Example — Setting permissions for an object version

The following request sets the permission of the grantee with canonical user ID `b4bf1b36f9716f094c3079dcf5ac9982d4f2847de46204d47448bc557fb5ac2a`, to FULL_CONTROL on the key, `my-image.jpg`, version ID, `3HL4kqtJvjVBH40Nrjfkd`.

```
PUT /my-image.jpg?acl&versionId=3HL4kqtJvjVBH40Nrjfkd HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
Content-Length: 124

<AccessControlPolicy>
  <Owner>
    <ID>75cc57f09aa0c8caeab4f8c24e99d10f8e7faebf76c078efc7c6caea54ba06a</ID>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
        <ID>a9a7b886d6fd24a52fe8ca5bef65f89a64e0193f23000e241bf9b1c61be666e9</ID>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
</AccessControlPolicy>
```

Likewise, to get the permissions of a specific object version, you must specify its version ID in a `GET Object versionId acl` request. You need to include the version ID because, by default, `GET Object acl` returns the permissions of the current version of the object.

Example — Retrieving the permissions for a specified object version

In the following example, Amazon S3 returns the permissions for the key, my-image.jpg, version ID, DVBH40Nr8X8gUMLUo.

```
GET /my-image.jpg?versionId=DVBH40Nr8X8gUMLUo&acl HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU
```

For more information, see [GetObjectAcl](#) in the *Amazon Simple Storage Service API Reference*.

Working with objects in a versioning-suspended bucket

In Amazon S3, you can suspend versioning to stop accruing new versions of the same object in a bucket. You might do this because you only want a single version of an object in a bucket. Or, you might not want to accrue charges for multiple versions.

When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. The topics in this section explain various object operations in a versioning-suspended bucket, including adding, retrieving, and deleting objects.

For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#). For more information about retrieving object versions, see [Retrieving object versions from a versioning-enabled bucket](#).

Topics

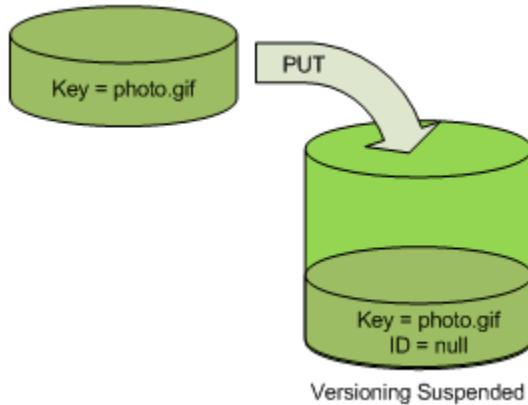

- [Adding objects to versioning-suspended buckets](#)
- [Retrieving objects from versioning-suspended buckets](#)
- [Deleting objects from versioning-suspended buckets](#)

Adding objects to versioning-suspended buckets

You can add objects to versioning-suspended buckets in Amazon S3 to create the object with a null version ID or overwrite any object version with a matching version ID.

After you suspend versioning on a bucket, Amazon S3 automatically adds a null version ID to every subsequent object stored thereafter (using PUT, POST, or CopyObject) in that bucket.

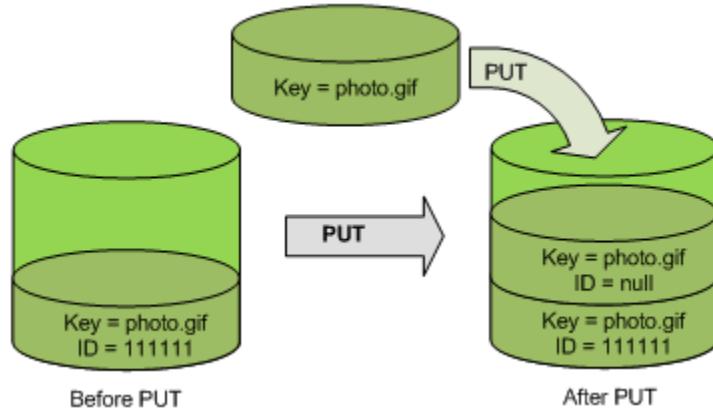

The following figure shows how Amazon S3 adds the version ID of null to an object when it is added to a version-suspended bucket.

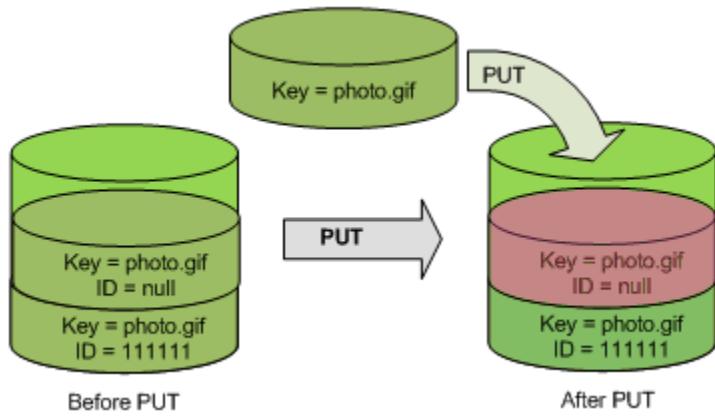

If a null version is already in the bucket and you add another object with the same key, the added object overwrites the original null version.

If there are versioned objects in the bucket, the version you PUT becomes the current version of the object. The following figure shows how adding an object to a bucket that contains versioned objects does not overwrite the object already in the bucket.

In this case, version 111111 was already in the bucket. Amazon S3 attaches a version ID of null to the object being added and stores it in the bucket. Version 111111 is not overwritten.

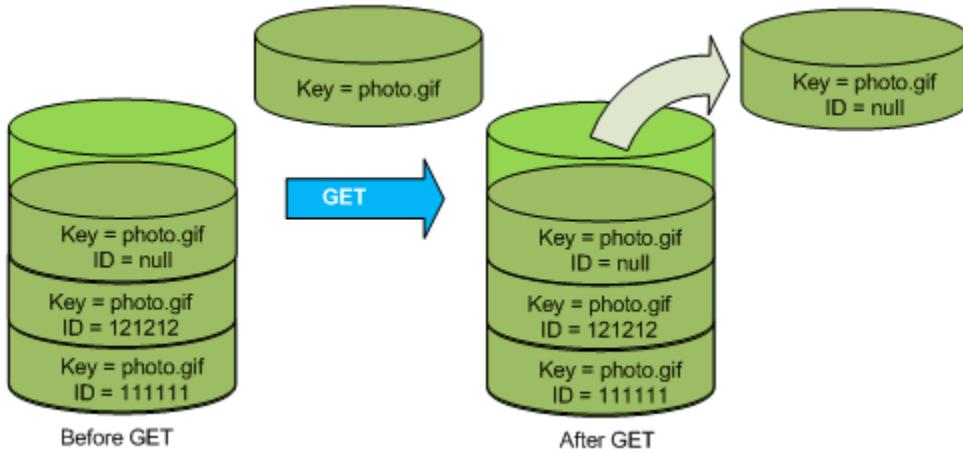

If a null version already exists in a bucket, the null version is overwritten, as shown in the following figure.

Although the key and version ID (null) of the null version are the same before and after the PUT, the contents of the null version originally stored in the bucket are replaced by the contents of the object PUT into the bucket.

Retrieving objects from versioning-suspended buckets

A GET Object request returns the current version of an object whether you've enabled versioning on a bucket or not. The following figure shows how a simple GET returns the current version of an object.

Deleting objects from versioning-suspended buckets

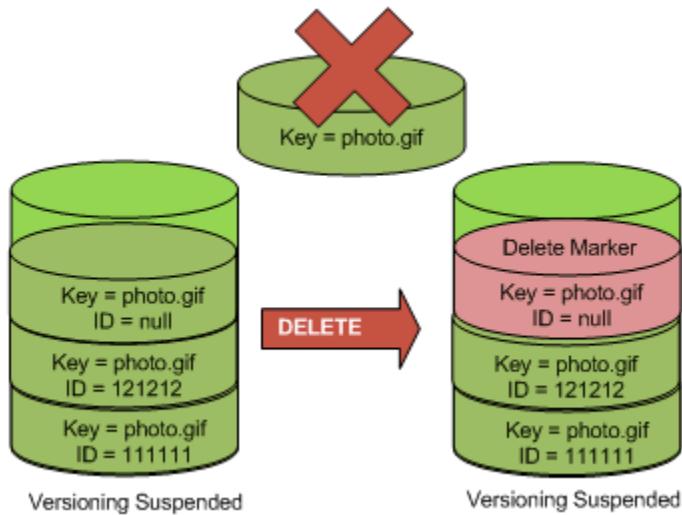

You can delete objects from versioning-suspended buckets to remove an object with a null version ID.

If versioning is suspended for a bucket, a DELETE request:

- Can only remove an object whose version ID is null.
- Doesn't remove anything if there isn't a null version of the object in the bucket.

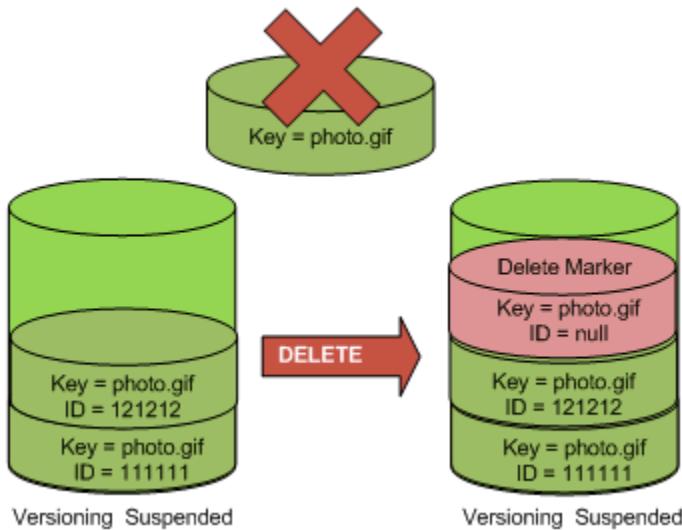

- Inserts a delete marker into the bucket.

If bucket versioning is suspended, the operation removes the object that has a null `versionId`. If a version ID exists, Amazon S3 inserts a delete marker that becomes the current version of the object. The following figure shows how a simple `DELETE` removes a null version and Amazon S3 inserts a delete marker in its place instead with a null `versionId`.

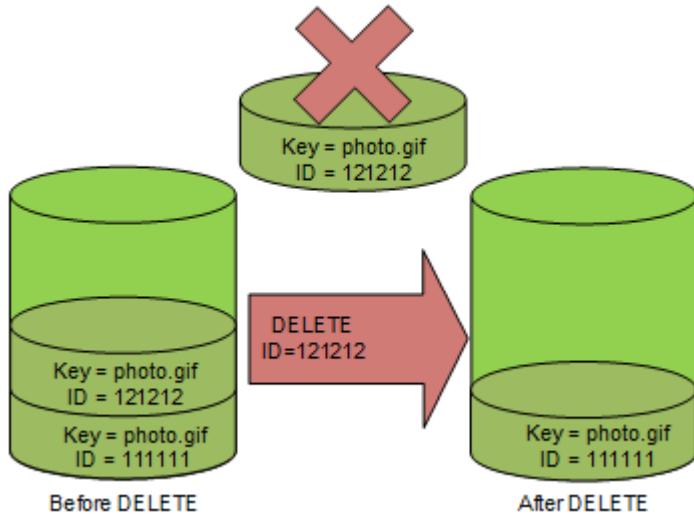

To permanently delete an object that has a `versionId`, you must include the object's `versionId` in the request. Since a delete marker doesn't contain any content, you'll lose the content for the null version when a delete marker replaces it.

The following figure shows a bucket that doesn't have a null version. In this case, the `DELETE` removes nothing. Instead, Amazon S3 just inserts a delete marker.

Even in a versioning-suspended bucket, the bucket owner can permanently delete a specified version by including the version ID in the DELETE request, unless permissions for the DELETE request have been explicitly denied. For example, to deny deletion of any objects that have a null version ID, you must explicitly deny the `s3:DeleteObject` and `s3:DeleteObjectVersions` permissions.

The following figure shows that deleting a specified object version permanently removes that version of the object. Only the bucket owner can delete a specified object version.

Troubleshooting versioning

The following topics can help you troubleshoot some common Amazon S3 versioning issues.

Topics

- [I want to recover objects that were accidentally deleted in a versioning-enabled bucket](#)
- [I want to permanently delete versioned objects](#)
- [I'm experiencing performance degradation after enabling bucket versioning](#)

I want to recover objects that were accidentally deleted in a versioning-enabled bucket

In general, when object versions are deleted from S3 buckets, there is no way for Amazon S3 to recover them. However, if you have enabled S3 Versioning on your S3 bucket, a DELETE request that doesn't specify a version ID cannot permanently delete an object. Instead, a delete marker is added as a placeholder. This delete marker becomes the current version of the object.

To verify whether your deleted objects are permanently deleted or temporarily deleted (with a delete marker in their place), do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object.
4. In the **Objects** list, Turn on the **Show versions** toggle to the right of the search bar, and then search for the deleted object in the search bar. This toggle is available only if versioning was previously enabled on the bucket.

You can also use [S3 Inventory to search for deleted objects](#).

5. If you can't find the object after toggling **Show versions** or creating an inventory report, and you also cannot find a [delete marker](#) of the object, the deletion is permanent and the object cannot be recovered.

You can also verify a deleted object's status by using the HeadObject API operation from the AWS Command Line Interface (AWS CLI). To do so, use the following head-object command and replace the *user input placeholders* with your own information:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key index.html
```

If you run the head-object command on a versioned object whose current version is a delete marker, you will receive a 404 Not Found error. For example:

An error occurred (404) when calling the HeadObject operation: Not Found

If you run the head-object command on a versioned object and provide the object's version ID, Amazon S3 retrieves the object's metadata, confirming that the object still exists and is not permanently deleted.

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key index.html --version-id versionID
```

```
{  
  "AcceptRanges": "bytes",  
  "ContentType": "text/html",  
  "LastModified": "Thu, 16 Apr 2015 18:19:14 GMT",  
  "Size": 123456789}
```

```
"ContentLength": 77,  
"VersionId": "Zg5HyL7m.eZU9iM7AV1JkrqAiE.0UG4q",  
"ETag": "\"30a6ec7e1a9ad79c203d05a589c8b400\"",  
"Metadata": {}  
}
```

If the object is found and the newest version is a delete marker, the previous version of the object still exists. Because the delete marker is the current version of the object, you can recover the object by deleting the delete marker.

After you permanently remove the delete marker, the second newest version of the object becomes the current version of the object, making your object available once again. For a visual depiction of how objects are recovered, see [Removing delete markers](#).

To remove a specific version of an object, you must be the bucket owner. To delete a delete marker permanently, you must include its version ID in a DeleteObject request. To delete the delete marker, use the following command, and replace the *user input placeholders* with your own information:

```
aws s3api delete-object --bucket amzn-s3-demo-bucket --key index.html --  
version-id versionID
```

For more information about the delete-object command, see [delete-object](#) in the *AWS CLI Command Reference*. For more information about permanently deleting delete markers, see [Managing delete markers](#).

I want to permanently delete versioned objects

In a versioning-enabled bucket, a DELETE request without a version ID cannot permanently delete an object. Instead, such a request inserts a delete marker.

To permanently delete versioned objects, you can choose from the following methods:

- Create an S3 Lifecycle rule to permanently delete noncurrent versions. To permanently delete noncurrent versions, select **Permanently delete noncurrent versions of objects**, and then enter a number under **Days after objects become noncurrent**. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**. For more information about creating this rule, see [Setting an S3 Lifecycle configuration](#).
- Delete a specified version by including the version ID in the DELETE request. For more information, see [How to delete versioned objects permanently](#).

- Create a lifecycle rule to expire current versions. To expire current versions of objects, select **Expire current versions of objects**, and then add a number under **Days after object creation**. For more information about creating this lifecycle rule, see [Setting an S3 Lifecycle configuration](#).
- To permanently delete all versioned objects and delete markers, create two lifecycle rules: one to expire current versions and permanently delete noncurrent versions of objects, and the other to delete expired object delete markers.

In a versioning-enabled bucket, a DELETE request that doesn't specify a version ID can remove only objects with a NULL version ID. If the object was uploaded when versioning was enabled, a DELETE request that doesn't specify a version ID creates a delete marker of that object.

Note

For S3 Object Lock-enabled buckets, a DELETE object request with a protected object version ID causes a 403 Access Denied error. A DELETE object request without a version ID adds a delete marker as the newest version of the object with a 200 OK response. Objects protected by Object Lock cannot be permanently deleted until their retention periods and legal holds are removed. For more information, see [the section called "How S3 Object Lock works"](#).

I'm experiencing performance degradation after enabling bucket versioning

Performance degradation can occur on versioning-enabled buckets if there are too many delete markers or versioned objects, and if best practices aren't followed.

Too many delete markers

After you enable versioning on a bucket, a DELETE request without a version ID made to an object creates a delete marker with a unique version ID. Lifecycle configurations with an **Expire current versions of objects** rule add a delete marker with a unique version ID to every object. Excessive delete markers can reduce performance in the bucket.

When versioning is suspended on a bucket, Amazon S3 marks the version ID as NULL on newly created objects. An expiration action in a versioning-suspended bucket causes Amazon S3 to create a delete marker with NULL as the version ID. In a versioning-suspended bucket, a NULL delete marker is created for any delete request. These NULL delete markers are also called expired object

delete markers when all object versions are deleted and only a single delete marker remains. If too many NULL delete markers accumulate, performance degradation in the bucket occurs.

Too many versioned objects

If a versioning-enabled bucket contains objects with millions of versions, an increase in 503 Service Unavailable errors can occur. If you notice a significant increase in the number of HTTP 503 Service Unavailable responses received for PUT or DELETE object requests to a versioning-enabled bucket, you might have one or more objects in the bucket with millions of versions. When you have objects with millions of versions, Amazon S3 automatically throttles requests to the bucket. Throttling requests protects your bucket from an excessive amount of request traffic, which could potentially impede other requests made to the same bucket.

To determine which objects have millions of versions, use S3 Inventory. S3 Inventory generates a report that provides a flat file list of the objects in a bucket. For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

To verify if there are high number of versioned objects in the bucket, use S3 Storage Lens metrics to view the **Current version object count**, **Noncurrent version object count**, and **Delete marker object count**. For more information about Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

The Amazon S3 team encourages customers to investigate applications that repeatedly overwrite the same object, potentially creating millions of versions for that object, to determine whether the application is working as intended. For instance, an application overwriting the same object every minute for a week can create over ten thousand versions. We recommend storing less than one hundred thousand versions for each object. If you have a use case that requires millions of versions for one or more objects, contact the AWS Support team for assistance with determining a better solution.

Best practices

To prevent versioning-related performance degradation issues, we recommend that you employ the following best practices:

- Enable a lifecycle rule to expire the previous versions of objects. For example, you can create a lifecycle rule to expire noncurrent versions after 30 days of the object being noncurrent. You can also retain multiple noncurrent versions if you don't want to delete all of them. For more information, see [Setting an S3 Lifecycle configuration](#).

- Enable a lifecycle rule to delete expired object delete markers that don't have associated data objects in the bucket. For more information, see [Removing expired object delete markers](#).

For additional Amazon S3 performance-optimization best practices, see [Best practices design patterns](#).

Locking objects with Object Lock

S3 Object Lock can help prevent Amazon S3 objects from being deleted or overwritten for a fixed amount of time or indefinitely. Object Lock uses a *write-once-read-many* (WORM) model to store objects. You can use Object Lock to help meet regulatory requirements that require WORM storage, or to add another layer of protection against object changes or deletion.

Note

S3 Object Lock has been assessed by Cohasset Associates for use in environments that are subject to SEC 17a-4, CFTC, and FINRA regulations. For more information about how Object Lock relates to these regulations, see the [Cohasset Associates Compliance Assessment](#).

Object Lock provides two ways to manage object retention: *retention periods* and *legal holds*. An object version can have a retention period, a legal hold, or both.

- **Retention period** – A retention period specifies a fixed period of time during which an object version remains locked. You can set a unique retention period for individual objects. Additionally, you can set a default retention period on an S3 bucket. You may also restrict the minimum and maximum allowable retention periods with the `s3:object-lock-remaining-retention-days` condition key in the bucket policy. This condition key helps you establish the allowable retention period. For more information, see [Setting limits on retention periods with a bucket policy](#).
- **Legal hold** – A legal hold provides the same protection as a retention period, but it has no expiration date. Instead, a legal hold remains in place until you explicitly remove it. Legal holds are independent from retention periods and are placed on individual object versions.

Object Lock works only in buckets that have S3 Versioning enabled. When you lock an object version, Amazon S3 stores the lock information in the metadata for that object version. Placing a retention period or a legal hold on an object protects only the version that's specified in the

request. Retention periods and legal holds don't prevent new versions of the object from being created, or delete markers to be added on top of the object. For information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

If you put an object into a bucket that already contains an existing protected object with the same object key name, Amazon S3 creates a new version of that object. The existing protected version of the object remains locked according to its retention configuration.

How S3 Object Lock works

Topics

- [Retention periods](#)
- [Retention modes](#)
- [Legal holds](#)
- [How deletes work with S3 Object Lock](#)
- [Best practices for using S3 Object Lock](#)
- [Required permissions](#)

Retention periods

A *retention period* protects an object version for a fixed amount of time. When you place a retention period on an object version, Amazon S3 stores a timestamp in the object version's metadata to indicate when the retention period expires. After the retention period expires, the object version can be overwritten or deleted.

You can place a retention period explicitly on an individual object version or on a bucket's properties so that it applies to all objects in the bucket automatically. When you apply a retention period to an object version explicitly, you specify a *Retain Until Date* for the object version. Amazon S3 stores this date in the object version's metadata.

You can also set a retention period in a bucket's properties. When you set a retention period on a bucket, you specify a duration, in either days or years, for how long to protect every object version placed in the bucket. When you place an object in the bucket, Amazon S3 calculates a *Retain Until Date* for the object version by adding the specified duration to the object version's creation timestamp. The object version is then protected exactly as though you explicitly placed an individual lock with that retention period on the object version.

Note

When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

Like all other Object Lock settings, retention periods apply to individual object versions. Different versions of a single object can have different retention modes and periods.

For example, suppose that you have an object that is 15 days into a 30-day retention period, and you PUT an object into Amazon S3 with the same name and a 60-day retention period. In this case, your PUT request succeeds, and Amazon S3 creates a new version of the object with a 60-day retention period. The older version maintains its original retention period and becomes deletable in 15 days.

After you've applied a retention setting to an object version, you can extend the retention period. To do this, submit a new Object Lock request for the object version with a *Retain Until Date* that is later than the one currently configured for the object version. Amazon S3 replaces the existing retention period with the new, longer period. Any user with permissions to place an object retention period can extend a retention period for an object version. To set a retention period, you must have the `s3:PutObjectRetention` permission.

When you set a retention period on an object or S3 bucket, you must select one of two retention modes: *compliance* or *governance*.

Retention modes

S3 Object Lock provides two retention modes that apply different levels of protection to your objects:

- Compliance mode
- Governance mode

In *compliance* mode, a protected object version can't be overwritten or deleted by any user, including the root user in your AWS account. When an object is locked in compliance mode, its retention mode can't be changed, and its retention period can't be shortened. Compliance mode helps ensure that an object version can't be overwritten or deleted for the duration of the retention period.

Note

The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

In *governance* mode, users can't overwrite or delete an object version or alter its lock settings unless they have special permissions. With governance mode, you protect objects against being deleted by most users, but you can still grant some users permission to alter the retention settings or delete the objects if necessary. You can also use governance mode to test retention-period settings before creating a compliance-mode retention period.

To override or remove governance-mode retention settings, you must have the `s3:BypassGovernanceRetention` permission and must explicitly include `x-amz-bypass-governance-retention:true` as a request header with any request that requires overriding governance mode.

Note

By default, the Amazon S3 console includes the `x-amz-bypass-governance-retention:true` header. If you try to delete objects protected by *governance* mode and have the `s3:BypassGovernanceRetention` permission, the operation will succeed.

Legal holds

With Object Lock, you can also place a *legal hold* on an object version. Like a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal hold doesn't have an associated fixed amount of time and remains in effect until removed. Legal holds can be freely placed and removed by any user who has the `s3:PutObjectLegalHold` permission.

Legal holds are independent from retention periods. Placing a legal hold on an object version doesn't affect the retention mode or retention period for that object version.

For example, suppose that you place a legal hold on an object version and that object version is also protected by a retention period. If the retention period expires, the object doesn't lose its WORM protection. Rather, the legal hold continues to protect the object until an authorized user explicitly removes the legal hold. Similarly, if you remove a legal hold while an object version has a retention period in effect, the object version remains protected until the retention period expires.

How deletes work with S3 Object Lock

If your bucket has S3 Object Lock enabled and the object is protected by a retention period or legal hold and you try to delete an object, Amazon S3 returns one of the following responses, depending on how you tried to delete the object:

- **Permanent DELETE request** – If you issued a permanent DELETE request (a request that specifies a version ID), Amazon S3 returns an Access Denied (403 Forbidden) error when you try to delete the object. For more information about troubleshooting Access Denied errors with Object Lock, see [the section called “S3 Object Lock settings”](#).
- **Simple DELETE request** – If you issued a simple DELETE request (a request that doesn't specify a version ID), Amazon S3 returns a 200 OK response and inserts a [delete marker](#) in the bucket, and that marker becomes the current version of the object with a new ID. For more information about managing delete markers with Object Lock, see [the section called “Managing delete markers with Object Lock”](#).

Best practices for using S3 Object Lock

Consider using *Governance mode* if you want to protect objects from being deleted by most users during a pre-defined retention period, but at the same time want some users with special permissions to have the flexibility to alter the retention settings or delete the objects.

Consider using *Compliance mode* if you never want any user, including the root user in your AWS account, to be able to delete the objects during a pre-defined retention period. You can use this mode in case you have a requirement to store compliant data.

You can use *Legal Hold* when you are not sure for how long you want your objects to stay immutable. This could be because you have an upcoming external audit of your data and want to keep objects immutable till the audit is complete. Alternately, you may have an ongoing project utilizing a dataset that you want to keep immutable until the project is complete.

Required permissions

Object Lock operations require specific permissions. Depending on the exact operation that you're attempting, you might need any of the following permissions:

- `s3:BypassGovernanceRetention`
- `s3:GetBucketObjectLockConfiguration`

- s3:GetObjectLegalHold
- s3:GetObjectRetention
- s3:PutBucketObjectLockConfiguration
- s3:PutObjectLegalHold
- s3:PutObjectRetention

For a complete list of Amazon S3 permissions with descriptions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

For information about using conditions with permissions, see [Bucket policy examples using condition keys](#).

Object Lock considerations

Amazon S3 Object Lock can help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely.

You can use the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API to view or set Object Lock information. For general information about S3 Object Lock capabilities, see [Locking objects with Object Lock](#).

Important

- After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
- S3 buckets with Object Lock can't be used as destination buckets for server access logs.
For more information, see [the section called "Logging server access"](#).

Topics

- [Permissions for viewing lock information](#)
- [Bypassing governance mode](#)
- [Using Object Lock with S3 Replication](#)

- [Managing delete markers with Object Lock](#)
- [Using S3 Storage Lens with Object Lock](#)
- [Uploading objects to an Object Lock enabled bucket](#)
- [Configuring events and notifications](#)
- [Setting limits on retention periods with a bucket policy](#)

Permissions for viewing lock information

You can programmatically view the Object Lock status of an Amazon S3 object version by using the [HeadObject](#) or [GetObject](#) operations. Both operations return the retention mode, retain until date, and legal hold status for the specified object version. Additionally, you can view the Object Lock status for multiple objects in your S3 bucket using S3 Inventory.

To view an object version's retention mode and retention period, you must have the `s3:GetObjectRetention` permission. To view an object version's legal hold status, you must have the `s3:GetObjectLegalHold` permission. To view a bucket's default retention configuration, you must have the `s3:GetBucketObjectLockConfiguration` permission. If you make a request for an Object Lock configuration on a bucket that doesn't have S3 Object Lock enabled, Amazon S3 returns an error.

Bypassing governance mode

If you have the `s3:BypassGovernanceRetention` permission, you can perform operations on object versions that are locked in governance mode as if they were unprotected. These operations include deleting an object version, shortening the retention period, or removing the Object Lock retention period by placing a new `PutObjectRetention` request with empty parameters.

To bypass governance mode, you must explicitly indicate in your request that you want to bypass this mode. To do this, include the `x-amz-bypass-governance-retention:true` header with your `PutObjectRetention` API operation request, or use the equivalent parameter with requests made through the AWS CLI or AWS SDKs. The S3 console automatically applies this header for requests made through the S3 console if you have the `s3:BypassGovernanceRetention` permission.

Note

Bypassing governance mode doesn't affect an object version's legal hold status. If an object version has a legal hold enabled, the legal hold remains and prevents requests to overwrite or delete the object version.

Using Object Lock with S3 Replication

You can use Object Lock with S3 Replication to enable automatic, asynchronous copying of locked objects and their retention metadata, across S3 buckets. This means that for replicated objects, Amazon S3 takes the object lock configuration of the source bucket. In other words, if the source bucket has Object Lock enabled, the destination buckets must also have Object Lock enabled. If an object is directly uploaded to the destination bucket (outside of S3 Replication), it takes the Object Lock set on the destination bucket. When you use replication, objects in a *source bucket* are replicated to one or more *destination buckets*.

