAM](#). If you're accessing S3 Express One Zone in the Amazon S3 console, through the AWS Command Line Interface (AWS CLI), or by using the AWS SDKs, S3 Express One Zone creates a session on your behalf. However, you can't modify the SessionMode parameter when using the AWS CLI or AWS SDKs.

If you use the Amazon S3 REST API, you can then use the CreateSession API operation to obtain temporary security credentials that include an access key ID, a secret access key, a session token, and an expiration time. The temporary credentials provide the same permissions as long-term security credentials, such as IAM user credentials, but temporary security credentials must include a session token.

Session Mode

Session mode defines the scope of the session. In your bucket policy, you can specify the s3express:SessionMode condition key to control who can create a ReadWrite or ReadOnly session. For more information about ReadWrite or ReadOnly sessions, see the x-amz-create-session-mode parameter for [CreateSession](#) in the *Amazon S3 API Reference*. For more information about the bucket policy to create, see [Example bucket policies for directory buckets](#).

Session Token

When you make a call by using temporary security credentials, the call must include a session token. The session token is returned along with the temporary credentials. A session token is scoped to your directory bucket and is used to verify that the security credentials are valid and haven't expired. To protect your sessions, temporary security credentials expire after 5 minutes.

CopyObject and HeadBucket

Temporary security credentials are scoped to a specific directory bucket and are automatically enabled for all Zonal (object-level) operation API calls to a given directory bucket. Unlike other Zonal endpoint API operations, CopyObject and HeadBucket don't use CreateSession authentication. All CopyObject and HeadBucket requests must be authenticated and signed by using IAM credentials. However, CopyObject and HeadBucket are still authorized by s3express:CreateSession, like other Zonal endpoint API operations.

For more information, see [CreateSession](#) in the *Amazon Simple Storage Service API Reference*.

Security best practices for directory buckets

There are a number of security features to consider when working with directory buckets. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful recommendations rather than prescriptions.

Default Block Public Access and Object Ownership settings

Directory buckets support S3 Block Public Access and S3 Object Ownership. These S3 features are used to audit and manage access to your buckets and objects.

By default, all Block Public Access settings for directory buckets are enabled. In addition, Object Ownership is set to bucket owner enforced, which means that access control lists (ACLs) are disabled. These settings can't be modified. For more information about these features, see [the section called "Blocking public access"](#) and [the section called "Controlling object ownership"](#).

Note

You can't grant access to objects stored in directory buckets. You can grant access only to your directory buckets. The authorization model for S3 Express One Zone is different than the authorization model for Amazon S3. For more information, see [Authorizing Zonal endpoint API operations with CreateSession](#).

Authentication and authorization

The authentication and authorization mechanisms for directory buckets differ, depending on whether you are making requests to Zonal endpoint API operations or Regional endpoint API operations. Zonal API operations are object-level (data plane) operations. Regional API operations are bucket-level (control plane) operations.

You authenticate and authorize requests to Zonal endpoint API operations through a new session-based mechanism that is optimized to provide the lowest latency. With session-based authentication, the AWS SDKs use the `CreateSession` API operation to request temporary credentials that provide low-latency access to your directory bucket. These temporary credentials are scoped to a specific directory bucket and expire after 5 minutes. You can use these temporary credentials to sign Zonal (object level) API calls. For more information, see [Authorizing Zonal endpoint API operations with `CreateSession`](#).

Signing requests with credentials for directory bucket management

You use your credentials to sign Zonal endpoint (object level) API requests with AWS Signature Version 4, with `s3express` as the service name. When you sign your requests, use the secret key that's returned from `CreateSession` and also provide the session token with the `x-amzn-s3session-token` header. For more information, see [CreateSession](#).

The [supported AWS SDKs](#) manage credentials and signing on your behalf. We recommend using the AWS SDKs to refresh credentials and sign requests for you.

Signing requests with IAM credentials

All Regional (bucket-level) API calls must be authenticated and signed by AWS Identity and Access Management (IAM) credentials instead of temporary session credentials. IAM credentials consist of the access key ID and secret access key for the IAM identities. All `CopyObject` and `HeadBucket` requests must also be authenticated and signed by using IAM credentials.

To achieve the lowest latency for your Zonal (object-level) operation calls, we recommend using credentials obtained from calling `CreateSession` to sign your requests, except for requests to `CopyObject` and `HeadBucket`.

Use AWS CloudTrail

AWS CloudTrail provides a record of the actions taken by a user, a role, or an AWS service in Amazon S3. You can use information collected by CloudTrail to determine the following:

- The request that was made to Amazon S3
- The IP address from which the request was made
- Who made the request
- When the request was made
- Additional details about the request

When you set up your AWS account, CloudTrail management events are enabled by default. The following Regional endpoint API operations (bucket-level, or control plane, API operations) are logged to CloudTrail.

- [CreateBucket](#)
- [DeleteBucket](#)
- [DeleteBucketPolicy](#)
- [PutBucketPolicy](#)
- [GetBucketPolicy](#)
- [ListDirectoryBuckets](#)
- [ListMultipartUploads](#)
- [PutBucketEncryption](#)
- [GetBucketEncryption](#)
- [DeleteBucketEncryption](#)

 **Note**

`ListMultipartUploads` is a Zonal endpoint API operation. However, it is logged to CloudTrail as a management event. For more information, see [ListMultipartUploads](#) in the *Amazon Simple Storage Service API Reference*.

By default, CloudTrail trails don't log data events, but you can configure trails to log data events for directory buckets that you specify, or to log data events for all the directory buckets in your AWS account. The following Zonal endpoint API operations (object-level, or data plane, API operations) are logged to CloudTrail.

- [AbortMultipartUpload](#)

- [CompleteMultipartUpload](#)
- [CreateSession](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)
- [DeleteObject](#)
- [DeleteObjects](#)
- [GetObject](#)
- [GetObjectAttributes](#)
- [HeadBucket](#)
- [HeadObject](#)
- [ListObjectsV2](#)
- [ListParts](#)
- [PutObject](#)
- [UploadPart](#)
- [UploadPartCopy](#)

For more information on using AWS CloudTrail with directory buckets , see [Logging with AWS CloudTrail for directory buckets](#).

Implement monitoring by using AWS monitoring tools

Monitoring is an important part of maintaining the reliability, security, availability, and performance of Amazon S3 and your AWS solutions. AWS provides several tools and services to help you monitor Amazon S3 and your other AWS services. For example, you can monitor Amazon CloudWatch metrics for Amazon S3, particularly the BucketSizeBytes and NumberOfObjects storage metrics.

Objects stored in the directory buckets won't be reflected in the BucketSizeBytes and NumberOfObjects storage metrics for Amazon S3. However, the BucketSizeBytes and NumberOfObjects storage metrics are supported for directory buckets. To see the metrics of your choice, you can differentiate between the Amazon S3 storage classes by specifying a StorageType dimension. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

For more information, see [Monitoring metrics with Amazon CloudWatch](#) and [Logging and monitoring in Amazon S3](#).

Managing access to shared datasets in directory buckets with access points

Amazon S3 Access Points simplify managing data access at scale for shared datasets in Amazon S3. Access points are unique hostnames you create to enforce distinct permissions and network controls for all requests made through an access point. You can create hundreds of access points per bucket, each with a distinct name and permissions customized for each application. Each access point works in conjunction with the bucket policy that is attached to the underlying bucket.

In directory buckets, an access point name consists of a base name you provide, followed by the Zone ID (AWS Availability Zone or Local Zone) of your directory bucket location, and then `--xa-s3`. For example, `accesspointname--zoneID--xa-s3`. After you create an access point, you can't change the name or the Zone ID.

With access points for directory buckets, you can use the access point scope to restrict access to specific prefixes or API operations. You can specify any amount of prefixes, but the total length of characters of all prefixes must be less than 256 bytes.

You can configure any access point to accept requests only from a virtual private cloud (VPC). This restricts Amazon S3 data access to a private network.

In this section, the topics explain how to use access points for directory buckets. For information about directory buckets, see [Working with directory buckets](#).

Access points for directory buckets naming rules, restrictions, and limitations

Access points simplify managing data access at scale for shared datasets in Amazon S3. The following topics provide information about access point naming rules and restrictions and limitations.

Topics

- [Naming rules for access points for directory buckets](#)
- [Restrictions and limitations for access points for directory buckets](#)

Naming rules for access points for directory buckets

An access point must be created in the same zone that the bucket is in. An access point name must be unique within the zone.

Access point names must be DNS-compliant and must meet the following conditions:

- Must begin with a number or lowercase letter
- The base name you provide must be between 3 and 50 characters long
- Can't begin or end with a hyphen (-)
- Can't contain underscores (_), uppercase letters, spaces, or periods (.)
- Must end with the suffix ***zoneid*--xa--s3**.

Restrictions and limitations for access points for directory buckets

Access points for directory buckets have the following restrictions and limitations:

- Each access point is associated to one directory bucket. After you create an access point, you can't associate it to a different bucket. However, you can delete an access point, and then create a new one with the same name and associate it to a different bucket.
- After you create an access point, you can't change its virtual private cloud (VPC) configuration.
- Access point policies are limited to 20 KB in size.
- Access point scope prefixes are limited to 256 bytes in total size.
- You can create a maximum of 10,000 access points per AWS account per AWS Region. If you need more than 10,000 access points for a single account in a single Region, you can request a service

quota increase. For more information about service quotas and requesting an increase, see [AWS service quotas](#) in the *AWS General Reference*.

- You can only use access points to perform operations on objects. You can't use access points to perform Amazon S3 bucket operations, such as modifying or deleting buckets. For a complete list of supported operations, see [Object operations for access points for directory buckets](#).
- You can refer to access points by name, access point alias, or virtual-hosted-style URI. You cannot address access points by ARN. For more information, see [Referencing access points for directory buckets](#).
- API operations that control access point functionality (for example, `PutAccessPointPolicy` and `GetAccessPointPolicy`) must specify the AWS account that owns the access point.
- You must use AWS Signature Version 4 when making requests to an access point by using the REST API. For more information about authenticating requests, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.
- Access points only support requests over HTTPS. Amazon S3 will automatically respond with an HTTP redirect for any requests made through HTTP, to upgrade the request to HTTPS.
- Access points don't support anonymous access.
- If you create an access point to a bucket that's owned by another account (a cross-account access point), the cross-account access point doesn't grant you access to data until the bucket owner grants you permission to access the bucket. The bucket owner always retains ultimate control over access to the data and must update the bucket policy to authorize requests from the cross-account access point. To view a bucket policy example, see [Configuring IAM policies for using access points for directory buckets](#).

Referencing access points for directory buckets

After you create an access point, you can use it as an endpoint to perform object operations. For access points for directory buckets, the access point alias is the same as the access point name. You can use the access point name instead of a bucket name for all data operations. For a list of these supported operations, see [Object operations for access points for directory buckets](#).

Referring to access points by virtual-hosted-style URLs

Access points only support virtual-host-style addressing. Access points use the same format as directory bucket endpoints. For more information, see [Regional and Zonal endpoints for directory buckets](#).

S3 access points don't support access through HTTP. Access points support only secure access through HTTPS.

Object operations for access points for directory buckets

You can use access points to access an object using the following S3 data operations.

- [AbortMultipartUpload](#)
- [CompleteMultipartUpload](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)
- [CreateSession](#)
- [DeleteObject](#)
- [DeleteObjects](#)
- [GetObject](#)
- [GetObjectAttributes](#)
- [HeadBucket](#)

- [PutObject](#)
- [UploadPart](#)
- [UploadPartCopy](#)

Configuring IAM policies for using access points for directory buckets

Access points support AWS Identity and Access Management (IAM) resource policies that allow you to control the use of the access point by resource, user, or other conditions. For an application or user to access objects through an access point, both the access point and the underlying bucket policy must permit the request.

Important

Adding an access point to a directory bucket doesn't change the bucket's behavior when the bucket is accessed directly through the bucket's name. All existing operations against the bucket will continue to work as before. Restrictions that you include in an access point policy or access point scope apply only to requests made through that access point.

When using IAM resource policies, make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide recommendations to help you author policies that are functional and conform to security best practices.

To learn more about validating policies by using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

Access points for directory buckets policy examples

The following access point policies demonstrate how to control requests to a directory bucket. Access point policies require bucket ARNs or access point ARNs. Access point aliases are not supported in policies. Following is an example of an access point ARN:

```
arn:aws:s3express:region:account-id:accesspoint/myaccesspoint--zoneID--xa-s3
```

You can view the access point ARN in the details of an access point. For more information, see [View details for your access points for directory buckets](#).

Note

Permissions granted in an access point policy are effective only if the underlying bucket also allows the same access. You can accomplish this in two ways:

1. **(Recommended)** Delegate access control from the bucket to the access point, as described in [Delegating access control to access points](#).

2. Add the same permissions contained in the access point policy to the underlying bucket's policy.

Example 1 – Service control policy to limit access points to VPC network origins

The following service control policy requires all new access points are to be created with a virtual private cloud (VPC) network origin. With this policy in place, users in your organization can't create any access point that is accessible from the internet.

                }  
            }  
        }

Condition keys

Access points for directory buckets have condition keys that you can use in IAM policies to control access to your resources. The following condition keys represent only part of an IAM policy. For full policy examples, see [Access points for directory buckets policy examples](#), [Delegating access control to access points](#), and [Granting permissions for cross-account access points](#).

s3express:DataAccessPointArn

This example shows how to filter access by the Amazon resource name (ARN) of an access point and matches all access points for AWS account **111122223333** in Region **region**:

```
"Condition" : {
    "StringLike": {
        "s3express:DataAccessPointArn":
        "arn:aws:s3express:region:111122223333:accesspoint/*"
    }
}
```

s3express:DataAccessPointAccount

This example shows a string operator that you can use to match on the account ID of the owner of an access point. The following example matches all access points that are owned by the AWS account **111122223333**.

```
"Condition" : {
    "StringEquals": {
        "s3express:DataAccessPointAccount": "111122223333"
    }
}
```

s3express:AccessPointNetworkOrigin

This example shows a string operator that you can use to match on the network origin, either Internet or VPC. The following example matches only access points with a VPC origin.

```
"Condition" : {  
    "StringEquals": {  
        "s3express:AccessPointNetworkOrigin": "VPC"  
    }  
}
```

s3express:Permissions

You can use s3express:Permissions to restrict access to specific API operations in access point scope. The following API operations are supported:

- PutObject
- GetObject
- DeleteObject
- ListBucket (required for ListObjectsV2)
- GetObjectAttributes
- AbortMultipartUpload
- ListBucketMultipartUploads
- ListMultipartUploadParts

Note

When using multi-value condition keys, we recommend you use ForAllValues with Allow statements and ForAnyValue with Deny statements. For more information, see [Multivalued context keys](#) in the IAM User Guide.

For more information about using condition keys with Amazon S3, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the required permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Delegating access control to access points

You can delegate access control from the bucket policy to the access point policy. The following example bucket policy allows full access to all access points that are owned by the bucket owner's account. After applying the policy, all access to this bucket is controlled by access point policies. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket.

Example bucket policy that delegates access control to access points

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Effect": "Allow",  
            "Principal" : { "AWS": "*" },  
            "Action" : "*",  
            "Resource" : [ "Bucket ARN",  
            "Condition": {  
                "StringEquals" : { "s3express:DataAccessPointAccount" : "Bucket owner's  
account ID" }  
            }  
        }]  
    ]  
}
```

Granting permissions for cross-account access points

To create an access point to a bucket that's owned by another account, you must first create the access point by specifying the bucket name and account owner ID. Then, the bucket owner must update the bucket policy to authorize requests from the access point. Creating an access point is similar to creating a DNS CNAME in that the access point doesn't provide access to the bucket contents. All bucket access is controlled by the bucket policy. The following example bucket policy allows GET and LIST requests on the bucket from an access point that's owned by a trusted AWS account.

Replace *Bucket ARN* with the ARN of the bucket.

Example of bucket policy delegating permissions to another AWS account

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Sid": "AllowCreateSessionForDirectoryBucket",  
            "Effect": "Allow",  
            "Principal" : { "AWS": "*" },  
            "Action" : "s3express:CreateSession",  
            "Resource" : [ "arn:aws:s3express:us-west-2:111122223333:bucket/amzn-s3-demo-bucket--usw2-az1--x-s3" ],  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "s3express:Permissions": [  
                        "GetObject",  
                        "ListBucket"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

Monitoring and logging access points for directory buckets

You can log requests made through access points and requests made to the APIs that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`, by using AWS CloudTrail. CloudTrail log entries for requests made through access points include the access point ARN (which includes the access point name) in the `resources` section of the log.

For example, suppose you have the following configuration:

- A bucket named [amzn-s3-demo-bucket--zone-id--x-s3](#) in Region `region` that contains an object named `my-image.jpg`.
- An access point named `my-bucket-ap--zoneID--xa-s3` that is associated with [amzn-s3-demo-bucket--zone-id--x-s3](#)

- An AWS account ID of 123456789012

The following example shows the resources section of a CloudTrail log entry for the preceding configuration:

```
"resources": [  
    {"type": "AWS::S3Express::Object",  
  
        "ARN": "arn:aws:s3express-region:123456789012:bucket/amzn-s3-demo-bucket--zone-id--x-s3/my-image.jpg"  
    },  
    {"accountId": "c",  
        "type": "AWS::S3Express::DirectoryBucket",  
        "ARN": "arn:aws:s3express:region:123456789012:bucket/amzn-s3-demo-bucket--zone-id--x-s3"  
    },  
    {"accountId": "123456789012",  
        "type": "AWS::S3::AccessPoint",  
        "ARN": "arn:aws:s3express:region:123456789012:accesspoint/my-bucket-ap--zoneID--xa-s3"  
    }  
]
```

For more information about AWS CloudTrail, see [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

Creating access points for directory buckets

Like Directory buckets, access points can be created in Availability Zones or in Dedicated Local Zones. The access point must be created in the same zone as the directory bucket associated with it.

An access point is associated with exactly one Amazon S3 directory bucket. If you want to use a directory bucket in your AWS account, you must first create a directory bucket. For more information about creating directory buckets, see [Creating directory buckets in an Availability Zone](#) or [Creating a directory bucket in a Local Zone](#).

You can also create a cross-account access point that's associated with a bucket in another AWS account, as long as you know the bucket name and the bucket owner's account ID. However, creating cross-account access points doesn't grant you access to data in the bucket until you are granted permissions from the bucket owner. The bucket owner must grant the access point owner's

account (your account) access to the bucket through the bucket policy. For more information, see [Granting permissions for cross-account access points](#).

You can create an access point for any directory bucket with the AWS Management Console, AWS CLI, REST API, or AWS SDKs. Each access point is associated with a single directory bucket, and you can create hundreds of access points per bucket. When creating an access point, you choose the name of the access point and the directory bucket to associate it with. The access point name consists of a base name that you provide and suffix that includes the Zone ID of your bucket location, followed by --xa-s3. For example, *myaccesspoint-zoneID--xa-s3*. You can also restrict access to the access point through a Virtual Private Cloud (VPC). Then, you can immediately begin reading and writing data through your access point by using its name, just like you use a directory bucket name.

You can use the access point scope to restrict access to the directory bucket through the access point to specific prefixes or API operations. If you don't add a scope to the access point, all prefixes in the directory bucket and all API operations can be performed on objects in the bucket when accessed through the access point. After you create the access point, you can add, modify, or delete scope using the AWS CLI, AWS SDKs, or REST API. For more information, see [Manage the scope of your access points for directory buckets](#).

After you create the access point, you can configure your access point IAM resource policy. For more information, see [Viewing, editing or deleting access point policies](#).

Using the S3 console

Note

You can also create an access point for a directory bucket from the directory bucket screen.

When you do this, the directory bucket name is provided and you don't need to choose a bucket when creating the access point. For more information, see [Listing directory buckets](#).

To create an access point for directory buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create an access point. The access point must be created in the same Region as the associated bucket.

3. In the left navigation pane, choose **Access points for directory buckets**.
4. On the **Access Points** page, choose **Create access point**.
5. You can create an access point for a directory bucket in your account or in another account. To create an access point for a directory bucket in another account:

 **Note**

If you're using a bucket in a different AWS account, the bucket owner must update the bucket policy to authorize requests from the access point. For an example bucket policy, see [Granting permissions for cross-account access points](#).

- a. In the **Directory bucket** field, choose **Specify a bucket in another account**.
- b. In the **Bucket owner account ID** field, enter the AWS account ID that owns the bucket.
- c. In the **Bucket name** field, enter the name of the bucket, including the base name and the zone ID. For example, **bucket-base-name--zone-id--x-s3**.
6. To create an access point for a directory bucket in your account:
 - a. In the **Directory bucket** field, choose **Choose a bucket in this account**.
 - b. In the **Bucket name** field, enter the name of the bucket, including the base name and the zone ID. For example, **bucket-base-name--zone-id--x-s3**. To choose the bucket from a list, choose **Browse S3** and choose the directory bucket.
7. In **Access point name**, in the **Base name** field, enter the base name for the access point. The zone ID and full access point name appear. For more information about naming access points, see [Naming rules for access points for directory buckets](#).
8. In **Network origin**, choose either **virtual private cloud (VPC)** or **Internet**. If you choose **virtual private cloud (VPC)**, in the **VPC ID** field, enter the ID of the VPC that you want to use with the access point.
9. (Optional) In **Access point scope**, to apply a scope to this access point, choose **Limit the scope of this access point using prefixes or permissions**.
 - a. To limit access to prefixes in the directory bucket, in **Prefixes**, enter one or more prefixes. To add another prefix, choose **Add prefix**. To remove a prefix, choose **Remove**.

Note

An access point scope has a character limit of 512 total characters for all prefixes. You can see the quantity of characters remaining below **Add prefix**.

- b. In **Permissions**, choose one or more API operations that the access point will allow. To remove a data operation, choose the X next to the data operation name.
10. To not apply a scope to the access point and allow access to all prefixes in the directory bucket and all API operations through the access point, in **Access point scope**, choose **Apply access to the entire bucket**.
11. Choose **Create access point for directory bucket**. The access point name and other information about it appear in the **Access points for directory buckets** list.

Using the AWS CLI

The following example command creates an access point named *example-ap* for the bucket *amzn-s3-demo-bucket--zone-id--x-s3* in the account *111122223333*.

```
aws s3control create-access-point --name example-ap--zoneID--xa-s3 --account-id 111122223333 --bucket amzn-s3-demo-bucket--zone-id--x-s3
```

To restrict access to the access point through a VPC, include the **--vpc** parameter and the VPC ID.

```
aws s3control create-access-point --name example-ap--zoneID--xa-s3 --account-id 111122223333 --bucket amzn-s3-demo-bucket--zone-id--x-s3 --vpc vpc-id
```

When you create an access point for a cross-account bucket, include the **--bucket-account-id** parameter. The following example command creates an access point in the AWS account *111122223333*, for the bucket *amzn-s3-demo-bucket--zone-id--x-s3*, owned by the AWS account *444455556666*.

```
aws s3control create-access-point --name example-ap--zoneID--xa-s3 --account-id 111122223333 --bucket amzn-s3-demo-bucket--zone-id--x-s3 --bucket-account-id 444455556666
```

For more information and examples, see [create-access-point](#) in the AWS CLI Command Reference.

Using the REST API

The following example command creates an access point named *example-ap* for the bucket *amzn-s3-demo-bucket--zone-id--x-s3* in the account *111122223333* and access restricted through the VPC *vpc-id* (optional).

```
PUT /v20180820/accesspoint/example-ap--zoneID--xa-s3 HTTP/1.1
Host: s3express-control.region.amazonaws.com
x-amz-account-id: 111122223333
<?xml version="1.0" encoding="UTF-8"?>
<CreateAccessPointRequest>
  <Bucket>amzn-s3-demo-bucket--zone-id--x-s3</Bucket>
  <BucketAccountId>111122223333</BucketAccountId>
  <VpcConfiguration>
    <VpcId>vpc-id</VpcId>
  </VpcConfiguration>
</CreateAccessPointRequest>
```

Response:

```
HTTP/1.1 200
<?xml version="1.0" encoding="UTF-8"?>
<CreateAccessPointResult>
  <AccessPointArn>
    "arn:aws:s3express:region:111122223333:accesspoint/example-ap--zoneID--xa-s3"
  </AccessPointArn>
  <Alias>example-ap--zoneID--xa-s3</Alias>
</CreateAccessPointResult>
```

Using the AWS SDKs

You can use the AWS SDKs to create an access point. For more information, see [list of supported SDKs](#) in the Amazon Simple Storage Service API Reference.

Managing your access points for directory buckets

This section explains how to manage your access points for directory buckets using the AWS Command Line Interface, Amazon S3 REST API, or AWS SDK.

Topics

- [List your access points for directory buckets](#)

List your access points for directory buckets

This section explains how to list access points for a directory bucket using the AWS Management Console, AWS Command Line Interface (AWS CLI), REST API, or AWS SDKs.

Using the S3 console

To list access points in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access points for directory buckets**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage.

Using the AWS CLI

The following `list-access-points-for-directory-buckets` example command shows how you can use the AWS CLI to list the access points owned by an AWS account and associated with a directory bucket.

The following command lists access points for AWS account `111122223333` that are attached to bucket `amzn-s3-demo-bucket--zone-id--x-s3`.

```
aws s3control list-access-points-for-directory-buckets --account-id 111122223333 --  
directory-bucket amzn-s3-demo-bucket--zone-id--x-s3
```

For more information and examples, see [list-access-points-for-directory-buckets](#) in the AWS CLI Command Reference.

Using the REST API

The following example shows how you can use the REST API to list your access points.