To set up replication on a bucket with Object Lock enabled, you can use the S3 console, AWS CLI, Amazon S3 REST API, or AWS SDKs.

Note

To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [Setting up permissions for live replication](#).

For general information about S3 Replication, see [Replicating objects within and across Regions](#).

For examples of setting up S3 Replication, see [Examples for configuring live replication](#).

Using Object Lock with encryption

Amazon S3 encrypts all new objects by default. You can use Object Lock with your encrypted objects. For more information, see [Protecting data with encryption](#).

While Object Lock can help prevent Amazon S3 objects from being deleted or overwritten, it does not protect against losing access to the encryption keys or encryption keys being deleted. For example, if you encrypt your objects with AWS KMS server-side encryption and your AWS KMS key is deleted your objects may become unreadable.

Using Object Lock with Amazon S3 Inventory

You can configure Amazon S3 Inventory to create lists of the objects in an S3 bucket on a defined schedule. You can configure Amazon S3 Inventory to include the following Object Lock metadata for your objects:

- The retain until date
- The retention mode
- The legal hold status

For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

Managing S3 Lifecycle policies with Object Lock

Object lifecycle management configurations continue to function normally on protected objects, including placing delete markers. However, a locked version of an object cannot be deleted by a S3 Lifecycle expiration policy. Object Lock is maintained regardless of which storage class the object resides in and throughout S3 Lifecycle transitions between storage classes.

For more information about managing object lifecycles, see [Managing the lifecycle of objects](#).

Managing delete markers with Object Lock

Although you can't delete a protected object version, you can still create a delete marker for that object. Placing a delete marker on an object doesn't delete the object or its object versions. However, it makes Amazon S3 behave in most ways as though the object has been deleted. For more information, see [Working with delete markers](#).

Note

Delete markers are not WORM-protected, regardless of any retention period or legal hold in place on the underlying object.

Using S3 Storage Lens with Object Lock

To see metrics for Object Lock-enabled storage bytes and object count, you can use Amazon S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity.

For more information, see [Using S3 Storage Lens to protect your data](#).

For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Uploading objects to an Object Lock enabled bucket

The Content-MD5 or x-amz-sdk-checksum-algorithm header is required for any request to upload an object with a retention period configured using Object Lock. These headers are a way to verify the integrity of your object during upload.

When uploading an object with the Amazon S3 console, S3 automatically adds the Content-MD5 header. You can optionally specify an additional checksum function and checksum value through the console as the x-amz-sdk-checksum-algorithm header. If you use the [PutObject](#) API you must specify the Content-MD5 header, the x-amz-sdk-checksum-algorithm header, or both to configure the Object Lock retention period.

For more information, see [Checking object integrity in Amazon S3](#).

Configuring events and notifications

You can use Amazon S3 Event Notifications to track access and changes to your Object Lock configurations and data by using AWS CloudTrail. For information about CloudTrail, see [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

You can also use Amazon CloudWatch to generate alerts based on this data. For information about CloudWatch, see the [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*.

Setting limits on retention periods with a bucket policy

You can set minimum and maximum allowable retention periods for a bucket by using a bucket policy. The maximum retention period is 100 years.

The following example shows a bucket policy that uses the s3:object-lock-remaining-retention-days condition key to set a maximum retention period of 10 days.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "SetRetentionLimits",  
    "Statement": [  
        {  
            "Sid": "SetRetentionPeriod",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": [  
                "s3:PutObjectRetention"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
            "Condition": {  
                "NumericGreaterThan": {  
                    "s3:object-lock-remaining-retention-days": "10"  
                }  
            }  
        }  
    ]  
}
```

Note

If your bucket is the destination bucket for a replication configuration, you can set up minimum and maximum allowable retention periods for object replicas that are created by using replication. To do so, you must allow the `s3:ReplicateObject` action in your bucket policy. For more information about replication permissions, see [the section called “Setting up permissions”](#).

For more information about bucket policies, see the following topics:

- [Actions, resources, and condition keys for Amazon S3 in the Service Authorization Reference](#)

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

- [Object operations](#)

- [Bucket policy examples using condition keys](#)

Configuring S3 Object Lock

With Amazon S3 Object Lock, you can store objects in Amazon S3 general purpose buckets by using a *write-once-read-many* (WORM) model. You can use S3 Object Lock to prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. For general information about Object Lock capabilities, see [Locking objects with Object Lock](#).

Before you lock any objects, you must enable S3 Versioning and Object Lock on a general purpose bucket. Afterward, you can set a retention period, a legal hold, or both.

To work with Object Lock, you must have certain permissions. For a list of the permissions related to various Object Lock operations, see [the section called “Required permissions”](#).

Important

- After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
- S3 buckets with Object Lock can't be used as destination buckets for server access logs. For more information, see [the section called “Logging server access”](#).

Topics

- [Enable Object Lock when creating a new S3 general purpose bucket](#)
- [Enable Object Lock on an existing S3 bucket](#)
- [Set or modify a legal hold on an S3 object](#)
- [Set or modify a retention period on an S3 object](#)
- [Set or modify a default retention period on an S3 bucket](#)

Enable Object Lock when creating a new S3 general purpose bucket

You can enable Object Lock when creating a new S3 general purpose bucket by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. Choose **Create bucket**.

The **Create bucket** page opens.

4. For **Bucket name**, enter a name for your bucket.

 **Note**

After you create a bucket, you can't change its name. For more information about naming buckets, see [General purpose bucket naming rules](#).

5. For **Region**, choose the AWS Region where you want the bucket to reside.
6. Under **Object Ownership**, choose to disable or enable access control lists (ACLs) and control ownership of objects uploaded in your bucket.
7. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.
8. Under **Bucket Versioning**, choose **Enabled**.

Object Lock works only with versioned buckets.

9. (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs that are used to categorize storage and allocate costs.
10. Under **Advanced settings**, find **Object Lock** and choose **Enable**.

You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.

11. Choose **Create bucket**.

Using the AWS CLI

The following `create-bucket` example creates a new S3 bucket named `amzn-s3-demo-bucket1` with Object Lock enabled:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket1 --object-lock-enabled-for-bucket
```

For more information and examples, see [create-bucket](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to create a new S3 bucket with Object Lock enabled. For more information, see [CreateBucket](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to enable Object Lock when creating a new S3 bucket with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the current Object Lock configuration with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Enable Object Lock on an existing S3 bucket

You can enable Object Lock for an existing S3 bucket by using the Amazon S3 console, the AWS CLI, AWS SDKs, or Amazon S3 REST API.

Using the S3 console

Note

Object Lock works only with versioned buckets.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to enable Object Lock on.
4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Object Lock**, choose **Enable**.

You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.

7. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example command sets a 50-day Object Lock retention period on a bucket named `amzn-s3-demo-bucket1`:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled", "Rule": {"DefaultRetention": {"Mode": "COMPLIANCE", "Days": 50 }}}'
```

For more information and examples, see [put-object-lock-configuration](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the Amazon S3 REST API to enable Object Lock on an existing S3 bucket. For more information, see [PutObjectLockConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to enable Object Lock for an existing S3 bucket with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the current Object Lock configuration with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Set or modify a legal hold on an S3 object

You can set or remove a legal hold on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Important

- If you want to set a legal hold on an object, the object's bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

For more information, see [the section called “Legal holds”](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a legal hold on.
4. In the **Objects** list, select the object that you want to set or modify a legal hold on.

5. On the **Object properties** page, find the **Object Lock legal hold** section, and choose **Edit**.
6. Choose **Enable** to set a legal hold or **Disable** to remove a legal hold.
7. Choose **Save changes**.

Using the AWS CLI

The following put-object-legal-hold example sets a legal hold on the object *my-image.fs* in the bucket named *amzn-s3-demo-bucket1*:

```
aws s3api put-object-legal-hold --bucket amzn-s3-demo-bucket1 --key my-image.fs --  
legal-hold="Status=ON"
```

The following put-object-legal-hold example removes a legal hold on the object *my-image.fs* in the bucket named *amzn-s3-demo-bucket1*:

```
aws s3api put-object-legal-hold --bucket amzn-s3-demo-bucket1 --key my-image.fs --  
legal-hold="Status=OFF"
```

For more information and examples, see [put-object-legal-hold](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set or modify a legal hold on an object. For more information, see [PutObjectLegalHold](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a legal hold on an object with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the current legal hold status with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Set or modify a retention period on an S3 object

You can set or modify a retention period on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Important

- If you want to set a retention period on an object, the object's bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see [Retention periods](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a retention period on.
4. In the **Objects** list, select the object that you want to set or modify a retention period on.
5. On the **Object properties** page, find the **Object Lock retention** section, and choose **Edit**.
6. Under **Retention**, choose **Enable** to set a retention period or **Disable** to remove a retention period.

7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see [Retention modes](#).
8. Under **Retain until date**, choose the date that you want to have the retention period end on. During this period, your object is WORM-protected and can't be overwritten or deleted. For more information, see [Retention periods](#).
9. Choose **Save changes**.

Using the AWS CLI

The following put-object-retention example sets a retention period on the object *my-image.fs* in the bucket named *amzn-s3-demo-bucket1* until January 1, 2025:

```
aws s3api put-object-retention --bucket amzn-s3-demo-bucket1 --key my-image.fs --  
retention='{"Mode": "GOVERNANCE", "RetainUntilDate": "2025-01-01T00:00:00"}'
```

For more information and examples, see [put-object-retention](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a retention period on an object. For more information, see [PutObjectRetention](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a retention period on an object with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the retention period on an object with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Set or modify a default retention period on an S3 bucket

You can set or modify a default retention period on an S3 bucket by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API. You specify a duration, in either days or years, for how long to protect every object version placed in the bucket.

Important

- If you want to set a default retention period on a bucket, the bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see [Retention periods](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to set or modify a default retention period on.
4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Default retention**, choose **Enable** to set a default retention or **Disable** to remove a default retention.

7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see [Retention modes](#).
8. Under **Default retention period**, choose the number of days or years that you want the retention period to last for. Objects placed in this bucket will be locked for this number of days or years. For more information, see [Retention periods](#).
9. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example command sets a 50-day Object Lock retention period on the bucket named `amzn-s3-demo-bucket1` by using compliance mode:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled", "Rule": {"DefaultRetention": {"Mode": "COMPLIANCE", "Days": 50 }}}'
```

The following `put-object-lock-configuration` example removes the default retention configuration on a bucket:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled"}'
```

For more information and examples, see [put-object-lock-configuration](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a default retention period on an existing S3 bucket. For more information, see [PutObjectLockConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a default retention period on an existing S3 bucket with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Backing up your Amazon S3 data

Amazon S3 is natively integrated with AWS Backup, a fully managed, policy-based service that you can use to centrally define backup policies to protect your data in Amazon S3. After you define your backup policies and assign Amazon S3 resources to the policies, AWS Backup automates the creation of Amazon S3 backups and securely stores the backups in an encrypted backup vault that you designate in your backup plan.

When using AWS Backup for Amazon S3, you can perform the following actions:

- Create continuous backups and periodic backups. Continuous backups are useful for point-in-time restore, and periodic backups are useful to meet your long-term data-retention needs.
- Automate backup scheduling and retention by centrally configuring backup policies.
- Restore backups of Amazon S3 data to a point in time that you specify.

Along with AWS Backup, you can use S3 Versioning and S3 Replication to help recover from accidental deletions and perform your own self-recovery operations.

Prerequisites

You must activate [S3 Versioning](#) on your bucket before AWS Backup can back it up.

Note

We recommend that you [set a lifecycle expiration rule for versioning-enabled buckets](#) that are being backed up. If you do not set a lifecycle expiration period, your Amazon S3 storage costs might increase because AWS Backup retains all versions of your Amazon S3 data.

Getting started

To get started with AWS Backup for Amazon S3, see [Creating Amazon S3 backups](#) in the *AWS Backup Developer Guide*.

Restrictions and limitations

To learn about the limitations, see [Creating Amazon S3 backups](#) in the *AWS Backup Developer Guide*.

Cost optimization

Amazon S3 offers a range of features and storage classes to help you optimize costs throughout your data lifecycle. Storage classes offer the flexibility to manage your costs, by providing different data-access levels at corresponding costs, with no upfront fees or commitment to how much content you store. Like other AWS services, you pay as you go and pay only for what you use.

Amazon S3 storage classes are purpose-built to provide the lowest cost storage for different access patterns. These include:

- S3 Standard for general-purpose storage of frequently accessed data.
- Amazon S3 Express One Zone for high-performance frequently accessed data in a single-Availability Zone.
- S3 Intelligent-Tiering to automatically optimize costs for data with unknown or changing access patterns.
- S3 Standard-IA (S3 Standard-IA) and S3 One Zone-IA (S3 One Zone-IA) for long-lived, but less frequently accessed data.
- S3 Glacier Instant Retrieval for archive data that needs immediate access.
- S3 Glacier Flexible Retrieval for archive data that doesn't require immediate access but needs the flexibility to retrieve large sets of data at no cost.
- S3 Glacier Deep Archive for long-term archive and digital preservation at the lowest storage costs in the cloud.

You can move objects to the most cost-effective storage class at any time. Additionally, Amazon S3 provides features to manage your data lifecycle. For example, you can use S3 Lifecycle configuration to automate transitioning objects to more cost-effective storage classes, or to automatically delete expired objects based on the rules that you define.

Features such as S3 Storage Class Analysis, cost allocation tagging, and billing and usage reports help you analyze your cost and usage patterns.

Topics

- [Billing and usage reporting for Amazon S3](#)
- [Understanding and managing Amazon S3 storage classes](#)

- [Managing the lifecycle of objects](#)

Billing and usage reporting for Amazon S3

When using Amazon S3, you don't have to pay any upfront fees or commit to how much content you'll store. Like other AWS services, you pay as you go and pay only for what you use.

AWS provides the following reports for Amazon S3:

- **Billing reports** – Multiple reports that provide high-level views of all of the activity for the AWS services that you're using, including Amazon S3. AWS always bills the owner of the S3 bucket for Amazon S3 fees, unless the bucket was created as a Requester Pays bucket. For more information about Requester Pays, see [Using Requester Pays general purpose buckets for storage transfers and usage](#). For more information about billing reports, see [AWS Billing reports for Amazon S3](#).
- **Usage report** – A summary of activity for a specific service, aggregated by hour, day, or month. You can choose which usage type and operation to include. You can also choose how the data is aggregated. For more information, see [AWS usage reports for Amazon S3](#).

The following topics provide information about billing and usage reporting for Amazon S3.

Topics

- [Using cost allocation S3 bucket tags](#)
- [AWS Billing reports for Amazon S3](#)
- [AWS usage reports for Amazon S3](#)
- [Understanding your AWS billing and usage reports for Amazon S3](#)
- [Billing for Amazon S3 error responses](#)

Using cost allocation S3 bucket tags

To track the storage cost or other criteria for individual projects or groups of projects, label your Amazon S3 buckets using cost allocation tags. A *cost allocation tag* is a key-value pair that you associate with an S3 bucket. After you activate cost allocation tags, AWS uses the tags to organize your resource costs on your cost allocation report. Cost allocation tags can only be used to label buckets. For information about tags used for labeling objects, see [Categorizing your objects using tags](#).

The *cost allocation report* lists the AWS usage for your account by product category and linked account user. The report contains the same line items as the detailed billing report (see [Understanding your AWS billing and usage reports for Amazon S3](#)) and additional columns for your tag keys.

AWS provides two types of cost allocation tags, an AWS-generated tag and user-defined tags. AWS defines, creates, and applies the AWS-generated `createdBy` tag for you after an Amazon S3 `CreateBucket` event. You define, create, and apply *user-defined* tags to your S3 bucket.

You must activate both types of tags separately in the Billing and Cost Management console before they can appear in your billing reports. For more information about AWS-generated tags, see [AWS-Generated Cost Allocation Tags](#).

For more information about activating tags, see [Using cost allocation tags](#) in the *AWS Billing User Guide*.

User-defined cost allocation tags

A user-defined cost allocation tag has the following components:

- The tag key. The tag key is the name of the tag. For example, in the tag `project/Trinity`, `project` is the key. The tag key is a case-sensitive string that can contain 1 to 128 Unicode characters.
- The tag value. The tag value is a required string. For example, in the tag `project/Trinity`, `Trinity` is the value. The tag value is a case-sensitive string that can contain from 0 to 256 Unicode characters.

For details on the allowed characters for user-defined tags and other restrictions, see [User-Defined Tag Restrictions](#) in the *AWS Billing User Guide*. For more information about user-defined tags, see [User-Defined Cost Allocation Tags](#) in the *AWS Billing User Guide*.

S3 bucket tags

Each S3 bucket has a tag set. A *tag set* contains all of the tags that are assigned to that bucket. A tag set can contain as many as 50 tags, or it can be empty. Keys must be unique within a tag set, but values in a tag set don't have to be unique. For example, you can have the same value in tag sets named `project/Trinity` and `cost-center/Trinity`.

Within a bucket, if you add a tag that has the same key as an existing tag, the new value overwrites the old value.

AWS doesn't apply any semantic meaning to your tags. We interpret tags strictly as character strings.

To add, list, edit, or delete tags, you can use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API.

Managing tags for general purpose buckets

You can add or manage tags for general purpose buckets using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs. For more information, see the following.

Using the Amazon S3 Console

To create tags in the console, see:

- [Viewing the properties for an S3 general purpose bucket.](#)

Using the API

To manage tags using the Amazon S3 API, see the following API pages in the *Amazon Simple Storage Service API Reference*.

- [PutBucketTagging](#)
- [GetBucketTagging](#)
- [DeleteBucketTagging](#)

Note

After you enable ABAC, the PutBucketTagging or DeleteBucketTagging operations will no longer work. Instead, use the TagResource and UntagResource APIs to add or delete tags on your buckets. We recommend you use the TagResource and UntagResource APIs to manage tagging before enabling ABAC on your buckets. To learn more about ABAC, see [Enabling ABAC in general purpose buckets](#).

Using the CLI

To manage tags using the AWS CLI, see the following pages in the AWS CLI Command Reference.

- [put-bucket-tagging](#)
- [get-bucket-tagging](#)
- [delete-bucket-tagging](#)

More Info

- [Using Cost Allocation Tags](#) in the *AWS Billing User Guide*
- [Understanding your AWS billing and usage reports for Amazon S3](#)
- [AWS Billing reports for Amazon S3](#)

AWS Billing reports for Amazon S3

Your monthly bill from AWS separates your usage information and cost by AWS service and function. There are several AWS Billing reports available: the monthly report, the cost allocation report, and detailed billing reports. For information about how to see your billing reports, see [Viewing Your Bill](#) in the *AWS Billing User Guide*.

To track your AWS usage and provide estimated charges associated with your account, you can set up AWS Cost and Usage Reports. For more information, see [What are AWS Cost and Usage Reports?](#) in the *AWS Data Exports Guide*.

You can also download a usage report that gives more detail about your Amazon S3 storage usage than the billing reports. For more information, see [AWS usage reports for Amazon S3](#).

The following table lists the charges associated with Amazon S3 usage.

Charge	Comments
Storage	You pay for storing objects in your S3 buckets. The rate you're charged depends on your objects' size, how long you stored the objects during the month, and the storage class. Amazon S3 offers the following storage classes: S3 Standard, S3 Express One Zone, S3 Intelligent-Tiering, S3 Standard-IA (IA for infrequent access), S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible

Charge	Comments
	<p>Retrieval, S3 Glacier Deep Archive, or Reduced Redundancy Storage (RRS). For more information about storage classes, see Understanding and managing Amazon S3 storage classes.</p> <p>Be aware that if you have S3 Versioning enabled, you're charged for each version of an object that is retained. For more information about versioning, see How S3 Versioning works.</p>
General purpose buckets	You're not billed for the first 2000 general purpose buckets that you create in your account. However, there is a per-bucket rate for each bucket that you create beyond the first 2000. This rate is billed per bucket/month. For information about general purpose bucket pricing, see Amazon S3 Pricing .
Monitoring and automation	You pay a monthly monitoring and automation fee per object stored in the S3 Intelligent-Tiering storage class to monitor access patterns and move objects between access tiers in S3 Intelligent-Tiering.
Requests	You pay for requests, for example, GET requests, made against your S3 buckets and objects. This includes lifecycle requests. The rates for requests depend on what kind of request you're making. For information about request pricing, see Amazon S3 Pricing .
Retrievals	You pay for retrieving objects that are stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive storage.

Charge	Comments
Early deletes	If you delete an object stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage before the minimum storage commitment has passed, you pay an early deletion fee for that object.
Storage management	You pay for the storage management features (Amazon S3 Inventory, analytics, and object tagging) that are enabled on your account's buckets.
Bandwidth	<p>You pay for all bandwidth into and out of Amazon S3, except for the following:</p> <ul style="list-style-type: none">• Data transferred in from the internet• Data transferred out to an Amazon Elastic Compute Cloud (Amazon EC2) instance, when the instance is in the same AWS Region as the S3 bucket• Data transferred out to Amazon CloudFront (CloudFront) <p>You also pay a fee for any data transferred by using Amazon S3 Transfer Acceleration.</p>

For detailed information about Amazon S3 usage charges for storage, data transfer, and services, see [Amazon S3 Pricing](#) and the [Amazon S3 FAQs](#).

For information about understanding the codes and abbreviations used in the billing and usage reports for Amazon S3, see [Understanding your AWS billing and usage reports for Amazon S3](#).

More info

- [AWS usage reports for Amazon S3](#)
- [Using cost allocation S3 bucket tags](#)
- [AWS Billing and Cost Management](#)
- [Amazon S3 Pricing](#)

AWS usage reports for Amazon S3

When you download a usage report, you can choose to aggregate usage data by hour, day, or month. The Amazon S3 usage report lists operations by usage type and AWS Region. For more detailed reports about your Amazon S3 storage usage, download dynamically generated AWS usage reports. You can choose which usage type, operation, and time period to include. You can also choose how the data is aggregated. For more information about usage reports, see [AWS Usage Report](#)in the *AWS Data Exports User Guide*.

The Amazon S3 usage report includes the following information:

- **Service** – Amazon S3
- **Operation** – The operation performed on your bucket or object. For a detailed explanation of Amazon S3 operations, see [Tracking Operations in Your Usage Reports](#).
- **UsageType** – One of the following values:
 - A code that identifies the type of storage
 - A code that identifies the type of request
 - A code that identifies the type of retrieval
 - A code that identifies the type of data transfer
 - A code that identifies early deletions from S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-Infrequent Access (S3 One Zone-IA), S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage
 - **StorageObjectCount** – The count of objects stored within a given bucket

For a detailed explanation of Amazon S3 usage types, see [Understanding your AWS billing and usage reports for Amazon S3](#).

- **Resource** – The name of the bucket or table associated with the listed usage.
- **StartTime** – Start time of the day that the usage applies to, in Coordinated Universal Time (UTC).

- **EndTime** – End time of the day that the usage applies to, in Coordinated Universal Time (UTC).
- **UsageValue** – One of the following volume values. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.
 - The number of requests during the specified time period
 - The amount of data transferred
 - The amount of data stored in a given hour
 - The amount of data associated with restorations from S3 Standard-IA, S3 One Zone-IA, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage

 **Tip**

For detailed information about every request that Amazon S3 receives for your objects, turn on server access logging for your buckets. For more information, see [Logging requests with server access logging](#).

You can download a usage report as an XML or a comma-separated values (CSV) file. The following is an example CSV usage report opened in a spreadsheet application.

Service	Operation	UsageType	Resource	StartTime	EndTime	UsageValue
AmazonS3	HeadBucket	USW2-C3DataTransfer-Out-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	15309
AmazonS3	PutObject	USW2-C3DataTransfer-In-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	19062
AmazonS3	HeadBucket	USW2-Requests-Tier2	admin-created3	6/1/2017 0:00	7/1/2017 0:00	68
AmazonS3	PutObjectForRepl	USW1-Requests-SIA-Tier1	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	178294
AmazonS3	PutObjectForRepl	USW1-USW2-AWS-In-Bytes	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	387929083
AmazonS3	GetObjectForRepl	USW2-Requests-NoCharge	admin-created3	6/1/2017 0:00	7/1/2017 0:00	108
AmazonS3	GetObjectForRepl	USW2-USW1-AWS-Out-Bytes	my-test-bucket-bash	6/1/2017 0:00	7/1/2017 0:00	387910021

For more information, see [Understanding your AWS billing and usage reports for Amazon S3](#).

Downloading the AWS Usage Report

You can download a usage report as an XML or a CSV file.

To download the usage report

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the title bar, choose your username or account ID, and then choose **Billing and Cost Management**.
3. In the navigation pane, choose **Legacy Pages** and choose **Cost and usage reports**.
4. Under AWS Usage Report, choose **Create a Usage Report**.
5. On the **Download usage report** page, choose the following settings:
 - **Services** – Choose **Amazon Simple Storage Service**.
 - **Usage Types** – For a detailed explanation of Amazon S3 usage types, see [Understanding your AWS billing and usage reports for Amazon S3](#).
 - **Operation** – For a detailed explanation of Amazon S3 operations, see [Tracking Operations in Your Usage Reports](#).
 - **Time Period** – The time period that you want the report to cover.
 - **Report Granularity** – Whether you want the report to include subtotals by the hour, by the day, or by the month.
6. Choose **Download**, choose the download format (**XML Report** or **CSV Report**), and then follow the prompts to open or save the report.

Understanding your AWS billing and usage reports for Amazon S3

When you use Amazon S3, we include related codes in your AWS billing and usage reports. Reviewing these codes helps you understand your Amazon S3 costs and usage patterns. Tracking and managing your expenses is essential for optimizing your costs. For more information, see [Amazon S3 pricing](#).

Amazon S3 billing and usage reports use codes and abbreviations. For usage types in the table that follows, replace *region*, *region1*, and *region2* with abbreviations from [AWS Region billing codes](#) in the *AWS Regions and Availability Zones User Guide*.

For S3 Multi-Region Access Points usage types in the table that follows, replace *regiongroup1* and *regiongroup2* with abbreviations from this list:

- **AP:** Asia Pacific
- **AU:** Australia
- **EU:** Europe
- **IN:** India
- **NA:** North America
- **SA:** South America

Region groups are geographical groupings of several AWS Regions. For more information, see [Regions and Availability Zones](#). For information about pricing by AWS Region, see [Amazon S3 Pricing](#).

The first column in the following table lists usage types that appear in your billing and usage reports. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.

Usage Type	Units	Granularity	Description
<i>region1-region2-AWS-In-A Bytes</i>	GB	Hourly	The amount of accelerated data transferred to <i>region1</i> from <i>region2</i>
<i>region1-region2-AWS-In-A Bytes-T1</i>	GB	Hourly	The amount of T1 accelerated data transferred to <i>region1</i> from <i>region2</i> , where T1 refers to CloudFront requests to points of presence (POPs) in the United States, Europe, and Japan
<i>region1-region2-AWS-In-A Bytes-T2</i>	GB	Hourly	The amount of T2 accelerated data transferred to <i>region1</i> from <i>region2</i> , where

Usage Type	Units	Granularity	Description
			T2 refers to CloudFront requests to POPs in all other AWS edge locations
<i>region1</i> - <i>region2</i> -AWS-In-Bytes	GB	Hourly	The amount of data transferred to <i>region1</i> from <i>region2</i>
<i>region1</i> - <i>region2</i> -AWS-Out-ABytes	GB	Hourly	The amount of accelerated data transferred from <i>region1</i> to <i>region2</i>
<i>region1</i> - <i>region2</i> -AWS-Out-ABytes-T1	GB	Hourly	The amount of T1 accelerated data transferred from <i>region1</i> to <i>region2</i> , where T1 refers to CloudFront requests to POPs in the United States, Europe, and Japan
<i>region1</i> - <i>region2</i> -AWS-Out-ABytes-T2	GB	Hourly	The amount of T2 accelerated data transferred from <i>region1</i> to <i>region2</i> , where T2 refers to CloudFront requests to POPs in all other AWS edge locations
<i>region1</i> - <i>region2</i> -AWS-Out-Bytes	GB	Hourly	The amount of data transferred from <i>region1</i> to <i>region2</i>

Usage Type	Units	Granularity	Description
<i>region</i> -BatchOperations-Jobs	Count	Hourly	The number of S3 Batch Operations jobs performed
<i>region</i> -BatchOperations-Objects	Count	Hourly	The number of object operations performed by S3 Batch Operations
<i>region</i> -Bulk-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Bulk S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
<i>region</i> -BytesDeleted-GDA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Deep Archive storage
<i>region</i> -BytesDeleted-GIR	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -BytesDeleted-GLACIER	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Flexible Retrieval storage

Usage Type	Units	Granularity	Description
<i>region</i> -BytesDeleted-INT	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Intelligent-Tiering storage
<i>region</i> -BytesDeleted-RRS	GB	Monthly	The amount of data deleted by a DeleteObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -BytesDeleted-SIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard-IA storage
<i>region</i> -BytesDeleted-STANDARD	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard storage
<i>region</i> -BytesDeleted-ZIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 One Zone-IA storage
<i>region</i> -C3DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from Amazon EC2 within the same AWS Region

Usage Type	Units	Granularity	Description
<i>region</i> -C3DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to Amazon EC2 within the same AWS Region
<i>region</i> -CloudFront-In-Bytes	GB	Hourly	The amount of data transferred into an AWS Region from a CloudFront distribution
<i>region</i> -CloudFront-Out-Bytes	GB	Hourly	The amount of data transferred from an AWS Region to a CloudFront distribution
<i>region</i> -DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from the internet
<i>region</i> -DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to the internet ¹
<i>region</i> -DataTransfer-Regional-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to AWS resources within the same AWS Region
<i>region</i> -EarlyDelete-ByteHrs	GB-Hours	Hourly	Prorated storage usage for objects deleted from, S3 Glacier Flexible Retrieval storage before the 90-day minimum commitment ended ²

Usage Type	Units	Granularity	Description
<i>region</i> -EarlyDelete-GDA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Glacier Deep Archive storage before the 180-day minimum commitment ended ²
<i>region</i> -EarlyDelete-GIR	GB-Hours	Hourly	Prorated storage usage for objects deleted or transitioned from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.
<i>region</i> -EarlyDelete-GIR-SmallObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.
<i>region</i> -EarlyDelete-SIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Standard-IA before the 30-day minimum commitment ended ³

Usage Type	Units	Granularity	Description
<i>region</i> -EarlyDelete-SIA-SmObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Standard-IA before the 30-day minimum commitment ended ³
<i>region</i> -EarlyDelete-ZIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 One Zone-IA before the 30-day minimum commitment ended ³
<i>region</i> -EarlyDelete-ZIA-SmObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 One Zone-IA before the 30-day minimum commitment ended ³
<i>region</i> -Expedited-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Expedited S3 Glacier Flexible Retrieval requests
Global-Bucket-Hrs-FreeTier	Bucket	Monthly	The number of general purpose buckets in your account within the 2000 bucket account-level free tier

Usage Type	Units	Granularity	Description
Global-Bucket-Hrs	Bucket	Monthly	The number of general purpose buckets in your account beyond the 2000 bucket account-level free tier
<i>region</i> -Inventory-Objects Listed	Objects	Hourly	The number of objects listed for an object group (objects are grouped by bucket or prefix) with an inventory list
<i>region</i> -Metadata-Updates	Updates	Hourly	Per update fee for updates processed by S3 Metadata
<i>region</i> -Monitoring-Automation-INT	Objects	Hourly	The number of unique objects monitored and auto-tiered in the S3 Intelligent-Tiering storage class
<i>region</i> -MRAP-Out-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).

Usage Type	Units	Granularity	Description	
<i>region</i> -MRAP-In-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).	
<i>regiongroup1</i> - <i>regiongroup2</i> -MRAP-Out-Bytes	-	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint from a bucket in <i>regiongroup1</i> to a client in <i>regiongroup2</i> located outside of the AWS network.
<i>regiongroup1</i> - <i>regiongroup2</i> -MRAP-In-Bytes	-	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint to a bucket in <i>regiongroup1</i> from a client in <i>regiongroup2</i> located outside of the AWS network.
<i>region</i> -OverwriteBytes-Copy-GDA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Deep Archive storage	

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Copy-GIR	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -OverwriteBytes-Copy-GLACIER	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -OverwriteBytes-Copy-INT	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Intelligent-Tiering storage
<i>region</i> -OverwriteBytes-Copy-RRS	GB	Monthly	The amount of data overwritten by a CopyObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -OverwriteBytes-Copy-SIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Copy-STANDARD	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard storage
<i>region</i> -OverwriteBytes-Copy-ZIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 One Zone-IA storage
<i>region</i> -OverwriteBytes-Put-GDA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Deep Archive storage
<i>region</i> -OverwriteBytes-Put-GIR	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -OverwriteBytes-Put-GLACIER	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -OverwriteBytes-Put-INT	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Put-RRS	GB	Monthly	The amount of data overwritten by a PutObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -OverwriteBytes-Put-SIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard-IA storage
<i>region</i> -OverwriteBytes-Put-STANDARD	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard storage
<i>region</i> -OverwriteBytes-Put-ZIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 One Zone-IA storage

Usage Type	Units	Granularity	Description
<i>region1-region2</i> -S3RTC-In-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from <i>region2</i> to <i>region1</i> by the PutObjectReplTime , GetObjectReplTime , InitiateMultipartUploadReplTime , UploadPartReplTime , CompleteMultipartUploadReplTime , and WriteACLReplTime operations
<i>region1-region2</i> -S3RTC-Out-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from <i>region1</i> to <i>region2</i> by the PutObjectReplTime , GetObjectReplTime , InitiateMultipartUploadReplTime , UploadPartReplTime , CompleteMultipartUploadReplTime , and WriteACLReplTime operations

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-GDA-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Deep Archive objects ⁶
<i>region</i> -Requests-GDA-Tier2	Count	Hourly	The number of GET and HEAD requests on S3 Glacier Deep Archive objects
<i>region</i> -Requests-GDA-Tier3	Count	Hourly	The number of S3 Glacier Deep Archive standard restore requests
<i>region</i> -Requests-GDA-Tier5	Count	Hourly	The number of Bulk S3 Glacier Deep Archive restore requests
<i>region</i> -Requests-GIR-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Glacier Instant Retrieval objects.
<i>region</i> -Requests-GIR-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval-Tier1 requests on S3 Glacier Instant Retrieval objects.

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-GLACIER-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Flexible Retrieval objects ⁶
<i>region</i> -Requests-GLACIER-Tier2	Count	Hourly	The number of GET and all other requests not listed on S3 Glacier Flexible Retrieval objects
<i>region</i> -Requests-INT-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Intelligent-Tiering objects
<i>region</i> -Requests-INT-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests for S3 Intelligent-Tiering objects
<i>region</i> -Requests-SIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Standard-IA objects
<i>region</i> -Requests-SIA-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval -Tier1 requests on S3 Standard-IA objects

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests for S3 Standard, RRS, and tags, plus LIST requests for all buckets and objects
<i>region</i> -Requests-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests
<i>region</i> -Requests-Tier3	Count	Hourly	The number of lifecycle requests to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive and standard S3 Glacier Flexible Retrieval restore requests
<i>region</i> -Requests-Tier4	Count	Hourly	The number of lifecycle transitions to S3 Glacier Instant Retrieval, S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage
<i>region</i> -Requests-Tier5	Count	Hourly	The number of Bulk S3 Glacier Flexible Retrieval restore requests
<i>region</i> -Requests-Tier6	Count	Hourly	The number of Expedited S3 Glacier Flexible Retrieval restore requests

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-Tier8	Count	Hourly	The number of S3 Access Grants requests
<i>region</i> -Requests-XZ-Tier1	Count	Hourly	The number of PUT or COPY requests on S3 Express One Zone objects
<i>region</i> -Requests-XZ-Tier2	Count	Hourly	The number of GET and all other non-S3 Express One Zone-Tier1 requests on S3 Express One Zone objects
<i>region</i> -Requests-ZIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 One Zone-IA objects
<i>region</i> -Requests-ZIA-Tier2	Count	Hourly	The number of GET and all other non-S3 One Zone-IA-Tier1 requests on S3 One Zone-IA objects
<i>region</i> -Retrieval-GIR	GB	Hourly	The amount of data retrieved from S3 Glacier Instant Retrieval storage.
<i>region</i> -Retrieval-SIA	GB	Hourly	The amount of data retrieved from S3 Standard-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -Retrieval-XZ	GB	Hourly	The portion of the data that exceeds 512 KB in a given retrieval request (PUT or COPY) with S3 Express One Zone storage
<i>region</i> -Retrieval-ZIA	GB	Hourly	The amount of data retrieved from S3 One Zone-IA storage
<i>region</i> -S3DSSE-In-Bytes	GB	Monthly	The amount of data dual-encrypted by Amazon S3
<i>region</i> -S3DSSE-Out-Bytes	GB	Monthly	The amount of dual-encrypted data decrypted by Amazon S3
<i>region</i> -S3G-DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 to restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage
<i>region</i> -S3G-DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to transition objects to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage

Usage Type	Units	Granularity	Description
<i>region</i> -Select-Returned-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard storage
<i>region</i> -Select-Returned-GIR-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Glacier Instant Retrieval storage.
<i>region</i> -Select-Returned-INT-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Intelligent-Tiering storage
<i>region</i> -Select-Returned-SIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard-IA storage
<i>region</i> -Select-Returned-ZIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 One Zone-IA storage
<i>region</i> -Select-Scanned-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard storage
<i>region</i> -Select-Scanned-GIR-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Glacier Instant Retrieval storage.

Usage Type	Units	Granularity	Description
<i>region</i> -Select-Scanned-INT-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Intelligent-Tiering storage
<i>region</i> -Select-Scanned-SIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard-IA storage
<i>region</i> -Select-Scanned-ZIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 One Zone-IA storage
<i>region</i> -Standard-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with standard S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
<i>region</i> -StorageAnalytics-ObjCount	Objects	Hourly	The number of unique objects monitored in each Storage Class Analysis configuration.
<i>region</i> -StorageLens-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens advanced metrics and recommendations.

Usage Type	Units	Granularity	Description
<i>region</i> -StorageLensFreeTier-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens usage metrics.
StorageObjectCount	Count	Daily	The number of objects stored within a given bucket
<i>region</i> -Tables-CompactedObjects	Objects	Hourly	The number of objects compacted in Amazon S3 table buckets using the binpack compaction strategy in an Amazon S3 Tables compaction job.
<i>region</i> -Tables-SortCompactedObjects-	Objects	Hourly	The number of objects compacted in Amazon S3 table buckets using sort or z-order compaction strategies in an Amazon S3 Tables compaction job.
<i>region</i> -Tables-MonitoredObjects	Objects	Hourly	The number of objects in Amazon S3 table buckets
<i>region</i> -Tables-ProcessedBytes	GB	Hourly	The amount of data processed for compaction in Amazon S3 table buckets

Usage Type	Units	Granularity	Description
<i>region</i> -Tables-Requests-Tier1	Count	Hourly	The number of PUT requests on Amazon S3 table buckets
<i>region</i> -Tables-Requests-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests on Amazon S3 table buckets
<i>region</i> -Tables-TimedStorage-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in Amazon S3 table buckets
<i>region</i> -TagStorage-TagHrs	Tag-Hours	Daily	The total of tags on all objects in the bucket reported by hour
<i>region</i> -TimedStorage-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Standard storage
<i>region</i> -TimedStorage-GDA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Deep Archive storage
<i>region</i> -TimedStorage-GDA-Staging	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Deep Archive staging storage

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-GIR-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Instant Retrieval storage.
<i>region</i> -TimedStorage-GIR-Sm0bjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 Glacier Instant Retrieval storage.
<i>region</i> -TimedStorage-GlacierByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Flexible Retrieval storage
<i>region</i> -TimedStorage-GlacierStaging	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Flexible Retrieval staging storage
<i>region</i> -TimedStorage-INT-FA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Frequent Access tier of S3 Intelligent-Tiering storage ⁵

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-INT-IA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Infrequent Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-INT-AA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Archive Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-INT-AIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Archive Instant Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-INT-DAA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Deep Archive Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-RRS-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in Reduced Redundancy Storage (RRS) storage

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-SIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Standard-IA storage
<i>region</i> -TimedStorage-SIA-SmObjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 Standard-IA storage ⁴
<i>region</i> -TimedStorage-XZ-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Express One Zone storage
<i>region</i> -TimedStorage-ZIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 One Zone-IA storage
<i>region</i> -TimedStorage-ZIA-SmObjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 One Zone-IA storage
<i>region</i> -Upload-XZ	GB	Hourly	The amount of data that exceeds 512 KB in a given upload request (PUT or COPY) with S3 Express One Zone

Notes

1. The `Global-Bucket-Hrs` and `Global-Bucket-Hrs-FreeTier` usage types apply to general purpose buckets in commercial AWS Regions and AWS GovCloud (US).
2. If you terminate a transfer before completion, the amount of data that is transferred might exceed the amount of data that your application receives. This discrepancy can occur because a transfer termination request cannot be executed instantaneously, and some amount of data might be in transit, pending execution of the termination request. This data in transit is billed as data transferred "out."
3. For objects archived to S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes that are deleted, overwritten, or transitioned before their minimum storage commitment period (90 days for S3 Glacier Instant Retrieval and S3 Glacier Flexible Retrieval, 180 days for S3 Glacier Deep Archive), a prorated charge per gigabyte applies for the remaining days. These charges are reflected as `EarlyDelete-GIR`, `EarlyDelete-ByteHrs`, and `EarlyDelete-GDA` usage types respectively on your bill.
4. For objects that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
5. For small objects (smaller than 128 KB) that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
6. There is no minimum billable object size for objects in the S3 Intelligent-Tiering storage class. Objects that are smaller than 128 KB are not monitored or eligible for auto-tiering. Smaller objects are always stored in the S3 Intelligent-Tiering Frequent Access tier.
7. When you initiate a `CreateMultipartUpload`, `UploadPart`, or `UploadPartCopy` request to either the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, requests are billed at S3 Standard request rates until you complete the multipart upload. After the upload is completed, the single `CompleteMultipartUpload` request is billed at the PUT rate for the destination S3 Glacier storage. In-progress multipart upload parts for a PUT to the S3 Glacier Flexible Retrieval storage class are billed as S3 Glacier Flexible Retrieval Staging Storage at S3 Standard storage rates until the upload is completed. Similarly, in-progress multipart upload parts for a PUT to the S3 Glacier Deep Archive storage class are billed as S3 Glacier Deep Archive Staging Storage at S3 Standard storage rates until the upload is completed.

8. S3 Express One Zone applies a flat per-request charge for request sizes up to 512 KB. An additional per GB charge is applied for PUT requests and GET requests for the portion of request greater than 512 KB.
9. For information about supported features for S3 Express One Zone storage class, see [Amazon S3 features not supported by directory buckets](#).

10. Usage types with units that are billed in GB are calculated in bytes in the usage reports.

11. A GB-Month is derived by taking the total number of GB-hours, aggregating these over the course of a month, and then dividing by the number of hours in that month. To learn more see, [Frequently Asked Questions: How will I be charged and billed for my use of Amazon S3?](#)

 **Note**

In general, S3 bucket owners are billed for requests with HTTP 200 OK successful responses and HTTP 4XX client error responses. Bucket owners aren't billed for HTTP 5XX server error responses, such as HTTP 503 Slow Down errors. For more information on S3 error codes under HTTP 3XX and 4XX status codes that aren't billed, see [Billing for Amazon S3 error responses](#). For more information about billing charges if your bucket is configured as a Requester Pays bucket, see [How Requester Pays charges work](#).

Tracking Operations in Your Usage Reports

Operations describe the action taken on your AWS object or bucket by the specified usage type. Operations are indicated by self-explanatory codes, such as PutObject or ListBucket. To see which actions on your bucket generated a specific type of usage, use these codes. When you create a usage report, you can choose to include **All Operations**, or a specific operation, for example, GetObject, to report on.

Billing for Amazon S3 error responses

In general, S3 bucket owners are billed for requests with HTTP 200 OK successful responses and HTTP 4XX client error responses. Bucket owners aren't billed for HTTP 5XX server error responses, such as HTTP 503 Slow Down errors. For more information about billing charges if your bucket is configured as a Requester Pays bucket, see [How Requester Pays charges work](#).

The following table lists specific error codes under HTTP 3XX and 4XX status codes that aren't billed. For buckets configured with website hosting, applicable request and other charges will still apply when S3 returns a [custom error document](#) or for custom redirects.

 **Note**

For AccessDenied (HTTP 403 Forbidden), S3 doesn't charge the bucket owner when the request is initiated outside of the bucket owner's individual AWS account or the bucket owner's AWS organization.

HTTP status code	Error code	Description of error code
301 Moved Permanently	PermanentRedirect	The bucket that you are attempting to access must be addressed using the specified endpoint. Send all future requests to this endpoint.
	PermanentRedirectControlError	The API operation you are attempting to access must be addressed using the specified endpoint. Send all future requests to this endpoint.

HTTP status code	Error code	Description of error code
307 Temporary Redirect	TemporaryRedirect	You are being redirected to the bucket while the Domain Name System (DNS) server is being updated.
400 Bad Request	AuthorizationHeaderMalformed	The authorization header that you provided is not valid.
	AuthorizationQueryParametersError	The authorization query parameters that you provided are not valid.
	ConnectionClosedByRequester	Returned to the original caller when an error is encountered while reading the WriteGetObjectResponse body.
	DeviceNotActiveError	The device is not currently active.
	EndpointNotFound	Direct requests to the correct endpoint.
	ExpiredToken	The provided token has expired.

HTTP status code	Error code	Description of error code
	IllegalLocationConstraintException	<p>You are trying to access a bucket from a different Region than where the bucket exists. To avoid this error, use the --region option. For example:</p> <pre>aws s3 cp awsexample.txt s3:// amzn-s3-demo-bucket / --region ap-east-1 .</pre>

HTTP status code	Error code	Description of error code
	InvalidArgument	<p>This error might occur for the following reasons:</p> <ul style="list-style-type: none">• The specified argument was not valid.• The request was missing a required header.• The specified argument was incomplete or in the wrong format.• The specified argument must have a length greater than or equal to 3.
	InvalidBucketOwner AWSAccountId	The value of the expected bucket owner parameter must be an AWS account ID.
	InvalidDigest	The Content-MD5 or checksum value that you specified is not valid.

HTTP status code	Error code	Description of error code
400	InvalidEncryptionAlgorithmError	The encryption request that you specified is not valid. The valid value is AES256.
	InvalidHostHeader	The host headers provided in the request used the incorrect style addressing.
	InvalidHttpMethod	The request is made using an unexpected HTTP method.

HTTP status code	Error code	Description of error code
	InvalidRequest	<p>This error might occur for the following reasons:</p> <ul style="list-style-type: none">• The request is using the wrong signature version. Use AWS4-HMAC-SHA256 (Signature Version 4).• An access point can be created only for an existing bucket.• The access point is not in a state where it can be deleted.• An access point can be listed only for an existing bucket.• The next token is not valid.• At least one action must be specified in a lifecycle rule.• At least one lifecycle rule must be specified.•

HTTP status code	Error code	Description of error code
		<p>The number of lifecycle rules must not exceed the allowed limit of 1000 rules.</p> <ul style="list-style-type: none">• The range for the <code>MaxResults</code> parameter is not valid.• SOAP requests must be made over an HTTPS connection.• Amazon S3 Transfer Acceleration is not supported for buckets with non-DNS compliant names.• Amazon S3 Transfer Acceleration is not supported for buckets with periods (.) in their names.• The Amazon S3 Transfer Acceleration endpoint supports only virtual style requests.• Amazon S3 Transfer Acceleration is not

HTTP status code	Error code	Description of error code
		<p>configured on this bucket.</p> <ul style="list-style-type: none">• Amazon S3 Transfer Acceleration is disabled on this bucket.• Amazon S3 Transfer Acceleration is not supported on this bucket. For assistance, contact Support.• Amazon S3 Transfer Acceleration cannot be enabled on this bucket. For assistance, contact Support.• Conflicting values provided in HTTP headers and query parameters.• Conflicting values provided in HTTP headers and POST form fields.• CopyObject request made on objects larger than 5GB in size.

HTTP status code	Error code	Description of error code
	InvalidSessionException	Returned if the session doesn't exist anymore because it timed out or expired.
	InvalidSignature	The request signature that the server calculated does not match the signature that you provided. Check your AWS secret access key and signing method. For more information, see Signing and authenticating REST requests .
	InvalidSOAPRequest	The SOAP request body is not valid.
	InvalidStorageClass	The storage class that you specified is not valid.
	InvalidTag	Your request contains tag input that is not valid. For example, your request might contain duplicate keys, keys or values that are too long, or system tags.
	InvalidToken	The provided token is malformed or otherwise not valid.

HTTP status code	Error code	Description of error code
	InvalidURI	The specified URI couldn't be parsed.
	KeyTooLongError	Your key is too long.
	KMS.DisabledException	The request was rejected because the specified KMS key is not enabled.

HTTP status code	Error code	Description of error code
	KMS.InvalidKeyUsageException	<p>The request was rejected for one of the following reasons:</p> <ul style="list-style-type: none">• The KeyUsage value of the KMS key is incompatible with the API operation.• The encryption algorithm or signing algorithm specified for the operation is incompatible with the type of key material in the KMS key (KeySpec). <p>For encrypting, decrypting, re-encrypting, and generating data keys, the KeyUsage must be ENCRYPT_DECRYPT. For signing and verifying messages, the KeyUsage must be SIGN_VERIFY. For generating and verifying message authentication codes (MACs), the KeyUsage must be GENERATE_VERIFY_MAC. For deriving key agreement secrets, the KeyUsage</p>

HTTP status code	Error code	Description of error code	
		<p>must be KEY_AGREEMENT. To find the KeyUsage of a KMS key, use the <code>DescribeKey</code> operation.</p> <p>To find the encryption or signing algorithms supported for a particular KMS key, use the <code>DescribeKey</code> operation.</p>	

HTTP status code	Error code	Description of error code
	KMS.KMSInvalidStateException	<p>The request was rejected because the state of the specified resource is not valid for this request. This exception means one of the following:</p> <ul style="list-style-type: none">• The key state of the KMS key is not compatible with the operation. <p>To find the key state, use the <code>DescribeKey</code> operation. For more information about which key states are compatible with each KMS operation, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i>.</p> <ul style="list-style-type: none">• For cryptographic operations on KMS keys in custom key stores, this exception represents a general failure with many possible causes. To identify the cause, see the error message

HTTP status code	Error code	Description of error code
		that accompanies the exception.
	KMS.NotFoundException LambdaInvalidResponse	The request was rejected because the specified entity or resource could not be found. Returned to the original caller when WriteGetObjectResponse responds with ValidationError to AWS Lambda. See the ValidationError message for more details. Not all cases of ValidationError result in a LambdaInvalidResponse error.

HTTP status code	Error code	Description of error code
	LambdaInvocationFailed	<p>Lambda function invocation failed. Callers might receive the following error when S3 Object Lambda is unable to successfully invoke the configured Lambda function.</p> <p>The error message might contain details about an eventual error returned by the AWS Lambda service when invoking the function (for example, status code, error code, error message and request ID).</p>
	MalformedACLError	<p>The ACL that you provided was not well formed or did not validate against our published schema.</p>
	MalformedPOSTRequest	<p>The body of your POST request is not well-formed multipart/form-data.</p>
	MalformedXML	<p>The XML that you provided was not well formed or did not validate against our published schema.</p>

HTTP status code	Error code	Description of error code
	MaxPostPreDataLengthExceededError	Your POST request fields preceding the upload file were too large.
	MetadataTooLarge	Your metadata headers exceed the maximum allowed metadata size.
	MissingAttachment	A SOAP attachment was expected, but none was found.
	MissingRequestBodyError	You sent an empty XML document as a request.
	MissingSecurityHeader	Your request is missing a required header.
	NoLoggingStatusForKey	There is no such thing as a logging status subresource for a key.
	NotDeviceOwnerError	The device that generated the token is not owned by the authenticated user.
	ResponseInterrupted	Returned to the original caller when an error is encountered while reading the WriteGetObjectResponse body.

HTTP status code	Error code	Description of error code
	RequestHeaderSectionTooLarge	The request header and query parameters used to make the request exceed the maximum allowed sizes
	TokenCodeInvalidError	The serial number and/or token code you provided is not valid.
	UnexpectedContent	This request contains unsupported content.
	UnsupportedArgument	The request contained an unsupported argument.
	UnsupportedSignature	The provided request is signed with an unsupported STS Token version or the signature version is not supported.
	UserKeyMustBeSpecified	The bucket POST request must contain the specified field name. If it is specified, check the order of the fields.
	IncorrectEndpoint	The specified bucket exists in another Region. Direct requests to the correct endpoint.

HTTP status code	Error code	Description of error code
	ValidationError	Validation errors might be returned from the WriteGetObjectResponse API operation and can occur for numerous reasons. See the error message for more details.
403 Forbidden	RequestTimeTooSkewed	The difference between the request time and the server's time is too large.
	SignatureDoesNotMatch	The request signature that the server calculated does not match the signature that you provided. Check your AWS secret access key and signing method. For more information, see REST Authentication and SOAP Authentication .
	NotSignedUp	Your account is not signed up for the Amazon S3 service. You must sign up before you can use Amazon S3. You can sign up at the following URL: https://aws.amazon.com/s3

HTTP status code	Error code	Description of error code
	InvalidSecurity	The provided security credentials are not valid.
	InvalidPayer	All access to this object has been disabled. For further assistance, see Contact Us .
	InvalidAccessKeyId	The AWS access key ID that you provided does not exist in our records.
	AccountProblem	There is a problem with your AWS account that prevents the operation from completing successfully. For further assistance, see Contact Us .
	UnauthorizedAccessError	Applicable in China Regions only. Returned when a request is made to a bucket that doesn't have an ICP license. For more information, see ICP Recordal .
	UnexpectedIPError	Applicable in China Regions only. This request was rejected because the IP was unexpected.

HTTP status code	Error code	Description of error code
	MissingAuthenticationToken	The request was not signed.
	LambdaPermissionError	<p>The caller is not authorized to invoke the Lambda function.</p> <p>The caller must have permission to invoke the Lambda function.</p> <p>Check the policies attached to the caller and ensure that they've been allowed to use <code>lambda:Invoke</code> for the configured function.</p> <p>The error message might contain details about an eventual error returned by the Lambda service when invoking the function (for example, status code, error code, error message and request ID).</p>

HTTP status code	Error code	Description of error code
404 Not Found	LambdaNotFound	<p>The AWS Lambda function was not found. The configured Lambda function, version, or alias was not found when attempting to invoke it. Ensure that the S3 Object Lambda Access Point configuration points to the correct Lambda function ARN. The error message might contain details about an eventual error returned by the AWS Lambda service when invoking the function (for example, status code, error code, error message and request ID).</p>
	NoSuchAsyncRequest	<p>The specified request was not found.</p>
	NoSuchObjectLockConfiguration	<p>The specified object does not have an ObjectLock configuration.</p>

HTTP status code	Error code	Description of error code
	NoSuchUpload	The specified multipart upload does not exist. The upload ID might not be valid, or the multipart upload might have been aborted or completed.
	NoSuchWebsiteConfiguration	The specified bucket does not have a website configuration.
	NoTransformationDefined	No transformation found for this Object Lambda Access Point.
	ObjectLockConfigurationNotFoundError	The Object Lock configuration does not exist for this bucket.
	MethodNotAllowed	The specified method is not allowed against this resource.
409 Conflict	BucketAlreadyExists	The requested bucket name is not available. The bucket namespace is shared by all users of the system. Specify a different name and try again.

HTTP status code	Error code	Description of error code	
	InvalidBucketState	The request is not valid for the current state of the bucket.	
	OperationAborted	A conflicting conditional operation is currently in progress against this resource. Try again.	
411 Length Required	MissingContentLength	You must provide the Content-Length HTTP header.	
412 Precondition Failed	RequestIsNotMultiPartContent	A bucket POST request must be of the enclosure-type multipart/form-data.	
416 Requested Range Not Satisfiable	InvalidRange	The requested range is not valid for the request. Try another range.	

Understanding and managing Amazon S3 storage classes

Each object in Amazon S3 has a storage class associated with it. By default, objects in S3 are stored in the S3 Standard storage class, however Amazon S3 offers a range of other storage classes for the objects that you store. You choose a class depending on your use case scenario and performance access requirements. Choosing a storage class designed for your use case lets you optimize storage costs, performance, and availability for your objects. All of these storage classes offer high durability.

The following sections provide details of the various storage classes and how to set the storage class for your objects.

Topics

- [Storage classes for frequently accessed objects](#)
- [Storage class for automatically optimizing data with changing or unknown access patterns](#)
- [Storage classes for infrequently accessed objects](#)

- [Amazon S3 analytics – Storage Class Analysis](#)
- [Managing storage costs with Amazon S3 Intelligent-Tiering](#)
- [Understanding S3 Glacier storage classes for long-term data storage](#)
- [Working with archived objects](#)

Storage classes for frequently accessed objects

For performance-sensitive use cases (those that require millisecond access time) and frequently accessed data, Amazon S3 provides the following storage classes:

- **S3 Standard (STANDARD)** – The default storage class. If you don't specify the storage class when you upload an object, Amazon S3 assigns the S3 Standard storage class. To help you optimize costs between S3 Standard and S3 Standard-IA you can use [Amazon S3 analytics – Storage Class Analysis](#).
- **S3 Express One Zone (EXPRESS_ONEZONE)** – Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud object storage class available today, with data access speed up to 10x faster and with request costs 50 percent lower than S3 Standard. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. For more information, see [S3 Express One Zone](#).

- **Reduced Redundancy Storage (REDUCED_REDUNDANCY)** – The Reduced Redundancy Storage (RRS) class is designed for noncritical, reproducible data that can be stored with less redundancy than the S3 Standard storage class.

 **Important**

We recommend not using this storage class. The S3 Standard storage class is more cost-effective.

For durability, RRS objects have an average annual expected loss of 0.01 percent of objects. If an RRS object is lost, when requests are made to that object, Amazon S3 returns a 405 error.

Storage class for automatically optimizing data with changing or unknown access patterns

S3 Intelligent-Tiering (INTELLIGENT_TIERING) is an Amazon S3 storage class that's designed to optimize storage costs by automatically moving data to the most cost-effective access tier, without performance impact or operational overhead. S3 Intelligent-Tiering is the only cloud storage class that delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. S3 Intelligent-Tiering is the ideal storage class when you want to optimize storage costs for data that has unknown or changing access patterns. There are no retrieval fees for S3 Intelligent-Tiering.

For a small monthly object monitoring and automation fee, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers. S3 Intelligent-Tiering delivers automatic storage cost savings in three low-latency and high-throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is designed for 99.9% availability and 99.99999999% durability.

S3 Intelligent-Tiering automatically stores objects in three access tiers:

- **Frequent Access** – Objects that are uploaded or transitioned to S3 Intelligent-Tiering are automatically stored in the Frequent Access tier.
- **Infrequent Access** – S3 Intelligent-Tiering moves objects that have not been accessed in 30 consecutive days to the Infrequent Access tier.

- **Archive Instant Access** – With S3 Intelligent-Tiering, any existing objects that have not been accessed for 90 consecutive days are automatically moved to the Archive Instant Access tier.

In addition to these three tiers, S3 Intelligent-Tiering offers two optional archive access tiers:

- **Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier automatically archives objects that have not been accessed for a minimum of 90 consecutive days.
- **Deep Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier automatically archives objects that have not been accessed for a minimum of 180 consecutive days.

 **Note**

- Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower-cost storage with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.
- Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, first restore the object by using `RestoreObject`.

You can [move newly created data to S3 Intelligent-Tiering](#), setting it as your default storage class. You can also choose to activate one or both of the archive access tiers by using the [PutBucketIntelligentTieringConfiguration](#) API operation, the AWS CLI, or the Amazon S3 console. For more information about using S3 Intelligent-Tiering and activating the archive access tiers, see [Using S3 Intelligent-Tiering](#).

To access objects in the Archive Access or Deep Archive Access tiers, you first need to restore them. For more information, see [Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers](#).

Note

If the size of an object is less than 128 KB, it is not monitored and not eligible for auto-tiering. Smaller objects are always stored in the Frequent Access tier. For more information about S3 Intelligent-Tiering, see [S3 Intelligent-Tiering access tiers](#).

Storage classes for infrequently accessed objects

The **S3 Standard-IA** and **S3 One Zone-IA** storage classes are designed for long-lived and infrequently accessed data. (IA stands for *infrequent access*.) S3 Standard-IA and S3 One Zone-IA objects are available for millisecond access (similar to the S3 Standard storage class). Amazon S3 charges a retrieval fee for these objects, so they are most suitable for infrequently accessed data. For pricing information, see [Amazon S3 pricing](#).

For example, you might choose the S3 Standard-IA and S3 One Zone-IA storage classes to do the following:

- For storing backups.
- For older data that is accessed infrequently, but that still requires millisecond access. For example, when you upload data, you might choose the S3 Standard storage class, and use lifecycle configuration to tell Amazon S3 to transition the objects to the S3 Standard-IA or S3 One Zone-IA class.

For more information about lifecycle management, see [Managing the lifecycle of objects](#).

Note

The S3 Standard-IA and S3 One Zone-IA storage classes are suitable for objects larger than 128 KB that you plan to store for at least 30 days. If an object is less than 128 KB, Amazon S3 charges you for 128 KB. If you delete an object before the end of the 30-day minimum storage duration period, you are charged for 30 days. Objects that are deleted, overwritten, or transitioned to a different storage class before 30 days will incur the normal storage usage charge plus a pro-rated charge for the remainder of the 30-day minimum. For pricing information, see [Amazon S3 pricing](#).

These storage classes differ as follows:

- **S3 Standard-IA (STANDARD_IA)** – Amazon S3 stores the object data redundantly across multiple geographically separated Availability Zones (similar to the S3 Standard storage class). S3 Standard-IA objects are resilient to the loss of an Availability Zone. This storage class offers greater availability and resiliency than the S3 One Zone-IA class. To help you optimize costs between S3 Standard and S3 Standard-IA you can use [Amazon S3 analytics – Storage Class Analysis](#)
- **S3 One Zone-IA (ONEZONE_IA)** – Amazon S3 stores the object data in only one Availability Zone, which makes it less expensive than S3 Standard-IA. However, the data is not resilient to the physical loss of the Availability Zone resulting from disasters, such as earthquakes and floods. The S3 One Zone-IA storage class is as durable as S3 Standard-IA, but it is less available and less resilient. For a comparison of storage class durability and availability, see [Comparing the Amazon S3 storage classes](#) at the end of this section. For pricing information, see [Amazon S3 pricing](#). For data residency and isolation use cases, you can create directory buckets in AWS Local Zones and use the S3 Express One Zone (EXPRESS_ONEZONE) and S3 One Zone-IA (ONEZONE_IA) storage classes. For more information about directory buckets in Local Zones, see [Data residency workloads](#).

We recommend the following:

- **S3 Standard-IA (STANDARD_IA)** – Use for your primary or only copy of data that can't be re-created.
- **S3 One Zone-IA (ONEZONE_IA)** – Use if you can re-create the data if the Availability Zone fails, for object replicas when configuring S3 Cross-Region Replication (CRR). Also, for data residency and isolation, you can create directory buckets in AWS Local Zones and use the S3 One Zone-IA storage class.

Storage classes for rarely accessed objects

The **S3 Glacier Instant Retrieval (GLACIER_IR)**, **S3 Glacier Flexible Retrieval (GLACIER)**, and **S3 Glacier Deep Archive (DEEP_ARCHIVE)** storage classes are designed for low-cost, long-term data storage and data archiving. These storage classes require minimum storage durations and retrieval fees making them most effective for rarely accessed data. For more information about S3 Glacier storage classes, see [Understanding S3 Glacier storage classes for long-term data storage](#).

Amazon S3 provides the following S3 Glacier storage classes:

- **S3 Glacier Instant Retrieval (GLACIER_IR)** – Use for long-term data that's rarely accessed and requires milliseconds retrieval. Data in this storage class is available for real-time access.
- **S3 Glacier Flexible Retrieval (GLACIER)** – Use for archives where portions of the data might need to be retrieved in minutes. Data in this storage class is archived, and not available for real-time access.
- **S3 Glacier Deep Archive (DEEP_ARCHIVE)** – Use for archiving data that rarely needs to be accessed. Data in this storage class is archived, and not available for real-time access.

Retrieving archived objects

You can set the storage class of an object to S3 Glacier Flexible Retrieval (GLACIER) or S3 Glacier Deep Archive (DEEP_ARCHIVE) in the same ways that you do for the other storage classes as described in the section [Setting the storage class of an object](#). However, S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive objects are archived, and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#).

 **Note**

When you use S3 Glacier storage classes, your objects remain in Amazon S3. You can't access them directly through the separate Amazon Glacier service. For information about the Amazon Glacier service, see the [Amazon Glacier Developer Guide](#).

Storage class for Amazon S3 on Outposts

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use the same API operations and features on AWS Outposts as you do on Amazon S3, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API.

S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS). The S3 Outposts storage class is available only for objects stored in buckets on Outposts. If you try to use this storage class with an S3 bucket in an AWS Region, an InvalidStorageClass error occurs. In addition, if you try to use other S3 storage classes with objects stored in S3 on Outposts buckets, the same error occurs.

Objects stored in the S3 Outposts (OUTPOSTS) storage class are always encrypted by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

You can also explicitly choose to encrypt objects stored in the S3 Outposts storage class by using server-side encryption with customer-provided encryption keys (SSE-C). For more information, see [Using server-side encryption with customer-provided keys \(SSE-C\)](#).

 **Note**

S3 on Outposts doesn't support server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

For more information about S3 on Outposts, see [What is S3 on Outposts](#) in the *Amazon S3 on Outposts User Guide*.

Comparing the Amazon S3 storage classes

The following table compares the storage classes, including their availability, durability, minimum storage duration, and other considerations.

Storage Class	Designed for	Durability (designed for)	Availability (designed for)	Availability Zones	Min storage duration	Min billable object size	Other Considerations
STANDARD	Frequently accessed data	99.999999999%	99.99%	≥ 3	None	None	None
STANDARD_IA	Long-lived, infrequently accessed data	99.999999999%	99.9%	≥ 3	30 days	128 KB	Per GB retrieval fees apply.
INTELLIGENT_TIERING	Long-lived data with changing or unknown access patterns	99.999999999%	99.9%	≥ 3	30 days	None	Monitoring and automation fees per object apply. No retrieval fees.
ONEZONE_IA	Long-lived, infrequently accessed, non-critical data	99.999999999%	99.5%	1	30 days	128 KB	Per GB retrieval fees apply. Not resilient to the loss of the Availability Zone.
GLACIER	Long-term data archiving with retrieval times ranging from minutes to hours	99.999999999%	99.99% (after you restore objects)	≥ 3	90 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects .
DEEP_ARCHIVE	Archiving rarely accessed data with a default retrieval time of 12 hours	99.999999999%	99.99% (after you restore objects)	≥ 3	180 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects .
RRS (Not recommended)	Frequently accessed, non-critical data	99.99%	99.99%	≥ 3	None	None	None

* S3 Glacier Flexible Retrieval requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Flexible Retrieval rate (required to identify

and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to S3 Glacier Flexible Retrieval. For more information about storage classes, see [Amazon S3 storage classes](#).

** S3 Glacier Deep Archive requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Deep Archive rate (required to identify and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to Amazon S3 Glacier Deep Archive. For more information about storage classes, see [Amazon S3 storage classes](#).

Be aware that all of the storage classes except for S3 One Zone-IA (ONEZONE_IA) and S3 Express One Zone (EXPRESS_ONEZONE) are designed to be resilient to the physical loss of an Availability Zone resulting from disasters. Also, consider costs, in addition to the performance requirements of your application scenario. For storage class pricing, see [Amazon S3 pricing](#).

Setting the storage class of an object

You can specify a storage class for an object when you upload it. If you don't, Amazon S3 uses the default Amazon S3 Standard storage class for objects in general purpose buckets. You can also change the storage class of an object that's already stored in an Amazon S3 general purpose bucket to any other storage class using the Amazon S3 console, AWS SDKs, or the AWS Command Line Interface (AWS CLI). All of these approaches use Amazon S3 API operations to send requests to Amazon S3.

 **Note**

You can't change the storage class of objects stored in directory buckets.

You can direct Amazon S3 to change the storage class of objects automatically by adding an S3 Lifecycle configuration to a bucket. For more information, see [Managing the lifecycle of objects](#).

When setting up a S3 Replication configuration, you can set the storage class for replicated objects to any other storage class. However, you can't replicate objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see [Replication configuration file elements](#).

When setting the storage class programmatically you provide the value of the storage class. The following is a list of console names for storage classes with their corresponding API values:

- **Reduced Redundancy Storage** – REDUCED_REDUNDANCY
- **S3 Express One Zone** – EXPRESS_ONEZONE
- **S3 Glacier Deep Archive** – DEEP_ARCHIVE
- **S3 Glacier Flexible Retrieval** – GLACIER
- **S3 Glacier Instant Retrieval** – GLACIER_IR
- **S3 Intelligent-Tiering** – INTELLIGENT_TIERING
- **S3 One Zone-IA** – ONEZONE_IA
- **S3 Standard** – STANDARD
- **S3 Standard-IA** – STANDARD_IA

Setting the storage class on a new object

To set the storage class when you upload an object, you can use the following methods.

Using the S3 console

To set the storage class when uploading a new object in the console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at: <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to upload your folders or files to.
4. Choose **Upload**.
5. In the **Upload** window, choose **Properties**.
6. Under Storage class, choose a storage classes for the files you're uploading.
7. (Optional) Configure any additional properties for the files you're uploading, For more information, see [Uploading objects](#)
8. In the Upload window, do one of the following:
 - Drag files and folders to the Upload window.

- Choose **Add file or Add folder**, choose the files or folders to upload, and choose **Open**.
9. At the bottom of the page, Choose **Upload**.

Using the REST API

You can specify the storage class on an object when you create it using the PutObject, POST Object Object, and CreateMultipartUpload API operations, add the x-amz-storage-class request header. If you don't add this header, Amazon S3 uses the default S3 Standard (STANDARD) storage class.

This example request uses the [PutObject](#) command to set the storage class on a new object to S3 Intelligent-Tiering:

```
PUT /my-image.jpg HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.Region.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: INTELLIGENT_TIERING
```

Using the AWS CLI

This example uses the put-object command to upload the *my_images.tar.bz2* to *amzn-s3-demo-bucket1* in the *GLACIER* storage class:

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key dir-1/my_images.tar.bz2 --
storage-class GLACIER --body my_images.tar.bz2
```

If the object size is more than 5 GB, use the following command to set the storage class:

```
aws s3 cp large_test_file s3://amzn-s3-demo-bucket1 --storage-class GLACIER
```

Changing the storage class for an existing object

To set the storage class when you upload an object, you can use the following methods.

Using the S3 console

You can change an object's storage class using the Amazon S3 console if the object size is less than 5 GB. If larger, we recommend adding an S3 Lifecycle configuration to change the object's storage class.

To change the storage class of an object in the console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket containing the objects you want to change.
4. Select the check box to the left of the names of the objects you want to change.
5. On the **Actions** menu, choose **Edit storage class** from the list of options that appears.
6. Select from the storage classes available for your object.
7. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
8. Choose **Save changes** in the bottom-right corner. Amazon S3 saves your changes.

Using the REST API

To change the storage class of an existing object, use the following methods.

This example request uses the [PutObject](#) command to set the storage class for an existing object to S3 Intelligent-Tiering:

```
PUT /my-image.jpg HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.Region.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
```

```
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: INTELLIGENT_TIERING
```

Using the AWS CLI

This example uses the cp command to change the storage class of the of an existing object from its current storage class to *DEEP_ARCHIVE* storage class:

```
aws s3 cp object_S3_URI object_S3_URI --storage-class DEEP_ARCHIVE
```

Restricting access policy permissions to a specific storage class

When you grant access policy permissions for Amazon S3 operations, you can use the s3:x-amz-storage-class condition key to restrict which storage class to use when storing uploaded objects. For example, when you grant the s3:PutObject permission, you can restrict object uploads to a specific storage class. For an example policy, see [Example: Restricting object uploads to objects with a specific storage class](#).

For more information about using conditions in policies and a complete list of Amazon S3 condition keys, see the following topics:

- [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*
For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).
- [Bucket policy examples using condition keys](#)

Amazon S3 analytics – Storage Class Analysis

By using Amazon S3 analytics *Storage Class Analysis* you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. This new Amazon S3 analytics feature observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. You can configure storage class analysis to analyze all the objects in a bucket. Or, you can configure filters to group objects together for analysis by common prefix (that is, objects that have names that begin with a common string), by object tags, or by both prefix and tags. You'll most likely find that filtering by object groups is the best way to benefit from storage class analysis.

Important

Storage class analysis only provides recommendations for Standard to Standard IA classes.

You can have multiple storage class analysis filters per bucket, up to 1,000, and will receive a separate analysis for each filter. Multiple filter configurations allow you analyze specific groups of objects to improve your lifecycle configurations that transition objects to STANDARD_IA.

Storage class analysis provides storage usage visualizations in the Amazon S3 console that are updated daily. You can also export this daily usage data to an S3 bucket and view them in a spreadsheet application, or with business intelligence tools, like Quick Suite.

There are costs associated with the storage class analysis. For pricing information, see *Management and insights* [Amazon S3 pricing](#).

Topics

- [How do I set up storage class analysis?](#)
- [How do I use storage class analysis?](#)
- [How can I export storage class analysis data?](#)
- [Configuring storage class analysis](#)

How do I set up storage class analysis?

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

- For information about how to configure storage class analysis in the Amazon S3 console, see [Configuring storage class analysis](#).
- To use the Amazon S3 API, use the [PutBucketAnalyticsConfiguration](#) REST API, or the equivalent, from the AWS CLI or AWS SDKs.

How do I use storage class analysis?

You use storage class analysis to observe your data access patterns over time to gather information to help you improve the lifecycle management of your STANDARD_IA storage. After you configure a filter, you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. However, storage class analysis observes the access patterns of a filtered data set for 30 days or longer to gather information for analysis before giving a result. The analysis continues to run after the initial result and updates the result as the access patterns change.

When you first configure a filter, the Amazon S3 console may take a moment to analyze your data.

Storage class analysis observes the access patterns of a filtered object data set for 30 days or longer to gather enough information for the analysis. After storage class analysis has gathered sufficient information, you'll see a message in the Amazon S3 console that analysis is complete.

When performing the analysis for infrequently accessed objects storage class analysis looks at the filtered set of objects grouped together based on age since they were uploaded to Amazon

S3. Storage class analysis determines if the age group is infrequently accessed by looking at the following factors for the filtered data set:

- Objects in the STANDARD storage class that are larger than 128 KB.
- How much average total storage you have per age group.
- Average number of bytes transferred out (not frequency) per age group.
- Analytics export data only includes requests with data relevant to storage class analysis. This might cause differences in the number of requests, and the total upload and request bytes compared to what are shown in storage metrics or tracked by your own internal systems.
- Failed GET and PUT requests are not counted for the analysis. However, you will see failed requests in storage metrics.

How Much of My Storage did I Retrieve?

The Amazon S3 console graphs how much of the storage in the filtered data set has been retrieved for the observation period.

What Percentage of My Storage did I Retrieve?

The Amazon S3 console also graphs what percentage of the storage in the filtered data set has been retrieved for the observation period.

As stated earlier in this topic, when you are performing the analysis for infrequently accessed objects, storage class analysis looks at the filtered set of objects grouped together based on the age since they were uploaded to Amazon S3. The storage class analysis uses the following predefined object age groups:

- Amazon S3 Objects less than 15 days old
- Amazon S3 Objects 15-29 days old
- Amazon S3 Objects 30-44 days old
- Amazon S3 Objects 45-59 days old
- Amazon S3 Objects 60-74 days old
- Amazon S3 Objects 75-89 days old
- Amazon S3 Objects 90-119 days old
- Amazon S3 Objects 120-149 days old

- Amazon S3 Objects 150-179 days old
- Amazon S3 Objects 180-364 days old
- Amazon S3 Objects 365-729 days old
- Amazon S3 Objects 730 days and older

Usually it takes about 30 days of observing access patterns to gather enough information for an analysis result. It might take longer than 30 days, depending on the unique access pattern of your data. However, after you configure a filter you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. You can see analysis on a daily basis of object access broken down by object age group in the Amazon S3 console.

How Much of My Storage is Infrequently Accessed?

The Amazon S3 console shows the access patterns grouped by the predefined object age groups. The **Frequently accessed** or **Infrequently accessed** text shown is meant as a visual aid to help you in the lifecycle creation process.

How can I export storage class analysis data?

You can choose to have storage class analysis export analysis reports to a comma-separated values (CSV) flat file. Reports are updated daily and are based on the object age group filters you configure. When using the Amazon S3 console you can choose the export report option when you create a filter. When selecting data export you specify a destination bucket and optional destination prefix where the file is written. You can export the data to a destination bucket in a different account. The destination bucket must be in the same region as the bucket that you configure to be analyzed.

You must create a bucket policy on the destination bucket to grant permissions to Amazon S3 to verify what AWS account owns the bucket and to write objects to the bucket in the defined location. For an example policy, see [Grant permissions for S3 Inventory and S3 analytics](#).

After you configure storage class analysis reports, you start getting the exported report daily after 24 hours. After that, Amazon S3 continues monitoring and providing daily exports.

You can open the CSV file in a spreadsheet application or import the file into other applications like [Amazon Quick Suite](#). For information on using Amazon S3 files with Amazon Quick Suite, see [Create a Data Set Using Amazon S3 Files](#) in the *Amazon Quick Suite User Guide*.

Data in the exported file is sorted by date within object age group as shown in following examples. If the storage class is STANDARD the row also contains data for the columns ObjectAgeForSIATransition and RecommendedObjectAgeForSIATransition.

Date	ConfigId	Filter	StorageClass	ObjectAge	ObjectCount	DataUploaded_MB	Storage_MB	DataRetrieved_MB	GetRequestCount	CumulativeAccessRatio	ObjectAgeForSIATransition	RecommendedObjectAgeForSIATransition
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/2/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	000-014		0.4313				0		
9/5/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		

At the end of the report the object age group is given as ALL. The ALL rows contain cumulative totals, including objects smaller than 128 KB, for all the age groups for that day.

8/24/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
9/3/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.02426125 015-029		
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.03545875 015-029		
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.0209529 015-029		
9/4/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.02304819 015-029		
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.03073092 015-029		
8/20/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		

The next section describes the columns used in the report.

Exported file layout

The following table describes the Amazon S3 storage class analysis export file layout.

Configuring storage class analysis

By using the Amazon S3 analytics storage class analysis tool, you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. Storage class analysis observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about STANDARD_IA, see the [Amazon S3 FAQ](#) and [Understanding and managing Amazon S3 storage classes](#).

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

⚠ Important

Storage class analysis does not give recommendations for transitions to the ONEZONE_IA or S3 Glacier Flexible Retrieval storage classes.

If you want to configure storage class analysis to export your findings as a .csv file and the destination bucket uses default bucket encryption with a AWS KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

For more information about analytics, see [Amazon S3 analytics – Storage Class Analysis](#).

Using the S3 console

To configure storage class analysis

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the buckets list, choose the name of the bucket for which you want to configure storage class analysis.
4. Choose the **Metrics** tab.

5. Under **Storage Class Analysis**, choose **Create analytics configuration**.
6. Type a name for the filter. If you want to analyze the whole bucket, leave the **Prefix** field empty.
7. In the **Prefix** field, type text for the prefix for the objects that you want to analyze.
8. To add a tag, choose **Add tag**. Enter a key and value for the tag. You can enter one prefix and multiple tags.
9. Optionally, you can choose **Enable** under **Export CSV** to export analysis reports to a comma-separated values (.csv) flat file. Choose a destination bucket where the file can be stored. You can type a prefix for the destination bucket. The destination bucket must be in the same AWS Region as the bucket for which you are setting up the analysis. The destination bucket can be in a different AWS account.

If the destination bucket for the .csv file uses default bucket encryption with a KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

10. Choose **Create Configuration**.

Amazon S3 creates a bucket policy on the destination bucket that grants Amazon S3 write permission. This will allow it to write the export data to the bucket.

If an error occurs when you try to create the bucket policy, you'll be given instructions on how to fix it. For example, if you chose a destination bucket in another AWS account and do not have permissions to read and write to the bucket policy, you'll see the following message. You must have the destination bucket owner add the displayed bucket policy to the destination bucket. If the policy is not added to the destination bucket you won't get the export data because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, then the correct account ID of the source bucket must be substituted in the policy.

For information about the exported data and how the filter works, see [Amazon S3 analytics – Storage Class Analysis](#).

Using the REST API

To configure Storage Class Analysis using the REST API, use the [PutBucketAnalyticsConfiguration](#). You can also use the equivalent operation with the AWS CLI or AWS SDKs.

You can use the following REST APIs to work with Storage Class Analysis:

- [DELETE Bucket Analytics configuration](#)
- [GET Bucket Analytics configuration](#)
- [List Bucket Analytics Configuration](#)

Managing storage costs with Amazon S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class is designed to optimize storage costs by automatically moving data to the most cost-effective access tier when access patterns change, without operational overhead or impact on performance. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

S3 Intelligent-Tiering delivers automatic storage cost savings in three low latency and high throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. There are no retrieval charges in S3 Intelligent-Tiering. If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier. No additional tiering charges apply when objects are moved between access tiers within the S3 Intelligent-Tiering storage class.

S3 Intelligent-Tiering is the recommended storage class for data with unknown, changing, or unpredictable access patterns, independent of object size or retention period, such as data lakes, data analytics, and new applications.

The S3 Intelligent-Tiering storage class supports all Amazon S3 features, including the following:

- S3 Inventory, for verifying the access tier of objects
- S3 Replication, for replicating data to any AWS Region
- S3 Storage Lens, for viewing storage usage and activity metrics
- Server-side encryption, for protecting object data
- S3 Object Lock, for preventing accidental deletion of data
- AWS PrivateLink, for accessing Amazon S3 through a private endpoint in a virtual private cloud (VPC)

For information about using S3 Intelligent-Tiering, see the following sections:

Topics

- [How S3 Intelligent-Tiering works](#)
- [Using S3 Intelligent-Tiering](#)
- [Managing S3 Intelligent-Tiering](#)

How S3 Intelligent-Tiering works

The Amazon S3 Intelligent-Tiering storage class automatically stores objects in three access tiers. One tier is optimized for frequent access, one lower-cost tier is optimized for infrequent access, and another very low-cost tier is optimized for rarely accessed data. For a low monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects to the Infrequent Access tier when they haven't been accessed for 30 consecutive days. After 90 days of no access, the objects are moved to the Archive Instant Access tier without performance impact or operational overhead.

To get the lowest storage cost for data that can be accessed in minutes to hours, activate archiving capabilities to add two additional access tiers. You can tier down objects to the Archive Access tier, the Deep Archive Access tier, or both. With Archive Access, S3 Intelligent-Tiering moves objects that have not been accessed for a minimum of 90 consecutive days to the Archive Access tier. With Deep Archive Access, S3 Intelligent-Tiering moves objects to the Deep Archive Access tier after a minimum of 180 consecutive days of no access. For both tiers, you can configure the number of days of no access based on your needs.

The following actions constitute access that prevents tiering your objects down to the Archive Access tier or the Deep Archive Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking [CopyObject](#), [UploadPartCopy](#), or replicating objects with S3 Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking [GetObject](#), [PutObject](#), [RestoreObject](#), [CompleteMultipartUpload](#), or [SelectObjectContent](#).

For example, if your objects are accessed through `SelectObjectContent` before your specified number of days of no access (for example, 180 days), that action resets the timer. Your objects won't move to the Archive Access tier or the Deep Archive Access tier until the time after the last `SelectObjectContent` request reaches your specified number of days.

If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier.

The following actions constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking [CopyObject](#), [UploadPartCopy](#), or replicating objects with Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking [GetObject](#), [PutObject](#), [RestoreObject](#), or [CompleteMultipartUpload](#).

Other actions **don't** constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier. The following is a sample, not a definitive list, of such actions:

- Invoking [HeadObject](#), [GetObjectTagging](#), [PutObjectTagging](#), [ListObjects](#), [ListObjectsV2](#), or [ListObjectVersions](#).
- Invoking [SelectObjectContent](#) doesn't constitute access that tiers objects up to a Frequent Access tier. In addition, it doesn't prevent tiering objects down from the Frequent Access tier to the Infrequent Access tier, and then to the Archive Instant Access tier.

You can use S3 Intelligent-Tiering as your default storage class for newly created data by specifying INTELLIGENT-TIERING in the [x-amz-storage-class request header](#) when calling the PutObject, CopyObject, or CreateMultipartUpload operations. S3 Intelligent-Tiering is designed for 99.9% availability and 99.99999999% durability.

 **Note**

If the size of an object is less than 128 KB, it is not monitored and is not eligible for automatic tiering. Smaller objects are always stored in the Frequent Access tier.

S3 Intelligent-Tiering access tiers

The following section explains the different automatic and optional access tiers. When objects move between access tiers, the storage class remains the same (S3 Intelligent-Tiering).

Frequent Access tier (automatic)

This is the default access tier that any object created or transitioned to S3 Intelligent-Tiering begins its lifecycle in. An object remains in this tier as long as it is being accessed. The Frequent Access tier provides low latency and high-throughput performance.

Infrequent Access tier (automatic)

If an object is not accessed for 30 consecutive days, the object moves to the Infrequent Access tier. The Infrequent Access tier provides low latency and high-throughput performance.

Archive Instant Access tier (automatic)

If an object is not accessed for 90 consecutive days, the object moves to the Archive Instant Access tier. The Archive Instant Access tier provides low latency and high-throughput performance.

Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier automatically archives objects that have not been accessed for a minimum of 90 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Archive Access tier has the same performance as the [S3 Glacier Flexible Retrieval](#) storage class.

Standard retrieval times for this access tier can range from 3–5 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within minutes. For more information about retrieval options and times, see [the section called “Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers”](#).

Note

Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower storage costs, with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.

Deep Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier

automatically archives objects that have not been accessed for a minimum of 180 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Deep Archive Access tier has the same performance as the [S3 Glacier Deep Archive](#) storage class.

Standard retrieval of objects in this access tier occurs within 12 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within 9 hours. For more information about retrieval options and times, see [the section called “Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers”](#).

Note

Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, you must first restore the object by using the `RestoreObject` operation.

You can restore archived objects with up to 1,000 transactions per second (TPS) of object restore requests per account per AWS Region from S3 Intelligent-Tiering Archive Access, and S3 Intelligent-Tiering Deep Archive Access.

Using S3 Intelligent-Tiering

You can use the S3 Intelligent-Tiering storage class to automatically optimize storage costs. S3 Intelligent-Tiering delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. For data that can be accessed asynchronously, you can choose to enable automatic archiving within the S3 Intelligent-Tiering storage class using the AWS Management Console, AWS CLI, or Amazon S3 API.

Moving data to S3 Intelligent-Tiering

There are two ways to move data into S3 Intelligent-Tiering. You can upload objects directly into S3 Intelligent-Tiering from the console or programmatically using a PUT operation. For more information, see [Setting the storage class of an object](#). You can also configure S3 Lifecycle configurations to transition objects from S3 Standard or S3 Standard-Infrequent Access to S3 Intelligent-Tiering.

Uploading data to S3 Intelligent-Tiering using Direct PUT

When you upload an object to the S3 Intelligent-Tiering storage class using the [PUT](#) API operation, you specify S3 Intelligent-Tiering in the [`x-amz-storage-class`](#) request header.

The following request stores the image, `my-image.jpg`, in the `myBucket` bucket. The request uses the `x-amz-storage-class` header to request that the object is stored using the S3 Intelligent-Tiering storage class.

Example

```
PUT /my-image.jpg HTTP/1.1
Host: myBucket.s3.<Region>.amazonaws.com (http://amazonaws.com/)
Date: Wed, 1 Sep 2021 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: INTELLIGENT_TIERING
```

Transitioning data to S3 Intelligent-Tiering from S3 Standard or S3 Standard-Infrequent Access using S3 Lifecycle

You can add rules to an S3 Lifecycle configuration to tell Amazon S3 to transition objects from one storage class to another. For information on supported transitions and related constraints, see [Transitioning objects using S3 Lifecycle](#).