```
GET /v20180820/directoryaccesspoint?directoryBucket=amzn-s3-demo-bucket--zone-id--x-s3  
&maxResults=maxResults HTTP/1.1  
Host: s3express-control.region.amazonaws.com  
x-amz-account-id: 111122223333
```

Example of ListAccessPointsForDirectoryBuckets response

```
HTTP/1.1 200  
<?xml version="1.0" encoding="UTF-8"?>  
<ListDirectoryAccessPointsResult>  
  <AccessPointList>  
    <AccessPoint>  
      <AccessPointArn>arn:aws:s3express:region:111122223333:accesspoint/example-  
access-point--zoneID--xa-s3</AccessPointArn>  
      <Alias>example-access-point--zoneID--xa-s3</Alias>  
      <Bucket>amzn-s3-demo-bucket--zone-id--x-s3</Bucket>  
      <BucketAccountId>111122223333</BucketAccountId>  
      <Name>example-access-point--zoneID--xa-s3</Name>  
      <NetworkOrigin>VPC</NetworkOrigin>  
      <VpcConfiguration>  
        <VpcId>VPC-1</VpcId>  
      </VpcConfiguration>  
    </AccessPoint>  
  </AccessPointList>  
</ListDirectoryAccessPointsResult>
```

Using the AWS SDKs

You can use the AWS SDKs to list your access points. For more information, see [list of supported SDKs](#) in the Amazon Simple Storage Service API Reference.

View details for your access points for directory buckets

This section explains how to view details for your access point for directory buckets using the AWS Management Console, AWS CLI, AWS SDKs, or REST API.

Using the S3 console

View details of an access point for directory buckets to see the following information about the access point and the associated directory bucket:

- Properties:
 - Directory bucket name
 - Directory bucket owner account ID
 - AWS Region
 - Directory bucket location type
 - Directory bucket location name
 - Creation date of access point
 - Network origin
 - VPC ID
 - S3 URI
 - Access point ARN
 - Access point alias
- Permissions:
 - IAM external access analyzer findings
 - Access point scope
 - Access point policy

To view details for your access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access points for directory buckets**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage.
6. Choose the **Properties** tab or the **Permissions** tab.

Using the AWS CLI

The following get-access-point example command shows how you can use the AWS CLI to view details for your access point.

The following command lists details for the access point *my-access-point--zoneID--xa-s3* for AWS account *111122223333*.

```
aws s3control get-access-point --name my-access-point--zoneID--xa-s3 --account-id 111122223333
```

Example of output of get-access-point command

```
{  
    "Name": "example-access-point--zoneID--xa-s3",  
    "Bucket": "amzn-s3-demo-bucket--zone-id--x-s3",  
    "NetworkOrigin": "Internet",  
    "PublicAccessBlockConfiguration": {  
        "BlockPublicAcls": true,  
        "IgnorePublicAcls": true,  
        "BlockPublicPolicy": true,  
        "RestrictPublicBuckets": true  
    },  
    "CreationDate": "2025-04-23T18:26:22.146000+00:00",  
    "Alias": "example-access-point--zoneID--xa-s3",  
    "AccessPointArn": "arn:aws:s3express:region:111122223333:accesspoint/example-access-point--zoneID--xa-s3",  
    "BucketAccountId": "296805379465"  
}
```

For more information and examples, see [get-access-point](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to view details for your access point. For more information, see [GetAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

You can use the AWS SDKs to view details of your access points. For more information, see [list of supported SDKs](#) in the *Amazon Simple Storage Service API Reference*.

Viewing, editing or deleting access point policies

You can use an AWS Identity and Access Management (IAM) access point policy to control the principal and resource that can access the access point. The access point scope manages the prefixes and API permissions for the access point. You can create, edit, and delete an access point policy using the AWS Command Line Interface, REST API, or AWS SDKs. For more information about access point scope, see [Manage the scope of your access points for directory buckets](#).

 **Note**

Since directory buckets use session-based authorization, your policy must always include the `s3express:CreateSession` action.

Using the S3 console

To view, edit, or delete an access point policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access points for directory buckets**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.

5. Choose the name of the access point you want to manage.
6. Choose the **Permissions** tab.
7. To create or edit the access point policy, in **Access point policy**, choose **Edit**. Edit the policy. Choose **Save**.
8. To delete the access point policy, in **Access point policy**, choose **Delete**. In the **Delete access point policy** window, type **confirm** and choose **Delete**.

Using the AWS CLI

You can use the `get-access-point-policy`, `put-access-point-policy`, and `delete-access-point-policy` commands to view, edit, or delete an access point policy. For more information, see [get-access-point-policy](#), [put-access-point-policy](#), or [delete-access-point-policy](#) in the AWS CLI Command Reference.

Using the REST API

You can use the REST API `GetAccessPointPolicy`, `DeleteAccessPointPolicy`, and `PutAccessPointPolicy` operations to view, delete, or edit an access point policy. For more information, see [PutAccessPointPolicy](#), [GetAccessPointPolicy](#), or [DeleteAccessPointPolicy](#) in the Amazon Simple Storage Service API Reference.

Using the AWS SDKs

You can use the AWS SDKs to view, delete, or edit an access point policy. For more information, see the list of supported SDKs for [GetAccessControlPolicy](#), [DeleteAccessControlPolicy](#), and [PutAccessControlPolicy](#) in the Amazon Simple Storage Service API Reference.

Manage the scope of your access points for directory buckets

This section explains how to view and modify the scope of your access points for directory buckets using the AWS Command Line Interface, REST API, or AWS SDKs. You can use the access point scope to restrict access to specific prefixes or API operations.

Topics

- [View the scope of your access points for directory buckets](#)

View the scope of your access points for directory buckets

You can use the AWS Management Console, AWS Command Line Interface, REST API, or AWS SDKs to view the scope of your access point for directory buckets.

Using the S3 console

To view the scope of your access point for directory buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access points for directory buckets**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage.
6. Choose the **Permissions** tab.
7. In the **Access point scope**, you can see the prefixes and permissions applied to the access point.

Using the AWS CLI

The following get-access-point-scope example command shows how you can use the AWS CLI to view the scope of your access point.

The following command shows the scope of the access point *my-access-point--zoneID--xa-s3* for AWS account *111122223333*.

```
aws s3control get-access-point-scope --name my-access-point--zoneID--xa-s3 --account-id 111122223333
```

For more information and examples, see [get-access-point-scope](#) in the AWS CLI Command Reference.

Example result of get-access-point-scope

```
{  
    "Scope": {  
        "Permissions": [  
            "ListBucket",  
            "PutObject"  
        ]  
    },  
    "Prefixes": [  
        "Prefix": "MyPrefix1*",  
        "Prefix": "MyObjectName.csv"  
    ]  
}
```

Using the REST API

The following GetAccessPointScope example request shows how you can use the REST API to view the scope of your access point.

The following request shows the scope of the access point *my-access-point--region-zoneID--xa-s3* for AWS account *111122223333*.

```
GET /v20180820/accesspoint/my-access-point--zoneID--xa-s3/scope HTTP/1.1  
Host: s3express-control.region.amazonaws.com  
x-amz-account-id: 111122223333
```

Example result of GetAccessPointScope

```
HTTP/1.1 200  
<?xml version="1.0" encoding="UTF-8"?>  
<GetAccessPointScopeResult>  
    <Scope>  
        <Prefixes>  
            <Prefix>MyPrefix1*</Prefix>  
            <Prefix>MyObjectName.csv</Prefix>  
        </Prefixes>  
        <Permissions>  
            <Permission>ListBucket</Permission>  
            <Permission>PutObject</Permission>  
        </Permissions>
```

```
<Scope>
</GetAccessPointScopeResult>
```

Using the AWS SDKs

You can use the AWS SDKs to view the scope of your access point. For more information, see [List of supported SDKs](#) in the Amazon Simple Storage Service API Reference.

Modify the scope of your access point for directory buckets

You can use the AWS Management Console, AWS Command Line Interface, REST API, or AWS SDKs to modify the scope of your access points for directory buckets. Access point scope is used to restrict access to specific prefixes, API operations, or a combination of both.

You can include one or more of the following API operations as permissions:

- PutObject
- GetObject
- DeleteObject
- ListBucket (required for ListObjectsV2)
- GetObjectAttributes
- AbortMultipartUploads
- ListBucketMultipartUploads
- ListMultipartUploadParts

Note

You can specify any amount of prefixes, but the total length of characters of all prefixes must be less than 256 bytes in size.

Using the S3 console

To modify access point scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access points for directory buckets**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage.
6. Choose the **Permissions** tab.
7. In the **Access point scope** section, choose **Edit**.
8. To add or remove prefixes:
 - a. To add a prefix, choose **Add prefix**. In the **Prefix** field, enter a prefix of the directory bucket. Repeat to add more prefixes.
 - b. To remove a prefix, choose **Remove**.
9. To add or remove permissions:
 - a. To add a permission, in the **Choose data operations** field, choose the permission.
 - b. To remove a permission, choose the **X** next to the permission.
10. Choose **Save changes**.

Using the AWS CLI

The following put-access-point-scope example command shows how you can use the AWS CLI to modify the scope of your access point.

The following command modifies the access point scope of *my-access-point--zoneID--xa-s3* for AWS account *111122223333*.

Note

You can use wildcards in prefixes by using the asterisk (*) character. If you want to use the asterisk character as a literal, add a backslash character (\) before it to escape it.

All prefixes have an implicit '*' ending, meaning all paths within the prefix will be included. When you modify the scope of an access point with the AWS CLI, you replace the existing scope.

```
aws s3control put-access-point-scope --name my-access-point--zoneID--xa-s3 --account-id 111122223333 --scope Prefixes=string,Permissions=string
```

For more information and examples, see [put-access-point-scope](#) in the AWS CLI Command Reference.

Using the REST API

The following PutAccessPointScope example request shows how you can use the REST API to modify the scope of your access point.

The following request modifies the access point scope of *my-access-point--zoneID--xa-s3* for AWS account *111122223333*.

Note

You can use wildcards in prefixes by using the asterisk (*) character. If you want to use the asterisk character as a literal, add a backslash character (\) before it to escape it.

All prefixes have an implicit '*' ending, meaning all paths within the prefix will be included. When you modify the scope of an access point with the API, you replace the existing scope.

```
PUT /v20180820/accesspoint/my-access-point--zoneID--xa-s3/scope HTTP/1.1
Host: s3express-control.region.amazonaws.com
x-amz-account-id: 111122223333
<?xml version="1.0" encoding="UTF-8"?>
<PutAccessPointScopeRequest>
    <Scope>
        <Prefixes>
            <Prefix>Jane/*</Prefix>
        </Prefixes>
        <Permissions>
            <Permission>PutObject</Permission>
            <Permission>GetObject</Permission>
        </Permissions>
        <Scope>
    </PutAccessPointScopeRequest>
```

Using the AWS SDKs

You can use the AWS CLI, AWS SDKs, or REST API to modify the scope of your access point. For more information, see [list of supported SDKs](#) in the Amazon Simple Storage Service API Reference.

Delete the scope of your access points for directory buckets

You can use the AWS Management Console, AWS Command Line Interface, REST API, or AWS SDKs to delete the scope of your access points for directory buckets.

 **Note**

When you delete the scope of an access point, all prefixes and permissions are deleted.

Using the S3 console

To delete access point scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access points for directory buckets**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage.
6. Choose the **Permissions** tab.
7. In **Access point scope**, choose **Delete**.
8. In the **to confirm this deletion, type "confirm"**. field, enter **confirm**.
9. Choose **Delete**.

Using the AWS CLI

The following `delete-access-point-scope` example command shows how you can use the AWS CLI to delete the scope of your access point.

The following command deletes the scope of the access point *my-access-point--zoneID--xa-s3* for AWS account *111122223333*.

```
aws s3control delete-access-point-scope --name my-access-point--region-zoneID--xa-s3 --account-id 111122223333
```

For more information and examples, see [delete-access-point-scope](#) in the AWS CLI Command Reference.

Using the REST API

The following request deletes the scope of the access point *my-access-point--zoneID--xa-s3* for AWS account *111122223333*.

```
DELETE /v20180820/accesspoint/my-access-point--zoneID--xa-s3/scope HTTP/1.1  
Host: s3express-control.region.amazonaws.com  
x-amz-account-id: 111122223333
```

Using the AWS SDKs

You can use the AWS SDKs to delete the scope of your access point. For more information, see [list of supported SDKs](#) in the Amazon Simple Storage Service API Reference.

Delete your access point for directory buckets

This section explains how to delete your access point using the AWS Management Console, AWS Command Line Interface, REST API, or AWS SDKs.

Note

Before you can delete a directory bucket attached to an access point, you must delete the access point.

Using the S3 console

To delete access points for directory buckets in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access points for directory buckets**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to delete.
6. Choose **Delete**.
7. To confirm deletion, type **confirm** and choose **Delete**.

Using the AWS CLI

The following delete-access-point example command shows how you can use the AWS CLI to delete your access point.

The following command deletes the access point *my-access-point--zoneID--xa-s3* for AWS account *111122223333*.

```
aws s3control delete-access-point --name my-access-point--zoneID--xa-s3 --account-id 111122223333
```

For more information and examples, see [delete-access-point](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to delete your access point. For more information, see [DeleteAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

You can use the AWS SDKs to delete your access points. For more information, see [list of supported SDKs](#) in the *Amazon Simple Storage Service API Reference*.

Using tags with S3 Access Points for directory buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 Access Points for directory buckets. You can tag access points when you create them or manage tags on existing access points. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

Note

There is no additional charge for using tags on access points for directory buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with access points for directory buckets

Attribute-based access control (ABAC) allows you to scale access permissions and grant access to access points for directory buckets based on their tags. For more information about ABAC in Amazon S3, see [Using tags for ABAC](#).

ABAC for S3 Access Points

Amazon S3 Access Points support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and Access Points policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to access points for directory buckets based on the bucket's tags by using the following [global condition keys](#):

- aws:ResourceTag/key-name
 - Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key Dept with the value Marketing. For more information, see [Controlling access to AWS resources](#).
- aws:RequestTag/key-name
 - Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key Dept and that it has the value Accounting. For more information, see [Controlling access during AWS requests](#). You can use this condition key to restrict which tag key-value pairs can be passed during the TagResource and CreateAccessPoint API operations.
- aws:TagKeys
 - Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the aws:TagKeys condition key to define what tag keys are allowed. For example policies and more information, see [Controlling access based on tag keys](#). You can create an access point

for directory buckets with tags. To allow tagging during the `CreateAccessPoint` API operation, you must create a policy that includes both the `s3express:TagResource` and `s3express:CreateAccessPoint` actions. You can then use the `aws:TagKeys` condition key to enforce using specific tags in the `CreateAccessPoint` request.

- `s3express:AccessPointTag/tag-key`

- Use this condition key to grant permissions to specific data via access points using tags. When using `aws:ResourceTag/tag-key` in an IAM policy, both the access point as well as the bucket to which the access point points to are required to have the same tag as they are both considered during authorization. If you want to control access to your data specifically via the access-point tag only, you can use `s3express:AccessPointTag/tag-key` condition key.

Example ABAC policies for access points for directory buckets

See the following example ABAC policies for access points for directory buckets.

1.1 - IAM policy to create or modify access points with specific tags

In this IAM policy, users or roles with this policy can only create access points if they tag the access points with the tag key `project` and tag value `Trinity` in the access point creation request. They can also add or modify tags on existing access points for directory buckets as long as the `TagResource` request includes the tag key-value pair `project:Trinity`.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "CreateAccessPointWithTags",  
            "Effect": "Allow",  
            "Action": [  
                "s3express:CreateAccessPoint",  
                "s3express:TagResource"  
            ],  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:RequestTag/project": [  
                        "Trinity"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

```
    }
]
}
```

1.2 - Access Point policy to restrict operations on the bucket using tags

In this Access Point policy, IAM principals (users and roles) can perform operations using the `CreateSession` action on the access point only if the value of the access point's project tag matches the value of the principal's project tag.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowObjectOperations",
      "Effect": "Allow",
      "Principal": {
        "AWS": "111122223333"
      },
      "Action": "s3express:CreateSession",
      "Resource": "arn:aws::s3express:region:111122223333:access-point/my-access-point",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        }
      }
    }
  ]
}
```

1.3 - IAM policy to modify tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on an access point only if the value of the access point's project tag matches the value of the principal's project tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these access points. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your access points.

```
{
  "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Sid": "EnforceTaggingRulesOnModification",
        "Effect": "Allow",
        "Action": [
            "s3express:TagResource"
        ],
        "Resource": "arn:aws::s3express:region:111122223333:accesspoint/my-access-point",
        "Condition": {
            "StringEquals": {
                "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
            },
            "ForAllValues:StringEquals": {
                "aws:TagKeys": [
                    "project",
                    "environment",
                    "owner",
                    "cost-center"
                ]
            }
        }
    }
]
```

1.4 - Using the s3express:AccessPointTag condition key

In this IAM policy, the condition statement allows access to the bucket's data only if the access point used to access the bucket has the tag key Environment and tag value Production.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAccessToSpecificAccessPoint",
            "Effect": "Allow",
            "Action": "*",
            "Resource": "arn:aws::s3express:region:111122223333:accesspoint/my-access-point",
            "Condition": {
                "StringEquals": {
                    "s3express:AccessPointTag/Environment": "Production"
                }
            }
        }
]
```

```
    }  
]  
}
```

Working with tags for access points for directory buckets

You can add or manage tags for access points for directory buckets using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see:

Topics

- [Creating access points for directory buckets with tags](#)
- [Adding a tag to an access point for directory buckets](#)
- [Viewing the tags of an access point for directory buckets](#)
- [Deleting a tag from an access point for directory buckets](#)

Creating access points for directory buckets with tags

You can tag Amazon S3 Access Points for directory buckets when you create them. For additional information, see [Using tags with S3 Access Points for directory buckets](#).

Permissions

To create an access point for directory buckets with tags, you must have the following permissions:

- `s3express:CreateAccessPoint`
- `s3express:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create an access point for directory buckets with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the access point for directory buckets and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your access points for directory buckets only with specific tag keys and values. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

Steps

You can create an access point for directory buckets with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create an access point for directory buckets with tags using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (Directory Buckets)**.
3. Choose **create access point** to create a new access point.
4. Enter a name for the access point. For more information, see [Access points for directory buckets naming rules, restrictions, and limitations](#).
5. On the **Create access point** page, **Tags** is an option when creating a new access point.
6. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
7. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
8. After you complete specifying the options for your new access point, choose **Create access point**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to create an access point with tags by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
CreateAccessPointRequest createAccessPointRequest =
    CreateAccessPointRequest.builder()
        .accountId(111122223333)
        .name(my-access-point)
        .bucket(amzn-s3-demo-bucket--zone-id--x-s3)
        .tags(Collections.singletonList(Tag.builder().key("key1").value("value1").build()))
        .build();
awss3Control.createAccessPoint(createAccessPointRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for creating a directory bucket with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- [CreateBucket](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create an access point for directory buckets with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create an access point for directory buckets you must provide configuration details and use the following naming convention: *my-access-point*

Request:

```
aws s3control create-access-point \
--account-id 111122223333 \
--name my-access-point \
--bucket amzn-s3-demo-bucket--zone-id--x-s3 \
--profile personal \
--tags Key=key1,Value=value1 Key=MyKey2,Value=value2 \
--region region
```

Adding a tag to an access point for directory buckets

You can add tags to Amazon S3 Access Points for directory buckets and modify these tags. For additional information, see [Using tags with S3 Access Points for directory buckets](#).

Permissions

To add a tag to an access point for directory buckets, you must have the following permission:

- `s3express:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to an access point for directory buckets, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to an access point for directory buckets.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws :`, change the tag key and try again.

Steps

You can add tags to access points for directory buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To add tags to an access point for directory buckets using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (Directory Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to add tags to an access point for directory buckets by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;

import software.amazon.awssdk.services.s3control.model.TagResourceResponse;

public class TagResourceExample {
    public static void tagResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
            .resourceArn("arn:aws:s3:region:111122223333:accesspoint/my-access-
point/*")
            .accountId("111122223333")
            .tags(Tag.builder().key("key1").value("value1").build())
            .build();

        TagResourceResponse response = s3Control.tagResource(tagResourceRequest);
        System.out.println("Status code (should be 204):");
        System.out.println(response.sdkHttpResponse().statusCode());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for adding tags to an access point for directory buckets, see the following section in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control tag-resource \
```

```
--account-id 111122223333 \
--resource-arn arn:aws:s3express:region:444455556666:bucket/prefix--use1-az4--x-s3 \

Viewing the tags of an access point for directory buckets

You can view or list tags applied to Amazon S3 Access Points for directory buckets. For additional information, see [Using tags with S3 directory buckets](#).

Permissions

To view tags applied to an access point, you must have the following permission:

- `s3express>ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of an access point for directory buckets, you can do the following:

- Verify that you have the required [Permissions](#) to view or list the tags of the access point for directory buckets.

Steps

You can view tags applied to access points for directory buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to an access point for directory buckets using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (Directory Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the access point for directory buckets.
6. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your access point by AWS services.

Using the AWS SDKs

This section provides an example of how to view tags applied to an access point for directory buckets by using the AWS SDKs.

SDK for Java 2.x

This example shows you how to view tags applied to an access point for directory buckets by using the AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResourceExample {
    public static void listTagsForResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        ListTagsForResourceRequest listTagsForResourceRequest =
            ListTagsForResourceRequest.builder()
                .resourceArn("arn:aws:s3:::us-west-2:111122223333:accesspoint/my-
access-point/*")
                .accountId("111122223333")
                .build();
        ListTagsForResourceResponse response =
            s3Control.listTagsForResource(listTagsForResourceRequest);
```

```
        System.out.println("Tags on my resource:");
        System.out.println(response.toString());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a directory bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [ListTagsforResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to an access point for directory buckets. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn arn:aws:s3express:region:444455556666:bucket/prefix--use1-az4--x-s3 \
```

Response - tags present:

```
{
  "Tags": [
    {
      "Key": "MyKey1",
      "Value": "MyValue1"
    },
    {
      "Key": "MyKey2",
      "Value": "MyValue2"
    },
    {
      "Key": "MyKey3",
      "Value": "MyValue3"
    }
  ]
}
```

```
}
```

```
]
```

```
}
```

Response - no tags present:

```
{  
    "Tags": []  
}
```

Deleting a tag from an access point for directory buckets

You can remove tags from Access Points for directory buckets. For additional information, see [Using tags with S3 Access Points for directory buckets](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the access point for directory buckets.

Permissions

To delete a tag from an access point for directory buckets, you must have the following permission:

- `s3express:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from an access point for directory buckets, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from an access point for directory buckets.

Steps

You can delete tags from access points for directory buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from an access point for directory buckets using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Points (Directory Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to delete tags from a directory bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResourceExample {
    public static void listTagsForResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
            .resourceArn("arn:aws::s3:region:111122223333:accesspoint/my-access-point/*")
            .accountId("111122223333")
            .tagKeys("key1")
```

```
        .build();

    UntagResourceResponse response =
s3Control.untagResource(untagResourceRequest);
    System.out.println("Status code (should be 204):");
    System.out.println(response.sdkHttpResponse().statusCode());
}
}
```

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from an access point, see the following section in the *Amazon Simple Storage Service API Reference*:

- [UntagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from an access point by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control untag-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:region:111122223333:accesspoint/my-access-point/* \
--tag-keys "key1" "key2"
```