You can specify S3 Lifecycle configurations at the bucket or prefix level. In this S3 Lifecycle configuration rule, the filter specifies a key prefix (`documents/`). Therefore, the rule applies to objects with key name prefix `documents/`, such as `documents/doc1.txt` and `documents/doc2.txt`. The rule specifies a Transition action directing Amazon S3 to transition objects to the S3 Intelligent-Tiering storage class 0 days after creation. In this case, objects are eligible for transition to S3 Intelligent-Tiering at midnight UTC following creation.

Example

```
<LifecycleConfiguration>
  <Rule>
    <ID>ExampleRule</ID>
    <Filter>
      <Prefix>documents/</Prefix>
```

```
</Filter>
<Status>Enabled</Status>
<Transition>
  <Days>0</Days>
  <StorageClass>INTELLIGENT_TIERING</StorageClass>
</Transition>
</Rule>
</LifecycleConfiguration>
```

A versioning-enabled bucket maintains one current object version, and zero or more noncurrent object versions. You can define separate Lifecycle rules for current and noncurrent object versions.

For more information, see [Lifecycle configuration elements](#).

Enabling S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To get the lowest storage cost on data that can be accessed in minutes to hours, you can activate one or both of the archive access tiers by creating a bucket, prefix, or object tag level configuration using the AWS Management Console, AWS CLI, or Amazon S3 API.

Using the S3 console

To enable S3 Intelligent-Tiering automatic archiving

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. Choose **Properties**.
4. Navigate to the **S3 Intelligent-Tiering Archive configurations** section and choose **Create configuration**.
5. In the **Archive configuration settings** section, specify a descriptive configuration name for your S3 Intelligent-Tiering Archive configuration.
6. Under **Choose a configuration scope**, choose a configuration scope to use. Optionally, you can limit the configuration scope to specified objects within a bucket using a shared prefix, object tag, or combination of the two.
 - a. To limit the scope of the configuration, select **Limit the scope of this configuration using one or more filters**.
 - b. To limit the scope of the configuration using a single prefix, enter the prefix under **Prefix**.

- c. To limit the scope of the configuration using object tags, select **Add tag** and enter a value for Key.
7. Under **Status**, select **Enable**.
8. In the **Archive settings** section, select one or both of the Archive Access tiers to enable.
9. Choose **Create**.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Intelligent-Tiering configurations:

- [delete-bucket-intelligent-tiering-configuration](#)
- [get-bucket-intelligent-tiering-configuration](#)
- [list-bucket-intelligent-tiering-configurations](#)
- [put-bucket-intelligent-tiering-configuration](#)

For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the *Amazon S3 API Reference*.

When using the AWS CLI, you cannot specify the configuration as an XML file. You must specify the JSON instead. The following is an example XML S3 Intelligent-Tiering configuration and equivalent JSON that you can specify in an AWS CLI command.

The following example puts an S3 Intelligent-Tiering configuration to the specified bucket.

[Example put-bucket-intelligent-tiering-configuration](#)

JSON

```
{  
    "Id": "string",  
    "Filter": {  
        "Prefix": "string",  
        "Tag": {  
            "Key": "string",  
            "Value": "string"  
        },  
        "And": {

  <Status>string</Status>
  <Tiering>
```

```
<AccessTier>string</AccessTier>
<Days>integer</Days>
</Tiering>
...
</IntelligentTieringConfiguration>
```

Using the PUT API operation

You can use the [PutBucketIntelligentTieringConfiguration](#) operation for a specified bucket and up to 1,000 S3 Intelligent-Tiering configurations per bucket. You can define which objects within a bucket are eligible for the archive access tiers using a shared prefix or object tag. Using a shared prefix or object tag allows you to align to specific business applications, workflows, or internal organizations. You also have the flexibility to activate the Archive Access tier, the Deep Archive Access tier, or both.

Getting started with S3 Intelligent-Tiering

To learn more about how to use S3 Intelligent-Tiering, see [Tutorial: Getting started using S3 Intelligent-Tiering](#).

Managing S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class delivers automatic storage cost savings in three low-latency and high-throughput access tiers. It also offers optional archive capabilities to help you get the lowest storage costs in the cloud for data that can be accessed in minutes to hours.

Identifying which S3 Intelligent-Tiering access tier objects are stored in

To get a list of your objects and their corresponding metadata, including their S3 Intelligent-Tiering access tier, you can use [Amazon S3 Inventory](#). S3 Inventory provides CSV, ORC, or Parquet output files that list your objects and their corresponding metadata. You can receive these inventory reports on either a daily or weekly basis for an Amazon S3 bucket or a shared prefix. (*Shared prefix* refers to objects that have names that begin with a common string.)

Viewing the archive status of an object within S3 Intelligent-Tiering

To receive notice when an object within the S3 Intelligent-Tiering storage class has moved to either the Archive Access tier or the Deep Archive Access tier, you can set up S3 Event Notifications. For more information, see [Enabling event notifications](#).

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

The following is an example of a message that Amazon S3 sends to publish an s3:IntelligentTiering event. For more information, see [the section called “Event message structure”](#).

```
{  
    "Records": [  
        {  
            "eventVersion": "2.3",  
            "eventSource": "aws:s3",  
            "awsRegion": "us-west-2",  
            "eventTime": "1970-01-01T00:00:00.000Z",  
            "eventName": "IntelligentTiering",  
            "userIdentity": {  
                "principalId": "s3.amazonaws.com"  
            },  
            "requestParameters": {  
                "sourceIPAddress": "s3.amazonaws.com"  
            },  
            "responseElements": {  
                "x-amz-request-id": "C3D13FE58DE4C810",  
                "x-amz-id-2": "FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/  
JRWeUWerMUE5JgHvAN0jpD"  
            },  
            "s3": {  
                "s3SchemaVersion": "1.0",  
                "configurationId": "testConfigRule",  
                "bucket": {  
                    "name": "amzn-s3-demo-bucket",  
                    "ownerIdentity": {  
                        "principalId": "A3NL1K0ZZKExample"  
                    },  
                    "arn": "arn:aws:s3:::amzn-s3-demo-bucket"  
                },  
                "object": {  
                    "key": "HappyFace.jpg",  
                    "size": 1024,  
                    "eTag": "d41d8cd98f00b204e9800998ecf8427e",  
                }  
            },  
        },  
    ],  
}
```

```
        "intelligentTieringEventData":{  
            "destinationAccessTier": "ARCHIVE_ACCESS"  
        }  
    }  
]  
}
```

You can also use a [HEAD object request](#) to view an object's archive status. If an object is stored in the S3 Intelligent-Tiering storage class and is in one of the archive tiers, the HEAD object response shows the current archive tier. To show the archive tier, the request uses the [x-amz-archive-status](#) header.

The following HEAD object request returns the metadata of an object (in this case, *my-image.jpg*).

Example

```
HEAD /my-image.jpg HTTP/1.1  
Host: bucket.s3.region.amazonaws.com  
Date: Wed, 28 Oct 2009 22:32:00 GMT  
Authorization: AWS AKIAIOSFODNN7EXAMPLE:02236Q3V0RonhpaBX5sCYVf1bNRuU=
```

You can also use HEAD object requests to monitor the status of a `restore-object` request. If the archive restoration is in progress, the HEAD object response includes the [x-amz-restore](#) header.

The following sample HEAD object response shows an object archived by using S3 Intelligent-Tiering with a restore request in progress.

Example

```
HTTP/1.1 200 OK  
x-amz-id-2: FSVaTMjrmBp3Izs1NnwBZeum19ii8UbxBmi0A8AirHANJBo+hEftBuiESACOMJp  
x-amz-request-id: E5CEFCB143EB505A  
Date: Fri, 13 Nov 2020 00:28:38 GMT  
Last-Modified: Mon, 15 Oct 2012 21:58:07 GMT  
ETag: "1accb31fcf202eba0c0f41fa2f09b4d7"  
x-amz-storage-class: 'INTELLIGENT_TIERING'  
x-amz-archive-status: 'ARCHIVE_ACCESS'  
x-amz-restore: 'ongoing-request="true"'  
x-amz-restore-request-date: 'Fri, 13 Nov 2020 00:20:00 GMT'  
Accept-Ranges: bytes  
Content-Type: binary/octet-stream
```

Content-Length: 300
Server: AmazonS3

Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate a [restore request](#), and then wait until the object is moved into the Frequent Access tier. For more information about archived objects, see [the section called “Working with archived objects”](#).

When you restore an object from the Archive Access tier or Deep Archive Access tier, the object moves back into the Frequent Access tier. Afterwards, if the object isn't accessed for 30 consecutive days, it automatically moves into the Infrequent Access tier. Then, after a minimum of 90 consecutive days of no access, the object moves into the Archive Access tier. After a minimum of 180 consecutive days of no access, the object moves into the Deep Archive Access tier. For more information, see [the section called “How S3 Intelligent-Tiering works”](#).

You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the Amazon S3 REST API, the AWS SDKs, or the AWS Command Line Interface (AWS CLI). For more information, see [the section called “Working with archived objects”](#).

Understanding S3 Glacier storage classes for long-term data storage

You can use Amazon S3 S3 Glacier storage classes to provide cost-effective solutions to storing long-term data that isn't accessed often. The S3 Glacier storage classes are:

- S3 Glacier Instant Retrieval
- S3 Glacier Flexible Retrieval
- S3 Glacier Deep Archive

You choose one of these storage classes based on how often you access your data and how fast you need to retrieve it. Each of these storage classes offer the same durability and resiliency as the S3 Standard storage class, but at lower storage costs. For more information about the S3 Glacier storage classes, see <https://aws.amazon.com/s3/storage-classes/glacier/>.

Topics

- [Comparing the S3 Glacier storage classes](#)
- [S3 Glacier Instant Retrieval](#)

- [S3 Glacier Flexible Retrieval](#)
- [S3 Glacier Deep Archive](#)
- [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#)
- [How these storage classes differ from the Amazon Glacier service](#)

Comparing the S3 Glacier storage classes

Each S3 Glacier storage class has a minimum storage duration for all objects. If you delete, overwrite, or transition the object to a different storage class before the minimum, you are charged for the remainder of that duration.

Some S3 Glacier storage classes are archival, which means the objects stored in those classes are archived and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#).

Storage classes designed for less frequent access patterns with longer retrieval times offer lower storage costs. For pricing information, see <https://aws.amazon.com/s3/pricing/>.

The following table summarizes the key points to consider when choosing a S3 Glacier storage class:

S3 Glacier Instant Retrieval

We recommend using S3 Glacier Instant Retrieval for long-term data that's accessed once per quarter and requires millisecond retrieval times. This storage class is ideal for performance-sensitive use cases such as image hosting, file-sharing applications, and storing medical records for access during appointments.

S3 Glacier Instant Retrieval storage class offers real-time access to your objects with the same latency and throughput performance as the S3 Standard-IA storage class. When compared to S3 Standard-IA, S3 Glacier Instant Retrieval has lower storage costs but higher data access costs.

There is a minimum object size of 128 KB for data stored in the S3 Glacier Instant Retrieval storage class. This storage class also has a minimum storage duration period of 90 days.

S3 Glacier Flexible Retrieval

We recommend using S3 Glacier Flexible Retrieval for archive data that's accessed one to two times a year and doesn't require immediate access. S3 Glacier Flexible Retrieval offers flexible retrieval

times to help you balance costs, with access times ranging from a few minutes to hours, and free bulk retrievals. This storage class is ideal for backup and disaster recovery.

Objects stored in S3 Glacier Flexible Retrieval are archived and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#). To access these objects, you first initiate a restore request which creates a temporary copy of the object that you can access when the request completes. For information, see [Working with archived objects](#). When you restore an object, you can choose a retrieval tier to meet your use case, with lower costs for longer restore times.

The following retrieval tiers are available for S3 Glacier Flexible Retrieval:

- **Expedited retrieval** – Typically restores the object in 1–5 minutes. Expedited retrievals are subject to demand, so to make sure you have reliable and predictable restore times, we recommend that you purchase provisioned retrieval capacity. For more information, see [Provisioned capacity](#).
- **Standard retrieval** – Typically restores the object in 3–5 hours, or within 1 minute to 5 hours when you use S3 Batch Operations. For more information, see [Restore objects with Batch Operations](#).
- **Bulk retrieval** – Typically restores the object within 5–12 hours. Bulk retrievals are free.

For any retrieval option, objects larger than 5 TB typically finish within 48 hours with up to 300 megabytes per second (Mbps) of retrieval throughput. For more information, see [Understanding archive retrieval options](#).

The minimum storage duration for objects in S3 Glacier Flexible Retrieval storage class is 90 days.

S3 Glacier Flexible Retrieval requires 40 KB of additional metadata for each object. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for S3 Glacier Flexible Retrieval. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

S3 Glacier Deep Archive

We recommend using S3 Glacier Deep Archive for archive data that's accessed less than once a year. This storage class is designed for retaining data sets for multiple years to meet compliance requirements and can also be used for backup or disaster recovery or any infrequently accessed data that you can wait up to 72 hours to retrieve. S3 Glacier Deep Archive is the lowest-cost storage option in AWS.

Objects stored in S3 Glacier Deep Archive are archived and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#). To access these objects, you first initiate a restore request which creates a temporary copy of the object that you can access when the request completes. For information, see [Working with archived objects](#). When you restore an object, you can choose a retrieval tier to meet your use case, with lower costs for longer restore times.

The following retrieval tiers are available for S3 Glacier Deep Archive:

- **Standard retrieval** – Typically restores the object within 12 hours, or within 9–12 hours when you use S3 Batch Operations. For more information, see [Restore objects with Batch Operations](#).
- **Bulk retrieval** – Typically restores the object within 48 hours at a fraction of the cost of the Standard retrieval tier.

The minimum storage duration for objects in S3 Glacier Deep Archive storage class is 180 days.

S3 Glacier Deep Archive requires 40 KB of additional metadata for each object. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for S3 Glacier Deep Archive. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive

S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are archival storage classes. This means that when you store an object in these storage classes that object is archived, and cannot be accessed directly. To access an archived object, you submit a restore request for it, and then wait for the service to restore the object. The restore request restores a temporary copy of the object, and that copy is deleted when the duration you specified in the request expires. For more information, see [Working with archived objects](#).

The transition of objects to the S3 Glacier Deep Archive storage class can go only one way.

If you want to change the storage class of an archived object to another storage class, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Reduced Redundancy Storage as the storage class.

Note

The Copy operation for restored objects isn't supported in the Amazon S3 console for objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For this type of Copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API.

You can restore archived objects in these storage classes with up to 1,000 transactions per second (TPS) of [object restore requests](#) per account per AWS Region.

Cost considerations

If you are planning to archive infrequently accessed data for a period of months or years, the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes can reduce your storage costs. However, to ensure that the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class is appropriate for you, consider the following:

- **Storage overhead charges** – Each archived object requires 40 KB of additional metadata. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for that storage class. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

If you are archiving small objects, consider these storage charges. Also consider aggregating many small objects into a smaller number of large objects to reduce overhead costs.

- **Multipart upload pricing** – Objects in S3-storage-class-glacier; and S3 Glacier Deep Archive are billed at S3 Standard storage class rates when you upload them using multipart uploads. For more information, see [Multipart upload and pricing](#).
- **Minimum 30 day storage charges** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are long-term archival solutions. The minimal storage duration period is 90 days for the S3 Glacier Flexible Retrieval storage class and 180 days for S3 Glacier Deep Archive. Deleting data that is archived to these storage classes doesn't incur charges if the objects you delete are archived for more than the minimal storage duration period. If you delete or overwrite an archived object within the minimal duration period, Amazon S3 charges for the remainder of that duration.
- **Data retrieval charges** – When you restore an archived objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive there are per-request data retrieval charges. These charges vary based on the retrieval tier you choose when you initiate a restore. For pricing information, see [Amazon S3 pricing](#).

- **S3 Lifecycle** – When you restore an archived objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive there are per-request data retrieval charges. These charges vary based on the retrieval tier you choose when you initiate a restore. For pricing information, see [Amazon S3 pricing](#).

Restoring archived objects

Archived objects aren't accessible in real time. You must first initiate a restore request and then wait until a temporary copy of the object is available for the duration that you specify in the request. After you receive a temporary copy of the restored object, the object's storage class remains S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. (A [HeadObject](#) or [GetObject](#) API operation request will return S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)

Note

When you restore an archive, you are paying for both the archive (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rate) and a copy that you restored temporarily (S3 Standard storage rate). For information about pricing, see [Amazon S3 pricing](#).

You can restore an object copy programmatically or by using the Amazon S3 console. Amazon S3 processes only one restore request at a time per object. For more information, see [Restoring an archived object](#).

How these storage classes differ from the Amazon Glacier service

The S3 Glacier storage classes are part of the Amazon S3 service and store data as objects in S3 buckets. You can manage objects in these storage classes using the S3 console or programmatically using the S3 APIs or SDKs. When you store objects in S3 Glacier storage classes, you can use S3 features such as advanced encryption, object tagging, and S3 Lifecycle configurations to help manage data accessibility and cost.

Important

We recommend using the S3 Glacier storage classes within the Amazon S3 service for all of your long-term data.

The Amazon Glacier service is a separate service that stores data as archives within vaults. This service doesn't support Amazon S3 features and doesn't provide console support for data upload and download operations. We don't recommend using the Amazon Glacier service for your long-term data. Data stored in this service isn't accessible from the Amazon S3 service. If you are looking for information on the Amazon Glacier service, see the [Amazon Glacier Developer Guide](#). To transfer data from the Amazon Glacier service to a storage class in Amazon S3 see [Data Transfer from Amazon Glacier Vaults to Amazon S3](#) in the AWS solutions library.

Working with archived objects

To reduce your storage costs for infrequently accessed objects, you can *archive* those objects. When you archive an object, it is moved into low-cost storage, which means that you can't access it in real time.

Although archived objects are not accessible in real time, you can restore them in minutes or hours, depending on the storage class. You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the REST API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI). For instructions, see [Restoring an archived object](#).

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class
- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

To restore archived objects, you must do the following:

- For objects in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, you must initiate the restore request and wait until a temporary copy of the object is available. When a temporary copy of the restored object is created, the object's storage class remains the same. (A [HeadObject](#) or [GetObject](#) API operation request returns S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)
- For objects in the S3 Intelligent-Tiering Archive Access and S3 Intelligent-Tiering Deep Archive Access tiers, you must initiate the restore request and wait until the object is moved into the Frequent Access tier.

For more information about how all Amazon S3 storage classes compare, see [Understanding and managing Amazon S3 storage classes](#). For more information about S3 Intelligent-Tiering, see the section called "How S3 Intelligent-Tiering works".

The time it takes a restore job to finish depends on which archive storage class or storage tier you use and which retrieval option you specify: Expedited (only available for S3 Glacier Flexible Retrieval and S3 Intelligent-Tiering Archive Access), Standard, or Bulk. For more information, see [Understanding archive retrieval options](#).

You can be notified when your restore is complete by using Amazon S3 Event Notifications. For more information, see [Amazon S3 Event Notifications](#).

Restoring objects from Amazon Glacier

When you use S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 restores a temporary copy of the object only for the specified duration. After that, it deletes the restored object copy. You can modify the expiration period of a restored copy by reissuing a restore request. In this case, Amazon S3 updates the expiration period relative to the current time.

Note

When you restore an archived object from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, you pay for both the archived object and the copy that you restored temporarily. For information about pricing, see [Amazon S3 pricing](#).

Amazon S3 calculates the expiration time of the restored object copy by adding the number of days specified in the restoration request to the time when the requested restoration is completed. Amazon S3 then rounds the resulting time to the next day at midnight Universal Coordinated Time (UTC). For example, suppose that a restored object copy was created on October 15, 2012, at 10:30 AM UTC, and the restoration period was specified as 3 days. In this case, the restored copy expires on October 19, 2012, at 00:00 UTC, at which time Amazon S3 deletes the object copy.

Restoring objects from S3 Intelligent-Tiering

When you restore an object from the S3 Intelligent-Tiering Archive tier or S3 Intelligent-Tiering Deep Archive tier, the object moves back into the S3 Intelligent-Tiering Frequent Access tier. If the object is not accessed after 30 consecutive days, it automatically moves into the

Infrequent Access tier. After a minimum of 90 consecutive days of no access, the object moves into the S3 Intelligent-Tiering Archive Access tier. If the object is not accessed after a minimum of 180 consecutive days, the object moves into the Deep Archive Access tier.

Note

Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the Days value.

Using S3 Batch Operations with restore requests

To restore more than one Amazon S3 object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

Topics

- [Understanding archive retrieval options](#)
- [Restoring an archived object](#)

Understanding archive retrieval options

The following are the available retrieval options when restoring an archived object in Amazon S3:

- **Expedited** – Quickly access your data that is stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. You can use this option when occasional urgent requests for a subset of archives are required. For all but the largest archived objects (250 MB+), data that is accessed by using expedited retrievals is typically made available within 1–5 minutes.

Note

Expedited retrievals are a premium feature and are charged at the Expedited request and retrieval rate.

For information about Amazon S3 pricing, see [Amazon S3 Pricing](#).

Provisioned capacity helps ensure that retrieval capacity for expedited retrievals from S3 Glacier Flexible Retrieval is available when you need it. For more information, see [Provisioned capacity](#).

- **Standard** – Access any of your archived objects within several hours. Standard is the default option for retrieval requests that do not specify the retrieval option. Standard retrievals typically finish within 3–5 hours for objects stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. These retrievals typically finish within 12 hours for objects stored in the S3 Glacier Deep Archive storage class or S3 Intelligent-Tiering Deep Archive Access tier. Standard retrievals are free for objects that are stored in S3 Intelligent-Tiering.

 **Note**

- For objects stored in the S3 Glacier Flexible Retrieval storage class or the S3 Intelligent-Tiering Archive Access tier, Standard retrievals initiated by using the S3 Batch Operations restore operation typically start within minutes and finish within 3–5 hours.
- For objects in the S3 Glacier Deep Archive storage class or the S3 Intelligent-Tiering Deep Archive Access tier, Standard retrievals initiated by using the Batch Operations restore operation typically start within 9 hours and finish within 12 hours.

- **Bulk** – Access your data by using the lowest-cost retrieval option in S3 Glacier storage classes. With Bulk retrievals, you can retrieve large amounts, even petabytes, of data inexpensively.

For objects that are stored in the S3 Glacier Flexible Retrieval storage class or the S3 Intelligent-Tiering Archive Access tier, Bulk retrievals typically finish within 5–12 hours. For objects stored in the S3 Glacier Deep Archive storage class or the S3 Intelligent-Tiering Deep Archive Access tier, these retrievals typically finish within 48 hours.

Bulk retrievals are free for objects that are stored in the S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering storage classes.

The following table summarizes the archive retrieval options. For information about pricing, see [Amazon S3 pricing](#).

For any retrieval option, objects larger than 5 TB typically finish within 48 hours with up to 300 megabytes per second (Mbps) of retrieval throughput.

To make an Expedited, Standard, or Bulk retrieval, set the `Tier` request element in the [RestoreObject](#) REST API operation request to the option that you want, or the equivalent in the AWS Command Line Interface (AWS CLI) or AWS SDKs. If you purchased provisioned capacity, all Expedited retrievals are automatically served through your provisioned capacity.

Provisioned capacity

Provisioned capacity helps ensure that your retrieval capacity for Expedited retrievals from S3 Glacier Flexible Retrieval is available when you need it. Each unit of capacity provides that at least three Expedited retrievals can be performed every 5 minutes, and it provides up to 150 megabytes per second (MBps) of retrieval throughput.

If your workload requires highly reliable and predictable access to a subset of your data in minutes, consider purchasing provisioned retrieval capacity. Without provisioned capacity, Expedited retrievals might not be accepted during periods of high demand. If you require access to Expedited retrievals under all circumstances, we recommend that you purchase provisioned retrieval capacity.

Provisioned capacity units are allocated to an AWS account. Thus, the requester of the Expedited data retrieval should purchase the provisioned capacity unit, not the bucket owner.

You can purchase provisioned capacity by using the Amazon S3 console, the Amazon Glacier console, the [Purchase Provisioned Capacity](#) REST API operation, the AWS SDKs, or the AWS CLI. For provisioned capacity pricing information, see [Amazon S3 pricing](#).

S3 Glacier restore initiation request rates

When you initiate restore requests for objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, a retrieval-requests quota is applied for your AWS account. S3 Glacier supports restore requests at a rate of 1,000 transactions per second. If this rate is exceeded otherwise valid requests are throttled or rejected and Amazon S3 returns a `ThrottlingException` error.

Optionally, you can also use S3 Batch Operations to retrieve a large number of objects stored in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive with a single request. For more information, see [Performing object operations in bulk with Batch Operations](#).

Restoring an archived object

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class
- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

Amazon S3 objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not immediately accessible. To access an object in these storage classes, you must restore a temporary copy of the object to its S3 bucket for a specified duration (number of days). If you want a permanent copy of the object, restore the object, and then create a copy of it in your Amazon S3 bucket. Copying restored objects isn't supported in the Amazon S3 console. For this type of copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API. Unless you make a copy and change its storage class, the object will still be stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For information about using these storage classes, see [Storage classes for rarely accessed objects](#).

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate a restore request and wait until the object is moved into the Frequent Access tier. When you restore an object from the Archive Access tier or Deep Archive Access tier, the object moves back into the Frequent Access tier. For information about using these storage classes, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).

For general information about archived objects, see [Working with archived objects](#).

 **Note**

- When you restore an archived object from the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, you pay for both the archived object and the copy that you restored temporarily.
- When you restore an object from S3 Intelligent-Tiering, there are no retrieval charges for Standard or Bulk retrievals.
- Subsequent restore requests called on archived objects that have already been restored are billed as GET requests. For information about pricing, see [Amazon S3 pricing](#).

Restoring an archived object

You can restore an archived object by using the Amazon S3 console, the Amazon S3 REST API, the AWS SDKs, the AWS Command Line Interface (AWS CLI), or S3 Batch Operations.

Using the S3 console

Restore objects using the Amazon S3 console

Use the following procedure to Restore an object that has been archived to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, or the S3 Intelligent-Tiering Archive Access or Deep Archive Access storage tiers.

To restore an archived object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object or objects that you want to restore, choose **Actions**, and then choose **Initiate restore**.
5. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, enter the number of days that you want your archived data to be accessible in the **Number of days that the restored copy is available** box.
6. For **Retrieval tier**, do one of the following:
 - Choose **Bulk retrieval** or **Standard retrieval**, and then choose **Initiate restore**.
 - Choose **Expedited retrieval** (available only for S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering Archive Access). If you're restoring an object in S3 Glacier Flexible Retrieval, you can choose whether to buy provisioned capacity for your Expedited retrieval. If you want to purchase provisioned capacity, proceed to the next step. If you don't, choose **Initiate restore**.

Note

Objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers are automatically restored to the Frequent Access tier.

7. (Optional) If you're restoring an object in S3 Glacier Flexible Retrieval and you chose **Expedited retrieval**, you can choose whether to buy provisioned capacity. Provisioned capacity is available only for objects in S3 Glacier Flexible Retrieval. If you already have provisioned capacity, choose **Initiate restore** to start a provisioned retrieval.

If you have provisioned capacity, all of your Expedited retrievals are served by your provisioned capacity. For more information, see [Provisioned capacity](#).

- If you don't have provisioned capacity and you don't want to buy it, choose **Initiate restore**.
- If you don't have provisioned capacity, but you want to buy provisioned capacity units (PCUs), choose **Purchase PCUs**. In the **Purchase PCUs** dialog box, choose how many PCUs you want to buy, confirm your purchase, and then choose **Purchase PCUs**. When you get the **Purchase succeeded** message, choose **Initiate restore** to start provisioned retrieval.

Using the AWS CLI

Restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive

The following example uses the `restore-object` command to restore the object *dir1/example.obj* in the bucket *amzn-s3-demo-bucket* for 25 days.

```
aws s3api restore-object --bucket amzn-s3-demo-bucket --key dir1/example.obj --restore-request '{"Days":25,"GlacierJobParameters":{"Tier":"Standard"}}'
```

If the JSON syntax used in the example results in an error on a Windows client, replace the restore request with the following syntax:

```
--restore-request Days=25,GlacierJobParameters={"Tier"]="Standard"}
```

Restore objects from S3 Intelligent-Tiering Archive Access and Deep Archive Access

The following example uses the `restore-object` command to restore the object *dir1/example.obj* in the bucket *amzn-s3-demo-bucket* to the Frequent Access tier.

```
aws s3api restore-object --bucket amzn-s3-demo-bucket --key dir1/example.obj --restore-request '{}'
```

Note

Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the Days value.

Monitor restore status

To monitor the status of your `restore-object` request, use the following `head-object` command:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key dir1/example.obj
```

For more information, see [restore-object](#) in the *AWS CLI Command Reference*.

Using the REST API

Amazon S3 provides an API operation for you to initiate the restoration of an archived object. For more information, see [RestoreObject](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to restore archived objects in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

Using S3 Batch Operations

To restore more than one archived object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

To create a Batch Operations job, you must have a manifest that contains only the objects that you want to restore. You can create a manifest by using S3 Inventory, or you can supply a CSV file with the necessary information. For more information, see [the section called “Specifying a manifest”](#).

Before creating and running S3 Batch Operations jobs, you must grant permissions to Amazon S3 to perform S3 Batch Operations on your behalf. For the required permissions, see [the section called “Granting permissions”](#).

Note

Batch Operations jobs can operate either on S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage class objects or on S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tier objects. Batch Operations can't operate on both types of archived objects in the same job. To restore objects of both types, you *must* create separate Batch Operations jobs.

For more information about using Batch Operations to restore archive objects, see [the section called "Restore objects".](#)

To create an S3 Initiate Restore Object Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. For **AWS Region**, choose the Region where you want to create your job.
5. Under **Manifest format**, choose the type of manifest to use.
 - If you choose **S3 inventory report**, enter the path to the manifest.json object that Amazon S3 generated as part of the CSV-formatted inventory report. If you want to use a manifest version other than the most recent, enter the version ID for the manifest.json object.
 - If you choose **CSV**, enter the path to a CSV-formatted manifest object. The manifest object must follow the format described in the console. If you want to use a version other than the most recent, you can optionally include the version ID for the manifest object.
6. Choose **Next**.
7. In the **Operation** section, choose **Restore**.
8. In the **Restore** section, for **Restore source**, choose either **Glacier Flexible Retrieval** or **Glacier Deep Archive** or **Intelligent-Tiering Archive Access tier** or **Deep Archive Access tier**.

If you chose **Glacier Flexible Retrieval** or **Glacier Deep Archive**, enter a number for **Number of days that the restored copy is available**.

For **Retrieval tier**, choose the tier that you want to use.

9. Choose **Next**.

10.

On the **Configure additional options** page, fill out the following sections:

- In the **Additional options** section, provide a description for the job and specify a priority number for the job. Higher numbers indicate a higher priority. For more information, see [the section called “Assigning job priority”](#).
- In the **Completion report** section, select whether Batch Operations should create a completion report. For more information about completion reports, see [the section called “Completion reports”](#).
- In the **Permissions** section, you must grant permissions to Amazon S3 to perform Batch Operations on your behalf. For the required permissions, see [the section called “Granting permissions”](#).
- (Optional) In the **Job tags** section, add tags in key-value pairs. For more information, see [the section called “Using tags”](#).

When you're finished, choose **Next**.

11. On the **Review** page, verify the settings. If you need to make changes, choose **Previous**. Otherwise, choose **Create job**.

For more information about Batch Operations, see [Restore objects with Batch Operations](#) and [Creating an S3 Batch Operations job](#).

Checking the restore status and expiration date

You can check the status of a restore request or the expiration date by using the Amazon S3 console, Amazon S3 Event Notifications, the AWS CLI, or the Amazon S3 REST API.

Note

Objects restored from the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes are stored only for the number of days that you specify. The following procedures return the expiration date for these copies.

Objects restored from the S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tiers don't have expiration dates and instead are moved back to the Frequent Access tier.

Using the S3 console

To check an object's restore status and expiration date in the Amazon S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the object that you are restoring.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears.
 - If the restoration isn't finished, at the top of the page, you see a section that says **Restoration in progress**.
 - If the restoration is finished, at the top of the page, you see a section that says **Restoration complete**. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, this section also displays the **Restoration expiry date**. Amazon S3 will remove the restored copy of your archived object on this date.

Using Amazon S3 Event Notifications

You can be notified of object restoration completion by using the `s3:ObjectRestore:Completed` action with the Amazon S3 Event Notifications feature. For more information about enabling event notifications, see [Enabling notifications by using Amazon SQS, Amazon SNS, and AWS Lambda](#). For more information about the various `ObjectRestore` event types, see [the section called "Supported event types for SQS, SNS, and Lambda"](#).

Using the AWS CLI

Check an object's restore status and expiration date with the AWS CLI

The following example uses the `head-object` command to view metadata for the object `dir1/example.obj` in the bucket `amzn-s3-demo-bucket`. When you run this command on an object being restored Amazon S3 returns if the restore is ongoing and (if applicable) the expiration date.

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key dir1/example.obj
```

Expected output (restore ongoing):

```
{
```

```
"Restore": "ongoing-request=\\"true\\"",  
"LastModified": "2020-06-16T21:55:22+00:00",  
"ContentLength": 405,  
"ETag": "\\"b662d79adeb7c8d787ea7eafb9ef6207\\\"",  
"VersionId": "wbYaE2vt0V0iIBXr0qGAJt3fP1cHB8Wi",  
"ContentType": "binary/octet-stream",  
"ServerSideEncryption": "AES256",  
"Metadata": {},  
"StorageClass": "GLACIER"  
}
```

Expected output (restore finished):

```
{  
    "Restore": "ongoing-request=\\"false\\", expiry-date=\\"Wed, 12 Aug 2020 00:00:00 GMT  
\\"",  
    "LastModified": "2020-06-16T21:55:22+00:00",  
    "ContentLength": 405,  
    "ETag": "\\"b662d79adeb7c8d787ea7eafb9ef6207\\\"",  
    "VersionId": "wbYaE2vt0V0iIBXr0qGAJt3fP1cHB8Wi",  
    "ContentType": "binary/octet-stream",  
    "ServerSideEncryption": "AES256",  
    "Metadata": {},  
    "StorageClass": "GLACIER"  
}
```

For more information about `head-object`, see [head-object](#) in the *AWS CLI Command Reference*.

Using the REST API

Amazon S3 provides an API operation for you to retrieve object metadata. To check the restoration status and expiration date of an archived object using the REST API, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

Upgrading the speed of an in-progress restore

You can upgrade the speed of your restoration while it is in progress.

To upgrade an in-progress restore to a faster tier

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.

3. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears. On the object's details page, choose **Upgrade retrieval tier**. For information about checking the restoration status of an object, see [Checking the restore status and expiration date](#).
5. Choose the tier that you want to upgrade to, and then choose **Initiate restore**.

Managing the lifecycle of objects

S3 Lifecycle helps you store objects cost effectively throughout their lifecycle by transitioning them to lower-cost storage classes, or, deleting expired objects on your behalf. To manage the lifecycle of your objects, create an *S3 Lifecycle configuration* for your bucket. An S3 Lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. There are two types of actions:

- **Transition actions** – These actions define when objects transition to another storage class. For example, you might choose to transition objects to the S3 Standard-IA storage class 30 days after creating them, or archive objects to the S3 Glacier Flexible Retrieval storage class one year after creating them. For more information, see [Understanding and managing Amazon S3 storage classes](#).

There are costs associated with lifecycle transition requests. For pricing information, see [Amazon S3 pricing](#).

- **Expiration actions** – These actions define when objects expire. Amazon S3 deletes expired objects on your behalf. For example, you might choose to expire objects after they have been stored for a regulatory compliance period. For more information, see [Expiring objects](#).

There are potential costs associated with lifecycle expiration only when you expire objects in a storage class with a minimum storage duration. For more information, see [Minimum storage duration charge](#).

Important

General purpose buckets — You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old.

Changes in billing

If there is any delay between when an object becomes eligible for a lifecycle action and when Amazon S3 transfers or expires your object, billing changes are applied as soon as the object becomes eligible for the lifecycle action. For example, if an object is scheduled to expire and Amazon S3 doesn't immediately expire the object, you won't be charged for storage after the expiration time.

The one exception to this behavior is if you have a lifecycle rule to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For more information about S3 Lifecycle rules, see [Lifecycle configuration elements](#).

Note

There are no data retrieval charges for lifecycle transitions. However, there are per-request ingestion charges when using PUT, COPY, or lifecycle rules to move data into any S3 storage class. Consider the ingestion or transition cost before moving objects into any storage class. For more information about cost considerations, see [Amazon S3 pricing](#).

Monitoring the effect of lifecycle rules

To monitor the effect of updates made by active lifecycle rules, see [the section called “How do I monitor the actions taken by my lifecycle rules?”](#).

Managing the complete lifecycle of objects

With S3 Lifecycle configuration rules you can tell Amazon S3 to transition objects to less-expensive storage classes, archive or delete them. For example:

- If you upload periodic logs to a bucket, your application might need them for a week or a month. After that, you might want to delete them.

- Some documents are frequently accessed for a limited period of time. After that, they are infrequently accessed. At some point, you might not need real-time access to them, but your organization or regulations might require you to archive them for a specific period. After that, you can delete them.
- You might upload some types of data to Amazon S3 primarily for archival purposes. For example, you might archive digital media, financial, and healthcare records, raw genomics sequence data, long-term database backups, and data that must be retained for regulatory compliance.

By combining S3 Lifecycle actions to manage an object's complete lifecycle. For example, suppose that the objects you create have a well-defined lifecycle. Initially, the objects are frequently accessed for a period of 30 days. Then, objects are infrequently accessed for up to 90 days. After that, the objects are no longer needed, so you might choose to archive or delete them.

In this scenario, you can create an S3 Lifecycle rule in which you specify the initial transition action to S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage, another transition action to S3 Glacier Flexible Retrieval storage for archiving, and an expiration action. As you move the objects from one storage class to another, you save on storage costs. For more information about cost considerations, see [Amazon S3 pricing](#).

- [Lifecycle configuration elements](#)
- [How Amazon S3 handles conflicts in lifecycle configurations](#)
- [Examples of S3 Lifecycle configurations](#)
- [Troubleshooting Amazon S3 Lifecycle issues](#)

Transitioning objects using Amazon S3 Lifecycle

You can add transition actions to an S3 Lifecycle configuration to tell Amazon S3 to move objects to another Amazon S3 storage class. For more information about storage classes, see

[Understanding and managing Amazon S3 storage classes](#). Some examples of when you might use S3 Lifecycle configurations in this way include the following:

- When you know that objects are infrequently accessed, you might transition them to the S3 Standard-IA storage class.
- You might want to archive objects that you don't need to access in real time to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.

 **Note**

Encrypted objects remain encrypted throughout the storage class transition process.

Supported transitions

In an S3 Lifecycle configuration, you can define rules to transition objects from one storage class to another to save on storage costs. When you don't know the access patterns of your objects, or if your access patterns are changing over time, you can transition the objects to the S3 Intelligent-Tiering storage class for automatic cost savings. For information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

Amazon S3 supports a waterfall model for transitioning between storage classes, as shown in the following diagram.

Supported lifecycle transitions

Amazon S3 supports the following lifecycle transitions between storage classes using an S3 Lifecycle configuration.

- The S3 Standard storage class to the S3 Standard-IA, S3 Intelligent-Tiering, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 Intelligent-Tiering storage class can transition to different storage classes depending on the S3 Intelligent-Tiering access tier. The following transitions are possible for each access tier.
 - Frequent Access tier or Infrequent Access tier to S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
 - Archive Instant Access tier to S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
 - Archive Access tier to S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
 - Deep Archive Access tier to S3 Glacier Deep Archive storage classes.

- The S3 One Zone-IA storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Instant Retrieval storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Flexible Retrieval storage class to the S3 Glacier Deep Archive storage class.

 **Note**

For versioning enabled or versioning suspended buckets, you can't transition objects with a Pending replication status.

Constraints and considerations for transitions

Lifecycle storage class transitions have the following constraints:

Objects smaller than 128 KB will not transition by default to any storage class

Amazon S3 applies a default behavior to S3 Lifecycle configurations that prevents objects smaller than 128 KB from being transitioned to any storage class. We don't recommend transitioning objects less than 128 KB because you are charged a transition request for each object. This means, for smaller objects, the transition costs can outweigh the storage savings. For more information about transition request costs, see **Requests & data retrievals** on the **Storage & requests** tab of the [Amazon S3 pricing](#) page.

To allow smaller objects to transition, you can add an [object size filter](#) to your Lifecycle transition rules that specifies a custom minimum size (`ObjectSizeGreater Than`) or maximum size (`ObjectSizeLess Than`). For more information, see [Example: Allowing objects smaller than 128 KB to be transitioned](#).

 **Note**

In September 2024 Amazon S3 updated the default transition behavior for small objects, as follows:

- **Updated default transition behavior** — Starting September 2024, the default behavior prevents objects smaller than 128 KB from being transitioned to any storage class.

- **Previous default transition behavior** — Before September 2024, the default behavior allowed objects smaller than 128 KB to be transitioned only to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.

Configurations created before September 2024 retain the previous transition behavior unless you modify them. That is, if you create, edit, or delete rules, the default transition behavior for your configuration changes to the updated behavior. If your use case requires, you can change the default transition behavior so that objects smaller than 128KB will transition to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive. To do this, use the optional `x-amz-transition-default-minimum-object-size` header in a [PutBucketLifecycleConfiguration](#) request.

Objects must be stored for at least 30 days before transitioning to S3 Standard-IA or S3 One Zone-IA

Before you transition objects to S3 Standard-IA or S3 One Zone-IA, you must store them for at least 30 days in Amazon S3. For example, you cannot create a Lifecycle rule to transition objects to the S3 Standard-IA storage class one day after you create them. Amazon S3 doesn't support this transition within the first 30 days because newer objects are often accessed more frequently or deleted sooner than is suitable for S3 Standard-IA or S3 One Zone-IA storage.

Similarly, if you are transitioning noncurrent objects (in versioned buckets), you can transition only objects that are at least 30 days noncurrent to S3 Standard-IA or S3 One Zone-IA storage. For a list of minimum storage duration for all storage class, see [Comparing the Amazon S3 storage classes](#).

You are charged for transitioning objects before their minimum storage duration

Certain storage classes have a minimum object storage duration. If you transition objects out of these storage classes before the minimum duration, you are charged for the remainder of that duration. For more information on which storage classes have minimum storage durations, see [Comparing the Amazon S3 storage classes](#).

You can't create a single Lifecycle rule that transitions objects from one storage class to another before the minimum storage duration period has passed.

For example, S3 Glacier Instant Retrieval has a minimum storage duration of 90 days. You can't specify a lifecycle rule that transitions objects to S3 Glacier Instant Retrieval after 4 days, and

then transitions objects to S3 Glacier Deep Archive after 20 days. In this case the S3 Glacier Deep Archive transition must occur after at least 94 days.

You can specify two rules to accomplish this, but you pay the minimum duration storage charges. For more information about cost considerations, see [Amazon S3 pricing](#).

For more information about creating a S3 Lifecycle, see [Setting an S3 Lifecycle configuration on a bucket](#).

Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes (object archival)

By using an S3 Lifecycle configuration, you can transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes for archiving.

Before you archive objects, review the following sections for relevant considerations.

General considerations

The following are the general considerations for you to consider before you archive objects:

- Encrypted objects remain encrypted throughout the storage class transition process.
- Objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not available in real time.

Archived objects are Amazon S3 objects, but before you can access an archived object, you must first restore a temporary copy of it. The restored object copy is available only for the duration that you specify in the restore request. After that, Amazon S3 deletes the temporary copy, and the object remains archived in S3 Glacier Flexible Retrieval.

You can restore an object by using the Amazon S3 console or programmatically by using the AWS SDK wrapper libraries or the Amazon S3 REST API in your code. For more information, see [Restoring an archived object](#).

- Objects that are stored in the S3 Glacier Flexible Retrieval storage class can only be transitioned to the S3 Glacier Deep Archive storage class.

You can use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Flexible Retrieval to the S3 Glacier Deep Archive storage class only. If you want to change the storage class of an object that is stored in S3 Glacier Flexible Retrieval to a storage class

other than S3 Glacier Deep Archive, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, or Reduced Redundancy as the storage class.

- The transition of objects to the S3 Glacier Deep Archive storage class can go only one way.

You cannot use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Deep Archive to any other storage class. If you want to change the storage class of an archived object to another storage class, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Reduced Redundancy Storage as the storage class.

 **Note**

The Copy operation for restored objects isn't supported in the Amazon S3 console for objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For this type of Copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API.

The objects that are stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes are visible and available only through Amazon S3. They are not available through the separate Amazon Glacier service.

These are Amazon S3 objects, and you can access them only by using the Amazon S3 console or the Amazon S3 API. You cannot access the archived objects through the separate Amazon Glacier console or the Amazon Glacier API.

Cost considerations

If you are planning to archive infrequently accessed data for a period of months or years, the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes can reduce your storage costs. However, to ensure that the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class is appropriate for you, consider the following:

- **Storage overhead charges** – When you transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, a fixed amount of storage is added to each object to accommodate metadata for managing the object.
 - For each object archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. Amazon S3 stores this metadata so that you can get a real-time list of your archived objects by using the Amazon S3 API. For more information, see [Get Bucket \(List Objects\)](#). You are charged S3 Standard rates for this additional storage.
 - For each object that is archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rates for this additional storage.

If you are archiving small objects, consider these storage charges. Also consider aggregating many small objects into a smaller number of large objects to reduce overhead costs.

- **Number of days you plan to keep objects archived** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are long-term archival solutions. The minimal storage duration period is 90 days for the S3 Glacier Flexible Retrieval storage class and 180 days for S3 Glacier Deep Archive. Deleting data that is archived to Amazon Glacier doesn't incur charges if the objects you delete are archived for more than the minimal storage duration period. If you delete or overwrite an archived object within the minimal duration period, Amazon S3 charges a prorated early deletion fee. For information about the early deletion fee, see the "How am I charged for deleting objects from Amazon Glacier that are less than 90 days old?" question on the [Amazon S3 FAQ](#).
- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive transition request charges** – Each object that you transition to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class constitutes one transition request. There is a cost for each such request. If you plan to transition a large number of objects, consider the request costs. If you are archiving a mix of objects that includes small objects, especially those under 128KB, we recommend using the lifecycle object size filter to filter out small objects from your transition to reduce request costs.
- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive data restore charges** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are designed for long-term archival of data that you access infrequently. For information about data restoration charges, see the "How much does it cost to retrieve data from Amazon Glacier?" question on the [Amazon S3 FAQ](#). For information about how to restore data from Amazon Glacier, see [Restoring an archived object](#).

Note

S3 Lifecycle transitions objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive asynchronously. There might be a delay between the transition date in the S3 Lifecycle configuration rule and the date of the physical transition. In this case you are charged the default rate of the storage class you transitioned from based on the transition date specified in the rule.

The Amazon S3 product detail page provides pricing information and example calculations for archiving Amazon S3 objects. For more information, see the following topics:

- "How is my storage charge calculated for Amazon S3 objects archived to Amazon Glacier?" on the [Amazon S3 FAQ](#).
- "How am I charged for deleting objects from Amazon Glacier that are less than 90 days old?" on the [Amazon S3 FAQ](#).
- "How much does it cost to retrieve data from Amazon Glacier?" on the [Amazon S3 FAQ](#).
- [Amazon S3 pricing](#) for storage costs for the different storage classes.

Restoring archived objects

Archived objects aren't accessible in real time. You must first initiate a restore request and then wait until a temporary copy of the object is available for the duration that you specify in the request. After you receive a temporary copy of the restored object, the object's storage class remains S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. (A [HeadObject](#) or [GetObject](#) API operation request will return S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)

Note

When you restore an archive, you are paying for both the archive (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rate) and a copy that you restored temporarily (S3 Standard storage rate). For information about pricing, see [Amazon S3 pricing](#).

You can restore an object copy programmatically or by using the Amazon S3 console. Amazon S3 processes only one restore request at a time per object. For more information, see [Restoring an archived object](#).

Expiring objects

You can add transition actions to an S3 Lifecycle configuration to tell Amazon S3 to delete objects at the end of their lifetime. When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 takes an **Expiration** action based on which [S3 Versioning](#) state the bucket is in:

- **Nonversioned bucket** – Amazon S3 queues the object for removal and removes it asynchronously, permanently removing the object.
- **Versioning-enabled bucket** – If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.
- **Versioning-suspended bucket** – Amazon S3 creates a delete marker with null as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the **Expiration** action. For versioning-enabled or versioning-suspended buckets, the following applies:

- Object expiration applies only to an object's current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker. You can also use the **Expiration** action to direct Amazon S3 to remove any expired object delete markers. For example, see [Removing expired object delete markers in a versioning-enabled bucket](#).
- You can use the `NoncurrentVersionExpiration` action element to direct Amazon S3 to permanently delete noncurrent versions of objects. These deleted objects can't be recovered. You can base this expiration on a certain number of days since the objects became noncurrent. In

In addition to the number of days, you can also provide a maximum number of noncurrent versions to retain (between 1 and 100). This value specifies how many newer noncurrent versions must exist before Amazon S3 can perform the associated action on a given version. To specify the maximum number of noncurrent versions, you must also provide a `Filter` element. If you don't specify a `Filter` element, Amazon S3 generates an `InvalidRequest` error when you provide a maximum number of noncurrent versions. For more information about using the `NoncurrentVersionExpiration` action element, see [the section called “Elements to describe lifecycle actions”](#).

- Amazon S3 doesn't take any action on noncurrent versions of objects that have the S3 Object Lock configuration applied.
- For objects with a Pending replication status, Amazon S3 doesn't take any action on current or non-current versions of objects.

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation,

Amazon S3 will queue for removal any existing objects that are more than 30 days old and that have the specified prefix.

Important

You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

How to find when objects will expire

To find when the current version of an object is scheduled to expire, use the [HeadObject](#) or [GetObject](#) API operation. These API operations return response headers that provide the date and time at which the current version of the object is no longer cacheable.

Note

- There may be a delay between the expiration date and the date at which Amazon S3 removes an object. You are not charged for expiration or the storage time associated with an object that has expired.
- Before updating, disabling, or deleting Lifecycle rules, use the LIST API operations (such as [ListObjectsV2](#), [ListObjectVersions](#), and [ListMultipartUploads](#)) or [Cataloging and analyzing your data with S3 Inventory](#) to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases.

Minimum storage duration charge

If you create an S3 Lifecycle expiration rule that causes objects that have been in S3 Standard-IA or S3 One Zone-IA storage for less than 30 days to expire, you are charged for 30 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Flexible Retrieval storage for less than 90 days to expire, you are charged for 90 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Deep Archive storage for less than 180 days to expire, you are charged for 180 days.

For more information, see [Amazon S3 pricing](#).

Setting an S3 Lifecycle configuration on a bucket

You can set an Amazon S3 Lifecycle configuration on a bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API. For information about S3 Lifecycle configuration, see [Managing the lifecycle of objects](#).

Note

To view or edit the lifecycle configuration for a directory bucket, use the AWS CLI, AWS SDKs, or the Amazon S3 REST API. For more information, see [Working with S3 Lifecycle for directory buckets](#).

In your S3 Lifecycle configuration, you use *lifecycle rules* to define actions that you want Amazon S3 to take during an object's lifetime. For example, you can define rules to transition objects to another storage class, archive objects, or expire (delete) objects after a specified period of time.

S3 Lifecycle considerations

Before you set a lifecycle configuration, note the following:

Lifecycle configuration propagation delay

When you add an S3 Lifecycle configuration to a bucket, there is usually some lag before a new or updated Lifecycle configuration is fully propagated to all the Amazon S3 systems. Expect a delay of a few minutes before the configuration fully takes effect. This delay can also occur when you delete an S3 Lifecycle configuration.

Transition or expiration delay

There's a delay between when a lifecycle rule is satisfied and when the action for the rule is completed. For example, suppose that a set of objects is expired by a lifecycle rule on January 1. Even though the expiration rule has been satisfied on January 1, Amazon S3 might not actually delete these objects until days or even weeks later. This delay occurs because S3 Lifecycle queues objects for transitions or expirations asynchronously. However, changes in billing are usually applied when the lifecycle rule is satisfied, even if the action isn't complete. For more information, see [Changes in billing](#). To monitor the effect of updates made by active lifecycle rules, see [the section called "How do I monitor the actions taken by my lifecycle rules?"](#)

Updating, disabling, or deleting lifecycle rules

When you disable or delete lifecycle rules, Amazon S3 stops scheduling new objects for deletion or transition after a small delay. Any objects that were already scheduled are unscheduled and are not deleted or transitioned.

Note

Before updating, disabling, or deleting lifecycle rules, use the LIST API operations (such as [ListObjectsV2](#), [ListObjectVersions](#), and [ListMultipartUploads](#)) or [Cataloging and analyzing your data with S3 Inventory](#) to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases. If you're experiencing any issues with updating, disabling, or deleting lifecycle rules, see [Troubleshooting Amazon S3 Lifecycle issues](#).

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old and that have the specified prefix.

Monitoring the effect of lifecycle rules

To monitor the effect of updates made by active lifecycle rules, see [the section called “How do I monitor the actions taken by my lifecycle rules?”](#)

Changes in billing

There might be a lag between when the Lifecycle configuration rules are satisfied and when the action triggered by satisfying the rule is taken. However, changes in billing happen as soon as the Lifecycle configuration rule is satisfied, even if the action isn't yet taken.

For example, after the object expiration time, you aren't charged for storage, even if the object isn't deleted immediately. Likewise, as soon as the object transition time elapses, you're charged S3 Glacier Flexible Retrieval storage rates, even if the object isn't immediately transitioned to the S3 Glacier Flexible Retrieval storage class.

However, lifecycle transitions to the S3 Intelligent-Tiering storage class are the exception. Changes in billing don't happen until after the object has transitioned into the S3 Intelligent-Tiering storage class.

Multiple or conflicting rules

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

How to set an S3 Lifecycle configuration

You can set an Amazon S3 Lifecycle configuration on a general purpose bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

For information about AWS CloudFormation templates and examples, see [Working with AWS CloudFormation templates](#) and [AWS::S3::Bucket](#) in the *CloudFormation User Guide*.

Using the S3 console

You can define lifecycle rules for all objects or a subset of objects in a bucket by using a shared prefix (objects names that begin with a common string) or a tag. In your lifecycle rule, you can define actions specific to current and noncurrent object versions. For more information, see the following:

- [Managing the lifecycle of objects](#)
- [Retaining multiple versions of objects with S3 Versioning](#)

To create a lifecycle rule

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a lifecycle rule for.

4. Choose the **Management** tab, and choose **Create lifecycle rule**.

5. In **Lifecycle rule name**, enter a name for your rule.

The name must be unique within the bucket.

6. Choose the scope of the lifecycle rule:

- To apply this lifecycle rule to *all objects with a specific prefix or tag*, choose **Limit the scope to specific prefixes or tags**.

- To limit the scope by prefix, in **Prefix**, enter the prefix.

- To limit the scope by tag, choose **Add tag**, and enter the tag key and value.

For more information about object name prefixes, see [Naming Amazon S3 objects](#). For more information about object tags, see [Categorizing your objects using tags](#).

- To apply this lifecycle rule to *all objects in the bucket*, choose **This rule applies to all objects in the bucket**, and then choose **I acknowledge that this rule applies to all objects in the bucket**.

7. To filter a rule by object size, you can select **Specify minimum object size**, **Specify maximum object size**, or both options.

- When you're specifying a value for **Minimum object size** or **Maximum object size**, the value must be larger than 0 bytes and up to 50 TB. You can specify this value in bytes, KB, MB, or GB.

- When you're specifying both values, the maximum object size must be larger than the minimum object size.

 **Note**

The **Minimum object size** and **Maximum object size** filters exclude the specified values. For example, if you set a filter to expire objects that have a **Minimum object size** of 128 KB, objects that are exactly 128 KB don't expire. Instead, the rule applies only to objects that are greater than 128 KB in size.

8. Under **Lifecycle rule actions**, choose the actions that you want your lifecycle rule to perform:

- Transition *current* versions of objects between storage classes
- Transition *previous* versions of objects between storage classes
- Expire *current* versions of objects

Note

For buckets that don't have [S3 Versioning](#) enabled, expiring current versions causes Amazon S3 to permanently delete the objects. For more information, see [the section called "Lifecycle actions and bucket versioning state"](#).

- Permanently delete *previous* versions of objects
- Delete expired delete markers or incomplete multipart uploads

Depending on the actions that you choose, different options appear.

9. To transition *current* versions of objects between storage classes, under **Transition current versions of objects between storage classes**, do the following:
 - a. In **Storage class transitions**, choose the storage class to transition to. For a list of possible transitions, see [the section called "Supported lifecycle transitions"](#). You can choose from the following storage classes:
 - S3 Standard-IA
 - S3 Intelligent-Tiering
 - S3 One Zone-IA
 - S3 Glacier Instant Retrieval
 - S3 Glacier Flexible Retrieval
 - S3 Glacier Deep Archive
 - b. In **Days after object creation**, enter the number of days after creation to transition the object.

For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#). You can define transitions for current or previous object versions or for both current and previous versions. Versioning enables you to keep multiple versions of an object in one bucket. For more information about versioning, see [Using the S3 console](#).

⚠ Important

When you choose the S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Glacier Deep Archive storage class, your objects remain in Amazon S3. You

cannot access them directly through the separate Amazon Glacier service. For more information, see [Transitioning objects using Amazon S3 Lifecycle](#).

10. To transition *noncurrent* versions of objects between storage classes, under **Transition noncurrent versions of objects between storage classes**, do the following:
 - a. In **Storage class transitions**, choose the storage class to transition to. For a list of possible transitions, see the section called “[Supported lifecycle transitions](#)”. You can choose from the following storage classes:
 - S3 Standard-IA
 - S3 Intelligent-Tiering
 - S3 One Zone-IA
 - S3 Glacier Instant Retrieval
 - S3 Glacier Flexible Retrieval
 - S3 Glacier Deep Archive
 - b. In **Days after object becomes noncurrent**, enter the number of days after creation to transition the object.
11. To expire *current* versions of objects, under **Expire current versions of objects**, in **Number of days after object creation**, enter the number of days.

 **Important**

In a nonversioned bucket, the expiration action results in Amazon S3 permanently removing the object. For more information about lifecycle actions, see [Elements to describe lifecycle actions](#).