Response:

```

Logging with AWS CloudTrail for directory buckets

Amazon S3 is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details. When a supported event activity occurs in Amazon S3, that activity is recorded in a CloudTrail event. You can use AWS CloudTrail trail to log management events and data events for directory buckets.

For more information, see [Amazon S3 CloudTrail events](#) and [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

CloudTrail management events for directory buckets

By default, CloudTrail logs bucket-level actions for directory buckets as management events. The eventsource for CloudTrail management events for directory buckets is `s3express.amazonaws.com`. When you set up your AWS account, CloudTrail management events are enabled by default. The following Regional endpoint API operations (bucket-level, or control plane, API operations) are logged to CloudTrail.

- [CreateBucket](#)
- [DeleteBucket](#)
- [DeleteBucketPolicy](#)
- [PutBucketPolicy](#)
- [GetBucketPolicy](#)
- [ListDirectoryBuckets](#)
- [ListMultipartUploads](#)
- [GetBucketEncryption](#)
- [PutBucketEncryption](#)
- [DeleteBucketEncryption](#)

Note

`ListMultipartUploads` is a Zonal endpoint API operation. However, this API operation is logged to CloudTrail as a management event. For more information, see [ListMultipartUploads](#) in the *Amazon Simple Storage Service API Reference*.

For more information on CloudTrail management events, see [Logging management events](#) in the *AWS CloudTrail User Guide*.

CloudTrail data events for directory buckets

Data events provide information about the resource operations performed on or in a resource (for example, reading or writing to an Amazon S3 object). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail trails don't log data events, but you can configure trails to log data events for objects stored in general purpose buckets and directory buckets. For more information, see [Enable logging for objects in a bucket using the console](#).

When you log data events for a trail in CloudTrail, you can choose to use advanced event selectors or basic event selectors. To log data events for objects stored in directory buckets, you must use advanced event selectors. When configuring advanced resource selectors, you will choose or specify the resource type which is `AWS::S3Express::Object`.

The following Zonal endpoint API operations (object-level, or, data plane, API operations) are logged to CloudTrail.

- [AbortMultipartUpload](#)
- [CompleteMultipartUpload](#)
- [CreateSession](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)
- [DeleteObject](#)
- [DeleteObjects](#)
- [GetObject](#)
- [GetObjectAttributes](#)
- [HeadBucket](#)

- [HeadObject](#)
- [ListObjectsV2](#)
- [ListParts](#)
- [PutObject](#)
- [RenameObject](#)
- [UploadPart](#)
- [UploadPartCopy](#)

For more information on CloudTrail data events, see [Logging data events](#) in the *AWS CloudTrail User Guide*.

For additional information about CloudTrail events for directory buckets, see the following topics:

To use Zonal endpoint API operations (object-level, or data plane, operations), you can use the `CreateSession` API operation to create and manage sessions that are optimized for low-latency authorization of data requests. You can also use `CreateSession` to reduce the amount of logging. To identify which Zonal API operations were performed during a session, you can match the `accessKeyId` under the `responseElements` in your `CreateSession` log file to the `accessKeyId` in the log file of other Zonal API operations. For more information, see [CreateSession authorization](#).

The following example shows a CloudTrail log file example that demonstrates the [GetObject](#) API operation that was authenticated by `CreateSession`.

Optimizing directory bucket performance

To obtain the best performance when using directory buckets, we recommend the following guidelines.

For more information about best practices for S3 Express One Zone, see [Best practices to optimize S3 Express One Zone performance](#).

Use session-based authentication

Directory buckets support a new session-based authorization mechanism to authenticate and authorize requests to a directory bucket. With session-based authentication, the AWS SDKs automatically use the `CreateSession` API operation to create a temporary session token that can be used for low-latency authorization of data requests to a directory bucket.

The AWS SDKs use the `CreateSession` API operation to request temporary credentials, and then automatically create and refresh tokens for you on your behalf every 5 minutes. To take advantage of the performance benefits of directory buckets, we recommended that you use the AWS SDKs to initiate and manage the `CreateSession` API request. For more information about this session-based model, see [Authorizing Zonal endpoint API operations with CreateSession](#).

S3 additional checksum best practices

Directory buckets offer you the option to choose the checksum algorithm that is used to validate your data during upload or download. You can select one of the following Secure Hash Algorithms (SHA) or Cyclic Redundancy Check (CRC) data-integrity check algorithms: CRC32, CRC32C, SHA-1, and SHA-256. MD5-based checksums are not supported with the S3 Express One Zone storage class.

CRC32 is the default checksum used by the AWS SDKs when transmitting data to or from directory buckets. We recommend using CRC32 and CRC32C for the best performance with directory buckets.

Use the latest version of the AWS SDKs and common runtime libraries

Several of the AWS SDKs also provide the AWS Common Runtime (CRT) libraries to further accelerate performance in S3 clients. These SDKs include the AWS SDK for Java 2.x, the AWS SDK for C++, and the AWS SDK for Python (Boto3). The CRT-based S3 client transfers objects to and from directory buckets with enhanced performance and reliability by automatically using the multipart upload API operation and byte-range fetches to automate horizontally scaling connections.

To achieve the highest performance with the directory buckets, we recommend using the latest version of the AWS SDKs that include the CRT libraries or using the AWS Command Line Interface (AWS CLI).

Developing with directory buckets

After you create your directory bucket, you can then immediately begin very low-latency reads and writes. You can communicate with your directory bucket by using an endpoint connection over a virtual private cloud (VPC), or you can use Zonal and Regional API operations to manage your objects and directory buckets. You can work with directory buckets by using the AWS SDKs, Amazon S3 console, AWS Command Line Interface (AWS CLI), and Amazon S3 REST APIs.

Regional and Zonal endpoints for directory buckets

To access the Regional and Zonal endpoints for directory buckets from your virtual private cloud (VPC), you can use gateway VPC endpoints. After you create a gateway endpoint, you can add it as a target in your route table for traffic destined from your VPC to your bucket. There is no additional charge for using gateway endpoints. For more information about how to configure gateway VPC endpoints, see [Networking for directory buckets](#).

Bucket-level (control plane) API operations are available through a Regional endpoint and are referred to as Regional endpoint API operations. Examples of Regional endpoint API operations are `CreateBucket` and `DeleteBucket`.

You use Zonal (object level, or data plane endpoint API operations) to upload and manage your objects. Zonal endpoint API operations are available through a Zonal endpoint. Examples of Zonal API operations are `PutObject` and `CopyObject`.

For more information about Regional and Zonal endpoints for directory buckets in Availability Zones, see [Regional and Zonal endpoints for directory buckets in an Availability Zone](#).

For more information about Regional and Zonal endpoints for directory buckets in Local Zones, see [Concepts for directory buckets in Local Zones](#).

Working with directory buckets by using the S3 console, AWS CLI, and AWS SDKs

You can work with the S3 Express One Zone storage class and directory buckets by using the AWS SDKs, Amazon S3 console, AWS Command Line Interface (AWS CLI), and Amazon S3 REST API.

S3 Console

To get started using the S3 console, follow these steps:

- [Creating directory buckets in an Availability Zone](#)
- [Emptying a directory bucket](#)
- [Deleting a directory bucket](#)

For a full tutorial, see [Tutorial: Getting started with S3 Express One Zone](#).

AWS SDKs

S3 Express One Zone supports the following AWS SDKs:

- AWS SDK for C++
- AWS SDK for Go v2
- AWS SDK for Java 2.x
- AWS SDK for JavaScript v3
- AWS SDK for .NET
- AWS SDK for PHP
- AWS SDK for Python (Boto3)
- AWS SDK for Ruby
- AWS SDK for Kotlin
- AWS SDK for Rust

When you're working with S3 Express One Zone, we recommend using the latest version of the AWS SDKs. The supported AWS SDKs for S3 Express One Zone handle session establishment, refreshment, and termination on your behalf. This means that you can immediately start using API operations after you download and install the AWS SDKs and configure the necessary IAM permissions. For more information, see [Authorizing Regional endpoint API operations with IAM](#).

For information about the AWS SDKs, including how to download and install them, see [Tools to Build on AWS](#).

For AWS SDK examples, see the following:

- [Creating directory buckets in an Availability Zone](#)
- [Emptying a directory bucket](#)
- [Deleting a directory bucket](#)

AWS Command Line Interface (AWS CLI)

You can use the AWS Command Line Interface (AWS CLI) to create directory buckets and use supported Regional and Zonal endpoint API operations for S3 Express One Zone.

To get started with the AWS CLI, see [Get started with the AWS CLI](#) in the *AWS CLI Command Reference*.

 **Note**

To use directory buckets with the [high-level aws s3 commands](#), update your AWS CLI to the latest version. For more information about how to install and configure the AWS CLI, see [Install or update the latest version of the AWS CLI](#) in the *AWS CLI Command Reference*.

For AWS CLI examples, see the following:

- [Creating directory buckets in an Availability Zone](#)
- [Emptying a directory bucket](#)
- [Deleting a directory bucket](#)

Directory bucket API operations

To manage directory buckets, you can use Regional (bucket level, or control plane) endpoint API operations. To manage objects in your directory buckets, you can use Zonal (object level, or data plane) endpoint API operations. For more information, see [Networking for directory buckets](#) and [Endpoints and gateway VPC endpoints](#).

Regional endpoint API operations

The following Regional endpoint API operations are supported for directory buckets:

- [CreateAccessPoint](#)
- [CreateBucket](#)
- [DeleteAccessPoint](#)
- [DeleteAccessPointPolicy](#)
- [DeleteAccessPointScope](#)
- [DeleteBucket](#)
- [DeleteBucketLifecycle](#)

- [PutBucketLifecycleConfiguration](#)
- [PutBucketPolicy](#)
- [DeleteBucketEncryption](#)
- [GetBucketEncryption](#)
- [PutBucketEncryption](#)
- [TagResource](#)
- [UntagResource](#)

Zonal endpoint API operations

The following Zonal endpoint API operations are supported for directory buckets:

- [CreateSession](#)
- [CopyObject](#)
- [DeleteObject](#)
- [DeleteObjects](#)
- [GetObject](#)
- [GetObjectAttributes](#)
- [HeadBucket](#)
- [HeadObject](#)
- [ListObjectsV2](#)
- [PutObject](#)

Using tags with S3 directory buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 directory buckets. You can tag S3 directory buckets when you create them or manage tags on existing directory buckets. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

 **Note**

There is no additional charge for using tags on directory buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with directory buckets

Use tags on your S3 directory buckets for:

1. **Cost allocation** – Track storage costs by bucket tag in AWS Billing and Cost Management. For more information, see [Using tags for cost allocation](#).
2. **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 directory buckets based on their tags. For more information, see [Using tags for ABAC](#).

 **Note**

You can use the same tags for both cost allocation and access control.

ABAC for S3 directory buckets

Amazon S3 directory buckets support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and S3 directory bucket policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 directory buckets based on the bucket's tags by using the following [global condition keys](#):

- `aws:ResourceTag/key-name`
 - Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key `Dept` with the value `Marketing`. For more information, see [Controlling access to AWS resources](#).
- `aws:RequestTag/key-name`
 - Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key `Dept` and that it has the value `Accounting`. For more information, see [Controlling access during AWS requests](#). You can use this condition key to restrict which tag key-value pairs can be passed during the `TagResource` and `CreateBucket` API operations.
- `aws:TagKeys`
 - Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see [Controlling access based on tag keys](#). You can create an S3 directory bucket with tags. To allow tagging during the `CreateBucket` API operation, you must create a policy that includes both the `s3express:TagResource` and `s3express>CreateBucket` actions. You can then use the `aws:TagKeys` condition key to enforce using specific tags in the `CreateBucket` request.
- `s3express:BucketTag/tag-key`
 - Use this condition key to grant permissions to specific data in directory buckets using tags. When accessing a directory bucket by using an access point, this condition key references the tags on the directory bucket both when authorizing against the access point and the directory bucket, while the `aws:ResourceTag/tag-key` will reference the tags only of the resource it is being authorized against.

Example ABAC policies for directory buckets

See the following example ABAC policies for Amazon S3 directory buckets.

1.1 - IAM policy to create or modify buckets with specific tags

In this IAM policy, users or roles with this policy can only create S3 directory buckets if they tag the bucket with the tag key project and tag value Trinity in the bucket creation request. They can also add or modify tags on existing S3 directory buckets as long as the TagResource request includes the tag key-value pair project:Trinity. This policy does not grant read, write, or delete permissions on the buckets or its objects.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "CreateBucketWithTags",  
            "Effect": "Allow",  
            "Action": [  
                "s3express:CreateBucket",  
                "s3express:TagResource"  
            ],  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:RequestTag/project": [  
                        "Trinity"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

1.2 - Bucket policy to restrict operations on the bucket using tags

In this bucket policy, IAM principals (users and roles) can perform operations using the CreateSession action on the bucket only if the value of the bucket's project tag matches the value of the principal's project tag.

```
{  
    "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Sid": "AllowObjectOperations",
        "Effect": "Allow",
        "Principal": {
            "AWS": "111122223333"
        },
        "Action": "s3express>CreateSession",
        "Resource": "arn:aws::s3express:us-west-2:111122223333:bucket/amzn-s3-demo-
bucket--usw2-az1--x-s3",
        "Condition": {
            "StringEquals": {
                "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
            }
        }
    }
]
```

1.3 - IAM policy to modify tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a bucket only if the value of the bucket's project tag matches the value of the principal's project tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these directory buckets. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your buckets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceTaggingRulesOnModification",
            "Effect": "Allow",
            "Action": [
                "s3express:TagResource"
            ],
            "Resource": "arn:aws::s3express:us-west-2:111122223333:bucket/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
                },
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": [
                        "project", "environment", "owner", "cost-center"
                    ]
                }
            }
        }
]
```

```
        "project",
        "environment",
        "owner",
        "cost-center"
    ]
}
}
]
}
```

1.4 - Using the s3express:BucketTag condition key

In this IAM policy, the condition statement allows access to the bucket's data only if the bucket has the tag key Environment and tag value Production.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToSpecificAccessPoint",
      "Effect": "Allow",
      "Action": "*",
      "Resource": "arn:aws::s3express:us-west-2:111122223333:accesspoint/*",
      "Condition": {
        "StringEquals": {
          "s3express:BucketTag/Environment": "Production"
        }
      }
    }
  ]
}
```

Managing tags for directory buckets

You can add or manage tags for S3 directory buckets using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see:

Topics

- [Creating directory buckets with tags](#)

- [Adding a tag to a directory bucket](#)
- [Viewing directory bucket tags](#)
- [Deleting a tag from a directory bucket](#)

Creating directory buckets with tags

You can tag Amazon S3 directory buckets when you create them. There is no additional charge for using tags on directory buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging directory buckets, see [Using tags with S3 directory buckets](#).

Permissions

To create a directory bucket with tags, you must have the following permissions:

- `s3express:CreateBucket`
- `s3express:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a directory bucket with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the directory bucket and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your directory buckets only with specific tag keys and values. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

Steps

You can create a directory bucket with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create a directory bucket with tags using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **directory buckets**.
3. Choose **create bucket** to create a new directory bucket.
4. You can create two types of directory buckets:

Create a directory bucket in an Availability Zone for a high performance workload. For more information, see [High performance workloads](#).

Create a directory bucket in a Local Zone for a data residency workload. For more information, see [Data residency workloads](#).

5. For both types of directory buckets, on the **Create bucket** page, **Tags** is an option when creating a new directory bucket.
6. Enter a name for the bucket. For more information, see [Directory bucket naming rules](#).
7. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
8. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
9. After you complete specifying the options for your new directory bucket, choose **Create bucket**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to create a directory bucket with tags by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.BucketInfo;
import software.amazon.awssdk.services.s3.model.BucketType;
import software.amazon.awssdk.services.s3.model.CreateBucketConfiguration;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateBucketResponse;
import software.amazon.awssdk.services.s3.model.DataRedundancy;
import software.amazon.awssdk.services.s3.model.LocationInfo;
import software.amazon.awssdk.services.s3.model.LocationType;
import software.amazon.awssdk.services.s3.model.Tag;

public class CreateBucketWithTagsExample {
```

```
public static void createBucketWithTagsExample() {
    S3Client s3 = S3Client.builder().region(Region.US_WEST_2).build();

    CreateBucketConfiguration bucketConfiguration =
CreateBucketConfiguration.builder()
        .location(LocationInfo.builder()
            .type(LocationType.AVAILABILITY_ZONE)
            .name("usw2-az1").build())
        .bucket(BucketInfo.builder()
            .type(BucketType.DIRECTORY)
            .dataRedundancy(DataRedundancy.SINGLE_AVAILABILITY_ZONE)
            .build())
        .tags(Tag.builder().key("MyTagKey").value("MyTagValue").build())
        .build();

    CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
        .bucket("amzn-s3-demo-bucket--usw2-az1--x-s3--usw2-az1--x-s3")
        .createBucketConfiguration(bucketConfiguration)
        .build();

    CreateBucketResponse response = s3.createBucket(createBucketRequest);
    System.out.println("Status code (should be 200):");
    System.out.println(response.sdkHttpResponse().statusCode());
}
}
```

Using the REST API

For information about the Amazon S3 REST API support for creating a directory bucket with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- [CreateBucket](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a directory bucket with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create a directory bucket you must provide configuration details and use the following naming convention: *bucket-base-name--zone-id--x-s3*

Request:

```
aws s3api create-bucket \
--bucket bucket-base-name--zone-id--x-s3 \
--create-bucket-configuration "Location={Type=AvailabilityZone,Name=zone-id},Bucket={DataRedundancy=SingleAvailabilityZone,Type=Directory},Tags=[{Key=mykey1,Value=myvalue1},{Key=mykey2,Value=myvalue2}]"
```

Response:

```
{
  "Location": "http://bucket--use1-az4--x-s3.s3express-use1-az4.us-east-1.amazonaws.com/"
}
```

Adding a tag to a directory bucket

You can add tags to Amazon S3 directory buckets and modify these tags. There is no additional charge for using tags on directory buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging directory buckets, see [Using tags with S3 directory buckets](#).

Permissions

To add a tag to a directory bucket, you must have the following permission:

- `s3express:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a directory bucket, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to a directory bucket.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.

Steps

You can add tags to directory buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To add tags to a directory bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **directory buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to add tags to a directory bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;
import software.amazon.awssdk.services.s3control.model.TagResourceResponse;

public class TagResourceExample {
    public static void tagResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
```

```
        .resourceArn("arn:aws::s3express:us-west-2:111122223333:bucket/my-
directory-bucket--usw2-az1--x-s3")
        .accountId("111122223333")
        .tags(Tag.builder().key("MyTagKey").value("MyTagValue").build())
        .build();

    TagResourceResponse response = s3Control.tagResource(tagResourceRequest);
    System.out.println("Status code (should be 204):");
    System.out.println(response.sdkHttpResponse().statusCode());
}
}
```

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a directory bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control tag-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3express:us-east-1:44445556666:bucket/prefix--use1-az4--x-s3
\
--tags "Key=mykey,Value=myvalue"
```

Response:

```
{
  "ResponseMetadata": {
    "RequestId": "EXAMPLE123456789",
    "HTTPStatusCode": 200,
    "HTTPHeaders": {

Viewing directory bucket tags

You can view or list tags applied to S3 directory buckets. For more information about tags, see [Using tags with S3 directory buckets](#).

Permissions

To view tags applied to a directory bucket, you must have the following permission:

- `s3express>ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a directory bucket, you can do the following:

- Verify that you have the required [Permissions](#) to view or list the tags of the directory bucket.

Steps

You can view tags applied to directory buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a directory bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **directory buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the directory bucket.

6. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your directory bucket by AWS services.

Using the AWS SDKs

This section provides an example of how to view tags applied to a directory bucket by using the AWS SDKs.

SDK for Java 2.x

This example shows you how to view tags applied to a directory bucket by using the AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResourceExample {
    public static void listTagsForResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        ListTagsForResourceRequest listTagsForResourceRequest =
            ListTagsForResourceRequest.builder()
                .resourceArn("arn:aws::s3express:us-west-2:111122223333:bucket/my-
directory-bucket--usw2-az1--x-s3")
                .accountId("111122223333")
                .build();

        ListTagsForResourceResponse response =
            s3Control.listTagsForResource(listTagsForResourceRequest);
        System.out.println("Tags on my resource:");
        System.out.println(response.toString());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a directory bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [ListTagsforResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a directory bucket. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3express:us-east-1:444455556666:bucket/prefix--use1-az4--x-s3 \
\
```

Response - tags present:

```

Deleting a tag from a directory bucket

You can remove tags from S3 directory buckets. An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 directory buckets. For more information about tags, see [Using tags with S3 directory buckets](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the directory bucket.

Permissions

To delete a tag from a directory bucket, you must have the following permission:

- `s3express:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a directory bucket, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from a directory bucket.

Steps

You can delete tags from directory buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from a directory bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **directory buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.

5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to delete tags from a directory bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;
import software.amazon.awssdk.services.s3control.model.UntagResourceResponse;

public class UntagResourceExample {
    public static void untagResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
            .resourceArn("arn:aws::s3express:us-west-2:111122223333:bucket/my-
directory-bucket--usw2-az1--x-s3")
            .accountId("111122223333")
            .tagKeys("myTagKey")
            .build();

        UntagResourceResponse response =
        s3Control.untagResource(untagResourceRequest);
        System.out.println("Status code (should be 204):");
        System.out.println(response.sdkHttpResponse().statusCode());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a directory bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [UnTagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a directory bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control untag-resource \

Resilience testing in S3 Express One Zone

Amazon S3 Express One Zone storage class supports resilience testing with AWS Fault Injection Service (AWS FIS), a fully managed service for performing fault injection experiments on your AWS

workloads. With AWS FIS, you can simulate connectivity disruptions to your directory buckets, causing Zonal (object level, or data plane) endpoint API operations to timeout as would occur during an Availability Zone disruption.

These experiments can help you:

- Verify your monitoring systems can detect S3 Express One Zone access issues
- Test and strengthen recovery processes
- Validate that application failover mechanisms work as expected
- Ensure your application recovery time meets your organization's service level objectives (SLOs) and service level agreements (SLAs)

By testing your application's response to simulated disruptions, you can better prepare for the unlikely event of an actual Availability Zone outage that affects access to your data in S3 Express One Zone.

How it works

The test uses the `aws :network:disrupt-connectivity` action with scope set to S3 Express. This action disrupts network connectivity to S3 Express One Zone endpoints, causing requests to directory buckets to timeout.

You can target subnets where your applications are running or Gateway VPC endpoints used to access S3 Express One Zone. For more information, see [AZ Availability: Power Interruption](#) in the *AWS Fault Injection Service User Guide*.

To test the resilience of applications that store data in S3 Express One Zone, see [Simulate a connectivity event](#) in the *AWS Fault Injection Service User Guide*.

Considerations and limitations

Keep in mind the following considerations and limitations for disrupting connectivity in Amazon S3 Express One Zone storage class:

Considerations

- **IAM Permissions:** To use AWS FIS with S3 Express One Zone, you must configure an IAM role with appropriate permissions. For more information on AWS FIS roles, see [Create an IAM role for](#)

[AWS FIS](#) in the *AWS Fault Injection Service User Guide*. We recommend scoping these permissions to only the necessary resources.

- **Target Resolution:** Targets are resolved at the beginning of the experiment. If a target subnet or gateway VPC endpoint is deleted during the experiment, the experiment will fail.
- **Shared Resources Impact:** If multiple applications share the same subnets or gateway VPC endpoints, all traffic to S3 Express One Zone from these applications will be affected during the experiment.
- **Rollback Behavior:** When the AWS FIS action ends, connectivity is automatically restored and requests will resume the expected operation without manual intervention.
- **Stop Conditions:** Configure appropriate CloudWatch alarms as stop conditions to automatically terminate experiments if unexpected impacts occur.

Limitations

- **Target Selection:** You can't target specific S3 directory buckets. The action affects all directory buckets accessed through the targeted networking components.
- **Maximum Targets:** There is a maximum number of subnets you can target per AWS FIS action. For more information, see [Service quotas for AWS Fault Injection Service](#) in the *AWS FIS User Guide*.
- **Access Methods:** The AWS FIS action only affects requests made through the internet or gateway virtual private cloud (VPC) endpoints. Requests from interface VPC endpoints (AWS PrivateLink) aren't supported.
- **Regional Availability:** This feature is available only in [AWS Regions where S3 Express One Zone is supported](#).

Working with Amazon S3 Tables and table buckets

Amazon S3 Tables provide S3 storage that's optimized for analytics workloads, with features designed to continuously improve query performance and reduce storage costs for tables. S3 Tables are purpose-built for storing tabular data, such as daily purchase transactions, streaming sensor data, or ad impressions. Tabular data represents data in columns and rows, like in a database table.

The data in S3 Tables is stored in a new bucket type: a *table bucket*, which stores tables as subresources. Table buckets support storing tables in the Apache Iceberg format. Using standard SQL statements, you can query your tables with query engines that support Iceberg, such as Amazon Athena, Amazon Redshift, and Apache Spark.

Features of S3 Tables

Purpose-built storage for tables

S3 table buckets are specifically designed for tables. Table buckets provide higher transactions per second (TPS) and better query throughput compared to self-managed tables in S3 general purpose buckets. Table buckets deliver the same durability, availability, and scalability as other Amazon S3 bucket types.

Built-in support for Apache Iceberg

Tables in your table buckets are stored in [Apache Iceberg](#) format. You can query these tables using standard SQL in query engines that support Iceberg. Iceberg has a variety of features to optimize query performance, including schema evolution and partition evolution.

With Iceberg, you can change how your data is organized so that it can evolve over time without requiring you to rewrite your queries or rebuild your data structures. Iceberg is designed to help ensure data consistency and reliability through its support for transactions. To help you correct issues or perform time travel queries, you can track how data changes over time and roll back to historical versions.

Automated table optimization

To optimize your tables for querying, S3 continuously performs automatic maintenance operations, such as compaction, snapshot management, and unreferenced file removal. These operations increase table performance by compacting smaller objects into fewer, larger files. Maintenance operations also reduce your storage costs by cleaning up unused objects. This automated maintenance streamlines the operation of data lakes at scale by reducing the need for manual table maintenance. For each table and table bucket, you can customize maintenance configurations.

Access management and security

You can manage access for both table buckets and individual tables with AWS Identity and Access Management (IAM) and [Service Control Policies](#) in AWS Organizations. S3 Tables uses a different service namespace than Amazon S3: the *s3tables* namespace. Therefore, you can design policies specifically for the S3 Tables service and its resources. You can design policies to grant access to individual tables, all tables within a table namespace, or entire table buckets. All Amazon S3 Block Public Access settings are always enabled for table buckets and cannot be disabled.

Integration with AWS analytics services

You can automatically integrate your Amazon S3 table buckets with Amazon SageMaker Lakehouse through the S3 console. This integration allows AWS analytics services to automatically discover and access your table data through the AWS Glue Data Catalog. After the integration, you can work with your tables using analytics services such as Amazon Athena, Amazon Redshift, Quick Suite, and more. For more information about how the integration works, see [Integrating Amazon S3 Tables with AWS analytics services](#).

Related services

You can use the following AWS services with S3 Tables to support your specific analytics applications.

- **[Amazon Athena](#)** – Athena is an interactive query service that you can use to analyze data directly in Amazon S3 by using standard SQL. You can also use Athena to interactively run data analytics by using Apache Spark without having to plan for, configure, or manage resources. When you run Apache Spark applications on Athena, you submit Spark code for processing and receive the results directly.
- **[AWS Glue](#)** – AWS Glue is a serverless data-integration service that allows you to discover, prepare, move, and integrate data from multiple sources. You can use AWS Glue for analytics, machine learning (ML), and application development. AWS Glue also includes additional productivity and data-operations tooling for authoring, running jobs, and implementing business workflows.
- **[Amazon SageMaker Unified Studio](#)** – SageMaker Unified Studio delivers an integrated experience for analytics and AI with unified access to all your data. Collaborate and build in SageMaker Unified Studio using familiar AWS tools for SQL analytics, data processing, model development, and generative AI, accelerated by [Amazon Q Developer](#).
- **[Amazon EMR](#)** – Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data.
- **[Amazon Redshift](#)** – Amazon Redshift is a petabyte-scale data warehouse service in the cloud. You can use Amazon Redshift Serverless to access and analyze data without all of the configurations of a provisioned data warehouse. Resources are automatically provisioned and data warehouse capacity is intelligently scaled to deliver fast performance for even the most

demanding and unpredictable workloads. You don't incur charges when the data warehouse is idle, so you only pay for what you use. You can load data and start querying right away in the Amazon Redshift query editor v2 or in your favorite business intelligence (BI) tool.

- **Quick Suite** – Quick Suite is a business analytics service to build visualizations, perform ad hoc analysis, and quickly get business insights from your data. Quick Suite seamlessly discovers AWS data sources and delivers fast and responsive query performance by using the Quick Suite Super-fast, Parallel, In-Memory, Calculation Engine (SPICE).
- **AWS Lake Formation** – Lake Formation is a managed service that streamlines the process to set up, secure, and manage your data lakes. Lake Formation helps you discover your data sources and then catalog, cleanse, and transform the data. With Lake Formation, you can manage fine-grained access control for your data lake data on Amazon S3 and its metadata in AWS Glue Data Catalog.

Tutorial: Getting started with S3 Tables

In this tutorial, you create a table bucket and integrate table buckets in your Region with AWS analytics services. Next, you will use the AWS CLI to create your first namespace and table in your table bucket. Then, you use AWS Lake Formation to grant permission on your table, so you can begin querying your table with Athena.

Tip

If you're migrating tabular data from general purpose buckets to table buckets, the AWS Solutions Library has a guided solution to assist you. This solution automates moving Apache Iceberg and Apache Hive tables that are registered in AWS Glue Data Catalog and stored in general purpose buckets to table buckets by using AWS Step Functions and Amazon EMR with Apache Spark. For more information, see [Guidance for Migrating Tabular Data from Amazon S3 to S3 Tables](#) in the AWS Solutions Library.

Topics

- [Step 1: Create a table bucket and integrate it with AWS analytics services](#)
- [Step 2: Create a table namespace and a table](#)
- [\(Optional\) Step 3: Grant Lake Formation permissions on your table](#)
- [Step 4: Query data with SQL in Athena](#)

Step 1: Create a table bucket and integrate it with AWS analytics services

In this step, you use the Amazon S3 console to create your first table bucket. For other ways to create a table bucket, see [Creating a table bucket](#).

Note

By default, the Amazon S3 console automatically integrates your table buckets with Amazon SageMaker Lakehouse, which allows AWS analytics services to automatically discover and access your S3 Tables data. If you create your first table bucket programmatically by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API, you must manually complete the AWS analytics services integration. For more information, see [Integrating Amazon S3 Tables with AWS analytics services](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create the table bucket.
3. In the left navigation pane, choose **Table buckets**.
4. Choose **Create table bucket**.
5. Under **General configuration**, enter a name for your table bucket.

The table bucket name must:

- Be unique within for your AWS account in the current Region.
- Be between 3 and 63 characters long.
- Consist only of lowercase letters, numbers, and hyphens (-).
- Begin and end with a letter or number.

After you create the table bucket, you can't change its name. The AWS account that creates the table bucket owns it. For more information about naming table buckets, see [Table bucket naming rules](#).

6. In the **Integration with AWS analytics services** section, make sure that the **Enable integration** checkbox is selected.

If **Enable integration** is selected when you create your first table bucket by using the console, Amazon S3 attempts to integrate your table bucket with AWS analytics services. This integration allows you to use AWS analytics services to access all tables in the current Region. For more information, see [Integrating Amazon S3 Tables with AWS analytics services](#).

7. Choose **Create bucket**.

Step 2: Create a table namespace and a table

For this step, you create a namespace in your table bucket, and then create a new table under that namespace. You can create a table namespace and a table by using either the console or the AWS CLI.

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.

If your table definition contains capital letters, you receive the following error message when running a SELECT query in Athena: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Using the S3 console and Amazon Athena

The following procedure uses the Amazon S3 console to create a namespace and a table with Amazon Athena.

To create a table namespace and a table

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the table bucket that you want to create a table in.

4. On the table bucket details page, choose **Create table with Athena**.
5. In the **Create table with Athena** dialog box, choose **Create a namespace**, and then enter a name in the **Namespace name** field. Namespace names must be 1 to 255 characters and unique within the table bucket. Valid characters are a–z, 0–9, and underscores (_). Underscores aren't allowed at the start of namespace names.
6. Choose **Create namespace**.
7. Choose **Create table with Athena**.
8. The Amazon Athena console opens and the Athena query editor appears. The query editor is populated with a sample query that you can use to create a table. Modify the query to specify the table name and columns that you want your table to have.
9. When you're finished modifying the query, choose **Run** to create your table.

If your table creation was successful, the name of your new table appears in the list of tables in Athena. When you navigate back to the Amazon S3 console, your new table appears in the **Tables** list on the details page for your table bucket after you refresh the list.

Using the AWS CLI

To use the following AWS CLI example commands to create a namespace in your table bucket, and then create a new table with a schema under that namespace, replace the *user input placeholder* values with your own.

Prerequisites

- Attach the [AmazonS3TablesFullAccess](#) policy to your IAM identity.
- Install AWS CLI version 2.23.10 or higher. For more information, see [Installing or updating the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

1. Create a new namespace in your table bucket by running the following command:

```
aws s3tables create-namespace \
--table-bucket-arn arn:aws:s3tables:us-east-1:11122223333:bucket/amzn-s3-demo-
table-bucket \
--namespace my_namespace
```

- Confirm that your namespace was created successfully by running the following command:

```
aws s3tables list-namespaces \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

2. Create a new table with a table schema by running the following command:

```
aws s3tables create-table --cli-input-json file://mytabledefinition.json
```

For the `mytabledefinition.json` file, use the following example table definition:

```
{
    "tableBucketARN": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket",
    "namespace": "my_namespace",
    "name": "my_table",
    "format": "ICEBERG",
    "metadata": {
        "iceberg": {
            "schema": {
                "fields": [
                    {"name": "id", "type": "int", "required": true},
                    {"name": "name", "type": "string"},
                    {"name": "value", "type": "int"}
                ]
            }
        }
    }
}
```

(Optional) Step 3: Grant Lake Formation permissions on your table

For this step, you grant Lake Formation permissions on your new table to other IAM principals. These permissions allow principals other than you to access table bucket resources by using Athena and other AWS analytics services. For more information, see [Granting Lake Formation permission on a table or database](#). If you're the only user who will access your tables, you can skip this step.