12. To permanently delete previous versions of objects, under **Permanently delete noncurrent versions of objects**, in **Days after objects become noncurrent**, enter the number of days. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**.
13. Under **Delete expired delete markers or incomplete multipart uploads**, choose **Delete expired object delete markers** and **Delete incomplete multipart uploads**. Then, enter the number of days after the multipart upload initiation that you want to end and clean up incomplete multipart uploads.

For more information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

14. Choose **Create rule**.

If the rule does not contain any errors, Amazon S3 enables it, and you can see it on the **Management** tab under **Lifecycle rules**.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Lifecycle configurations:

- `put-bucket-lifecycle-configuration`
- `get-bucket-lifecycle-configuration`
- `delete-bucket-lifecycle`

For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the [Amazon S3 API Reference](#).

The Amazon S3 Lifecycle configuration is an XML file. But when you're using the AWS CLI, you cannot specify the XML format. You must specify the JSON format instead. The following are example XML lifecycle configurations and the equivalent JSON configurations that you can specify in an AWS CLI command.

Consider the following example S3 Lifecycle configuration.

Example Example 1

Example

XML

```
<LifecycleConfiguration>
  <Rule>
    <ID>ExampleRule</ID>
    <Filter>
      <Prefix>documents/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
```

```
<Days>365</Days>
<StorageClass>GLACIER</StorageClass>
</Transition>
<Expiration>
    <Days>3650</Days>
</Expiration>
</Rule>
</LifecycleConfiguration>
```

JSON

```
{
    "Rules": [
        {
            "Filter": {
                "Prefix": "documents/"
            },
            "Status": "Enabled",
            "Transitions": [
                {
                    "Days": 365,
                    "StorageClass": "GLACIER"
                }
            ],
            "Expiration": {
                "Days": 3650
            },
            "ID": "ExampleRule"
        }
    ]
}
```

Example Example 2

Example

XML

```
<LifecycleConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <Rule>
        <ID>id-1</ID>
```

```
<Expiration>
    <Days>1</Days>
</Expiration>
<Filter>
    <And>
        <Prefix>myprefix</Prefix>
        <Tag>
            <Key>mytagkey1</Key>
            <Value>mytagvalue1</Value>
        </Tag>
        <Tag>
            <Key>mytagkey2</Key>
            <Value>mytagvalue2</Value>
        </Tag>
    </And>
</Filter>
<Status>Enabled</Status>
</Rule>
</LifecycleConfiguration>
```

JSON

```
{
    "Rules": [
        {
            "ID": "id-1",
            "Filter": {
                "And": [
                    {
                        "Prefix": "myprefix",
                        "Tags": [
                            {
                                "Value": "mytagvalue1",
                                "Key": "mytagkey1"
                            },
                            {
                                "Value": "mytagvalue2",
                                "Key": "mytagkey2"
                            }
                        ]
                    }
                ],
                "Status": "Enabled",
            }
        }
    ]
}
```

```
        "Expiration": {
            "Days": 1
        }
    ]
}
```

You can test the put-bucket-lifecycle-configuration as follows.

To test the configuration

1. Save the JSON Lifecycle configuration in a file (for example, *lifecycle.json*).
2. Run the following AWS CLI command to set the Lifecycle configuration on your bucket. Replace the *user input placeholders* with your own information.

```
$ aws s3api put-bucket-lifecycle-configuration \
--bucket amzn-s3-demo-bucket \
--lifecycle-configuration file:///lifecycle.json
```

3. To verify, retrieve the S3 Lifecycle configuration by using the get-bucket-lifecycle-configuration AWS CLI command as follows:

```
$ aws s3api get-bucket-lifecycle-configuration \
--bucket amzn-s3-demo-bucket
```

4. To delete the S3 Lifecycle configuration, use the delete-bucket-lifecycle AWS CLI command as follows:

```
aws s3api delete-bucket-lifecycle \
--bucket amzn-s3-demo-bucket
```

Using the AWS SDKs

Java

You can use the AWS SDK for Java to manage the S3 Lifecycle configuration of a bucket. For more information about managing S3 Lifecycle configuration, see [Managing the lifecycle of objects](#).

Note

When you add an S3 Lifecycle configuration to a bucket, Amazon S3 replaces the bucket's current Lifecycle configuration, if there is one. To update a configuration, you retrieve it, make the desired changes, and then add the revised configuration to the bucket.

To manage lifecycle configuration using the AWS SDK for Java, you can:

- Add a Lifecycle configuration to a bucket.
- Retrieve the Lifecycle configuration and update it by adding another rule.
- Add the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing configuration.
- Retrieve the configuration again and verify that it has the right number of rules by printing the number of rules.
- Delete the Lifecycle configuration and verify that it has been deleted by attempting to retrieve it again.

For examples of how to set lifecycle configuration on a bucket with the AWS SDK for Java, see [Set lifecycle configuration on a bucket](#) in the *Amazon S3 API Reference*.

.NET

You can use the AWS SDK for .NET to manage the S3 Lifecycle configuration on a bucket.

For more information about managing Lifecycle configuration, see [Managing the lifecycle of objects](#).

Note

When you add a Lifecycle configuration, Amazon S3 replaces the existing configuration on the specified bucket. To update a configuration, you must first retrieve the Lifecycle configuration, make the changes, and then add the revised Lifecycle configuration to the bucket.

The following example shows how to use the AWS SDK for .NET to add, update, and delete a bucket's Lifecycle configuration. The code example does the following:

- Adds a Lifecycle configuration to a bucket.
- Retrieves the Lifecycle configuration and updates it by adding another rule.
- Adds the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing Lifecycle configuration.
- Retrieves the configuration again and verifies it by printing the number of rules in the configuration.
- Deletes the Lifecycle configuration and verifies the deletion.

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class LifecycleTest
    {
        private const string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            AddUpdateDeleteLifecycleConfigAsync().Wait();
        }

        private static async Task AddUpdateDeleteLifecycleConfigAsync()
        {
            try
            {
                var lifeCycleConfiguration = new LifecycleConfiguration()
                {
                    Rules = new List<LifecycleRule>
```

```
{  
    new LifecycleRule

Ruby

You can use the AWS SDK for Ruby to manage an S3 Lifecycle configuration on a bucket by using the class [AWS::S3::BucketLifecycleConfiguration](#). For more information about managing S3 Lifecycle configuration, see [Managing the lifecycle of objects](#).

Using the REST API

The following topics in the *Amazon Simple Storage Service API Reference* describe the REST API operations related to S3 Lifecycle configuration:

- [PutBucketLifecycleConfiguration](#)
- [GetBucketLifecycleConfiguration](#)
- [DeleteBucketLifecycle](#)

Troubleshooting S3 Lifecycle

For common issues that might occur when working with S3 Lifecycle, see [the section called "Troubleshooting lifecycle issues"](#).

How S3 Lifecycle interacts with other bucket configurations

In addition to S3 Lifecycle configurations, you can associate other configurations with your bucket. This section explains how S3 Lifecycle configuration relates to other bucket configurations.

S3 Lifecycle and S3 Versioning

You can add S3 Lifecycle configurations to unversioned buckets and versioning-enabled buckets. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

A versioning-enabled bucket maintains one current object version, and zero or more noncurrent object versions. You can define separate lifecycle rules for current and noncurrent object versions.

For more information, see [Lifecycle configuration elements](#).

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

S3 Lifecycle configuration on MFA-enabled buckets

S3 Lifecycle configuration on multi-factor authentication buckets configured for MFA delete isn't supported. For more information, see [Configuring MFA delete](#).

S3 Lifecycle and logging

Amazon S3 Lifecycle actions aren't captured by AWS CloudTrail object level logging. CloudTrail captures API requests made to external Amazon S3 endpoints, whereas S3 Lifecycle actions are performed by using internal Amazon S3 endpoints.

You can enable Amazon S3 server access logs in an S3 bucket to capture S3 Lifecycle-related actions, such as object transitions to another storage class and object expirations that result in

permanent deletion or logical deletion. For more information, see [the section called “Logging server access”](#).

If you have logging enabled on your bucket, Amazon S3 server access logs report the results of the following operations.

Operation log	Description
S3.EXPIRE.OBJECT	Amazon S3 permanently deletes the object because of the lifecycle Expiration action.
S3.CREATE.DELETEMARKER	Amazon S3 logically deletes the current version by adding a delete marker in a versioning-enabled bucket.
S3.TRANSITION_SIA.OBJECT	Amazon S3 transitions the object to the S3 Standard-IA storage class.
S3.TRANSITION_ZIA.OBJECT	Amazon S3 transitions the object to the S3 One Zone-IA storage class.
S3.TRANSITION_INT.OBJECT	Amazon S3 transitions the object to the S3 Intelligent-Tiering storage class.
S3.TRANSITION_GIR.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Instant Retrieval storage class.
S3.TRANSITION.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Flexible Retrieval storage class.
S3.TRANSITION_GDA.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Deep Archive storage class.
S3.DELETE.UPLOAD	Amazon S3 aborts an incomplete multipart upload.

Note

Amazon S3 server access log records are delivered on a best-effort basis and can't be used for a complete accounting of all Amazon S3 requests.

Configuring S3 Lifecycle event notifications

To receive notice when Amazon S3 deletes an object or transitions it to another Amazon S3 storage class as the result of following an S3 Lifecycle rule, you can set up an Amazon S3 event notification.

You can receive notifications for the following S3 Lifecycle events:

- **Transition events** – By using the `s3:LifecycleTransition` event type, you can receive notification when an object is transitioned from one Amazon S3 storage class to another by an S3 Lifecycle configuration.
- **Expiration (delete) events** – By using the `LifecycleExpiration` event types, you can receive notifications whenever Amazon S3 deletes an object based on your S3 Lifecycle configuration.

There are two expiration event types:

- The `s3:LifecycleExpiration:Delete` event type notifies you when an object in an unversioned bucket is deleted. `s3:LifecycleExpiration:Delete` also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration.
- The `s3:LifecycleExpiration:DeleteMarkerCreated` event type notifies you when S3 Lifecycle creates a delete marker after a current version of an object in a versioned bucket is deleted. S3 Lifecycle sets the delete marker's creation time to 00:00 UTC (midnight) of the current day. This creation time might differ from the event time in the `s3:LifecycleExpiration:DeleteMarkerCreated` notification that S3 sends. For more information, see [the section called “Deleting object versions”](#).

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

For instructions on how to configure Amazon S3 Event Notifications, see [Enabling event notifications by using Amazon SQS, Amazon SNS, and AWS Lambda](#).

The following is an example of a message that Amazon S3 sends to publish an `s3:LifecycleExpiration:Delete` event. For more information, see [the section called “Event message structure”](#).

```
{  
    "Records": [  
        {  
            "eventVersion": "2.3",  
            "eventSource": "aws:s3",  
            "awsRegion": "us-west-2",  
            "eventTime": "1970-01-01T00:00:00.000Z",  
            "eventName": "LifecycleExpiration:Delete",  
            "userIdentity": {  
                "principalId": "s3.amazonaws.com"  
            },  
            "requestParameters": {  
                "sourceIPAddress": "s3.amazonaws.com"  
            },  
            "responseElements": {  
                "x-amz-request-id": "C3D13FE58DE4C810",  
                "x-amz-id-2": "FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/  
JRWeUWerMUE5JgHvANOjpD"  
            },  
            "s3": {  
                "s3SchemaVersion": "1.0",  
                "configurationId": "testConfigRule",  
                "bucket": {  
                    "name": "amzn-s3-demo-bucket",  
                    "ownerIdentity": {  
                        "principalId": "A3NL1K0ZZKExample"  
                    },  
                    "arn": "arn:aws:s3:::amzn-s3-demo-bucket"  
                },  
                "object": {  
                    "key": "expiration/delete",  
                    "sequencer": "0055AED6DCD90281E5",  
                }  
            }  
        }  
    ]  
}
```

Messages that Amazon S3 sends to publish an s3:LifecycleTransition event also include the following information:

```
"lifecycleEventData":{  
    "transitionEventData": {  
        "destinationStorageClass": the destination storage class for the object  
    }  
}
```

Lifecycle configuration elements

A S3 Lifecycle configuration consist of Lifecycle rules that include various elements that describe the actions Amazon S3 takes during an object's lifetime. Each S3 bucket can have one lifecycle configuration assigned to it, which can contain up to 1,000 rules. You specify an Amazon S3 Lifecycle configuration as XML, consisting of one or more Lifecycle rules, where each rule consists of one or more elements.

```
<LifecycleConfiguration>  
  <Rule>  
    <Element>  
  </Rule>  
  <Rule>  
    <Element>  
    <Element>  
  </Rule>  
</LifecycleConfiguration>
```

Each rule consists of the following:

- Rule metadata that includes a rule ID, and a status that indicates whether the rule is enabled or disabled. If a rule is disabled, Amazon S3 doesn't perform any actions specified in the rule.
- A filter that identifies the objects to which the rule applies. You can specify a filter by using the object size, the object key prefix, one or more object tags, or a combination of filters.
- One or more transition or expiration actions with a date or a time period in the object's lifetime when you want Amazon S3 to perform the specified action.

Topics

- [ID element](#)

- [Status element](#)
- [Filter element](#)
- [Elements to describe lifecycle actions](#)
- [Adding filters to Lifecycle rules](#)

The following sections describe the XML elements in an S3 Lifecycle configuration. For example configurations, see [Examples of S3 Lifecycle configurations](#).

ID element

Lifecycle configurations are set at the bucket level, with each bucket having its own lifecycle configuration. An S3 Lifecycle configuration can have up to 1,000 rules per bucket. This limit is not adjustable. The <ID> element uniquely identifies a rule within a bucket's lifecycle configuration. ID length is limited to 255 characters.

Status element

The <Status> element value can be either Enabled or Disabled. If a rule is disabled, Amazon S3 doesn't perform any of the actions defined in the rule.

Filter element

A S3 Lifecycle rule can apply to all or a subset of objects in a bucket based on the <Filter> element that you specify in the rule.

You can filter objects by key prefix, object tags, or a combination of both (in which case Amazon S3 uses a logical AND to combine the filters). For examples and more information about filters see, [Adding filters to Lifecycle rules](#).

- **Specifying a filter by using key prefixes** – This example shows an S3 Lifecycle rule that applies to a subset of objects based on the key name prefix (logs/). For example, the Lifecycle rule applies to the objects logs/mylog.txt, logs/temp1.txt, and logs/test.txt. The rule does not apply to the object example.jpg.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
```

```
transition/expiration actions  
...  
</Rule>  
...  
</LifecycleConfiguration>
```

If you want to apply a lifecycle action to a subset of objects based on different key name prefixes, specify separate rules. In each rule, specify a prefix-based filter. For example, to describe a lifecycle action for objects with the key prefixes projectA/ and projectB/, you specify two rules as follows:

```
<LifecycleConfiguration>  
  <Rule>  
    <Filter>  
      <Prefix>projectA/</Prefix>  
    </Filter>  
    transition/expiration actions  
    ...  
  </Rule>  
  
  <Rule>  
    <Filter>  
      <Prefix>projectB/</Prefix>  
    </Filter>  
    transition/expiration actions  
    ...  
  </Rule>  
</LifecycleConfiguration>
```

For more information about object keys, see [Naming Amazon S3 objects](#).

- **Specifying a filter based on object tags** – In the following example, the Lifecycle rule specifies a filter based on a tag (**key**) and value (**value**). The rule then applies only to a subset of objects with the specific tag.

```
<LifecycleConfiguration>  
  <Rule>  
    <Filter>  
      <Tag>  
        <Key>key</Key>  
        <Value>value</Value>  
      </Tag>
```

```
</Filter>
transition/expiration actions
...
</Rule>
</LifecycleConfiguration>
```

You can specify a filter based on multiple tags. You must wrap the tags in the `<And>` element, as shown in the following example. The rule directs Amazon S3 to perform lifecycle actions on objects with two tags (with the specific tag key and value).

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Tag>
          <Key>key1</Key>
          <Value>value1</Value>
        </Tag>
        <Tag>
          <Key>key2</Key>
          <Value>value2</Value>
        </Tag>
        ...
      </And>
    </Filter>
    transition/expiration actions
  </Rule>
</Lifecycle>
```

The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match *both* the key and value exactly. If you specify only a `<Key>` element and no `<Value>` element, the rule will apply only to objects that match the tag key and that do *not* have a value specified.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

Note

When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both the prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these filter elements in the <And> element, as follows:

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <Tag>
          <Key>key1</Key>
          <Value>value1</Value>
        </Tag>
        <Tag>
          <Key>key2</Key>
          <Value>value2</Value>
        </Tag>
        ...
      </And>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters by using a logical AND. That is, the rule applies to the subset of objects with the specified key prefix and the specified tags. A filter can have only one prefix, and zero or more tags.

- You can specify an **empty filter**, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

```
</Rule>  
</LifecycleConfiguration>
```

- To filter a rule by **object size**, you can specify a minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes.

Object size values are in bytes. By default, objects smaller than 128 KB will not be transitioned to any storage class, unless you specify a smaller minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLessThan`). For more information, see [Example: Allowing objects smaller than 128 KB to be transitioned](#).

```
<LifecycleConfiguration>  
<Rule>  
  <Filter>  
    <ObjectSizeGreater Than>500</ObjectSizeGreater Than>  
  </Filter>  
  <Status>Enabled</Status>  
  transition/expiration actions  
</Rule>  
</LifecycleConfiguration>
```

Note

The `ObjectSizeGreater Than` and `ObjectSizeLessThan` filters exclude the specified values. For example, if you set objects sized 128 KB to 1024 KB to move from the S3 Standard storage class to the S3 Standard-IA storage class, objects that are exactly 1024 KB and 128 KB won't transition to S3 Standard-IA. Instead, the rule will apply only to objects that are greater than 128 KB and less than 1024 KB in size.

If you're specifying an object size range, the `ObjectSizeGreater Than` integer must be less than the `ObjectSizeLessThan` value. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes.

```
<LifecycleConfiguration>  
<Rule>  
  <Filter>
```

```
<And>
  <Prefix>key-prefix</Prefix>
  <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
  <ObjectSizeLess Than>64000</ObjectSizeLess Than>
</And>
</Filter>
<Status>Enabled</Status>
transition/expiration actions
</Rule>
</LifecycleConfiguration>
```

Elements to describe lifecycle actions

You can direct Amazon S3 to perform specific actions in an object's lifetime by specifying one or more of the following predefined actions in an S3 Lifecycle rule. The effect of these actions depends on the versioning state of your bucket.

- **Transition action element** – You specify the Transition action to transition objects from one storage class to another. For more information about transitioning objects, see [Supported transitions](#). When a specified date or time period in the object's lifetime is reached, Amazon S3 performs the transition.

For a versioned bucket (versioning-enabled or versioning-suspended bucket), the Transition action applies to the current object version. To manage noncurrent versions, Amazon S3 defines the NoncurrentVersionTransition action (described later in this topic).

- **Expiration action element** – The Expiration action expires objects identified in the rule and applies to eligible objects in any of the Amazon S3 storage classes. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#). Amazon S3 makes all expired objects unavailable. Whether the objects are permanently removed depends on the versioning state of the bucket.
 - **Nonversioned bucket** – The Expiration action results in Amazon S3 permanently removing the object.
 - **Versioned bucket** – For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the Expiration action. For versioning-enabled or versioning-suspended buckets, the following applies:

- The **Expiration** action applies only to the current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker. You can also use the expiration action to direct Amazon S3 to remove any expired object delete markers. For an example, see [Removing expired object delete markers in a versioning-enabled bucket](#).

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Also consider the following when setting up Amazon S3 to manage expiration:

- **Versioning-enabled bucket**

If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.

- **Versioning-suspended bucket**

In a versioning-suspended bucket, the expiration action causes Amazon S3 to create a delete marker with null as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

In addition, Amazon S3 provides the following actions that you can use to manage noncurrent object versions in a versioned bucket (that is, versioning-enabled and versioning-suspended buckets).

- **NoncurrentVersionTransition** action element – Use this action to specify when Amazon S3 transitions objects to the specified storage class. You can base this transition on a certain number of days since the objects became noncurrent (`<NoncurrentDays>`). In addition to the number of days, you can also specify the number of noncurrent versions (`<NewerNoncurrentVersions>`) to retain (between 1 and 100). This value determines how many newer noncurrent versions must exist before Amazon S3 can transition a given version. Amazon S3 will transition any additional noncurrent versions beyond the specified

number to retain. For the transition to occur, both the <NoncurrentDays> **and** the <NewerNoncurrentVersions> values must be exceeded.

To specify the number of noncurrent versions to retain, you must also provide a <Filter> element. If you don't specify a <Filter> element, Amazon S3 generates an InvalidRequest error when you specify the number of noncurrent versions to retain.

For more information about transitioning objects, see [Supported transitions](#). For details about how Amazon S3 calculates the date when you specify the number of days in the NoncurrentVersionTransition action, see [Lifecycle rules: Based on an object's age](#).

- **NoncurrentVersionExpiration action element** – Use this action to direct Amazon S3 to permanently delete noncurrent versions of objects. These deleted objects can't be recovered. You can base this expiration on a certain number of days since the objects became noncurrent (<NoncurrentDays>). In addition to the number of days, you can also specify the number of noncurrent versions (<NewerNoncurrentVersions>) to retain (between 1 and 100). This value specifies how many newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the <NoncurrentDays> **and** the <NewerNoncurrentVersions> values must be exceeded.

To specify the number of noncurrent versions to retain, you must also provide a <Filter> element. If you don't specify a <Filter> element, Amazon S3 generates an InvalidRequest error when you specify the number of noncurrent versions to retain.

Delayed removal of noncurrent objects can be helpful when you need to correct any accidental deletes or overwrites. For example, you can configure an expiration rule to delete noncurrent versions five days after they become noncurrent. For example, suppose that on 1/1/2014 at 10:30 AM UTC, you create an object called photo.gif (version ID 111111). On 1/2/2014 at 11:30 AM UTC, you accidentally delete photo.gif (version ID 111111), which creates a delete marker with a new version ID (such as version ID 4857693). You now have five days to recover the original version of photo.gif (version ID 111111) before the deletion is permanent. On 1/8/2014 at 00:00 UTC, the Lifecycle rule for expiration runs and permanently deletes photo.gif (version ID 111111), five days after it became a noncurrent version.

For details about how Amazon S3 calculates the date when you specify the number of days in an NoncurrentVersionExpiration action, see [Lifecycle rules: Based on an object's age](#).

Note

Object expiration lifecycle configurations don't remove incomplete multipart uploads. To remove incomplete multipart uploads, you must use the `AbortIncompleteMultipartUpload` Lifecycle configuration action that's described later in this section.

In addition to the transition and expiration actions, you can use the following Lifecycle configuration actions to direct Amazon S3 to stop incomplete multipart uploads or to remove expired object delete markers:

- **AbortIncompleteMultipartUpload action element** – Use this element to set a maximum time (in days) that you want to allow multipart uploads to remain in progress. If the applicable multipart uploads (determined by the key name prefix specified in the Lifecycle rule) aren't successfully completed within the predefined time period, Amazon S3 stops the incomplete multipart uploads. For more information, see [Aborting a multipart upload](#).

Note

You can't specify this lifecycle action in a rule that has a filter that uses object tags.

- **ExpiredObjectDeleteMarker action element** – In a versioning-enabled bucket, a delete marker with zero noncurrent versions is referred to as an *expired object delete marker*. You can use this lifecycle action to direct Amazon S3 to remove expired object delete markers. For an example, see [Removing expired object delete markers in a versioning-enabled bucket](#).

Note

You can't specify this lifecycle action in a rule that has a filter that uses object tags.

How Amazon S3 calculates how long an object has been noncurrent

In a versioning-enabled bucket, you can have multiple versions of an object. There is always one current version, and zero or more noncurrent versions. Each time you upload an object, the current version is retained as the noncurrent version and the newly added version, the successor, becomes

the current version. To determine the number of days an object is noncurrent, Amazon S3 looks at when its successor was created. Amazon S3 uses the number of days since its successor was created as the number of days an object is noncurrent.

Restoring previous versions of an object when using S3 Lifecycle configurations

As explained in [Restoring previous versions](#), you can use either of the following two methods to retrieve previous versions of an object:

- **Method 1 – Copy a noncurrent version of the object into the same bucket.** The copied object becomes the current version of that object, and all object versions are preserved.
- **Method 2 – Permanently delete the current version of the object.** When you delete the current object version, you, in effect, turn the noncurrent version into the current version of that object.

When you're using S3 Lifecycle configuration rules with versioning-enabled buckets, we recommend as a best practice that you use Method 1.

S3 Lifecycle operates under an eventually consistent model. A current version that you permanently deleted might not disappear until the changes propagate to all of the Amazon S3 systems. (Therefore, Amazon S3 might be temporarily unaware of this deletion.) In the meantime, the lifecycle rule that you configured to expire noncurrent objects might permanently remove noncurrent objects, including the one that you want to restore. So, copying the old version, as recommended in Method 1, is the safer alternative.

Lifecycle actions and bucket versioning state

Lifecycle rules: Based on an object's age

You can specify a time period, in the number of days from the creation (or modification) of the object, when Amazon S3 can take the specified action.

When you specify the number of days in the Transition and Expiration actions in an S3 Lifecycle configuration, note the following:

- The value that you specify is the number of days since object creation when the action will occur.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the object creation time and rounding up the resulting time to the next day at midnight UTC. For example,

if an object was created on 1/15/2014 at 10:30 AM UTC and you specify 3 days in a transition rule, then the transition date of the object would be calculated as 1/19/2014 00:00 UTC.

Note

Amazon S3 maintains only the last modified date for each object. For example, the Amazon S3 console shows the **Last modified** date in the object's **Properties** pane. When you initially create a new object, this date reflects the date that the object is created. If you replace the object, the date changes accordingly. Therefore, the creation date is synonymous with the **Last modified** date.

When specifying the number of days in the `NoncurrentVersionTransition` and `NoncurrentVersionExpiration` actions in a Lifecycle configuration, note the following:

- The value that you specify is the number of days from when the version of the object becomes noncurrent (that is, when the object is overwritten or deleted) that Amazon S3 will perform the action on the specified object or objects.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the time when the new successor version of the object is created and rounding up the resulting time to the next day at midnight UTC. For example, in your bucket, suppose that you have a current version of an object that was created on 1/1/2014 at 10:30 AM UTC. If the new version of the object that replaces the current version is created on 1/15/2014 at 10:30 AM UTC, and you specify 3 days in a transition rule, the transition date of the object is calculated as 1/19/2014 00:00 UTC.

Lifecycle rules: Based on a specific date

When specifying an action in an S3 Lifecycle rule, you can specify a date when you want Amazon S3 to take the action. When the specific date arrives, Amazon S3 applies the action to all qualified objects (based on the filter criteria).

If you specify an S3 Lifecycle action with a date that is in the past, all qualified objects become immediately eligible for that lifecycle action.

Important

The date-based action is not a one-time action. Amazon S3 continues to apply the date-based action even after the date has passed, as long as the rule status is Enabled.

For example, suppose that you specify a date-based Expiration action to delete all objects (assume that no filter is specified in the rule). On the specified date, Amazon S3 expires all the objects in the bucket. Amazon S3 also continues to expire any new objects that you create in the bucket. To stop the lifecycle action, you must either remove the action from the lifecycle rule, disable the rule, or delete the rule from the lifecycle configuration.

The date value must conform to the ISO 8601 format. The time is always midnight UTC.

Note

You can't create date-based Lifecycle rules by using the Amazon S3 console, but you can view, disable, or delete such rules.

Adding filters to Lifecycle rules

Filters are an optional Lifecycle rule element that you can use to specify which objects that the rule applies to.

The following elements can be used to filter objects:

Key prefix

You can filter objects based on a prefix. If you want to apply a lifecycle action to a subset of objects with different prefixes, create separate rules for each action.

Object tags

You can filter objects based on one or more tags. Each tag must match both the key and value exactly, and, if you specify multiple tags each tag key must be unique. A filter with multiple object tags applies to a subset of objects that has all the tags specified. If an object has additional tags specified, the filter will still apply.

Note

If you specify only a Key element and no Value element, the rule will apply only to objects that match the tag key and that do not have a value specified.

Minimum or maximum object size

You can filter objects based on size. You can specify a minimum size (ObjectSizeGreaterThan) or a maximum size (ObjectSizeLessThan), or you can specify a range of object sizes in the same filter. Object size values are in bytes. Maximum filter size is 50 TB. Amazon S3 applies a default minimum object size to lifecycle configuration. For more information, see [Example: Allowing objects smaller than 128 KB to be transitioned](#).

You can combine different filter elements in which case Amazon S3 uses a logical AND.