1. Open the AWS Lake Formation console at <https://console.aws.amazon.com/lakeformation/>, and sign in as a data lake administrator. For more information about how to create a data lake administrator, see [Create a data lake administrator](#).

2. In the navigation pane, choose **Data permissions** and then choose **Grant**.
3. On the **Grant Permissions** page, under **Principals**, choose **IAM users and roles** and choose the IAM user or role that you want to allow to run queries on your table.
4. Under **LF-Tags or catalog resources**, choose **Named Data Catalog resources**.
5. Do one of the following, depending on whether you want to grant access to all of the tables in your account or whether you want to grant access to only the resources within the table bucket that you created:
 - For **Catalogs**, choose the account-level catalog that you created when you integrated your table bucket. For example, **111122223333:s3tablescatalog**.
 - For **Catalogs**, choose the subcatalog for your table bucket. For example, **111122223333:s3tablescatalog/amzn-s3-demo-table-bucket**.
6. (Optional) If you chose the subcatalog for your table bucket, do one or both of the following:
 - For **Databases**, choose the table bucket namespace that you created.
 - For **Tables**, choose the table that you created in your table bucket, or choose **All tables**.
7. Depending on whether you chose a catalog or subcatalog and depending on whether you then chose a database or a table, you can set permissions at the catalog, database, or table level. For more information about Lake Formation permissions, see [Managing Lake Formation permissions](#) in the *AWS Lake Formation Developer Guide*.

Do one of the following:

- For **Catalog permissions**, choose **Super** to grant the other principal all permissions on your catalog, or choose more fine-grained permissions, such as **Describe**.
- For **Database permissions**, you can't choose **Super** to grant the other principal all permissions on your database. Instead, choose more fine-grained permissions, such as **Describe**.
- For **Table permissions**, choose **Super** to grant the other principal all permissions on your table, or choose more fine-grained permissions, such as **Select** or **Describe**.

 **Note**

When you grant Lake Formation permissions on a Data Catalog resource to an external account or directly to an IAM principal in another account, Lake Formation uses the AWS Resource Access Manager (AWS RAM) service to share the resource. If the grantees account is in the same organization as the grantor account, the shared resource is available immediately to the grantees. If the grantees account is not in

the same organization, AWS RAM sends an invitation to the grantee account to accept or reject the resource grant. Then, to make the shared resource available, the data lake administrator in the grantee account must use the AWS RAM console or AWS CLI to accept the invitation. For more information about cross-account data sharing, see [Cross-account data sharing in Lake Formation](#) in the *AWS Lake Formation Developer Guide*.

8. Choose **Grant**.

Step 4: Query data with SQL in Athena

You can query your table with SQL in Athena. Athena supports Data Definition Language (DDL), Data Manipulation Language (DML), and Data Query Language (DQL) queries for S3 Tables.

You can access the Athena query either from the Amazon S3 console or through the Amazon Athena console.

Using the S3 console and Amazon Athena

The following procedure uses the Amazon S3 console to access the Athena query editor so that you can query a table with Amazon Athena.

To query a table

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the table bucket that contains the table that you want to query.
4. On the table bucket details page, choose the option button next to the name of the table that you want to query.
5. Choose **Query table with Athena**.
6. The Amazon Athena console opens and the Athena query editor appears with a sample SELECT query loaded for you. Modify this query as needed for your use case.
7. To run the query, choose **Run**.

Using the Amazon Athena console

To query a table

1. Open the Athena console at <https://console.aws.amazon.com/athena/>.
2. Query your table. The following is a sample query that you can modify. Make sure to replace the *user input placeholders* with your own information.

```
SELECT * FROM "s3tablescatalog/amzn-s3-demo-table-bucket"."my_namespace"."my_table"  
LIMIT 10
```

3. To run the query, choose **Run**.

Table buckets

Amazon S3 table buckets are an S3 bucket type that you can use to create and store tables as S3 resources. Table buckets are used to store tabular data and metadata as objects for use in analytics workloads. S3 performs maintenance in your table buckets automatically to help reduce your table storage costs. For more information, see [S3 Tables maintenance](#).

To interact with the tables stored inside your table buckets, you can integrate your table buckets with analytics applications that support [Apache Iceberg](#). Table buckets integrate with AWS analytics services through the AWS Glue Data Catalog. For more information, see [Integrating Amazon S3 Tables with AWS analytics services](#). You can also interact with your tables using open-source query engines using the Amazon S3 Tables Catalog for Apache Iceberg. For more information, see [Accessing tables using the Amazon S3 Tables Iceberg REST endpoint](#).

Each table bucket has a unique Amazon Resource Name (ARN) and resource policy attached to it. Table bucket ARNs follow this format:

```
arn:aws:s3tables:Region:OwnerAccountID:bucket/bucket-name
```

All table buckets and tables are private and can't be made public. These resources can only be accessed by users who are explicitly granted access. To grant access, you can use IAM resource-based policies for table buckets and tables, and IAM identity-based policies for users and roles.

By default, you can create up to 10 table buckets per AWS Region in an AWS account. To request a quota increase for table buckets or tables, contact [Support](#).

Types of table buckets

Amazon S3 supports the following types of table buckets:

Customer-managed table buckets

Customer-managed table buckets are resources for storing Amazon S3 Tables created and managed by customers. You create these buckets explicitly, choose their names, and maintain full control over the tables and namespaces within them. For customer-managed table buckets, you can create, delete, set custom default encryption, or configure maintenance options as needed.

AWS managed table buckets

AWS managed table buckets are AWS managed resources that automatically store tables created by AWS services, such as the live inventory and journal tables created by S3 Metadata. These buckets provide a centralized location for all system-generated tables. These buckets follow a standard naming convention, use a standard namespace for all tables, and have preset maintenance and default encryption configurations which S3 modifies on your behalf. You have read-only access to query the data, while AWS handles all table creation, updates, and maintenance operations. For more information, see [Working with AWS managed table buckets](#).

There are several types of Amazon S3 buckets. Before creating a bucket, make sure that you choose the bucket type that best fits your application and performance requirements. For more information about the various bucket types and the appropriate use cases for each, see [Buckets](#).

Amazon S3 table bucket, table, and namespace naming rules

When you create a table bucket, you choose a bucket name and AWS Region, the name must be unique for your account in the chosen Region. After you create a table bucket, you can't change the bucket name or Region. Table bucket names must follow specific naming rules. For more information about naming rules for table buckets and the tables and namespaces within them, see the following topic.

Topics

- [Table bucket naming rules](#)
- [Naming rules for tables and namespaces](#)

Table bucket naming rules

When you create Amazon S3 table buckets, you specify a table bucket name. Like other bucket types, table buckets can't be renamed. Unlike other bucket types, table buckets aren't in a global namespace, so each bucket name in your account needs to be unique only within your current AWS Region.

For general purpose bucket naming rules, see [General purpose bucket naming rules](#). For directory bucket naming rules, see [Directory bucket naming rules](#).

The following naming rules apply for table buckets.

- Bucket names must be between 3 and 63 characters long.
- Bucket names can consist only of lowercase letters, numbers, and hyphens (-).
- Bucket names must begin and end with a letter or number.
- Bucket names must not contain any underscores (_) or periods (.).
- Bucket names must not start with any of the following reserved prefixes:
 - xn--
 - sthree-
 - amzn-s3-demo-
 - aws
- Bucket names must not end with any of the following reserved suffixes:
 - -s3alias

- --ol-s3
- --x-s3
- --table-s3

Naming rules for tables and namespaces

The following naming rules apply to tables and namespaces within table buckets:

- Names must be between 1 and 255 characters long.
- Names can consist only of lowercase letters, numbers, and underscores (_).
- Names must begin with a letter or number.
- Names must not contain hyphens (-) or periods (.).
- A table name must be unique within a namespace.
- A namespace must be unique within a table bucket.
- Namespace names must not start with the reserved prefix aws.

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.

If your table definition contains capital letters, you receive the following error message when running a SELECT query in Athena: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Creating a table bucket

Amazon S3 table buckets are an S3 bucket type that you can use to create and store tables as S3 resources. To start using S3 Tables, you create a table bucket where you store and manage tables.

When you create a table bucket, you choose a bucket name and AWS Region. The table bucket name must be unique for your account in the chosen Region. After you create a table bucket, you can't change the bucket name or Region. For information about naming table buckets, see [Amazon S3 table bucket, table, and namespace naming rules](#).

Table buckets have the following Amazon Resource Name (ARN) format:

```
arn:aws:s3tables:region:owner-account-id:bucket/bucket-name
```

By default, you can create up to 10 table buckets per Region in an AWS account. To request a quota increase for table buckets or tables, contact [Support](#).

When you create a table bucket you can specify the encryption type for that will be used to encrypt the tables you create in that bucket. For more information about bucket encryption options, see [the section called “Encryption”](#).

Prerequisites for creating table buckets

To create a table bucket, you must first do the following:

- Make sure that you have AWS Identity and Access Management (IAM) permissions for s3tables:CreateTableBucket.

Note

If you choose SSE-KMS as the default encryption type, you must have permissions for s3tables:PutTableBucketEncryption, and have DescribeKey permission on the chosen AWS KMS key. Additionally the AWS KMS key you use needs to grant S3 Tables permission to perform automatic table maintenance. For more information, see [Permission requirements for S3 Tables SSE-KMS encryption](#).

To create a table bucket, you can use the Amazon S3 console, Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.
3. In the left navigation pane, choose **Table buckets**.
4. Choose **Create table bucket** to open the **Create table bucket** page.
5. Under **Properties**, enter a name for your table bucket.

The table bucket name must:

- Be unique within for your account in the current Region.
- Be between 3 and 63 characters long
- Consist only of lowercase letters, numbers, and hyphens (-).
- Begin and end with a letter or number.

After you create the bucket, you can't change its name. The AWS account that creates the bucket owns it. For information about naming table buckets, see [Amazon S3 table bucket, table, and namespace naming rules](#).

6. If you want to integrate your table buckets with AWS analytics services, make sure **Enable integration** is selected under **Integration with AWS analytics services**.

 **Note**

When you create your first table bucket by using the console with the **Enable integration** option selected, Amazon S3 attempts to automatically integrate your table bucket with AWS analytics services. This integration allows you to use AWS analytics services to query all tables in the current Region. For more information, see [Integrating Amazon S3 Tables with AWS analytics services](#).

7. To configure default encryption, under **Encryption type**, choose one of the following:

- **Server-side encryption with Amazon S3 managed key (SSE-S3)**
- **Server-side encryption with AWS Key Management Service key (SSE-KMS)**

For more information about encryption options for table data, see [Protecting S3 table data with encryption](#).

8. Choose **Create bucket**.

Using the AWS CLI

This example shows how to create a table bucket by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables create-table-bucket \
--region us-east-2 \
--name amzn-s3-demo-bucket1
```

By default S3 table buckets use SSE-S3 as their default encryption setting, however, you can use the optional --encryption-configuration parameter to specify a different encryption type. The following examples shows how to create a bucket that uses SSE-KMS encryption. For more information on encryption settings for table buckets, see [Protecting S3 table data with encryption](#).

```
aws s3tables create-table-bucket \
--region us-east-2 \
--name amzn-s3-demo-bucket1 \
--encryption-configuration '{
    "sseAlgorithm": "aws:kms",
    "kmsKeyArn":
"arn:aws:kms:Region:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab" }'
```

Deleting a table bucket

You can use the Amazon S3 APIs, AWS Command Line Interface, or AWS SDKs to delete a table bucket. Before you delete a table bucket, you must first delete all namespaces and tables within the bucket.

Important

When you delete a table bucket, you need to know the following:

- Bucket deletion is permanent and can't be undone.
- All data and configurations associated with the bucket are permanently lost.

Using the AWS CLI

This example shows how to delete a table bucket by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables delete-table-bucket \
--region us-east-2 \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket1
```

Viewing details about an Amazon S3 table bucket

You can view the general details of an Amazon S3 table bucket, such as bucket owner and type, in the console or programmatically. You can view default encryption settings, and maintenance settings programmatically by using the S3 Tables REST API, AWS CLI or AWS SDKs.

Viewing table bucket details

Using the AWS CLI

This example shows how to get details about a table bucket by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-bucket --table-bucket-arn arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Select your table bucket.
4. Select the **Properties** tab.

Viewing table bucket encryption settings

For more information about table bucket encryption, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in table buckets](#).

Using the AWS CLI

This example shows how to get details about encryption settings for a table bucket by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-bucket-encryption --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

Viewing table bucket maintenance configurations

For information about maintenance settings, see [Maintenance for table buckets](#)

Using the AWS CLI

This example shows how to get details about maintenance configuration settings for a table bucket by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-bucket-maintenance-configuration --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

Managing table bucket policies

You can add, delete, update, and view bucket policies for Amazon S3 table buckets by using the Amazon S3 REST API, AWS SDKs, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

For more information, see the following topics. For more information about supported AWS Identity and Access Management (IAM) actions and condition keys for Amazon S3 Tables, see [Access management for S3 Tables](#). For example bucket policies for table buckets, see [Resource-based policies for S3 Tables](#).

Note

The table bucket policy provides access to the tables stored in the bucket. Table bucket policies don't apply to tables owned by other accounts.

Adding a table bucket policy

To add a bucket policy to a table bucket, use the following AWS CLI example.

Using the AWS CLI

This example shows how to create a table bucket policy by using the AWS CLI. To use the command, replace the *user input placeholders* with your own information.

```
aws s3tables put-table-bucket-policy \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket1 \
    --resource-policy your-policy-JSON
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that you want to add a policy to.
4. Choose the **Permissions** tab.
5. Under **Table bucket policy**, Choose **Edit**.
6. In the policy editor, enter your policy JSON.
7. (Optional) Choose **Policy examples** to see sample policies that you can adapt to your needs.
8. After entering your policy, choose **Save changes**.

Viewing a table bucket policy

To view the bucket policy that's attached to a table bucket, use the following AWS CLI example.

Using the AWS CLI

This example shows how to view the policy that's attached to a table bucket by using the AWS CLI. To use the command, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-bucket-policy --table-bucket-arn arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-bucket1
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that you want to view the policy for.
4. Choose the **Permissions** tab.

Deleting a table bucket policy

To delete a bucket policy that's attached to a table bucket, use the following AWS CLI example.

Using the AWS CLI

This example shows how to delete a table bucket policy by using the AWS CLI. To use the command, replace the *user input placeholders* with your own information.

```
aws s3tables delete-table-bucket-policy --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-bucket1
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that you want to delete a policy for.
4. Choose the **Permissions** tab.
5. Under **Table bucket policy**, choose **Delete**.

Working with AWS managed table buckets

AWS managed table buckets are specialized Amazon S3 table buckets designed to store AWS managed tables, such as [S3 Metadata](#) journal and live inventory tables. Unlike customer-managed table buckets that you create and manage directly, AWS managed table buckets are automatically provisioned by AWS when you configure features that require AWS managed tables. When managed tables are created, they belong to a predefined namespace that's based on the name of the source bucket. This predefined namespace can't be modified.

Each AWS account has one AWS managed table bucket per Region, following the naming convention `aws-s3`. This bucket serves as a centralized location for all managed tables associated with your account's resources in that Region.

The following table compares AWS managed table buckets with customer-managed table buckets.

Feature	AWS managed table buckets	Customer-managed table buckets
Creation	Automatically created by AWS services	You create these manually
Naming	Use a standard naming convention (<code>aws-s3</code>)	You define your own names
Table creation	Only AWS services can create tables	You can create tables
Namespace control	You can't create or delete namespaces (all tables belong to a fixed namespace)	You can create and delete namespaces
Access	Read-only access	Full access
Encryption	You can change the default encryption (SSE-S3) settings only if you encrypted the initial table with a customer managed AWS Key Management Service (AWS KMS) key	You can set bucket-level default encryption and modify it anytime
Maintenance	Managed by AWS services	You can customize automated maintenance at the bucket level

Permissions to work with AWS managed table buckets and to query tables

To work with AWS managed table buckets, you need permissions to create AWS managed table buckets and tables and to specify encryption settings for AWS managed tables. You also need permissions to query the tables in your AWS managed table buckets.

The following example policy allows you to create an AWS managed table bucket through an S3 Metadata configuration:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PermissionsToWorkWithMetadataTables",  
            "Effect": "Allow",  
            "Action": [  
                "s3:CreateBucketMetadataTableConfiguration",  
                "s3tables CreateTableBucket",  
                "s3tables CreateNamespace",  
                "s3tables CreateTable",  
                "s3tables GetTable",  
                "s3tables PutTablePolicy"  
                "s3tables PutTableEncryption",  
                "kms:DescribeKey"  
            ],  
            "Resource": [  
                "arn:aws:s3:::bucket/amzn-s3-demo-source-bucket",  
                "arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3",  
                "arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3/table/*",  
                "arn:aws:kms:us-east-1:111122223333:key/01234567-89ab-cdef-0123-456789abcdef"  
            ]  
        }  
    ]  
}
```

The following example policy allows you to query tables in AWS managed table buckets:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PermissionsToQueryMetadataTables",  
            "Effect": "Allow",  
            "Action": [  
                "s3tables:GetTable",  
                "s3tables:GetTableData",  
                "s3tables:GetTableMetadataLocation",  
                "kms:Decrypt"  
            ],  
            "Resource": [  
                "arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3",  
            ]  
        }  
    ]  
}
```

```
    "arn:aws:s3tables:us-east-1:111122223333:bucket/aws-s3/table/*",
    "arn:aws:kms:us-east-1:111122223333:key/01234567-89ab-
cdef-0123-456789abcdef"
]
}
]
```

Querying tables in AWS managed table buckets

You can query AWS managed tables in AWS managed table buckets using access methods and engines supported by S3 Tables. The following are some example queries.

Using standard SQL

The following example shows how to query AWS managed tables using standard SQL syntax:

```
SELECT *
FROM "s3tablescatalog/aws-s3"."b_amzn-s3-demo-source-bucket"."inventory"
LIMIT 10;
```

The following example shows how to join AWS managed tables with your own tables:

```
SELECT *
FROM "s3tablescatalog/aws-s3"."b_amzn-s3-demo-source-bucket"."inventory" a
JOIN "s3tablescatalog/amzn-s3-demo-table-bucket"."my_namespace"."my_table" b
ON a.key = b.key
LIMIT 10;
```

Using Spark

The following example shows how to query your table with Spark:

```
spark.sql("""
    SELECT *
    FROM ice_catalog.inventory a
    JOIN ice_catalog.my_table b
    ON a.key = b.key
""").show(10, true)
```

The following example shows how to joining your AWS managed table with another table:

```
SELECT *
FROM inventory a
JOIN my_table b
ON a.key = b.key
LIMIT 10;
```

Encryption for AWS managed table buckets

By default, AWS managed table buckets are encrypted with server-side encryption using Amazon S3 managed keys (SSE-S3). After your AWS managed table bucket is created, you can use [PutTableBucketEncryption](#) to set the bucket's default encryption setting to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

During creation of your AWS managed tables, you can choose to encrypt them with SSE-KMS. If you choose to use SSE-KMS, you must provide a customer managed KMS key in the same Region as your AWS managed table bucket. You can set the encryption type for your AWS managed tables only during table creation. After an AWS managed table is created, you can't change its encryption setting.

If you want the AWS managed table bucket and the tables stored in it to use the same KMS key, make sure to use the same KMS key that you used to encrypt your tables to encrypt your table bucket after it's been created. After you've changed the default encryption settings for your table bucket to use SSE-KMS, those encryption settings are used for any future tables that are created in the bucket.

Using tags with S3 table buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 table buckets. You can tag S3 table buckets when you create them or manage tags on existing table buckets. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

Note

There is no additional charge for using tags on table buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with table buckets

Use tags on your S3 table buckets for:

Attribute-based access control (ABAC) – Scale access permissions and grant access to S3 table buckets based on their tags. For more information, see [Using tags for ABAC](#).

ABAC for S3 table buckets

Amazon S3 table buckets support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, AWS Identity and Access Management (IAM), and S3 table bucket policies. ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 table buckets based on the table bucket's tags by using the `s3tables:TableBucketTag/tag-key` condition key or the [AWS global condition keys](#): `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys`.

aws:ResourceTag/key-name

Use this condition key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a table bucket is allowed only if the table bucket has the tag key `Department` with the value `Marketing`.

This condition key applies to all table bucket actions that are performed using the Amazon S3 Console, the AWS Command Line Interface (CLI), S3 APIs, or the AWS SDKs, except for the `CreateBucket` API request.

For an example policy, see [1.1 - table bucket policy to restrict operations on the tables inside of the table bucket using tags](#).

For additional example policies and more information, see [Controlling access to AWS resources](#) in the *AWS Identity and Access Management User Guide*.

Note

For actions performed on tables, this condition key acts on the tags applied to the table and not on the tags applied to the table bucket containing the table. Use the `s3tables:TableBucketTag/tag-key` instead if you would like your ABAC policies to act on the tags of the table bucket when performing table actions.

aws:RequestTag/key-name

Use this condition key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request to tag a table bucket includes the tag key Department and that it has the value Accounting.

This condition key applies when tag keys are passed in a TagResource or CreateTableBucket API operation request, or when tagging or creating a table bucket with tags using the Amazon S3 Console, the AWS Command Line Interface (CLI), or the AWS SDKs.

For an example policy, see [1.2 - IAM policy to create or modify table buckets with specific tags](#).

For additional example policies and more information, see [Controlling access during AWS requests](#) in the *AWS Identity and Access Management User Guide*.

aws:TagKeys

Use this condition key to compare the tag keys in a request with the keys that you specify in the policy to define what tag keys are allowed for access. For example, to allow tagging during the CreateTableBucket action, you must create a policy that allows both the s3tables:TagResource and s3tables>CreateTableBucket actions. You can then use the aws:TagKeys condition key to enforce that only specific tags are used in the CreateTableBucket request.

This condition key applies when tag keys are passed in a TagResource, UntagResource, or CreateTableBucket API operations or when tagging, untagging, or creating a table bucket with tags using the Amazon S3 Console, the AWS Command Line Interface (CLI), or the AWS SDKs.

For an example policy, see [1.3 - IAM policy to control the modification of tags on existing resources maintaining tagging governance](#).

For additional example policies and more information, see [Controlling access based on tag keys](#) in the *AWS Identity and Access Management User Guide*.

s3tables:TableBucketTag/tag-key

Use this condition key to grant permissions to specific data in table buckets using tags. This condition key acts, on the most part, on the tags assigned to the table bucket for all S3 tables actions. Even when you create a table with tags, this condition key acts on the tags applied to the table bucket that contains that table. The exceptions are:

- When you create a table bucket with tags, this condition key acts on the tags in the request.

For an example policy, see [1.4 - Using the s3tables:TableBucketTag condition key](#).

Example ABAC policies for table buckets

See the following example ABAC policies for Amazon S3 table buckets.

Note

If you are using Lake Formation to manage access to your Amazon S3 Tables and you have an IAM or S3 Tables resource-based policy that restricts IAM users and IAM roles based on principal tags, you must attach the same principal tags to the IAM role that Lake Formation uses to access your Amazon S3 data (for example, `LakeFormationDataAccessRole`) and grant this role the necessary permissions. This is required for your tag-based access control policy to work correctly with your S3 Tables analytics integration.

1.1 - table bucket policy to restrict operations on the tables inside of the table bucket using tags

In this table bucket policy, the specified IAM principals (users and roles) can perform the `GetTable` action on any table in the table bucket only if the value of the table's project tag matches the value of the principal's project tag.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowGetTable",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "111122223333"  
            },  
            "Action": "s3tables:GetTable",  
            "Resource": "arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/project": "${aws:PrincipalTag/project}"  
                }  
            }  
        }  
    ]  
}
```

```
    }
}
]
}
```

1.2 - IAM policy to create or modify table buckets with specific tags

Note

If you are using AWS Lake Formation to manage access to your Amazon S3 tables, and you are using ABAC with Amazon S3 Tables, make sure that you also give the IAM role that Lake Formation assumes the required access. For more information on setting up the IAM role for Lake Formation, see [Prerequisites for integrating Amazon S3 tables catalog with the Data Catalog and Lake Formation](#) in the *AWS Lake Formation developer guide*.

In this IAM policy, users or roles with this policy can only create S3 table buckets if they tag the table bucket with the tag key `project` and tag value `Trinity` in the table bucket creation request. They can also add or modify tags on existing S3 table buckets as long as the `TagResource` request includes the tag key-value pair `project:Trinity`. This policy does not grant read, write, or delete permissions on the table buckets or its objects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateTableBucketWithTags",
      "Effect": "Allow",
      "Action": [
        "s3tables:CreateTableBucket",
        "s3tables:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/projectTrinity"
          ]
        }
      }
    }
  ]
}
```

```
]  
}
```

1.3 - IAM policy to control the modification of tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a table bucket only if the value of the table bucket's project tag matches the value of the principal's project tag. Only the four tags project, environment, owner, and cost-center specified in the aws:TagKeys condition keys are permitted for these table buckets. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your table buckets.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceTaggingRulesOnModification",
      "Effect": "Allow",
      "Action": [
        "s3tables:TagResource",
        "s3tables:UntagResource"
      ],
      "Resource": "arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
            "project",
            "environment",
            "owner",
            "cost-center"
          ]
        }
      }
    }
  ]
}
```

1.4 - Using the s3tables:TableBucketTag condition key

In this IAM policy, the condition statement allows access to the table bucket's data only if the table bucket has the tag key Environment and tag value Production. The s3tables:TableBucketTag/<tag-key> differs from the aws:ResourceTag/<tag-key> condition key because, in addition to controlling access to table buckets depending on their tags, it allows you to control access to tables based on the tags on their parent table bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAccessToSpecificTables",  
            "Effect": "Allow",  
            "Action": "*",

Managing tags for table buckets

You can add or manage tags for S3 table buckets using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see the following:

Topics

- [Creating table buckets with tags](#)
- [Adding a tag to a table bucket](#)
- [Viewing table bucket tags](#)
- [Deleting a tag from a table bucket](#)

Creating table buckets with tags

You can tag Amazon S3 table buckets when you create them. There is no additional charge for using tags on table buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging table buckets, see [Using tags with S3 table buckets](#).

Permissions

To create a table bucket with tags, you must have the following permissions:

- `s3tables:CreateTableBucket`
- `s3tables:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a table bucket with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the table bucket and apply a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. Your policy may require you to tag your table buckets with only specific tag keys and values. For more information about ABAC and example table bucket ABAC policies, see [ABAC for S3 table buckets](#).

Steps

You can create a table bucket with tags applied by using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and the AWS SDKs.

Using the S3 console

To create a table bucket with tags using the Amazon S3 console:

1. Sign in to the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. To create a new table bucket, choose **Create table bucket**.
4. Enter a name for the table bucket. For more information, see [Amazon S3 table bucket, table, and namespace naming rules](#).

5. On the **Create table bucket** page, there is a **Tags** section.
6. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
7. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
8. Specify the remaining options for your new table bucket. For more information, see [Creating a table bucket](#).
9. Choose **Create table bucket**.

Using the REST API

For information about the Amazon S3 Tables REST API support for creating a table bucket with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- [CreateTableBucket](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a table bucket with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create a table bucket you must provide configuration details. For more information, see [Creating a table bucket](#). You must also name the table bucket with a name that follows the table bucket naming convention. For more information see [Amazon S3 table bucket, table, and namespace naming rules](#).

Request:

```
aws --region us-west-2 \
s3tables create-table-bucket \
--tags '{"Department":"Engineering"}' \
--name amzn-s3-demo-table-bucket
```

Adding a tag to a table bucket

You can add tags to Amazon S3 table buckets and modify these tags. For more information about tagging table buckets, see [Using tags with S3 table buckets](#).

Permissions

To add a tag to a table bucket, you must have the following permission:

- `s3tables:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a table bucket, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to a table bucket.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws :`, change the tag key and try again.
- The tag key is required. Also, make sure that the tag key and the tag value do not exceed the maximum character length and do not contain restricted characters. For more information, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

Steps

You can add tags to table buckets by using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and the AWS SDKs.

Using the S3 console

To add tags to a table bucket using the Amazon S3 console:

1. Sign in to the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the table bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.

9. After you have added the tag(s), choose **Save changes**.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a table bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a table bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws --region us-west-2 \
s3tables tag-resource \
--resource-arn arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket \
--tags '{"Department":"Engineering"}'
```

Viewing table bucket tags

You can view or list tags applied to Amazon S3 table buckets. For more information about tagging table buckets, see [Using tags with S3 table buckets](#).

Permissions

To view tags applied to a table bucket, you must have the following permission:

- s3tables>ListTagsForResource

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a table bucket, you can do the following:

- Verify that you have the required [Permissions](#) to view the tags of the table bucket.

Steps

You can view tags applied to table buckets by using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To view tags applied to a table bucket using the Amazon S3 console:

1. Sign in to the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the table bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the table bucket.
6. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your table bucket by AWS services.

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a table bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [ListTagsForResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a table bucket. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws --region us-west-2 \
s3tables list-tags-for-resource \
```

```
--resource-arn arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/table/example_table
```

Response - tags present:

```
{  
    "tags": {  
        "project": "Trinity",  
        "code": "123456"  
    }  
}
```

Response - no tags present:

```
{  
    "Tags": []  
}
```

Deleting a tag from a table bucket

You can remove tags from Amazon S3 table buckets. For more information about tagging table buckets, see [Using tags with S3 table buckets](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the table bucket.

Permissions

To delete a tag from a table bucket, you must have the following permission:

- s3tables:UntagResource

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a table bucket, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from a table bucket.

Steps

You can delete tags from table buckets by using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and the AWS SDKs.

Using the S3 console

To delete tags from a table bucket using the Amazon S3 console:

1. Sign in to the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the table bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a table bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [UntagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a table bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws --region us-west-2 \
s3tables untag-resource \
```

```
--resource-arn arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket \
--tags-keys '[{"Department"}]'
```

S3 Tables maintenance

Amazon S3 automatically performs maintenance to enhance the performance of your tables in S3 table buckets. Maintenance is performed at the table bucket and individual table level and includes the following:

Table bucket-level maintenance:

- **Unreferenced file removal** – Cleans up orphaned files to optimize storage usage and costs.

Table-level maintenance:

- **File compaction** – Consolidates small files to improve query performance and reduce storage costs.
- **Snapshot management** – Controls table version history and prevents excessive metadata growth.

These options are enabled by default. You can edit or disable these operations through maintenance configuration files.

In addition to these options, you can also enable and configure record expiration settings for tables. With this option, Amazon S3 automatically removes records from a table when the records expire.

S3 Tables maintenance job status

S3 Tables maintenance jobs run periodically for your S3 tables or table buckets. You can query the status of these jobs with the GetTableMaintenanceJobStatus API.

To get the status of your maintenance jobs by using the AWS CLI

The following example will get the statuses of maintenance jobs using the GetTableMaintenanceJobStatus API.

```
aws s3tables get-table-maintenance-job-status \
--table-bucket-arn="arn:aws:s3tables:arn:aws::111122223333:bucket/amzn-s3-demo-bucket1" \
--namespace="mynamespace" \
--name="testtable"
```

For more information, see [get-table-maintenance-job-status](#) in the *AWS CLI Command Reference*.

S3 Tables maintenance jobs can transition between four possible statuses:

- Successful
- Failed
- Disabled
- Not_Yet_Run

Jobs with a failed status will include a failure message. The following list describes possible failure messages.

- Encountered Iceberg validation exception when trying to read table. Ensure that your table is readable, adheres to the Iceberg specification, and contains only S3 paths that begin with your S3 Table alias.
- Iceberg Snapshot management does not currently support user defined tags or references.
- Iceberg table maintenance configuration is incompatible with 'history.expire.max-snapshot-age-ms' and 'history.expire.min-snapshots-to-keep' table properties.
- Iceberg snapshot management and unreferenced file removal is not supported when the 'gc.enabled' table property is false. Ensure that this property is unset or explicitly set to true.

- Failed to commit because of out of date metadata. Maintenance will be retried at the next available opportunity.
- Insufficient access to perform table maintenance. Ensure that the key used to encrypt the table is active, exists, and has a resource policy granting access to the S3 service principal `maintenance.s3tables.amazonaws.com`.

 **Note**

For more information on AWS KMS permissions for S3 Tables, see [Permission requirements for S3 Tables SSE-KMS encryption](#).

Maintenance for table buckets

Amazon S3 offers maintenance operations to enhance the management and performance of your table buckets. The following option is enabled by default for all table buckets. You can edit or disable this option by specifying a maintenance configuration file for your table bucket.

Editing this configuration requires the `s3tables:PutTableBucketMaintenanceConfiguration` permission.

Topics

- [Unreferenced file removal](#)
- [Consideration and limitations](#)

Unreferenced file removal

Unreferenced file removal identifies and deletes all objects that are not referenced by any table snapshots. As part of your unreferenced file removal policy, you can configure two properties: `unreferencedDays` (3 days by default) and `nonCurrentDays` (10 days by default).

For any object not referenced by your table and older than the `unreferencedDays` property, S3 marks the object as noncurrent. S3 deletes noncurrent objects after the number of days specified by the `nonCurrentDays` property.

Note

Deletes of noncurrent objects are permanent with no way to recover these objects.

To view or recover objects that have been marked as noncurrent, you must contact AWS Support. For information about contacting AWS Support, see [Contact AWS](#) or the [AWS Support Documentation](#).

Unreferenced file removal determines the objects to delete from your table with reference only to that table. Any reference made to these objects outside of the table will not prevent unreferenced file removal from deleting an object.

If you disable unreferenced file removal, any in-progress jobs will not be affected. The new configuration will take effect for the next job after the configuration change. For more information, see the pricing information in the [Amazon S3 pricing](#).

You can only configure unreferenced file removal at the table bucket level. This configuration will apply to every table in your bucket.

To configure unreferenced file removal by using the AWS CLI

The following example will set the `unreferencedDays` to 4 days and the `nonCurrentDays` to 10 days using the `PutTableBucketMaintenanceConfiguration` API.

```
aws s3tables put-table-bucket-maintenance-configuration \
  --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
  table-bucket \
  --type icebergUnreferencedFileRemoval \
  --value '{"status":"enabled","settings":{"icebergUnreferencedFileRemoval": {
    "unreferencedDays":4,"nonCurrentDays":10}}}'
```

For more information, see [put-table-bucket-maintenance-configuration](#) in the *AWS CLI Command Reference*.

Consideration and limitations

To learn more about additional consideration and limits for unreferenced file removal, see [the section called “Considerations and limitations”](#).

Maintenance for tables

S3 Tables offers maintenance operations to enhance the management and performance of your individual tables. The following options are enabled by default for all tables in table buckets. You can edit or disable these by specifying maintenance configuration files for your S3 table.

Editing this configuration requires the `s3tables:GetTableMaintenanceConfiguration` and `s3tables:PutTableMaintenanceConfiguration` permissions.

 **Note**

You can track S3 Tables automated maintenance operations on your tables through CloudTrail logs, for more information, see [CloudTrail management events for S3 Tables maintenance](#).

Topics

- [Compaction](#)
- [Snapshot management](#)
- [Consideration and limitations](#)

Compaction

Compaction is configured at the table level and combines multiple smaller objects into fewer, larger objects to improve Apache Iceberg query performance. When combining objects, compaction also applies the effects of row-level deletes in your table.

Compaction is enabled by default for all tables, with a default target file size of 512MB, or a custom value you specify between 64MB to 512MB. The compacted files are written as the most recent snapshot of your table.

 **Note**

Compaction is supported on Apache Parquet, Avro, and ORC file types.

Compaction Strategies

You can choose from multiple compaction strategies which can further increase query performance depending on your query patterns and table sort order.

S3 Tables supports these compaction strategies for tables:

- **Auto (Default)**
 - Amazon S3 selects the best compaction strategy based on your table sort order. This is the default compaction strategy for all tables.
 - For tables with a defined sort order in their metadata, auto will automatically apply sort compaction.
 - For tables without a sort order, auto will default to using binpack compaction.
- **Binpack**
 - Combines small files into larger files, typically targeting sizes over 100MB, while applying any pending deletes. This is the default compaction strategy for unsorted tables.
- **Sort**
 - Organizes data based on specified columns which are sorted automatically by hierarchy during compaction, improving query performance for filtered operations. This strategy is recommended when your queries frequently filter on specific columns. When you use this strategy, S3 Tables automatically applies hierarchical sorting on columns when a `sort_order` is defined in table properties.
- **Z-order**
 - Optimizes data organization by blending multiple attributes into a single scalar value that can be used for sorting, allowing efficient querying across multiple dimensions. This strategy is recommended when you need to query data across multiple dimensions simultaneously. This strategy requires you to define a sort order in your Iceberg table properties using the `sort_order` table property.

Compaction will incur additional costs. The `z-order` and `sort` compaction strategies may incur a higher cost than `binpack`. For more information, see the pricing information in the [Amazon S3 pricing](#).

Compaction Examples

The following examples show configurations for table compaction.

To configure the compaction target file size by using the AWS CLI

The minimum target compaction file size is 64MB; the maximum is 512MB.

The following example will change the target file size to 256MB using the PutTableMaintenanceConfiguration API.

```
aws s3tables put-table-maintenance-configuration \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket1 \
--type icebergCompaction \
--namespace mynamespace \
--name testtable \
--value='{"status":"enabled","settings":{"icebergCompaction": {
"targetFileSizeMB":256}}}'
```

For more information, see [put-table-maintenance-configuration](#) in the *AWS CLI Command Reference*.

To configure the compaction strategy by using the AWS CLI

The following example will change the compaction strategy to sort using the PutTableMaintenanceConfiguration API. When setting compaction you can choose from the following compaction strategies: auto,binpack,sort, or z-order

Note

To set the compaction strategy to sort or z-order you need the following prerequisites:

- A sort order defined in your Iceberg table properties.
- The s3tables:GetTableData permission.

```
aws s3tables put-table-maintenance-configuration \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket \
--type icebergCompaction \
--namespace mynamespace \
--name testtable \
--value='{"status":"enabled","settings":{"icebergCompaction": {
"strategy":"sort"}}}'
```

For more information, see [put-table-maintenance-configuration](#) in the *AWS CLI Command Reference*.

To disable compaction by using the AWS CLI

The following example will disable compaction using the PutTableMaintenanceConfiguration API.

```
aws s3tables put-table-maintenance-configuration \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket \
    --type icebergCompaction \
    --namespace mynamespace \
    --name testtable \
    --value='{"status":"disabled","settings":{"icebergCompaction": \
    {"targetFileSizeMB":256}}}'
```

For more information, see [put-table-maintenance-configuration](#) in the *AWS CLI Command Reference*.

Snapshot management

Snapshot management determines the number of active snapshots for your table. This is based on the MinimumSnapshots (1 by default) and MaximumSnapshotAge (120 hours by default). Snapshot management expires and removes table snapshots based on these configurations.

When a snapshot expires, Amazon S3 marks any objects referenced only by that snapshot as noncurrent. These noncurrent objects are deleted after the number of days specified by the NoncurrentDays property in your unreferenced file removal policy.

Note

Deletes of noncurrent objects are permanent with no way to recover these objects.

To view or recover objects that has been marked as noncurrent you must contact AWS Support. For information about contacting AWS Support, see [Contact AWS](#) or the [AWS Support Documentation](#).

Snapshot management determines the objects to delete from your table with references only to that table. References to these objects from outside the table will not prevent snapshot management from deleting them.

Note

Snapshot management does not support retention values you configure as Iceberg table properties in the `metadata.json` file or through an `ALTER TABLE SET TBLPROPERTIES` SQL command, including branch or tag-based retention. Snapshot management is disabled when you configure a branch or tag-based retention policy, or configure a retention policy on the `metadata.json` file that is longer than the values configured through the `PutTableMaintenanceConfiguration` API. In these cases S3 will not expire or remove snapshots and you will need to manually delete snapshots or remove the properties from your Iceberg table to avoid storage charges.

You can only configure snapshot management at the table level. For more information, see the pricing information in the [Amazon S3 pricing](#).

Snapshot Management Examples

The following examples show configurations for table snapshot management.

To configure the snapshot management by using the AWS CLI

The following example will set the `MinimumSnapshots` to 10 and the `MaximumSnapshotAge` to 2500 hours using the `PutTableMaintenanceConfiguration` API.

```
aws s3tables put-table-maintenance-configuration \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket \
--namespace my_namespace \
--name my_table \
--type icebergSnapshotManagement \
--value '{"status":"enabled","settings":{"icebergSnapshotManagement": {"minSnapshotsToKeep":10,"maxSnapshotAgeHours":2500}}}'
```

To disable snapshot management by using the AWS CLI

The following example will disable snapshot management using the `PutTableMaintenanceConfiguration` API.

```
aws s3tables put-table-maintenance-configuration \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket \
```

```
--namespace my_namespace \
--name my_table \
--type icebergSnapshotManagement \
--value '{"status":"disabled","settings":{"icebergSnapshotManagement": {"minSnapshotsToKeep":1,"maxSnapshotAgeHours":120}}}'
```

For more information, see [put-table-maintenance-configuration](#) in the *AWS CLI Command Reference*.

Consideration and limitations

To learn more about additional consideration and limits for compaction and snapshot management, see [the section called “Considerations and limitations”](#).

Note

S3 Tables applies the parquets row-group-default size of 128 MB.

Record expiration for tables

By default, records in your S3 tables don't expire. To help minimize storage costs for your tables, you can enable and configure record expiration for the tables. With this option, Amazon S3 automatically removes records from a table when the records expire.

If you enable record expiration for a table, you specify the number of days to retain records in the table before the records expire. This can be any number of days ranging from 1 day through 2,147,483,647 days. For example, to retain table records for one year, specify 365 days. The records then persist for 365 days. After 365 days, the records expire and Amazon S3 automatically removes them.

You can enable and configure record expiration for AWS managed tables that store specific data sets from certain AWS services, currently Amazon S3 Storage Lens and Amazon SageMaker Catalog. Record expiration options aren't currently available for other AWS managed tables. The exception is Amazon S3 metadata journal tables. Journal tables use distinct record expiration settings that you specify at the service level. For information about configuring record expiration for this type of table, see [Expiring journal table records](#). Note that record expiration options aren't available for S3 tables that you create.

After you enable record expiration for a table, you can disable it at any time. Amazon S3 then stops expiring and removing records from the table.

Topics

- [Configuring record expiration for a table](#)
- [Monitoring record expiration for a table](#)
- [Considerations](#)

How record expiration works

Record expiration automatically removes records from an S3 table when the records are older than the number of days that you specify in the record expiration settings for the table. To determine when records expire, Amazon S3 uses specific timestamps in the records. The choice of timestamp column derives directly from the table schema for a table. You don't need to specify which timestamp column to use. The tables are managed by AWS and Amazon S3 automatically chooses the appropriate column to use when you enable record expiration for a table.

You can enable and configure record expiration settings for AWS managed tables that store specific Amazon S3 Storage Lens metrics or specific Amazon SageMaker Catalog metadata. Record expiration options are available for the following AWS managed tables for those services:

- S3 Storage Lens – `bucket_property_metrics`, `default_activity_metrics`, `default_storage_metrics`, `expanded_prefixes_activity_metrics`, and `expanded_prefixes_storage_metrics`. To determine when records in these tables expire, Amazon S3 uses the `report_time` field in the records.
- Amazon SageMaker Catalog – ASSET. To determine when records in this table expire, Amazon S3 uses the `snapshot_time` field in the records.

After you enable record expiration for a table, Amazon S3 starts running record expiration jobs that perform the following operations for the table:

1. Identify records that are older than the specified expiration setting.
2. Create a new snapshot that excludes references to the expired records.

Removal is also based on snapshot expiration and unreferenced file removal settings in the maintenance configuration settings for the table. To learn more about these settings, see [Maintenance for tables](#).

Warning

Amazon S3 expires and removes records within 24 to 48 hours after the records become eligible for expiration. Table records are removed from the latest snapshot. Data and storage for the records are removed through table maintenance operations. Table records can't be recovered after they expire.

Configuring record expiration for a table

You can enable, configure, and otherwise manage the record expiration settings for an S3 table by using the Amazon S3 console, Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

Before you try to perform these tasks for a table, make sure that you have the following AWS Identity and Access Management (IAM) permissions:

- `s3tables:GetTableRecordExpirationConfiguration` – This action allows you to access current record expiration settings for tables.
- `s3tables:PutTableRecordExpirationConfiguration` – This action allows you to enable, configure, and disable record expiration settings for tables.
- `s3tables:GetTableRecordExpirationJobStatus` – This action allows you to monitor the status of record expiration operations (jobs) for tables and access metrics for the operations.

The following sections explain how to enable, configure, and disable record expiration settings for a table by using the Amazon S3 console and the AWS CLI. To perform these tasks with the Amazon S3 REST API or an AWS SDK, use the [PutTableRecordExpirationConfiguration](#) operation. For more information, see [Developing with Amazon S3](#) in the *Amazon Simple Storage Service API Reference*.

Using the S3 console

To enable and configure record expiration settings for an S3 table by using the console, follow these steps.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that stores the table.
4. On the **Tables** tab, choose the table.
5. On the **Maintenance** tab, in the **Record expiration** section, choose **Edit**.
6. Under **Record expiration**, choose **Enable**.
7. For **Days after which records expire**, enter the number of days to retain records in the table. This can be any whole number ranging from 1 through 2,147,483,647. For example, to retain records for one year, enter **365**.

 **Warning**

As you determine the appropriate retention period for records in the table, note that records can't be recovered after they expire.

8. Choose **Save changes**.

To subsequently change the retention period, repeat the preceding steps.

To subsequently disable record expiration, repeat steps 1 through 5. Then, for step 6, choose **Disable**. When you finish, choose **Save changes**.

Using the AWS CLI

To configure and manage record expiration settings for an S3 table by using the AWS CLI, run the [put-table-record-expiration-configuration](#) command.

You can start by creating a JSON file that contains the record expiration settings to apply to the table. The following example shows the contents of a JSON file that enables record expiration for a table. It also specifies a retention period of 30 days for records in the table. In other words, it specifies that table records should expire after 30 days.

```
{  
    "status": "enabled",  
    "settings": {  
        "days": 30  
    }  
}
```

```
}
```

To use the preceding example, replace the *user input placeholders* with your own information.

Warning

As you determine the appropriate retention period for records in the table, note that records can't be recovered after they expire.

To disable record expiration for a table, specify disabled for the status field and omit the settings object from the file. For example:

```
{
  "status": "disabled"
}
```

After you create a JSON file with the settings to apply, run the `put-table-record-expiration-configuration` command. For the `table-arn` parameter, specify the Amazon Resource Name (ARN) of the table. For the `value` parameter, specify the name of the file that stores the settings.

For example, the following command updates the record expiration settings for a table. The settings are specified in a file named `record-expiration-config.json`.

```
aws s3tables put-table-record-expiration-configuration \
  --table-arn arn:aws:s3tables:us-east-1:123456789012:bucket/amzn-s3-demo-table-
  bucket/table/amzn-s3-demo-table \
  --value file://./record-expiration-config.json
```

To use the preceding example, replace the *user input placeholders* with your own information.

Monitoring record expiration for a table

To monitor the status and results of record expiration operations for your S3 tables, use the [GetTableRecordExpirationJobStatus](#) operation or, if you're using the AWS CLI, run the [get-table-record-expiration-job-status](#) command. In your request, specify the Amazon Resource Name (ARN) of the table.

For example, the following AWS CLI command retrieves the status of record expiration operations for a specific table in a table bucket. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-record-expiration-job-status \
--table-arn arn:aws:s3tables:us-east-1:123456789012:bucket/amzn-s3-demo-table-
bucket/table/amzn-s3-demo-table
```

If your request succeeds, you receive a response that provides details such as when Amazon S3 most recently ran record expiration operations for the table and the status of that run. If the most recent run succeeded, the response also includes processing metrics—for example, the number of data files and records that were removed, and the total size of the data that was removed. If errors occurred during the most recent run, the response includes a failure message that describes why the run failed.

Considerations

As you configure and manage record expiration settings for your AWS managed S3 tables, keep the following in mind:

- Record expiration is available only for certain AWS managed tables created by supported AWS services, Amazon S3 Storage Lens and Amazon SageMaker Catalog. In addition, record expiration is available only for individual tables, not entire table buckets.
- To determine when records expire, Amazon S3 uses specific timestamps in the tables. These timestamps represent when the data was created, not when Amazon S3 ingested the records in a table. The timestamp column that's used depends on the service that publishes the table: for S3 Storage Lens metrics, the `report_time` field; and, for Amazon SageMaker Catalog metadata, the `snapshot_time` field. You cannot specify which field to use because the tables are managed by AWS.
- If there are delays when data is exported to a table, records might become eligible for expiration sooner than you expect. For this reason, we recommend that you account for potential ingestion delays by adding buffer to the retention period in the expiration settings for your tables.
- Records expire and are removed within 24 to 48 hours after they become eligible for expiration. Amazon S3 doesn't expire and remove records immediately after they become eligible for expiration.
- Records cannot be recovered after they expire and are removed.

Considerations and limitations for maintenance jobs

Amazon S3 offers maintenance operations to enhance the performance of your S3 tables or table buckets. These options are file compaction, snapshot management, and unreferenced file removal. The following are limitations and consideration for these management options.

Topics

- [Considerations for compaction](#)
- [Considerations for snapshot management](#)
- [Considerations for unreferenced file removal](#)
- [S3 table and table buckets maintenance operations limits and related APIs](#)

Considerations for compaction

The following considerations apply to compaction. For more information about compaction, see [the section called “Table maintenance”](#).

- Compaction is supported on Apache Parquet, Avro, and ORC file types.
- Compaction writes new files in Apache Parquet format by default. To compact files into Avro or ORC formats instead, set the `write.format.default` table property to `avro` or `orc`.
- Compaction doesn't support data type: Fixed.
- Compaction doesn't support compression types: brotli, lz4.
- Compaction occurs on an automated schedule. If you want to prevent charges associated with compaction you can manually disable it for a table using the [PutTableMaintenanceConfiguration](#) API operation.

Note

Apache Iceberg uses an optimistic concurrency model along with conflict detection to arbitrate write transactions. With optimistic concurrency, user and compaction transactions can conflict causing transactions to fail. If conflicts occur, compaction jobs will retry on failure. It is recommended that your pipelines also use retry logic to overcome transactions that fail from conflicting operations.

Considerations for snapshot management

The following considerations apply to snapshot management. For more information about snapshot management, see [the section called “Table maintenance”](#).

- Snapshots will be preserved only when both criteria are satisfied: the minimum number of snapshots to keep and the specified retention period.
- Snapshot management deletes expired snapshot metadata from Apache Iceberg, preventing time travel queries for expired snapshots and optionally deleting associated data files.
- Snapshot management does not support retention values you configure as Iceberg table properties in the `metadata.json` file or through an `ALTER TABLE SET TBLPROPERTIES` SQL command, including branch or tag-based retention. Snapshot management is disabled when you configure a branch or tag-based retention policy, or configure a retention policy on the `metadata.json` file that is longer than the values configured through the `PutTableMaintenanceConfiguration` API. In these cases S3 will not expire or remove snapshots and you will need to manually delete snapshots or remove the properties from your Iceberg table to avoid storage charges.

Considerations for unreferenced file removal

The following considerations apply to unreferenced file removal. For more information about unreferenced file removal, see [the section called “Table bucket maintenance”](#).

- Unreferenced file removal deletes data and metadata files that are no longer referenced by Iceberg metadata if their creation time is before the retention period.

Cost optimization for tables with Intelligent-Tiering

You can automatically optimize storage costs for tables by using S3 Intelligent-Tiering. The S3 Tables Intelligent-Tiering storage class automatically moves data to the most cost-effective access tier when access patterns change. When you use S3 Intelligent-Tiering, data accessed less frequently is automatically moved to lower-cost tiers, and moved back to the Frequent Access tier whenever you access it again.

All data is moved between tiers without retrieval fees, performance impact, or changes to availability. Additionally, table maintenance operations such as compaction are optimized based on access patterns, processing only actively accessed data in the Frequent Access tier while reducing maintenance costs on less frequently accessed data in lower-cost tiers.

S3 Tables Intelligent-Tiering access tiers

When your table is stored in the S3 Intelligent-Tiering storage class, Amazon S3 continuously monitors access patterns and automatically moves table data between access tiers.

Tiering happens at the individual file level, so a single table can have files in different tiers based on access patterns. Table data is automatically moved to one of the following access tiers based on access patterns:

- **Frequent Access:** The default tier for all files. Files in other tiers automatically move back to the Frequent Access tier when accessed.
- **Infrequent Access:** If you do not access a file for 30 consecutive days, it moves to the Infrequent Access tier.
- **Archive Instant Access:** If you do not access a file for 90 consecutive days, it moves to the Archive Instant Access tier.

All tiers provide millisecond latency, high throughput performance, and are designed for 99.9% availability and 99.99999999% durability.

Auto-tiering behavior with S3 Intelligent-Tiering

The following actions constitute access that automatically moves files from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier:

- Any read or write operations on table data or metadata files using `GetObject`, `PutObject`, or `CompleteMultipartUpload` actions
- `LoadTable` or `UpdateTable` actions using [Iceberg REST API Operations](#)
- S3 Tables replication operations

Other actions don't constitute access that automatically moves files from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier.

 **Note**

Files smaller than 128 KB are not eligible for auto-tiering and remain in the Frequent Access tier. Compaction may combine these files into fewer, larger objects and commit them back to your table as a new snapshot. The newly compacted files become eligible for auto-tiering if the new file is 128 KB or larger.

Table maintenance behavior

Automatic table maintenance operations performed by Amazon S3, such as snapshot management, unreferenced file removal, and record expiration, continue to run on your tables regardless of tier. Compaction runs only on files in the Frequent Access tier, optimizing performance for frequently accessed data while reducing maintenance costs on data in lower-cost tiers.

Maintenance operations do not affect the access tier of files in your table. Reads performed by maintenance operations do not cause files to change tiers. However, if a maintenance operation, such as compaction or record expiration, writes a new file, that file is created in the Frequent Access tier.

Note

Because compaction only processes files in the Frequent Access tier, delete operations on data in lower-cost tiers create delete files that are not automatically compacted. These delete files become eligible for compaction when the associated data files are accessed and move back to the Frequent Access tier. For tables that are not frequently accessed, you can manually run compaction using Amazon EMR to compact these delete files with their associated data files. For more information, see [Maintaining tables by using compaction](#). You can monitor file growth in your table using Amazon CloudWatch metrics to determine when manual compaction may be beneficial.

Specifying S3 Intelligent-Tiering as your storage class

By default, all tables are created in the S3 Standard storage class and cannot be moved to S3 Intelligent-Tiering. To use S3 Intelligent-Tiering, you must specify it at table creation. You can also set S3 Intelligent-Tiering as the default storage class for your table bucket to automatically store any new tables created there in the S3 Intelligent-Tiering storage class.

Specifying S3 Intelligent-Tiering for table buckets

You can specify S3 Intelligent-Tiering as the default storage class when creating a new table bucket by using the `storage-class-configuration` header with the `CreateTableBucket` operation.

To check the default storage class on an existing table bucket, use the `GetTableBucketStorageClass` operation. To modify the default storage class of an existing table bucket, use the `PutTableBucketStorageClass` operation.

Note

When you modify the default storage class on a table bucket, that setting applies only to new tables created in that bucket. The storage class for pre-existing tables is not changed.

Specifying S3 Intelligent-Tiering for tables

You can specify S3 Intelligent-Tiering as the storage class when creating a new table using the `storage-class-configuration` header with the `CreateTable` operation.

If you do not specify a storage class at table creation, the table is created in the default storage class configured on the table bucket at that time. Once a table is created, you cannot modify its storage class.

To check the default storage class on an existing table bucket, use the `GetTableBucketStorageClass` operation.

Monitoring storage usage

You can view your storage usage breakdown by access tier in the AWS Cost and Usage Reports for your account. For more information, see [Creating Cost and Usage Reports](#) in the *AWS Data Exports User Guide*.

The following usage types are available in your billing reports:

Usage Type	Unit	Granularity	Description

Table namespaces

When you create tables within your Amazon S3 table bucket, you organize them into logical groupings called *namespaces*. Unlike S3 tables and table buckets, namespaces aren't resources. Namespaces are constructs that help you organize and manage your tables in a scalable manner. For example, all the tables belonging to the human resources department in a company could be grouped under a common namespace value of hr.

To control access to specific namespaces, you can use table bucket resource policies. For more information, see [the section called “Resource-based policies”](#).

The following rules apply to table namespaces:

- Each namespace must be unique within a table bucket.

- You can create up to 10,000 namespaces per table bucket.
- Each table name must be unique within a namespace.
- Each table can have only one level of namespaces. Namespaces can't be nested.
- Each table belongs to a single namespace.
- You can move your tables between namespaces.

Table namespaces are referred to as databases in various AWS services and query engines. The following table maps the terminology used for S3 Tables namespaces to some common engines and services.

Service or Engine	Terminology
AWS Lake Formation	Database
AWS Glue Data Catalog	Database
Athena	Database
Spark	Namespace

Topics

- [Creating a namespace](#)
- [Delete a namespace](#)

Creating a namespace

A table namespace is a logical construct that you group tables under within an Amazon S3 table bucket. Each table belongs to a single namespace. Before creating a table in a table bucket, you must create a namespace to group tables under. You can create a namespace by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), Amazon S3 REST API, AWS SDKs, or integrated query engines.

Namespace names

The following naming rules apply to namespaces:

- Names must be between 1 and 255 characters long.
- Names can consist only of lowercase letters, numbers, and underscores (_). Underscores aren't allowed at the start or end of namespace names.
- Names must begin and end with a letter or number.
- Names must not contain hyphens (-) or periods (.).
- A namespace must be unique within a table bucket.
- Namespace names must not start with the reserved prefix aws.

For more information about valid namespace names, see [Naming rules for tables and namespaces](#).

Using the S3 console and Amazon Athena

The following procedure uses the **Create table with Athena** workflow to create a namespace in the Amazon S3 console. If you don't want to also use Amazon Athena to create a table in your namespace, you can cancel the workflow after creating your namespace.

To create a namespace

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that you want to create a namespace in.
4. On the bucket details page, choose **Create table with Athena**.
5. In the **Create table with Athena** dialog box, choose **Create a namespace**, and then choose **Create namespace**.
6. Enter a name in the **Namespace name** field. Namespace names must be 1 to 255 characters and unique within the table bucket. Valid characters are a–z, 0–9, and underscores (_). Underscores aren't allowed at the start or end of namespace names.
7. Choose **Create namespace**.
8. If you also want to create a table, choose **Create table with Athena**. For more information about creating a table with Athena, see [the section called "Using the S3 console and Amazon Athena"](#). If you don't want to create a table right now, choose **Cancel**.

Using the AWS CLI

This example shows how to create a table namespace by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables create-namespace \
--table-bucket-arn arn:aws:s3tables:us-east-1:11122223333:bucket/amzn-s3-demo-
bucket1 \
--namespace example_namespace
```

Using a query engine

You can create a namespace in an Apache Spark session connected to your Amazon S3 table buckets.

This example shows you how to create a table by using CREATE statements in a query engine integrated with S3 Tables. To use this example, replace the *user input placeholders* with your own information.

```
spark.sql("CREATE NAMESPACE IF NOT EXISTS s3tablesbucket.my_namespace")
```

Delete a namespace

Before you delete a table namespace from an Amazon S3 table bucket, you must delete all tables within the namespace, or move them under another namespace. You can delete a namespace by using the Amazon S3 REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or integrated query engines.

For information about the permissions required to delete a namespace, see [DeleteNamespace](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS CLI

This example shows you how to delete a table namespace by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables delete-namespace \
--table-bucket-arn arn:aws:s3tables:us-east-1:11122223333:bucket/amzn-s3-demo-
bucket1 \
--namespace example_namespace
```

Tables in S3 table buckets

An S3 table represents a structured dataset consisting of underlying table data and related metadata. This data is stored inside a table bucket as a subresource. All tables in a table bucket are stored in the [Apache Iceberg](#) table format. Amazon S3 manages maintenance of your tables through automatic file compaction and snapshot management. For more information, see [Maintenance for tables](#).

To make tables in your account accessible by AWS analytics services, you integrate your Amazon S3 table buckets with Amazon SageMaker Lakehouse. This integration allows AWS analytics services such as Amazon Athena and Amazon Redshift to automatically discover and access your table data.

When you create a table, Amazon S3 automatically generates a warehouse location for the table. This is a unique S3 location that stores objects associated with the table. The following example shows the format of a warehouse location:

```
s3://63a8e430-6e0b-46f5-k833abtwr6s8tmtsycedn8s4yc3xhuse1b--table-s3
```

Within your table bucket, you can organize tables into logical groupings called namespaces. For more information, see [Table namespaces](#).

You can rename tables, but each table has its own unique Amazon Resource Name (ARN) and unique table ID. Each table also has a resource policy attached to it. You can use this policy to manage access to the table.

Table ARNs use the following format:

```
arn:aws:s3tables:region:owner-account-id:bucket/bucket-name/table/table-id
```

By default, you can create up to 10,000 tables in a table bucket. To request a quota increase for table buckets or tables, contact [Support](#).

Amazon S3 supports the following types of tables in table buckets:

Customer tables

Customer tables are tables that you can read and write to. You can retrieve data from these tables using integrated query engines. You can insert, update, or delete data within them by using S3 API operations or integrated query engines.

AWS tables

AWS tables are read-only tables that are generated by an AWS service on your behalf. These tables are managed by Amazon S3 and can't be modified by any IAM principal outside of Amazon S3 itself. You can retrieve information from these tables, but you can't modify the data in them. AWS tables include S3 Metadata tables, which contain metadata that's captured from the objects within an S3 general purpose bucket. For more information, see [Discovering your data with S3 Metadata tables](#).

Creating an Amazon S3 table

An Amazon S3 table is a subresource of a table bucket. Tables are stored in the Apache Iceberg format so that you can work with them by using query engines and other applications that support Apache Iceberg. Amazon S3 continuously optimizes your tables to help reduce storage costs and improve analytics query performance.

When you create a table, Amazon S3 automatically generates a *warehouse location* for the table. A warehouse location is a unique S3 location where you can read and write objects associated with the table. The following example shows the format of a warehouse location:

```
s3://63a8e430-6e0b-46f5-k833abtwr6s8tmtsycedn8s4yc3xhuse1b--table-s3
```

Tables have the following Amazon Resource Name (ARN) format:

```
arn:aws:s3tables:region:owner-account-id:bucket/bucket-name/table/table-id
```

By default, you can create up to 10,000 tables in a table bucket. To request a quota increase for table buckets or tables, contact [Support](#).

You can create a table by using the Amazon S3 console, Amazon S3 REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or query engines connected to your table buckets.

When you create a table you can specify the encryption settings for that table, unless you are creating the table with Athena. If you don't specify encryption settings the table is encrypted with the default settings for the table bucket. For more information, see [Specifying encryption for tables](#).

Prerequisites for creating tables

To create a table, you must first do the following:

- [Create a table bucket](#).
- [Create a namespace](#) in your table bucket.
- Make sure that you have AWS Identity and Access Management (IAM) permissions for s3tables:CreateTable and s3tables:PutTableData.
-

Note

If you are using SSE-KMS encryption for your table, you need permissions for s3tables:PutTableEncryption, and DescribeKey permission on the chosen AWS KMS key. Additionally the AWS KMS key you use needs to grant S3 Tables permission to perform automatic table maintenance. For more information, see [Permission requirements for S3 Tables SSE-KMS encryption](#)

For information about valid table names, see [Naming rules for tables and namespaces](#).

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.

If your table definition contains capital letters, you receive the following error message when running a SELECT query in Athena: "GENERIC_INTERNAL_ERROR: Get table request

failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Using the S3 console and Amazon Athena

The following procedure uses the Amazon S3 console to create a table with Amazon Athena. If you haven't already created a namespace in your table bucket, you can do so as part of this process. Before performing the following steps, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see [the section called "Integrating S3 Tables with AWS analytics services"](#).

Note

When you create a table using Athena that table inherits the default encryption settings from the table bucket. If you want to use a different encryption type you need to create the table using another method.

To create a table

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that you want to create a table in.
4. On the bucket details page, choose **Create table with Athena**.
5. In the **Create table with Athena** dialog box, do one of the following:
 - Create a new namespace. Choose **Create a namespace**, and then enter a name in the **Namespace name** field. Namespace names must be 1 to 255 characters and unique within the table bucket. Valid characters are a–z, 0–9, and underscores (_). Underscores aren't allowed at the start of namespace names.
 - Choose **Create namespace**.
 - Specify an existing namespace. Choose **Specify an existing namespace within this table bucket**. Then choose either **Choose from existing namespaces** or **Enter an existing namespace name**. If you have more than 1,000 namespaces in your bucket, you must enter the namespace name if it doesn't appear in the list.

6. Choose **Create table with Athena**.
7. The Amazon Athena console opens and the Athena query editor appears. The **Catalog** field should be populated with **s3tablescatalog/** followed by the name of your table bucket, for example, **s3tablescatalog/amzn-s3-demo-bucket**. The **Database** field should be populated with the namespace that you created or selected earlier.

 **Note**

If you don't see these values in the **Catalog** and **Database** fields, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see [the section called "Integrating S3 Tables with AWS analytics services"](#).

8. The query editor is populated with a sample query that you can use to create a table. Modify the query to specify the table name and columns that you want your table to have.
9. When you're finished modifying the query, choose **Run** to create your table.

 **Note**

- If you receive the error "Insufficient permissions to execute the query. Principal does not have any privilege on specified resource" when you try to run a query in Athena, you must be granted the necessary Lake Formation permissions on the table. For more information, see [the section called "Granting Lake Formation permission on a table or database"](#).
- If you receive the error "Iceberg cannot access the requested resource" when you try to run a query in Athena, go to the AWS Lake Formation console and make sure that you've granted yourself permissions on the table bucket catalog and database (namespace) that you created. Don't specify a table when granting these permissions. For more information, see [the section called "Granting Lake Formation permission on a table or database"](#).
- If you receive the following error message when running a SELECT query in Athena, this message is caused by having capital letters in your table name or your column names in your table definition: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names." Make sure that your table and column names are all lowercase.

If your table creation was successful, the name of your new table appears in the list of tables in Athena. When you navigate back to the Amazon S3 console, your new table appears in the **Tables** list on the bucket details page for your table bucket after you refresh the list.

Using the AWS CLI

This example shows how to create a table with a schema by using the AWS CLI and specifying table metadata with JSON. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables create-table --cli-input-json file://mytabledefinition.json
```

For the mytabledefinition.json file, use the following example table definition. To use this example, replace the *user input placeholders* with your own information.

```
{
    "tableBucketARN": "arn:aws:s3tables:us-east-1:11122223333:bucket/amzn-s3-demo-table-bucket",
    "namespace": "your_namespace",
    "name": "example_table",
    "format": "ICEBERG",
    "metadata": {
        "iceberg": {
            "schema": {
                "fields": [
                    {"name": "id", "type": "int", "required": true},
                    {"name": "name", "type": "string"},
                    {"name": "value", "type": "int"}
                ]
            }
        }
    }
}
```

Using a query engine

You can create a table in a supported query engine that's connected to your table buckets, such as in an Apache Spark session on Amazon EMR.

The following example shows how to create a table with Spark by using CREATE statements, and add table data by using INSERT statements or by reading data from an existing file. To use this example, replace the *user input placeholders* with your own information.

```
spark.sql(  
  " CREATE TABLE IF NOT EXISTS s3tablesbucket.example_namespace.`example_table` ("  
    id INT,  
    name STRING,  
    value INT  
)  
  USING iceberg "  
)
```

After you create the table, you can load data into the table. Choose from the following methods:

- Add data into the table by using the INSERT statement.

```
spark.sql(  
  """  
    INSERT INTO s3tablesbucket.my_namespace.my_table  
    VALUES  
      (1, 'ABC', 100),  
      (2, 'XYZ', 200)  
  """")
```

- Load an existing data file.

1. Read the data into Spark:

```
val data_file_location = "Path such as S3 URI to data file"  
val data_file = spark.read.parquet(data_file_location)
```

2. Write the data into an Iceberg table:

```
data_file.writeTo("s3tablesbucket.my_namespace.my_table").using("Iceberg").tableProperty  
  ("format-version", "2").createOrReplace()
```

Deleting an Amazon S3 table

You can delete a table by using the Amazon S3 REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or by using integrated query engines.

Note

S3 Tables doesn't support the DROP TABLE operation with `purge=false`. Some versions of Apache Spark always set this flag to `false` even when running `DROP TABLE PURGE` commands. To delete a table, you can retry `DROP TABLE` with `purge=true`, or use the S3 Tables [DeleteTable REST API operation](#).

Important

When you delete a table, you need to know the following:

- Deleting a table is permanent and cannot be undone. Before deleting a table, make sure that you have backed up or replicated any important data.
- All data and configurations associated with the table are permanently removed.

Using the AWS CLI

This example shows how to delete a table by using the AWS CLI. To use this command, replace the *user input placeholders* with your own information.

```
aws s3tables delete-table \
    --table-bucket-arn arn:aws:s3tables:us-east-1:1112223333:bucket/amzn-s3-demo-
table-bucket \
    --namespace example_namespace --name example_table
```

Using a query engine

You can delete a table in an Apache Spark session connected to your Amazon S3 table buckets.

This example shows how to delete a table by using the `DROP TABLE PURGE` command. To use the command, replace the *user input placeholders* with your own information.

```
spark.sql(
  " DROP TABLE [IF EXISTS] s3tablesbucket.example_namespace.example_table PURGE")
```

Viewing details about an Amazon S3 table

You can view the general details of a table in a table bucket, such creation details, format and type, in the console or programmatically. You can view table encryption settings, and maintenance settings programmatically by using the S3 Tables REST API, AWS CLI or AWS SDKs.

Viewing table details

Using the AWS CLI

This example shows how to get details about a table by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket --namespace my-namespace --name my-table
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Select your table bucket, then select your table.
4. Select the **Properties** tab.
5. (Optional) For information about the permission policy attached to the table, select **Permissions**.

Previewing table data

Using the S3 console

You can preview the data in your table directly from the Amazon S3 console using the following procedure.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that contains the table that you want to query.
4. Select the table you want to preview then, choose **Preview**.

Note

The preview shows the first 10 rows and up to 25 columns of your table. Tables over 50mb cannot be previewed.

Encryption details

For more information about table bucket encryption, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in table buckets](#).

Using the AWS CLI

This example shows how to get details about encryption settings for a table by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-encryption --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket --namespace my-namespace --name my-table
```

Maintenance details

For information about maintenance settings, see [Maintenance for table buckets](#)

Using the AWS CLI

This example shows how to get details about maintenance configuration settings for a table by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-maintenance-configuration --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket --namespace my-namespace --name my-table
```

Managing table policies

You can add, delete, update, and view table policies for tables by using the Amazon S3 console, Amazon S3 REST API, AWS SDK and the AWS CLI. For more information, see the following topics. For more information about supported AWS Identity and Access Management (IAM) actions and

condition keys for Amazon S3 Tables, see [Access management for S3 Tables](#). For example table policies, see [Resource-based policies for S3 Tables](#).

Adding a table policy

To add a table policy to a table, you can use the Amazon S3 REST API, AWS SDK and the AWS CLI.

Using the AWS CLI

This example shows how to view the policy attached to a table by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3tables get-table-policy \
    --table-bucket-arn arn:aws:s3tables:us-east-1:1112223333:bucket/amzn-s3-demo-
    bucket1/table/tableID \
    --namespace my-namespace \
    --name my-table
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that contains your table, then select your table from that bucket.
4. Choose the **Permissions** tab.
5. Under **Table policy**, Choose **Edit**.
6. In the policy editor, enter your policy JSON.
7. (Optional) Choose **Policy examples** to see sample policies that you can adapt to your needs.
8. After entering your policy, choose **Save changes**.

Viewing a table policy

To view the bucket policy attached to a table, you can use the Amazon S3 REST API, AWS SDK and the AWS CLI.

Using the AWS CLI

This example shows how to view the policy attached to a table by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3tables get-table-policy \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket \
--namespace my-namespace \
--name my-table
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that contains your table, then select your table from that bucket.
4. Choose the **Permissions** tab.

Deleting a table policy

To delete a policy attached to a table, you can use the Amazon S3 REST API, AWS SDK and the AWS CLI.

Using the AWS CLI

This example shows how to delete a table policy by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3tables delete-table-policy \
--table-ARN arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-
bucket \
--namespace your-namespace \
--name your-table
```

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that contains your table, then select your table from that bucket.
4. Choose the **Permissions** tab.

5. Under **Table bucket policy**, choose **Delete**.

Using tags with S3 tables

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 tables. You can tag S3 tables when you create them or manage tags on existing tables. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

 **Note**

There is no additional charge for using tags on tables beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with tables

Use tags on your S3 tables for:

1. **Cost allocation** – Track storage costs by table tag in AWS Billing and Cost Management. For more information, see [Using tags for cost allocation](#).
2. **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 tables based on their tags. For more information, see [Using tags for ABAC](#).

 **Note**

You can use the same tags for both cost allocation and access control.

ABAC for S3 tables

Amazon S3 tables support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, AWS Identity and Access Management (IAM), and S3 table policies. ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 tables based on the table's tags by using the `s3:TableBucketTag/tag-key` condition key or the [AWS global condition keys](#): `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys`.

aws:ResourceTag/key-name

Use this condition key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a table is allowed only if the table has the tag key `Department` with the value `Marketing`.

This condition key applies to table actions performed using the Amazon S3 Console, the AWS Command Line Interface (CLI), S3 APIs, or the AWS SDKs.

For an example policy, see [1.1 - table policy to restrict operations on the table using tags](#).

For additional example policies and more information, see [Controlling access to AWS resources](#) in the *AWS Identity and Access Management User Guide*.

Note

For actions performed on tables, this condition key acts on the tags applied to the table and not on the tags applied to the table bucket containing the table. Use the `s3tables:TableBucketTag/tag-key` instead if you would like your ABAC policies to act on the tags of the table bucket when performing table actions.

aws:RequestTag/key-name

Use this condition key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request to tag a table includes the tag key `Department` and that it has the value `Accounting`.

This condition key applies when tag keys are passed in a `TagResource` or `CreateTable` API operation request, or when tagging or creating a table with tags using the Amazon S3 Console, the AWS Command Line Interface (CLI), or the AWS SDKs.

For an example policy, see [1.2 - IAM policy to create or modify tables with specific tags](#).

For additional example policies and more information, see [Controlling access during AWS requests](#) in the *AWS Identity and Access Management User Guide*.

aws:TagKeys

Use this condition key to compare the tag keys in a request with the keys that you specify in the policy to define what tag keys are allowed for access. For example, to allow tagging during the

CreateTable action, you must create a policy that allows both the `s3tables:TagResource` and `s3tables:CreateTable` actions. You can then use the `aws:TagKeys` condition key to enforce that only specific tags are used in the CreateTable request.

This condition key applies when tag keys are passed in a TagResource, UntagResource, or CreateTable API operations or when tagging, untagging, or creating a table with tags using the AWS Command Line Interface (CLI), or the AWS SDKs.

For an example policy, see [1.3 - IAM policy to control the modification of tags on existing resources maintaining tagging governance](#).

For additional example policies and more information, see [Controlling access based on tag keys](#) in the *AWS Identity and Access Management User Guide*.

s3tables:TableBucketTag/tag-key

Use this condition key to grant permissions to specific data in table buckets using tags. This condition key acts, on the most part, on the tags assigned to the table bucket for all S3 tables actions. Even when you create a table with tags, this condition key acts on the tags applied to the table bucket that contains that table. The exceptions are:

- When you create a table bucket with tags, this condition key acts on the tags in the request.

For an example policy, see [1.4 - Using the s3tables:TableBucketTag condition key](#).

Example ABAC policies for tables

See the following example ABAC policies for Amazon S3 tables.

Note

If you have an IAM or S3 Tables resource-based policy that restricts IAM users and IAM roles based on principal tags, you must attach the same principal tags to the IAM role that Lake Formation uses to access your Amazon S3 data (for example, `LakeFormationDataAccessRole`) and grant this role the necessary permissions. This is required for your tag-based access control policy to work correctly with your S3 Tables analytics integration.

1.1 - table policy to restrict operations on the table using tags

In this table policy, the specified IAM principals (users and roles) can perform the GetTable action only if the value of the table's project tag matches the value of the principal's project tag.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowGetTable",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "111122223333"  
            },  
            "Action": "s3tables:GetTable",  
            "Resource": "arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/my_example_tab;e",  
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/project": "${aws:PrincipalTag/project}"  
                }  
            }  
        }  
    ]  
}
```

1.2 - IAM policy to create or modify tables with specific tags

In this IAM policy, users or roles with this policy can only create S3 tables if they tag the table with the tag key `project` and tag value `Trinity` in the table creation request. They can also add or modify tags on existing S3 tables as long as the TagResource request includes the tag key-value pair `project:Trinity`. This policy does not grant read, write, or delete permissions on the tables or its objects.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "CreateTableWithTags",  
            "Effect": "Allow",  
            "Action": [  
                "s3tables:CreateTable",  
                "s3tables:TagResource"  
            ],  
            "Resource": "arn:aws:s3tables:us-west-2:111122223333:table/*"  
        }  
    ]  
}
```

```
    "s3tables:TagResource"
],
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestTag/projectTrinity"
        ]
    }
}
]
}
```

1.3 - IAM policy to control the modification of tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a table only if the value of the table's project tag matches the value of the principal's project tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these tables. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your tables.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceTaggingRulesOnModification",
            "Effect": "Allow",
            "Action": [
                "s3tables:TagResource",
                "s3tables:UntagResource"
            ],
            "Resource": "arn:aws:s3:::us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/my_example_table",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
                },
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": [
                        "project",
                        "environment",
                        "owner",
                        "cost-center"
                    ]
                }
            }
        }
    ]
}
```

```
        "owner",
        "cost-center"
    ]
}
}
]
}
```

1.4 - Using the s3tables:TableBucketTag condition key

In this IAM policy, the condition statement allows access to the table bucket's data only if the table bucket has the tag key Environment and tag value Production. The s3tables:TableBucketTag/<tag-key> differs from the aws:ResourceTag/<tag-key> condition key because, in addition to controlling access to table buckets depending on their tags, it allows you to control access to tables based on the tags on their parent table bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAccessToSpecificTables",
            "Effect": "Allow",
            "Action": "*",
            "Resource": "arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3tables:TableBucketTag/Environment": "Production"
                }
            }
        }
    ]
}
```

Managing tags for tables

You can add or manage tags for S3 tables using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see:

Topics

- [Creating tables with tags](#)
- [Adding a tag to a table](#)
- [Viewing table tags](#)
- [Deleting a tag from a table](#)

Creating tables with tags

You can tag Amazon S3 tables when you create them. There is no additional charge for using tags on tables beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging tables, see [Using tags with S3 tables](#).

Permissions

To create a table with tags, you must have the following permissions:

- `s3tables:CreateTable`
- `s3tables:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a table with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the table and apply a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. Your policy may require you to tag your tables with only specific tag keys and values. For more information about ABAC and example table ABAC policies, see [ABAC for S3 tables](#).

Steps

You can create a table with tags applied by using the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and the AWS SDKs.

Using the REST API

For information about the Amazon S3 Tables REST API support for creating a table with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- [CreateTable](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a table with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create a table you must provide configuration details. For more information, see [Creating an Amazon S3 table](#). You must also name the table with a name that follows the table naming convention. For more information see [Amazon S3 table bucket, table, and namespace naming rules](#).

Request:

```
aws --region us-west-2 \
s3tables create-table \
--endpoint https://ufwae60e2k.execute-api.us-west-2.amazonaws.com/personal/ \
--table-bucket-arn arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket
--tags '{"Department":"Engineering"}' \
--name my_table_abc \
--namespace my_namesapce_123a \
--format ICEBERG
```

Adding a tag to a table

You can add tags to Amazon S3 tables and modify these tags. For more information about tagging tables, see [Using tags with S3 tables](#).

Permissions

To add a tag to a table, you must have the following permission:

- s3tables:TagResource

Troubleshooting errors

If you encounter an error when attempting to add a tag to a table, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to a table.

- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.
- The tag key is required. Also, make sure that the tag key and the tag value do not exceed the maximum character length and do not contain restricted characters. For more information, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

Steps

You can add tags to tables by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and AWS SDKs.

Using the S3 console

To add tags to a table using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the table bucket name.
4. Choose the table name.
5. Choose the **Properties** tab.
6. Scroll to the **Tags** section and choose **Add new Tag**.
7. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
8. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
9. You can also edit the values of existing tags on this page.
10. After you have added the tag(s), choose **Save changes**.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a table, see the following section in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a table by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws --region us-west-2 \
s3tables tag-resource \
--resource-arn arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket/table/my_example_table \
--tags '{"Department":"engineering"}'
```

Viewing table tags

You can view or list tags applied to Amazon S3 tables. For more information about tags, see [Using tags with S3 tables](#).

Permissions

To view tags applied to a table, you must have the following permission:

- s3tables>ListTagsForResource

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a table, you can do the following:

- Verify that you have the required [Permissions](#) to view or list the tags of the table.

Steps

You can view tags applied to tables by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a table using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the Table bucket name.
4. Choose the table name within the Table bucket.
5. Choose the **Properties** tab.
6. Scroll to the **Tags** section to view all of the tags applied to the table.
7. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your table by AWS services.

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a table, see the following section in the *Amazon Simple Storage Service API Reference*:

- [ListTagsForResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a table. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws --region us-west-2 \
s3tables list-tags-for-resource \
--resource-arn arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket/table/my_example_table
```

Deleting a tag from a table

You can remove tags from Amazon S3 tables. For more information about tagging tables, see [Using tags with S3 tables](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the table.

Permissions

To delete a tag from a table, you must have the following permission:

- `s3tables:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a table, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from a table.

Steps

You can delete tags from tables by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and AWS SDKs.

Using the S3 console

To delete tags from a table using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the table bucket name.
4. Choose the table name.
5. Choose the **Properties** tab.
6. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
7. Choose **Delete**.
8. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.

9. Choose **Delete** to confirm.

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a table, see the following section in the *Amazon Simple Storage Service API Reference*:

- [UnTagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a table by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws --region us-west-2 \
s3tables untag-resource \
--resource-arn arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket/table/my_example_table \
--tag-keys '[{"department"}]
```

Accessing table data

There are multiple ways to access tables in Amazon S3 table buckets, you can integrate tables with AWS analytics services using Amazon SageMaker Lakehouse, or access tables directly using the Amazon S3 Tables Iceberg REST endpoint or the Amazon S3 Tables Catalog for Apache Iceberg. The access method you use will depend on your catalog setup, governance model, and access control needs. The following is an overview of these access methods.

Amazon SageMaker Lakehouse integration

This is the recommended access method for working with tables in S3 table buckets. The integration gives you unified table management, centralized governance, and fine-grained access control across multiple AWS analytics services. After integration, you can query tables in services such as Athena and Amazon Redshift.

Direct access

Use this method if you need to work with AWS Partner Network (APN) catalog implementations, custom catalog implementations, or if you only need to perform basic read/write operations on tables within a single table bucket.

 **Note**

To access tables the IAM identity you use needs access to your table resources and S3 Tables actions. For more information, see [Access management for S3 Tables](#).

Accessing tables through the Amazon SageMaker Lakehouse integration

You can integrate S3 table buckets with Amazon SageMaker Lakehouse to access tables from AWS analytics services, such as Amazon Athena, Amazon Redshift, and Quick Suite. Amazon SageMaker Lakehouse unifies your data across Amazon S3 data lakes and Amazon Redshift data warehouses, so you can build analytics, machine learning (ML), and generative AI applications on a single copy of data. The integration populates the AWS Glue Data Catalog with your table resources, and federates access to these resources with AWS Lake Formation. For more information on integrating, see [Integrating Amazon S3 Tables with AWS analytics services](#).

The integration enables fine-grained access control through AWS Lake Formation to provide additional security. Lake Formation uses a combination of its own permissions model and the IAM permissions model to control access to table resources and underlying data. This means that a request to access your table must pass permission checks by both IAM and Lake Formation. For more information, see [Lake Formation permissions overview](#) in the *AWS Lake Formation Developer Guide*.

The following AWS analytics services can access tables through this integration:

- [Amazon Athena](#)
- [Amazon Redshift](#)
- [Amazon EMR](#)
- [Quick Suite](#)

- [Amazon Data Firehose](#)
- [AWS Glue ETL](#)
- [Querying S3 Tables with SageMaker Unified Studio](#)

Accessing tables using the AWS Glue Iceberg REST endpoint

Once your S3 table buckets are integrated with Amazon SageMaker Lakehouse, you can also use the AWS Glue Iceberg REST endpoint to connect to S3 tables from third-party query engines that support Iceberg. For more information, see [Accessing Amazon S3 tables using the AWS Glue Iceberg REST endpoint](#).

We recommend using the AWS Glue Iceberg REST endpoint when you want to access tables from Spark, Pylceberg, or other Iceberg-compatible clients.

The following clients can access tables directly through the AWS Glue Iceberg REST endpoint:

- Any Iceberg client, including Spark, Pylceberg, and more.

Accessing tables directly

You can access tables directly from open source query engines through methods that bridge S3 Tables management operations to your Apache Iceberg analytics applications. There are two direct access methods: the Amazon S3 Tables Iceberg REST endpoint or the Amazon S3 Tables Catalog for Apache Iceberg. The REST endpoint is recommended.

We recommend direct access if you access tables in self-managed catalog implementations, or only need to perform basic read/write operations on tables in a single table bucket. For other access scenarios, we recommend the Amazon SageMaker Lakehouse integration.

Direct access to tables is managed through either IAM identity-based policies or resource-based policies attached to tables and table buckets. You do not need to manage Lake Formation permissions for tables when you access them directly.

Accessing tables through the Amazon S3 Tables Iceberg REST endpoint

You can use the Amazon S3 Tables Iceberg REST endpoint to access your tables directly from any Iceberg REST compatible clients through HTTP endpoints, for more information, see [Accessing tables using the Amazon S3 Tables Iceberg REST endpoint](#).

The following AWS analytics services and query engines can access tables directly using the Amazon S3 Tables Iceberg REST endpoint:

Supported query engines

- Any Iceberg client, including Spark, PyIceberg, and more.
- [Amazon EMR](#)
- [AWS Glue ETL](#)

Accessing tables directly through the Amazon S3 Tables Catalog for Apache Iceberg

You can also access tables directly from query engines like Apache Spark by using the S3 Tables client catalog, for more information, see [Accessing Amazon S3 tables with the Amazon S3 Tables Catalog for Apache Iceberg](#). However, S3 recommends using the Amazon S3 Tables Iceberg REST endpoint for direct access because it supports more applications, without requiring language or engine-specific code.

The following query engines can access tables directly using the client catalog:

- [Apache Spark](#)

Amazon S3 Tables integration with AWS analytics services overview

To make tables in your account accessible by AWS analytics services, you integrate your Amazon S3 table buckets with Amazon SageMaker Lakehouse. This integration allows AWS analytics services to automatically discover and access your table data. You can use this integration to work with your tables in these services:

- [Amazon Athena](#)
- [Amazon Redshift](#)
- [Amazon EMR](#)
- [Quick Suite](#)
- [Amazon Data Firehose](#)

Note

This integration uses the AWS Glue and AWS Lake Formation services and might incur AWS Glue request and storage costs. For more information, see [AWS Glue Pricing](#).

Additional pricing applies for running queries on your S3 tables. For more information, see pricing information for the query engine that you're using.

How the integration works

When you create a table bucket in the console, Amazon S3 initiates the following actions to integrate table buckets in the Region that you have selected with AWS analytics services:

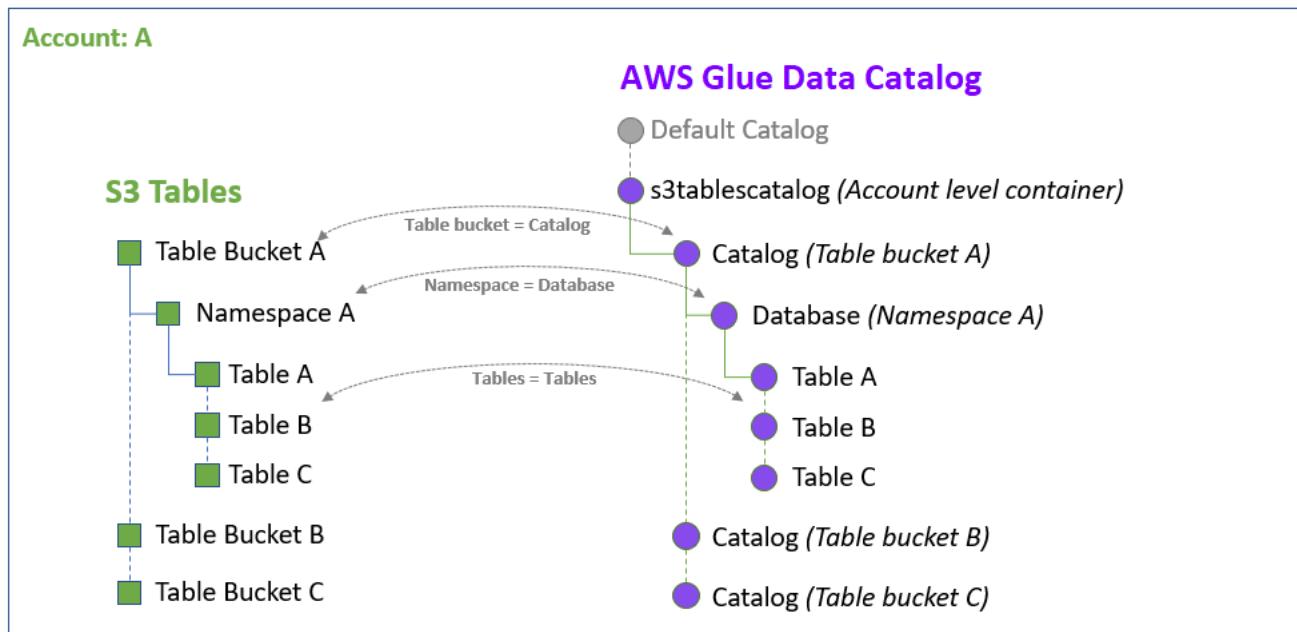

1. Creates a new AWS Identity and Access Management (IAM) [service role](#) that gives Lake Formation access to all your table buckets.
2. Using the service role, Lake Formation registers table buckets in the current Region. This allows Lake Formation to manage access, permissions, and governance for all current and future table buckets in that Region.
3. Adds the `s3tablescatalog` catalog to the AWS Glue Data Catalog in the current Region.
Adding the `s3tablescatalog` catalog allows all your table buckets, namespaces, and tables to be populated in the Data Catalog.

Note

These actions are automated through the Amazon S3 console. If you perform this integration programmatically, you must manually take all of these actions.

You integrate your table buckets once per AWS Region. After the integration is completed, all current and future table buckets, namespaces, and tables are added to the AWS Glue Data Catalog in that Region.

The following illustration shows how the `s3tablescatalog` catalog automatically populates table buckets, namespaces, and tables in the current Region as corresponding objects in the Data Catalog. Table buckets are populated as subcatalogs. Namespaces within a table bucket are populated as databases within their respective subcatalogs. Tables are populated as tables in their respective databases.

How permissions work

We recommend integrating your table buckets with AWS analytics services so that you can work with your table data across services that use the AWS Glue Data Catalog as a metadata store. The integration enables fine-grained access control through AWS Lake Formation. This security approach means that, in addition to AWS Identity and Access Management (IAM) permissions, you must grant your IAM principal Lake Formation permissions on your tables before you can work with them.

There are two main types of permissions in AWS Lake Formation:

- Metadata access permissions control the ability to create, read, update, and delete metadata databases and tables in the Data Catalog.
- Underlying data access permissions control the ability to read and write data to the underlying Amazon S3 locations that the Data Catalog resources point to.

Lake Formation uses a combination of its own permissions model and the IAM permissions model to control access to Data Catalog resources and underlying data:

- For a request to access Data Catalog resources or underlying data to succeed, the request must pass permission checks by both IAM and Lake Formation.

- IAM permissions control access to the Lake Formation and AWS Glue APIs and resources, whereas Lake Formation permissions control access to the Data Catalog resources, Amazon S3 locations, and the underlying data.

Lake Formation permissions apply only in the Region in which they were granted, and a principal must be authorized by a data lake administrator or another principal with the necessary permissions in order to be granted Lake Formation permissions.

For more information, see [Overview of Lake Formation permissions](#) in the *AWS Lake Formation Developer Guide*.

Make sure that you follow the steps in [Integrating S3 Tables with AWS analytics services](#) so that you have the appropriate permissions to access the AWS Glue Data Catalog and your table resources, and to work with AWS analytics services.

Integrating Amazon S3 Tables with AWS analytics services

This topic covers the prerequisites and procedures needed to integrate your Amazon S3 table buckets with AWS analytics services. For an overview of how the integration works, see [S3 Tables integration overview](#).

Note

This integration uses the AWS Glue and AWS Lake Formation services and might incur AWS Glue request and storage costs. For more information, see [AWS Glue Pricing](#).

Additional pricing applies for running queries on your S3 tables. For more information, see pricing information for the query engine that you're using.

Prerequisites for integration

The following prerequisites are required to integrate table buckets with AWS analytics services:

- [Create a table bucket.](#)
- Attach the [AWSLakeFormationDataAdmin](#) AWS managed policy to your AWS Identity and Access Management (IAM) principal to make that user a data lake administrator. For more information about how to create a data lake administrator, see [Create a data lake administrator](#) in the *AWS Lake Formation Developer Guide*.
- Add permissions for the `glue:PassConnection` operation to your IAM principal.
- Add permissions for the `lakeformation:RegisterResource` and `lakeformation:RegisterResourceWithPrivilegedAccess` operations to your IAM principal.
- [Update to the latest version of the AWS Command Line Interface \(AWS CLI\).](#)

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.

If your table definition contains capital letters, you receive the following error message when running a `SELECT` query in Athena: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Integrating table buckets with AWS analytics services

Amazon S3 Tables integrates with AWS Glue Data Catalog (Data Catalog) and registers the catalog as a Lake Formation data location. You can set up this registration from the Lake Formation console or by using the service APIs. When you register the location, you must specify an IAM role that grants read/write permissions to the Lake Formation registered role to access that location. Lake Formation assumes that role when supplying temporary credentials to integrated AWS services.

If you have an IAM or S3 Tables resource-based policy that restricts IAM users and IAM roles based on principal tags, you must attach the same principal tags to the IAM role that Lake Formation

uses to access your Amazon S3 data (for example, `LakeFormationDataAccessRole`) and grant this role the necessary permissions. This is required for your tag-based access control policy to work correctly with your S3 Tables analytics integration.

This integration must be configured once per AWS Region.

Important

The AWS analytics services integration now uses the `WithPrivilegedAccess` option in the `registerResource` Lake Formation API operation to register S3 table buckets. The integration also now creates the `s3tablescatalog` catalog in the AWS Glue Data Catalog by using the `AllowFullTableExternalDataAccess` option in the `CreateCatalog` AWS Glue API operation.

If you set up the integration with the preview release, you can continue to use your current integration. However, the updated integration process provides performance improvements, so we recommend migrating. To migrate to the updated integration, see [the section called “Migrating to the updated integration process”](#).

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. Choose **Create table bucket**.

The **Create table bucket** page opens.

4. Enter a **Table bucket name** and make sure that the **Enable integration** checkbox is selected.
5. Choose **Create table bucket**. Amazon S3 will attempt to automatically integrate your table buckets in that Region.

The first time that you integrate table buckets in any Region, Amazon S3 creates a new IAM service role on your behalf. This role allows Lake Formation to access all table buckets in your account and federate access to your tables in AWS Glue Data Catalog.

Using the AWS CLI

To integrate table buckets using the AWS CLI

The following steps show how to use the AWS CLI to integrate table buckets. To use these steps, replace the *user input placeholders* with your own information.

1. Create a table bucket.

```
aws s3tables create-table-bucket \
--region us-east-1 \
--name amzn-s3-demo-table-bucket
```

2. Create an IAM service role that allows Lake Formation to access your table resources.

- a. Create a file called Role-Trust-Policy.json that contains the following trust policy:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "LakeFormationDataAccessPolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "lakeformation.amazonaws.com"
            },
            "Action": [
                "sts:AssumeRole",
                "sts:SetContext",
                "sts:SetSourceIdentity"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                }
            }
        }
    ]
}
```

Create the IAM service role by using the following command:

```
aws iam create-role \
--role-name S3TablesRoleForLakeFormation \
--assume-role-policy-document file:///Role-Trust-Policy.json
```

- b. Create a file called LF-GluePolicy.json that contains the following policy:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "LakeFormationPermissionsForS3ListTableBucket",
            "Effect": "Allow",
            "Action": [
                "s3tables>ListTableBuckets"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "LakeFormationDataAccessPermissionsForS3TableBucket",
            "Effect": "Allow",
            "Action": [
                "s3tables>CreateTableBucket",
                "s3tables>GetTableBucket",
                "s3tables>CreateNamespace",
                "s3tables>GetNamespace",
                "s3tables>ListNamespaces",
                "s3tables>DeleteNamespace",
                "s3tables>DeleteTableBucket",
                "s3tables>CreateTable",
                "s3tables>DeleteTable",
                "s3tables>GetTable",
                "s3tables>ListTables",
                "s3tables>RenameTable",
                "s3tables>UpdateTableMetadataLocation",
                "s3tables>GetTableMetadataLocation",
                "s3tables>DescribeTable"
            ]
        }
    ]
}
```

```
        "s3tables:GetTableData",
        "s3tables:PutTableData"
    ],
    "Resource": [
        "arn:aws:s3tables:us-east-1:111122223333:bucket/*"
    ]
}
```

Attach the policy to the role by using the following command:

```
aws iam put-role-policy \
--role-name S3TablesRoleForLakeFormation \
--policy-name LakeFormationDataAccessPermissionsForS3TableBucket \
--policy-document file://LF-GluePolicy.json
```

3. Create a file called `input.json` that contains the following:

```
{
    "ResourceArn": "arn:aws:s3tables:us-east-1:111122223333:bucket/*",
    "WithFederation": true,
    "RoleArn": "arn:aws:iam::111122223333:role/S3TablesRoleForLakeFormation"
}
```

Register table buckets with Lake Formation by using the following command:

```
aws lakeformation register-resource \
--region us-east-1 \
--with-privileged-access \
--cli-input-json file://input.json
```

4. Create a file called `catalog.json` that contains the following catalog:

```
{
    "Name": "s3tablescatalog",
    "CatalogInput": {
        "FederatedCatalog": {
            "Identifier": "arn:aws:s3tables:us-east-1:111122223333:bucket/*",
            "ConnectionName": "aws:s3tables"
        }
    }
}
```

```
        },
        "CreateDatabaseDefaultPermissions": [],
        "CreateTableDefaultPermissions": [],
        "AllowFullTableExternalDataAccess": "True"
    }
}
```

Create the `s3tablescatalog` catalog by using the following command. Creating this catalog populates the AWS Glue Data Catalog with objects corresponding to table buckets, namespaces, and tables.

```
aws glue create-catalog \
--region us-east-1 \
--cli-input-json file://catalog.json
```

5. Verify that the `s3tablescatalog` catalog was added in AWS Glue by using the following command:

```
aws glue get-catalog --catalog-id s3tablescatalog
```

Migrating to the updated integration process

The AWS analytics services integration process has been updated. If you've set up the integration with the preview release, you can continue to use your current integration. However, the updated integration process provides performance improvements, so we recommend migrating by using the following steps. For more information about the migration or integration process, see [Creating an Amazon S3 Tables catalog in the AWS Glue Data Catalog](#) in the *AWS Lake Formation Developer Guide*.

1. Open the AWS Lake Formation console at <https://console.aws.amazon.com/lakeformation/>, and sign in as a data lake administrator. For more information about how to create a data lake administrator, see [Create a data lake administrator](#) in the *AWS Lake Formation Developer Guide*.
2. Delete your `s3tablescatalog` catalog by doing the following:
 - In the left navigation pane, choose **Catalogs**.
 - Select the option button next to the `s3tablescatalog` catalog in the **Catalogs** list. On the **Actions** menu, choose **Delete**.
3. Deregister the data location for the `s3tablescatalog` catalog by doing the following:

- In the left navigation pane, go to the **Administration** section, and choose **Data lake locations**.
 - Select the option button next to the s3tablescatalog data lake location, for example, s3://tables:*region:account-id*:bucket/*.
 - On the **Actions** menu, choose **Remove**.
 - In the confirmation dialog box that appears, choose **Remove**.
4. Now that you've deleted your s3tablescatalog catalog and data lake location, you can follow the steps to [integrate your table buckets with AWS analytics services](#) by using the updated integration process.

Note

If you want to work with SSE-KMS encrypted tables in integrated AWS analytics services, the role you use needs to have permission to use your AWS KMS key for encryption operations. For more information, see [Granting IAM principals permissions to work with encrypted tables in integrated AWS analytics services](#).

After you integrate your IAM principal is granted Lake Formation permissions to access your tables, if you want to allow other IAM principals to access tables, you need to grant Lake Formation permissions on your tables to those principals. For more information, see [Managing access to a table or database with Lake Formation](#).

Next steps

- [Create a namespace](#).
- [Create a table](#).

Accessing Amazon S3 tables using the AWS Glue Iceberg REST endpoint

Once your S3 table buckets are integrated with the AWS Glue Data Catalog you can use the AWS Glue Iceberg REST endpoint to connect to your S3 tables from Apache Iceberg-compatible clients, such as PyIceberg or Spark. The AWS Glue Iceberg REST endpoint implements the [Iceberg REST Catalog Open API specification](#) which provides a standardized interface for interacting with Iceberg tables. To access S3 tables using the endpoint you need to configure permissions through

a combination of IAM policies and AWS Lake Formation grants. The following sections explain how to set up access, including creating the necessary IAM role, defining the required policies, and establishing Lake Formation permissions for both database and table-level access.

For an end to end walkthrough using Pylceberg, see [Access data in Amazon S3 Tables using Pylceberg through the AWS Glue Iceberg REST endpoint](#).

Prerequisites

- Integrate your table buckets with AWS analytics services
 - Create a table namespace
 - Have access to a data lake administrator account

Create an IAM role for your client

To access tables through AWS Glue endpoints, you need to create an IAM role with permissions to AWS Glue and Lake Formation actions. This procedure explains how to create this role and configure its permissions.

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
 2. In the left navigation pane, choose **Policies**.
 3. Choose **Create a policy**, and choose **JSON** in policy editor.
 4. Add the following inline policy that grants permissions to access AWS Glue and Lake Formation actions:

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "VisualEditor0",  
      "Effect": "Allow",  
      "Action": [  
        "glue:GetCatalog",  
        "glue:GetDatabase",  
        "glue:GetDatabases",  
        "glue:GetTable",  
        "glue:GetTables",  
        "glue:ListTables"  
      ]  
    }  
  ]  
}
```

```
        "glue>CreateTable",
        "glue>UpdateTable"
    ],
    "Resource": [
        "arn:aws:glue:us-east-1:111122223333:catalog",
        "arn:aws:glue:us-east-1:111122223333:catalog/
s3tablescatalog",
        "arn:aws:glue:us-east-1:111122223333:catalog/s3tablescatalog/
amzn-s3-demo-table-bucket",
        "arn:aws:glue:us-east-1:111122223333:table/s3tablescatalog/
amzn-s3-demo-table-bucket/<namespace>/*",
        "arn:aws:glue:us-east-1:111122223333:database/
s3tablescatalog/amzn-s3-demo-table-bucket/<namespace>""
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "lakeformation:GetDataAccess"
    ],
    "Resource": "*"
}
]
}
```

5. After you create the policy, create an IAM role and choose **Custom trust policy** as the **Trusted entity type**.
6. Enter the following for the **Custom trust policy**.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/Admin_role"
            },
            "Action": "sts:AssumeRole",
            "Condition": {}
        }
    ]
}
```

Define access in Lake Formation

Lake Formation provides fine-grained access control for your data lake tables. When you integrated your S3 bucket with the AWS Glue Data Catalog, your tables were automatically registered as resources in Lake Formation. To access these tables, you must grant specific Lake Formation permissions to your IAM identity, in addition to its IAM policy permissions.

The following steps explain how to apply Lake Formation access controls to allow your Iceberg client to connect to your tables. You must sign in as a data lake administrator to apply these permissions.

Allow external engines to access table data

In Lake Formation, you must enable full table access for external engines to access data. This allows third-party applications to get temporary credentials from Lake Formation when using an IAM role that has full permissions on the requested table.

Open the Lake Formation console at <https://console.aws.amazon.com/lakeformation/>.

1. Open the Lake Formation console at <https://console.aws.amazon.com/lakeformation/>, and sign in as a data lake administrator.
2. In the navigation pane under **Administration**, choose **Application integration settings**.
3. Select **Allow external engines to access data in Amazon S3 locations with full table access**. Then choose **Save**.

Grant Lake Formation permissions on your table resources

Next, grant Lake Formation permissions to the IAM role you created for your Iceberg-compatible client. These permissions will allow the role to create and manage tables in your namespace. You need to provide both database and table-level permissions. For more information, see [Granting Lake Formation permission on a table or database](#).

Set up your environment to use the endpoint

After you have setup the IAM role with the permissions required for table access you can use it to run Iceberg clients from your local machine by configuring the AWS CLI with your role, using the following command:

```
aws sts assume-role --role-arn "arn:aws:iam::<accountid>:role/<glue-irc-role>" --role-session-name <glue-irc-role>
```

To access tables through the AWS Glue REST endpoint, you need to initialize a catalog in your Iceberg-compatible client. This initialization requires specifying custom properties, including sigv4 properties, the endpoint URI and the warehouse location. Specify these properties as follows:

- Sigv4 properties - Sigv4 must be enabled, the signing name is glue
- Warehouse location - This is your table bucket, specified in this format:
`<accountid>:s3tablescatalog/<table-bucket-name>`
- Endpoint URI - Refer to the AWS Glue service endpoints reference guide for the region-specific endpoint

The following example shows how to initialize a pylceberg catalog.

```
rest_catalog = load_catalog(  
    s3tablescatalog,  
    **{  
        "type": "rest",  
        "warehouse": "<accountid>:s3tablescatalog/<table-bucket-name>",  
        "uri": "https://glue.<region>.amazonaws.com/iceberg",  
        "rest.sigv4-enabled": "true",  
        "rest.signing-name": "glue",  
        "rest.signing-region": region  
    }  
)
```

For additional information about the AWS Glue Iceberg REST endpoint implementation, see [Connecting to the Data Catalog using AWS Glue Iceberg REST endpoint](#) in the [AWS Glue User Guide](#).

Accessing tables using the Amazon S3 Tables Iceberg REST endpoint

You can connect your Iceberg REST client to the Amazon S3 Tables Iceberg REST endpoint and make REST API calls to create, update, or query tables in S3 table buckets. The endpoint implements a set of standardized Iceberg REST APIs specified in the [Apache Iceberg REST Catalog Open API specification](#). The endpoint works by translating Iceberg REST API operations into corresponding S3 Tables operations.

Note

Amazon S3 Tables Iceberg REST endpoint can be used to access tables in AWS Partner Network (APN) catalog implementations or custom catalog implementations. It can also be used if you only need basic read/write access to a single table bucket. For other access scenarios we recommend using the AWS Glue Iceberg REST endpoint to connect to tables, which provides unified table management, centralized governance, and fine-grained access control. For more information, see [Accessing Amazon S3 tables using the AWS Glue Iceberg REST endpoint](#)

Configuring the endpoint

You connect to the Amazon S3 Tables Iceberg REST endpoint using the service endpoint. S3 Tables Iceberg REST endpoints have the following format:

```
https://s3tables.<REGION>.amazonaws.com/iceberg
```

Refer to [S3 Tables AWS Regions and endpoints](#) for the Region-specific endpoints.

Catalog configuration properties

When using an Iceberg client to connect an analytics engine to the service endpoint, you must specify the following configuration properties when you initialize the catalog. Replace the *placeholder values* with the information for your Region and table bucket.

- The region-specific endpoint as the endpoint URL: `https://s3tables.<REGION>.amazonaws.com/iceberg`
- Your table bucket ARN as the warehouse location:
`arn:aws:s3tables:<region>:<accountID>:bucket/<bucketname>`

- Sigv4 properties for authentication. The SigV4 signing name for the service endpoint requests is: s3tables

The following examples show you how to configure different clients to use the Amazon S3 Tables Iceberg REST endpoint.

Pylceberg

To use the Amazon S3 Tables Iceberg REST endpoint with Pylceberg, specify the following application configuration properties:

```
rest_catalog = load_catalog(  
    catalog_name,  
    **{  
        "type": "rest",  
        "warehouse": "arn:aws:s3tables:<Region>:<accountID>:bucket/<bucketname>",  
        "uri": "https://s3tables.<Region>.amazonaws.com/iceberg",  
        "rest.sigv4-enabled": "true",  
        "rest.signing-name": "s3tables",  
        "rest.signing-region": "<Region>"  
    }  
)
```

Apache Spark

To use the Amazon S3 Tables Iceberg REST endpoint with Spark, specify the following application configuration properties, replacing the *placeholder values* with the information for your Region and table bucket.

```
spark-shell \  
  --packages "org.apache.iceberg:iceberg-spark-  
runtime-3.5_2.12:1.4.1,software.amazon.awssdk:bundle:2.20.160,software.amazon.awssdk:url-  
connection-client:2.20.160" \  
  --master "local[*]" \  
  --conf  
  "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions"  
\  
  --conf "spark.sql.defaultCatalog=spark_catalog" \

Authenticating and authorizing access to the endpoint

API requests to the S3 Tables service endpoints are authenticated using AWS Signature Version 4 (SigV4). See [AWS Signature Version 4 for API requests](#) to learn more about AWS SigV4.

The SigV4 signing name for Amazon S3 Tables Iceberg REST endpoint requests is: s3tables

Requests to the Amazon S3 Tables Iceberg REST endpoint are authorized using s3tables IAM actions corresponding to the REST API operations. These permissions can be defined in either IAM identity-based policies or resource-based policies attached to tables and table buckets. For more information, see [Access management for S3 Tables](#).

You can track requests made to your tables through the REST endpoint with AWS CloudTrail. Requests will be logged as their corresponding S3 IAM action. For example, a LoadTable API will generate a management event for the GetTableMetadataLocation operation and a data event for the GetTableData operation. For more information, see [Logging with AWS CloudTrail for S3 Tables](#).

Prefix and path parameters

Iceberg REST catalog APIs have a free-form prefix in their request URLs. For example, the ListNamespaces API call uses the GET/v1/{prefix}/namespaces URL format. For S3 Tables the REST path {prefix} is always your url-encoded table bucket ARN.

For example, for the following table bucket ARN: arn:aws:s3tables:us-east-1:111122223333:bucket/*bucketname* the prefix would be: arn%3Aaws%3As3tables%3A*us-east-1*%3A*111122223333*%3Abucket%2F*bucketname*

Namespace path parameter

Namespaces in an Iceberg REST catalog API path can have multiple levels. However, S3 Tables only supports single-level namespaces. To access a namespace in a multi-level catalog hierarchy, you can connect to a multi-level catalog above the namespace when referencing the namespace. This allows any query engine that supports the 3-part notation of catalog.namespace.table to access objects in S3 Tables' catalog hierarchy without compatibility issues compared to using the multi-level namespace.

Supported Iceberg REST API operations

The following table contains the supported Iceberg REST APIs and how they correspond to S3 Tables actions.

Iceberg REST operation	REST path	S3 Tables IAM action	CloudTrail EventName
getConfig	GET /v1/config	s3tables: GetTableBucket	s3tables: GetTableBucket
listNamespaces	GET /v1/{prefix}/namespaces	s3tables: ListNamespaces	s3tables: ListNamespaces
createNamespace	POST /v1/{prefix}/namespaces	s3tables: CreateNamespace	s3tables: CreateNamespace
loadNamespaceMetadata	GET /v1/{prefix}/namespaces/{namespace}	s3tables: GetNamespace	s3tables: GetNamespace
dropNamespace	DELETE /v1/{prefix}/namespaces/{namespace}	s3tables: DeleteNamespace	s3tables: DeleteNamespace
listTables	GET /v1/{prefix}/namespaces	s3tables: ListTables	s3tables: ListTables

Iceberg REST operation	REST path	S3 Tables IAM action	CloudTrail EventName
	paces/{namespace}/tables		
createTable	POST /v1/{prefix}/namespaces/{namespace}/tables	s3tables:CreateTable, s3tables:PutTableData	s3tables:CreateTable, s3tables:PutObject
loadTable	GET /v1/{prefix}/namespaces/{namespace}/tables/{table}	s3tables:GetTableMetadata, s3tables:GetTableData	s3tables:GetTableMetadata, s3tables:GetObject
updateTable	POST /v1/{prefix}/namespaces/{namespace}/tables/{table}	s3tables:UpdateTableMetadata, s3tables:PutTableData, s3tables:GetTableData	s3tables:UpdateTableMetadata, s3tables:PutObject, s3tables:GetObject
dropTable	DELETE /v1/{prefix}/namespaces/{namespace}/tables/{table}	s3tables:DeleteTable	s3tables:DeleteTable
renameTable	POST /v1/{prefix}/tables/rename	s3tables:RenameTable	s3tables:RenameTable

Iceberg REST operation	REST path	S3 Tables IAM action	CloudTrail EventName

namespaceExists	HEAD /v1/{prefix}/namespaces/{namespace}	s3tables: GetNamespace	s3tables: GetNamespace

Considerations and limitations

Following are considerations and limitations when using the Amazon S3 Tables Iceberg REST endpoint.

Considerations

- **CreateTable API behavior** – The stage-create option is not supported for this operation, and results in a 400 Bad Request error. This means you cannot create a table from query results using CREATE TABLE AS SELECT (CTAS).
- **DeleteTable API behavior** – You can only drop tables with purge enabled. Dropping tables with purge=false is not supported and results in a 400 Bad Request error. Some versions of Spark always set this flag to false even when running DROP TABLE PURGE commands. You can try with DROP TABLE PURGE or use the S3 Tables [DeleteTable](#) operation to delete a table.
- The endpoint only supports standard table metadata operations. For table maintenance, such as snapshot management and compaction, use S3 Tables maintenance API operations. For more information, see [S3 Tables maintenance](#).

Limitations

- Multilevel namespaces are not supported.
- OAuth-based authentication is not supported.

- Only the owner property is supported for namespaces.
- View-related APIs defined in the [Apache Iceberg REST Open API specification](#) are not supported.
- Running operations on a table with a metadata.json file over 5MB is not supported, and will return a 400 Bad Request error. To control the size of your metadata.json files use table maintenance operations. For more information, see [S3 Tables maintenance](#).

Accessing Amazon S3 tables with the Amazon S3 Tables Catalog for Apache Iceberg

You can access S3 tables from open source query engines like Apache Spark by using the Amazon S3 Tables Catalog for Apache Iceberg client catalog. Amazon S3 Tables Catalog for Apache Iceberg is an open source library hosted by AWS Labs. It works by translating Apache Iceberg operations in your query engines (such as table discovery, metadata updates, and adding or removing tables) into S3 Tables API operations.

Amazon S3 Tables Catalog for Apache Iceberg is distributed as a Maven JAR called s3-tables-catalog-for-iceberg.jar. You can build the client catalog JAR from the [AWS Labs GitHub repository](#) or download it from [Maven](#). When connecting to tables, the client catalog JAR is used as a dependency when you initialize a Spark session for Apache Iceberg.

Using the Amazon S3 Tables Catalog for Apache Iceberg with Apache Spark

You can use the Amazon S3 Tables Catalog for Apache Iceberg client catalog to connect to tables from open-source applications when you initialize a Spark session. In your session configuration you specify Iceberg and Amazon S3 dependencies, and create a custom catalog that uses your table bucket as the metadata warehouse.

Prerequisites

- An IAM identity with access to your table bucket and S3 Tables actions. For more information, see [Access management for S3 Tables](#).

To initialize a Spark session using the Amazon S3 Tables Catalog for Apache Iceberg

- Initialize Spark using the following command. To use the command, replace the replace the Amazon S3 Tables Catalog for Apache Iceberg *version number* with the latest version from [AWS Labs GitHub repository](#), and the *table bucket ARN* with your own table bucket ARN.

```
spark-shell \
--packages org.apache.iceberg:iceberg-spark-
runtime-3.5_2.12:1.6.1,software.amazon.s3tables:s3-tables-catalog-for-iceberg-
runtime:0.1.4 \
--conf spark.sql.catalog.s3tablesbucket=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.s3tablesbucket.catalog-
impl=software.amazon.s3tables.iceberg.S3TablesCatalog \
--conf spark.sql.catalog.s3tablesbucket.warehouse=arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket \
--conf
spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
```

Querying S3 tables with Spark SQL

Using Spark, you can run DQL, DML, and DDL operations on S3 tables. When you query tables you use the fully qualified table name, including the session catalog name following this pattern:

CatalogName.*NamespaceName*.*TableName*

The following example queries show some ways you can interact with S3 tables. To use these example queries in your query engine, replace the *user input placeholder* values with your own.

To query tables with Spark

- Create a namespace

```
spark.sql(" CREATE NAMESPACE IF NOT EXISTS s3tablesbucket.my_namespace" )
```

- Create a table

```
spark.sql(" CREATE TABLE IF NOT EXISTS s3tablesbucket.my_namespace.`my_table` \
( id INT, name STRING, value INT ) USING iceberg " )
```

- Query a table

```
spark.sql(" SELECT * FROM s3tablesbucket.my_namespace.`my_table` " ).show()
```

- Insert data into a table

```
spark.sql(  
    """  
        INSERT INTO s3tablesbucket.my_namespace.my_table  
        VALUES  
        (1, 'ABC', 100),  
        (2, 'XYZ', 200)  
    """")
```

- Load an existing data file into a table

1. Read the data into Spark.

```
val data_file_location = "Path such as S3 URI to data file"  
val data_file = spark.read.parquet(data_file_location)
```

2. Write the data into an Iceberg table.

```
data_file.writeTo("s3tablesbucket.my_namespace.my_table").using("Iceberg").tableProperty  
    ("format-version", "2").createOrReplace()
```

Querying Amazon S3 tables with Athena

Amazon Athena is an interactive query service that you can use to analyze data directly in Amazon S3 by using standard SQL. For more information, see [What is Amazon Athena?](#) in the *Amazon Athena User Guide*.

After you integrate your table buckets with AWS analytics services, you can run Data Definition Language (DDL), Data Manipulation Language (DML), and Data Query Language (DQL) queries on S3 tables by using Athena. For more information about how to query tables in a table bucket, see [Register S3 Table bucket catalogs](#) in the *Amazon Athena User Guide*.

You can also run queries in Athena from the Amazon S3 console.

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to

AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.

If your table definition contains capital letters, you receive the following error message when running a SELECT query in Athena: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Using the S3 console and Amazon Athena

The following procedure uses the Amazon S3 console to access the Athena query editor so that you can query a table with Amazon Athena.

Note

Before performing the following steps, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see [the section called "Integrating S3 Tables with AWS analytics services".](#)

To query a table

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that contains the table that you want to query.
4. On the bucket details page, choose the option button next to the name of the table that you want to query.
5. Choose **Query table with Athena**.
6. The Amazon Athena console opens and the Athena query editor appears with a sample SELECT query loaded for you. Modify this query as needed for your use case.

In the query editor, the **Catalog** field should be populated with **s3tablescatalog/** followed by the name of your table bucket, for example, **s3tablescatalog/amzn-s3-demo-bucket**. The **Database** field should be populated with the namespace where your table is stored.

Note

If you don't see these values in the **Catalog** and **Database** fields, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see [the section called "Integrating S3 Tables with AWS analytics services"](#).

7. To run the query, choose **Run**.

Note

- If you receive the error "Insufficient permissions to execute the query. Principal does not have any privilege on specified resource" when you try to run a query in Athena, you must be granted the necessary Lake Formation permissions on the table. For more information, see [the section called "Granting Lake Formation permission on a table or database"](#).
- If you receive the error "Iceberg cannot access the requested resource" when you try to run the query, go to the AWS Lake Formation console and make sure that you've granted yourself permissions on the table bucket catalog and database (namespace) that you created. Don't specify a table when granting these permissions. For more information, see [the section called "Granting Lake Formation permission on a table or database"](#).
- If you receive the following error message when running a SELECT query in Athena, this message is caused by having capital letters in your table name or your column names in your table definition: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names." Make sure that your table and column names are all lowercase.

Accessing Amazon S3 tables with Amazon Redshift

Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools. Redshift Serverless lets you access and analyze data without all of the configurations of a provisioned data warehouse. For more information, see [Get started with serverless data warehouses](#) in the *Amazon Redshift Getting Started Guide*.

Query Amazon S3 tables with Amazon Redshift

Prerequisites

- [Integrate your table buckets with AWS analytics services.](#)
 - [Create a namespace.](#)
 - [Create a table.](#)
- [Managing access to a table or database with Lake Formation.](#)

After you complete the prerequisites, you can begin using Amazon Redshift to query tables in one of the following ways:

- [Using the Amazon Redshift query editor v2](#)
- [Connecting to an Amazon Redshift data warehouse using SQL client tools](#)
- [Using the Amazon Redshift Data API](#)

Accessing Amazon S3 tables with Amazon EMR

Amazon EMR (previously called Amazon Elastic MapReduce) is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data. Using these frameworks and related open-source projects, you can process data for analytics purposes and business intelligence workloads. Amazon EMR also lets you transform and move large amounts of data into and out of other AWS data stores and databases.

You can use Apache Iceberg clusters in Amazon EMR to work with S3 tables by connecting to table buckets in a Spark session. To connect to table buckets in Amazon EMR, you can use the AWS analytics services integration through AWS Glue Data Catalog, or you can use the open source Amazon S3 Tables Catalog for Apache Iceberg client catalog.

 **Note**

S3 Tables is supported on [Amazon EMR version 7.5](#) or higher.

Connecting to S3 table buckets with Spark on an Amazon EMR Iceberg cluster

In this procedure, you set up an Amazon EMR cluster configured for Apache Iceberg and then launch a Spark session that connects to your table buckets. You can set this up using the AWS analytics services integration through AWS Glue, or you can use the open source Amazon S3 Tables Catalog for Apache Iceberg client catalog. For information about the client catalog, see [Accessing tables using the Amazon S3 Tables Iceberg REST endpoint](#).

Choose your method of using tables with Amazon EMR from the following options.

Amazon S3 Tables Catalog for Apache Iceberg

The following prerequisites are required to query tables with Spark on Amazon EMR using the Amazon S3 Tables Catalog for Apache Iceberg.

Prerequisites

- Attach the `AmazonS3TablesFullAccess` policy to the IAM role you use for Amazon EMR.

To set up an Amazon EMR cluster to query tables with Spark

1. Create a cluster with the following configuration. To use this example, replace the *user input placeholders* with your own information.

```
aws emr create-cluster --release-label emr-7.5.0 \
--applications Name=Spark \
--configurations file://configurations.json \
--region us-east-1 \
--name My_Spark_Iceberg_Cluster \
--log-uri s3://amzn-s3-demo-bucket/ \
--instance-type m5.xlarge \
--instance-count 2 \
--service-role EMR_DefaultRole \
--ec2-attributes \
  
InstanceProfile=EMR_EC2_DefaultRole,SubnetId=subnet-1234567890abcdef0,KeyName=my-key-pair
```

configurations.json:

```
[{
```

```
"Classification":"iceberg-defaults",
"Properties": {"iceberg.enabled":"true"}
}]
```

2. [Connect to the Spark primary node using SSH.](#)
3. To initialize a Spark session for Iceberg that connects to your table bucket, enter the following command. Replace the *user input placeholders* with your table bucket ARN.

```
spark-shell \
--packages software.amazon.s3tables:s3-tables-catalog-for-iceberg-runtime:0.1.3 \
--conf spark.sql.catalog.s3tablesbucket=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.s3tablesbucket.catalog-
impl=software.amazon.s3tables.iceberg.S3TablesCatalog \
--conf spark.sql.catalog.s3tablesbucket.warehouse=arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-bucket1 \
--conf spark.sql.defaultCatalog=s3tablesbucket \
--conf
spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
```

4. Query your tables with Spark SQL. For example queries, see [the section called “Querying S3 tables with Spark SQL”](#).

AWS analytics services integration

The following prerequisites are required to query tables with Spark on Amazon EMR using the AWS analytics services integration.

Prerequisites

- [Integrate your table buckets with AWS analytics services.](#)
- Create the default service role for Amazon EMR (EMR_DefaultRole_V2). For details, see [Service role for Amazon EMR \(EMR role\)](#).
- Create the Amazon EC2 instance profile for Amazon EMR (EMR_EC2_DefaultRole). For details, see [Service role for cluster EC2 instances \(EC2 instance profile\)](#).
- Attach the AmazonS3TablesFullAccess policy to EMR_EC2_DefaultRole.

To set up an Amazon EMR cluster to query tables with Spark

1. Create a cluster with the following configuration. To use this example, replace the *user input placeholder* values with your own information.

```
aws emr create-cluster --release-label emr-7.5.0 \
--applications Name=Spark \
--configurations file://configurations.json \
--region us-east-1 \
--name My_Spark_Iceberg_Cluster \
--log-uri s3://amzn-s3-demo-bucket/ \
--instance-type m5.xlarge \
--instance-count 2 \
--service-role EMR_DefaultRole \
--ec2-attributes \
  
InstanceProfile=EMR_EC2_DefaultRole,SubnetId=subnet-1234567890abcdef0,KeyName=my-key-pair
```

configurations.json:

```
[{
  "Classification": "iceberg-defaults",
  "Properties": {"iceberg.enabled": "true"}
}]
```

2. [Connect to the Spark primary node using SSH.](#)
3. Enter the following command to initialize a Spark session for Iceberg that connects to your tables. Replace the *user input placeholders* for Region, account ID and table bucket name with your own information.

```
spark-shell \
--conf
  spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions \
\
--conf spark.sql.defaultCatalog=s3tables \
--conf spark.sql.catalog.s3tables=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.s3tables.catalog-
impl=org.apache.iceberg.aws.glue.GlueCatalog \
--conf spark.sql.catalog.s3tables.client.region=us-east-1 \
```

```
--conf spark.sql.catalog.s3tables.glue.id=111122223333:s3tablescatalog/amzn-s3-demo-table-bucket
```

4. Query your tables with Spark SQL. For example queries, see [the section called “Querying S3 tables with Spark SQL”](#)

Note

If you are using the `DROP TABLE PURGE` command with Amazon EMR:

- Amazon EMR version 7.5

Set the Spark config `spark.sql.catalog.your-catalog-name.cache-enabled` to `false`. If this config is set to `true`, run the command in a new session or application so the table cache is not activated.

- Amazon EMR versions higher than 7.5

`DROP TABLE` is not supported. You can use the S3 Tables `DeleteTable` REST API to delete a table.

Visualizing table data with Quick Suite

Quick Suite is a fast business analytics service to build visualizations, perform ad hoc analysis, and quickly get business insights from your data. Quick Suite seamlessly discovers AWS data sources, enables organizations to scale to hundreds of thousands of users, and delivers fast and responsive query performance by using the Quick Suite Super-fast, Parallel, In-Memory, Calculation Engine (SPICE). For more information, see [What is Quick Suite?](#) in the *Quick Suite user guide*.

After you [Integrate your table buckets with AWS analytics services](#), you can create data sets from your tables and work with them in Quick Suite using SPICE or direct SQL queries from your query engine. Quick Suite supports Athena as a data source for S3 tables.

Configure permissions for Quick Suite to access tables

Before working with S3 table data in Quick Suite you must grant permissions to the Quick Suite service role, the Quick Suite admin user, and grant Lake Formation permissions on the tables you want to access.

Grant permissions to the Quick Suite service role

When set up Quick Suite for the first time in your account, AWS creates a service role that allows Quick Suite to access data sources in other AWS services, such as Athena or Amazon Redshift. The default role name is `aws-quicksight-service-role-v0`.