Filter examples

The following examples show how you can use different filter elements:

- **Specifying a filter by using key prefixes** – This example shows an S3 Lifecycle rule that applies to a subset of objects based on the key name prefix (logs/). For example, the Lifecycle rule applies to the objects logs/mylog.txt, logs/temp1.txt, and logs/test.txt. The rule does not apply to the object example.jpg.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    transition/expiration actions
    ...
  </Rule>
  ...
</LifecycleConfiguration>
```

Note

If you have one or more prefixes that start with the same characters, you can include all of those prefixes in your rule by specifying a partial prefix with no trailing slash (/) in the filter. For example, suppose that you have these prefixes:

```
sales1999/  
          sales2000/  
          sales2001/
```

To include all three prefixes in your rule, specify `sales` as the prefix in your lifecycle rule.

If you want to apply a lifecycle action to a subset of objects based on different key name prefixes, specify separate rules. In each rule, specify a prefix-based filter. For example, to describe a lifecycle action for objects with the key prefixes `projectA/` and `projectB/`, you specify two rules as follows:

```
<LifecycleConfiguration>  
  <Rule>  
    <Filter>  
      <Prefix>projectA/</Prefix>  
    </Filter>  
    transition/expiration actions  
    ...  
  </Rule>  
  
  <Rule>  
    <Filter>  
      <Prefix>projectB/</Prefix>  
    </Filter>  
    transition/expiration actions  
    ...  
  </Rule>  
</LifecycleConfiguration>
```

For more information about object keys, see [Naming Amazon S3 objects](#).

- **Specifying a filter based on object tags** – In the following example, the Lifecycle rule specifies a filter based on a tag (*key*) and value (*value*). The rule then applies only to a subset of objects with the specific tag.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Tag>
        <Key>key</Key>
        <Value>value</Value>
      </Tag>
    </Filter>
    transition/expiration actions
    ...
  </Rule>
</LifecycleConfiguration>
```

You can specify a filter based on multiple tags. You must wrap the tags in the `<And>` element, as shown in the following example. The rule directs Amazon S3 to perform lifecycle actions on objects with two tags (with the specific tag key and value).

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Tag>
          <Key>key1</Key>
          <Value>value1</Value>
        </Tag>
        <Tag>
          <Key>key2</Key>
          <Value>value2</Value>
        </Tag>
        ...
      </And>
    </Filter>
    transition/expiration actions
  </Rule>
</Lifecycle>
```

The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match *both* the key and value exactly. If you specify only a <Key> element and no <Value> element, the rule will apply only to objects that match the tag key and that do *not* have a value specified.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

 **Note**

When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both the prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these filter elements in the <And> element, as follows:

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <Tag>
          <Key>key1</Key>
          <Value>value1</Value>
        </Tag>
        <Tag>
          <Key>key2</Key>
          <Value>value2</Value>
        </Tag>
        ...
      </And>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters by using a logical AND. That is, the rule applies to the subset of objects with the specified key prefix and the specified tags. A filter can have only one prefix, and zero or more tags.

- **Specifying an empty filter** – You can specify an empty filter, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

- **>Specifying an object size filter** – To filter a rule by object size, you can specify a minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLess Than`), or you can specify a range of object sizes.

Object size values are in bytes. Maximum filter size is 50 TB. Some storage classes have minimum object size limitations. For more information, see [Comparing the Amazon S3 storage classes](#).

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

Note

The `ObjectSizeGreater Than` and `ObjectSizeLess Than` filters exclude the specified values. For example, if you set objects sized 128 KB to 1024 KB to move from the S3 Standard storage class to the S3 Standard-IA storage class, objects that are exactly 1024

KB and 128 KB won't transition to S3 Standard-IA. Instead, the rule will apply only to objects that are greater than 128 KB and less than 1024 KB in size.

If you're specifying an object size range, the `ObjectSizeGreaterThan` integer must be less than the `ObjectSizeLessThan` value. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
        <ObjectSizeLessThan>64000</ObjectSizeLessThan>
      </And>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

How Amazon S3 handles conflicts in lifecycle configurations

Generally, Amazon S3 Lifecycle optimizes for cost. For example, if two expiration policies overlap, the shorter expiration policy is honored so that data is not stored for longer than expected. Likewise, if two transition policies overlap, S3 Lifecycle transitions your objects to the lower-cost storage class.

In both cases, S3 Lifecycle tries to choose the path that is least expensive for you. An exception to this general rule is with the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is favored by S3 Lifecycle over any storage class, aside from the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

Examples of overlapping filters and conflicting lifecycle actions

You might specify an S3 Lifecycle configuration in which you specify overlapping prefixes, or actions. The following examples show how Amazon S3 resolves potential conflicts.

Example 1: Overlapping prefixes (no conflict)

The following example configuration has two rules that specify overlapping prefixes as follows:

- The first rule specifies an empty filter, indicating all objects in the bucket.
- The second rule specifies a key name prefix (logs/), indicating only a subset of objects.

Rule 1 requests Amazon S3 to delete all objects one year after creation. Rule 2 requests Amazon S3 to transition a subset of objects to the S3 Standard-IA storage class 30 days after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>30</Days>
    </Transition>
```

```
</Rule>
</LifecycleConfiguration>
```

Since there is no conflict in this case, Amazon S3 will transition the objects with the logs/ prefix to the S3 Standard-IA storage class 30 days after creation. When any object reaches one year after creation, it will be deleted.

Example 2: Conflicting lifecycle actions

In this example configuration, there are two rules that direct Amazon S3 to perform two different actions on the same set of objects at the same time in the objects' lifetime:

- Both rules specify the same key name prefix, so both rules apply to the same set of objects.
- Both rules specify the same 365 days after object creation when the rules apply.
- One rule directs Amazon S3 to transition objects to the S3 Standard-IA storage class and another rule wants Amazon S3 to expire the objects at the same time.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>365</Days>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

In this case, because you want objects to expire (to be removed), there is no point in changing the storage class, so Amazon S3 chooses the expiration action on these objects.

Example 3: Overlapping prefixes resulting in conflicting lifecycle actions

In this example, the configuration has two rules, which specify overlapping prefixes as follows:

- Rule 1 specifies an empty prefix (indicating all objects).
- Rule 2 specifies a key name prefix (logs/) that identifies a subset of all objects.

For the subset of objects with the logs/ key name prefix, S3 Lifecycle actions in both rules apply. One rule directs Amazon S3 to transition objects 10 days after creation, and another rule directs Amazon S3 to transition objects 365 days after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>10</Days>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>365</Days>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

In this case, Amazon S3 chooses to transition them 10 days after creation.

Example 4: Tag-based filtering and resulting conflicting lifecycle actions

Suppose that you have the following S3 Lifecycle configuration that has two rules, each specifying a tag filter:

- Rule 1 specifies a tag-based filter (tag1/value1). This rule directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 365 days after creation.
- Rule 2 specifies a tag-based filter (tag2/value2). This rule directs Amazon S3 to expire objects 14 days after creation.

The S3 Lifecycle configuration is shown in following example.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Tag>
        <Key>tag1</Key>
        <Value>value1</Value>
      </Tag>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>GLACIER</StorageClass>
      <Days>365</Days>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Tag>
        <Key>tag2</Key>
        <Value>value2</Value>
      </Tag>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>14</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

If an object has both tags, then Amazon S3 has to decide which rule to follow. In this case, Amazon S3 expires the object 14 days after creation. The object is removed, and therefore the transition action does not apply.

Examples of S3 Lifecycle configurations

This section provides examples of S3 Lifecycle configuration. Each example shows how you can specify the XML in each of the example scenarios.

- [Lifecycle configuration to abort multipart uploads](#)
- [Expiring noncurrent objects that have no data](#)
- [Example: Allowing objects smaller than 128 KB to be transitioned](#)

Archiving all objects within one day after creation

Each S3 Lifecycle rule includes a filter that you can use to identify a subset of objects in your bucket to which the S3 Lifecycle rule applies. The following S3 Lifecycle configurations show examples of how you can specify a filter.

- In this S3 Lifecycle configuration rule, the filter specifies a key prefix (tax/). Therefore, the rule applies to objects with the key name prefix tax/, such as tax/doc1.txt and tax/doc2.txt.

The rule specifies two actions that direct Amazon S3 to do the following:

- Transition objects to the S3 Glacier Flexible Retrieval storage class 365 days (one year) after creation.
- Delete objects (the **Expiration** action) 3,650 days (10 years) after creation.

```
<LifecycleConfiguration>
```

```
<Rule>
  <ID>Transition and Expiration Rule</ID>
  <Filter>
    <Prefix>tax/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <Days>365</Days>
    <StorageClass>GLACIER</StorageClass>
  </Transition>
  <Expiration>
    <Days>3650</Days>
  </Expiration>
</Rule>
</LifecycleConfiguration>
```

Instead of specifying the object age in terms of days after creation, you can specify a date for each action. However, you can't use both Date and Days in the same rule.

- If you want the S3 Lifecycle rule to apply to all objects in the bucket, specify an empty prefix. In the following configuration, the rule specifies a Transition action that directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 0 days after creation. This rule means that the objects are eligible for archival to S3 Glacier Flexible Retrieval at midnight UTC following creation. For more information about lifecycle constraints, see [Constraints and considerations for transitions](#).

```
<LifecycleConfiguration>
  <Rule>
    <ID>Archive all object same-day upon creation</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

- You can specify zero or one key name prefix and zero or more object tags in a filter. The following example code applies the S3 Lifecycle rule to a subset of objects with the tax/ key

prefix and to objects that have two tags with specific key and value. When you specify more than one filter, you must include the `<And>` element as shown (Amazon S3 applies a logical AND to combine the specified filter conditions).

```
...
<Filter>
  <And>
    <Prefix>tax/</Prefix>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
  </And>
</Filter>
...
```

- You can filter objects based only on tags. For example, the following S3 Lifecycle rule applies to objects that have the two specified tags (it does not specify any prefix).

```
...
<Filter>
  <And>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
  </And>
</Filter>
...
```

⚠ Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Disabling Lifecycle rules temporarily

You can temporarily disable an S3 Lifecycle rule using the status element. This can be useful if you want to test new rules or troubleshoot issues with your configuration, without overwriting your existing rules. The following S3 Lifecycle configuration specifies two rules:

- Rule 1 directs Amazon S3 to transition objects with the logs/ prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.
- Rule 2 directs Amazon S3 to transition objects with the documents/ prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.

In the configuration, Rule 1 is enabled and Rule 2 is disabled. Amazon S3 ignores the disabled rule.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
```

```
<StorageClass>GLACIER</StorageClass>
</Transition>
</Rule>
<Rule>
<ID>Rule2</ID>
<Filter>
<Prefix>documents/</Prefix>
</Filter>
<Status>Disabled</Status>
<Transition>
<Days>0</Days>
<StorageClass>GLACIER</StorageClass>
</Transition>
</Rule>
</LifecycleConfiguration>
```

Tiering down the storage class over an object's lifetime

In this example, you use S3 Lifecycle configuration to tier down the storage class of objects over their lifetime. Tiering down can help reduce storage costs. For more information about pricing, see [Amazon S3 pricing](#).

The following S3 Lifecycle configuration specifies a rule that applies to objects with the key name prefix logs/. The rule specifies the following actions:

- Two transition actions:
 - Transition objects to the S3 Standard-IA storage class 30 days after creation.
 - Transition objects to the S3 Glacier Flexible Retrieval storage class 90 days after creation.
- One expiration action that directs Amazon S3 to delete objects a year after creation.

```
<LifecycleConfiguration>
<Rule>
<ID>example-id</ID>
<Filter>
<Prefix>logs/</Prefix>
</Filter>
<Status>Enabled</Status>
<Transition>
<Days>30</Days>
<StorageClass>STANDARD_IA</StorageClass>
```

```
</Transition>
<Transition>
  <Days>90</Days>
  <StorageClass>GLACIER</StorageClass>
</Transition>
<Expiration>
  <Days>365</Days>
</Expiration>
</Rule>
</LifecycleConfiguration>
```

Note

You can use one rule to describe all S3 Lifecycle actions if all actions apply to the same set of objects (identified by the filter). Otherwise, you can add multiple rules with each specifying a different filter.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Specifying multiple rules

You can specify multiple rules if you want different S3 Lifecycle actions of different objects. The following S3 Lifecycle configuration has two rules:

- Rule 1 applies to objects with the key name prefix classA/. It directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class one year after creation and expire these objects 10 years after creation.
- Rule 2 applies to objects with key name prefix classB/. It directs Amazon S3 to transition objects to the S3 Standard-IA storage class 90 days after creation and delete them one year after creation.

```
<LifecycleConfiguration>
    <Rule>
        <ID>ClassADocRule</ID>
        <Filter>
            <Prefix>classA/</Prefix>
        </Filter>

            <StorageClass>STANDARD_IA</StorageClass>
        </Transition>
        <Expiration>
            <Days>365</Days>
        </Expiration>
    </Rule>
</LifecycleConfiguration>
```

⚠ Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Specifying a lifecycle rule for a versioning-enabled bucket

Suppose that you have a versioning-enabled bucket, which means that for each object, you have a current version and zero or more noncurrent versions. (For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).)

In the following example, you want to maintain one year's worth of history, and retain 5 noncurrent versions. S3 Lifecycle configurations support keeping 1 to 100 versions of any object. Be aware that more than 5 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the NoncurrentDays and the NewerNoncurrentVersions values must be exceeded.

To save storage costs, you want to move noncurrent versions to S3 Glacier Flexible Retrieval 30 days after they become noncurrent (assuming that these noncurrent objects are cold data for which you don't need real-time access). In addition, you expect the frequency of access of the current versions to diminish 90 days after creation, so you might choose to move these objects to the S3 Standard-IA storage class.

```
<LifecycleConfiguration>
  <Rule>
    <ID>sample-rule</ID>
    <Filter>
```

```
<Prefix></Prefix>
</Filter>
<Status>Enabled</Status>
<Transition>
    <Days>90</Days>
    <StorageClass>STANDARD_IA</StorageClass>
</Transition>
<NoncurrentVersionTransition>
    <NoncurrentDays>30</NoncurrentDays>
    <StorageClass>GLACIER</StorageClass>
</NoncurrentVersionTransition>
<NoncurrentVersionExpiration>
    <NewerNoncurrentVersions>5</NewerNoncurrentVersions>
    <NoncurrentDays>365</NoncurrentDays>
</NoncurrentVersionExpiration>
</Rule>
</LifecycleConfiguration>
```

Removing expired object delete markers in a versioning-enabled bucket

A versioning-enabled bucket has one current version and zero or more noncurrent versions for each object. When you delete an object, note the following:

- If you don't specify a version ID in your delete request, Amazon S3 adds a delete marker instead of deleting the object. The current object version becomes noncurrent, and the delete marker becomes the current version.
- If you specify a version ID in your delete request, Amazon S3 deletes the object version permanently (a delete marker isn't created).
- A delete marker with zero noncurrent versions is referred to as an *expired object delete marker*.

This example shows a scenario that can create expired object delete markers in your bucket, and how you can use S3 Lifecycle configuration to direct Amazon S3 to remove the expired object delete markers.

Suppose that you write an S3 Lifecycle configuration that uses the NoncurrentVersionExpiration action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions, as shown in the following example. Be aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond

the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

```
<LifecycleConfiguration>
  <Rule>
    ...
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

The `NoncurrentVersionExpiration` action doesn't apply to the current object versions. It removes only the noncurrent versions.

For current object versions, you have the following options to manage their lifetime, depending on whether the current object versions follow a well-defined lifecycle:

- **The current object versions follow a well-defined lifecycle.**

In this case, you can use an S3 Lifecycle configuration with the `Expiration` action to direct Amazon S3 to remove the current versions, as shown in the following example.

```
<LifecycleConfiguration>
  <Rule>
    ...
    <Expiration>
      <Days>60</Days>
    </Expiration>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

In this example, Amazon S3 removes current versions 60 days after they're created by adding a delete marker for each of the current object versions. This process makes the current version noncurrent, and the delete marker becomes the current version. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Note

You can't specify both a Days and an `ExpiredObjectDeleteMarker` tag on the same rule. When you specify the Days tag, Amazon S3 automatically performs `ExpiredObjectDeleteMarker` cleanup when the delete markers are old enough to satisfy the age criteria. To clean up delete markers as soon as they become the only version, create a separate rule with only the `ExpiredObjectDeleteMarker` tag.

The `NoncurrentVersionExpiration` action in the same S3 Lifecycle configuration removes noncurrent objects 30 days after they become noncurrent. Thus, in this example, all object versions are permanently removed 90 days after object creation. Be aware that in this example, more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

Although expired object delete markers are created during this process, Amazon S3 detects and removes the expired object delete markers for you.

- **The current object versions don't have a well-defined lifecycle.**

In this case, you might remove the objects manually when you don't need them, creating a delete marker with one or more noncurrent versions. If your S3 Lifecycle configuration with the `NoncurrentVersionExpiration` action removes all the noncurrent versions, you now have expired object delete markers.

Specifically for this scenario, S3 Lifecycle configuration provides an `Expiration` action that you can use to remove the expired object delete markers.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
```

```
<ExpiredObjectDeleteMarker>true</ExpiredObjectDeleteMarker>
</Expiration>
<NoncurrentVersionExpiration>
    <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
    <NoncurrentDays>30</NoncurrentDays>
</NoncurrentVersionExpiration>
</Rule>
</LifecycleConfiguration>
```

By setting the `ExpiredObjectDeleteMarker` element to `true` in the `Expiration` action, you direct Amazon S3 to remove the expired object delete markers.

 **Note**

When you use the `ExpiredObjectDeleteMarker` S3 Lifecycle action, the rule cannot specify a tag-based filter.

Lifecycle configuration to abort multipart uploads

You can use the Amazon S3 multipart upload REST API operations to upload large objects in parts. For more information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

By using an S3 Lifecycle configuration, you can direct Amazon S3 to stop incomplete multipart uploads (identified by the key name prefix specified in the rule) if they aren't completed within a specified number of days after initiation. When Amazon S3 aborts a multipart upload, it deletes all the parts associated with the multipart upload. This process helps control your storage costs by ensuring that you don't have incomplete multipart uploads with parts that are stored in Amazon S3.

 **Note**

When you use the `AbortIncompleteMultipartUpload` S3 Lifecycle action, the rule cannot specify a tag-based filter.

The following is an example S3 Lifecycle configuration that specifies a rule with the AbortIncompleteMultipartUpload action. This action directs Amazon S3 to stop incomplete multipart uploads seven days after initiation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>sample-rule</ID>
    <Filter>
      <Prefix>SomeKeyPrefix</Prefix>
    </Filter>
    <Status>rule-status</Status>
    <AbortIncompleteMultipartUpload>
      <DaysAfterInitiation>7</DaysAfterInitiation>
    </AbortIncompleteMultipartUpload>
  </Rule>
</LifecycleConfiguration>
```

Expiring noncurrent objects that have no data

You can create rules that transition objects based only on their size. You can specify a minimum size (ObjectSizeGreaterThan) or a maximum size (ObjectSizeLessThan), or you can specify a range of object sizes in bytes. When using more than one filter, such as a prefix and size rule, you must wrap the filters in an <And> element.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition with a prefix and based on size</ID>
    <Filter>
      <And>
        <Prefix>tax/</Prefix>
        <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
      </And>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

If you're specifying a range by using both the `ObjectSizeGreater Than` and `ObjectSizeLessThan` elements, the maximum object size must be larger than the minimum object size. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes. When you're specifying a range, the `ObjectSizeGreater Than` and `ObjectSizeLessThan` filters exclude the specified values. For more information, see [the section called "Filter element"](#).

```
<LifecycleConfiguration>
  <Rule>
    ...
    <And>
      <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
      <ObjectSizeLessThan>64000</ObjectSizeLessThan>
    </And>
  </Rule>
</LifecycleConfiguration>
```

You can also create rules to specifically expire noncurrent objects that have no data, including noncurrent delete marker objects created in a versioning-enabled bucket. The following example uses the `NoncurrentVersionExpiration` action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions. This example also uses the `ObjectSizeLessThan` element to filter only objects with no data.

Be aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Expire noncurrent with size less than 1 byte</ID>
    <Filter>
      <ObjectSizeLessThan>1</ObjectSizeLessThan>
    </Filter>
    <Status>Enabled</Status>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
```

```
</LifecycleConfiguration>
```

Example: Allowing objects smaller than 128 KB to be transitioned

Amazon S3 applies a default behavior to your Lifecycle configuration that prevents objects smaller than 128 KB from being transitioned to any storage class. You can allow smaller objects to transition by adding a minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLessThan`) filter that specifies a smaller size to the configuration. The following example allows any object smaller than 128 KB to transition to the S3 Glacier Instant Retrieval storage class:

```
<LifecycleConfiguration>
<Rule>
  <ID>Allow small object transitions</ID>
  <Filter>
    <ObjectSizeGreater Than>1</ObjectSizeGreater Than>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <Days>365</Days>
    <StorageClass>GLACIER_IR</StorageClass>
  </Transition>
</Rule>
</LifecycleConfiguration>
```

Note

In September 2024, Amazon S3 updated the default transition behavior for small objects, as follows:

- **Updated default transition behavior** — Starting September 2024, the default behavior prevents objects smaller than 128 KB from being transitioned to any storage class.
- **Previous default transition behavior** — Before September 2024, the default behavior allowed objects smaller than 128 KB to be transitioned only to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.

Configurations created before September 2024 retain the previous transition behavior unless you modify them. That is, if you create, edit, or delete rules, the default transition behavior for your configuration changes to the updated behavior. If your use case requires,

you can change the default transition behavior so that objects smaller than 128KB will transition to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive. To do this, use the optional `x-amz-transition-object-size-minimum-default` header in a [PutBucketLifecycleConfiguration](#) request.

The following example shows how to use the `x-amz-transition-object-size-minimum-default` header in a [PutBucketLifecycleConfiguration](#) request to apply the `varies_by_storage_class` default transition behavior to an S3 Lifecycle configuration. This behavior allows object smaller than 128 KB to transition to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. By default, all other storage classes will prevent transitions smaller than 128 KB. You can still use custom filters to change the minimum transition size for any storage class. Custom filters always take precedence over the default transition behavior:

```
HTTP/1.1 200
x-amz-transition-object-size-minimum-default: varies_by_storage_class
<?xml version="1.0" encoding="UTF-8"?>
...
...
```

Troubleshooting Amazon S3 Lifecycle issues

The following information can help you troubleshoot common issues with Amazon S3 Lifecycle rules.

Topics

- [I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.](#)
- [How do I monitor the actions taken by my lifecycle rules?](#)
- [My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.](#)
- [How do I empty my S3 bucket by using lifecycle rules?](#)
- [My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.](#)
- [I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.](#)
- [Can I recover S3 objects that are expired by S3 Lifecycle rules?](#)
- [Why are my expiration and transition lifecycle actions not occurring?](#)

- [How can I exclude a prefix from my lifecycle rule?](#)
- [How can I include multiple prefixes in my lifecycle rule?](#)

I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.

S3 Lifecycle [object transitions](#) and [object expirations](#) are asynchronous operations. Therefore, there might be a delay between the time that the objects are eligible for expiration or transition and the time that they are actually transitioned or expired. Changes in billing are applied as soon as the lifecycle rule is satisfied, even if the action isn't complete. The exception to this behavior is if you have a lifecycle rule set to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For more information about changes in billing, see [Setting lifecycle configuration on a bucket](#).

 **Note**

Amazon S3 doesn't transition objects that are smaller than 128 KB from the S3 Standard or S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage class.

How do I monitor the actions taken by my lifecycle rules?

To monitor actions taken by lifecycle rules, you can use the following features:

- **S3 Event Notifications** – You can set up [S3 Event Notifications](#) so that you're notified of any S3 Lifecycle expiration or transition events.
- **S3 server access logs** – You can enable server access logs for your S3 buckets to capture S3 Lifecycle actions, such as object transitions to another storage class or object expirations. For more information, see [Lifecycle and logging](#).

To view the changes in your storage caused by lifecycle actions on a daily basis, we recommend using [S3 Storage Lens dashboards](#) instead of using Amazon CloudWatch metrics. In your Storage Lens dashboard, you can view the following metrics, which monitor the object count or size:

- **Current version bytes**
- **Current version object count**

- **Noncurrent version bytes**
- **Noncurrent version object count**
- **Delete marker object count**
- **Delete marker storage bytes**
- **Incomplete multipart upload bytes**
- **Incomplete multipart upload object count**

My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.

In a [versioning-enabled bucket](#), when an object is expired, the object isn't completely deleted from the bucket. Instead, a [delete marker](#) is created as the newest version of the object. Delete markers are still counted as objects. Therefore, if a lifecycle rule is created to expire only the current versions, then the object count in the S3 bucket actually increases instead of going down.

For example, let's say an S3 bucket is versioning-enabled with 100 objects, and a lifecycle rule is set to expire current versions of the object after 7 days. After the seventh day, the object count increases to 200 because 100 delete markers are created in addition to the 100 original objects, which are now the noncurrent versions. For more information about S3 Lifecycle configuration rule actions for versioning-enabled buckets, see [Setting lifecycle configuration on a bucket](#).

To permanently remove objects, add an additional lifecycle configuration to delete the previous versions of the objects, expired delete markers, and incomplete multipart uploads. For instructions on how to create new lifecycle rules, see [Setting lifecycle configuration on a bucket](#).

Note

- Amazon S3 rounds the transition or expiration date of an object to midnight UTC the next day.

When evaluating objects for lifecycle actions, Amazon S3 uses the object creation time in UTC. For example, consider a nonversioned bucket with a lifecycle rule that's configured to expire objects after one day. Suppose that an object was created on January 1 at 17:05 Pacific Daylight Time (PDT), which corresponds to January 2 at 00:05 UTC. The object becomes one day old at 00:05 UTC on January 3, which makes it eligible for expiration when S3 Lifecycle evaluates objects at 00:00 UTC on January 4.

Because Amazon S3 lifecycle actions occur asynchronously, there might be some delay between the date specified in the lifecycle rule and the actual physical transition of the object. For more information, see [Transition or expiration delay](#).

For more information, see [Lifecycle rules: Based on an object's age](#).

- For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

How do I empty my S3 bucket by using lifecycle rules?

S3 Lifecycle rules are an effective tool to [empty an S3 bucket](#) with millions of objects. To delete a large number of objects from your S3 bucket, make sure to use these two pairs of lifecycle rules:

- **Expire current versions of objects** and **Permanently delete previous versions of objects**
- **Delete expired delete markers** and **Delete incomplete multipart uploads**

For steps on how to create a lifecycle configuration rule, see [Setting lifecycle configuration on a bucket](#).

Note

For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.

There are several reasons that your bill might increase after transitioning objects to a lower-cost storage class:

- S3 Glacier overhead charges for small objects

For each object that is transitioned to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, a total overhead of 40 KB is associated with this storage update. As part of the 40 KB overhead, 8

KB is used to store metadata and the name of the object. This 8 KB is charged according to S3 Standard rates. The remaining 32 KB is used for indexing and related metadata. This 32 KB is charged according to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive pricing.

Therefore, if you're storing many smaller sized objects, we don't recommend using lifecycle transitions. Instead, to reduce any overhead charges, consider aggregating many smaller objects into a smaller number of large objects before storing them in Amazon S3. For more information about cost considerations, see [Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes \(object archival\)](#).

- Minimum storage charges

Some S3 storage classes have minimum storage-duration requirements. Objects that are deleted, overwritten, or transitioned from those classes before the minimum duration is satisfied are charged a prorated early transition or deletion fee. These minimum storage-duration requirements are as follows:

- S3 Standard-IA and S3 One Zone-IA – 30 days
- S3 Glacier Flexible Retrieval and S3 Glacier Instant Retrieval – 90 days
- S3 Glacier Deep Archive – 180 days

For more information about these requirements, see the *Constraints* section of [Transitioning objects using S3 Lifecycle](#). For general S3 pricing information, see [Amazon S3 pricing](#) and the [AWS Pricing Calculator](#).

- Lifecycle transition costs

Each time an object is transitioned to a different storage class by a lifecycle rule, Amazon S3 counts that transition as one transition request. The costs for these transition requests are in addition to the costs of these storage classes. If you plan to transition a large number of objects, consider the request costs when transitioning to a lower tier. For more information, see [Amazon S3 pricing](#).

I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.

Deny statements in a bucket policy don't prevent the expiration of the objects defined in a lifecycle rule. Lifecycle actions (such as transitions or expirations) don't use the S3 DeleteObject operation. Instead, S3 Lifecycle actions are performed by using internal S3 endpoints. (For more information, see [Lifecycle and logging](#).)

To prevent your lifecycle rule from taking any action, you must edit, delete, or [disable the rule](#).

Can I recover S3 objects that are expired by S3 Lifecycle rules?

The only way to recover objects that are expired by S3 Lifecycle is through versioning, which must be in place before the objects become eligible for expiration. You cannot undo the expiration operations that are performed by lifecycle rules. If objects are permanently deleted by the S3 Lifecycle rules that are in place, you cannot recover these objects. To enable versioning on a bucket, see [the section called “Retaining multiple versions of objects”](#).

If you have applied versioning to the bucket and the noncurrent versions of the objects are still intact, you can [restore previous versions of the expired objects](#). For more information about the behavior of S3 Lifecycle rule actions and versioning states, see the *Lifecycle actions and bucket versioning state* table in [Elements to describe lifecycle actions](#).

 **Note**

If the S3 bucket is protected by [AWS Backup](#) or [S3 Replication](#), you might also be able to use these features to recover your expired objects.

Why are my expiration and transition lifecycle actions not occurring?

For a versioning-enabled or versioning-suspended bucket, the following considerations guide how Amazon S3 handles the Expiration action:

- Object expiration applies only to an object's current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- Amazon S3 doesn't take any action on noncurrent versions of objects that have S3 Object Lock applied.
- For objects with a PENDING replication status, Amazon S3 doesn't take any action current or noncurrent versions of objects.

Lifecycle storage class transitions have the following constraints:

- By default, objects smaller than 128 KB won't transition to any storage class.

- Objects must be stored for at least 30 days before transitioning to S3 Standard-IA or S3 One Zone-IA.
- For versioning enabled or versioning suspended buckets, objects with a PENDING replication status can't be transitioned.

How can I exclude a prefix from my lifecycle rule?

S3 Lifecycle doesn't support excluding prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see [the section called "Archiving all objects within one day after creation"](#).

How can I include multiple prefixes in my lifecycle rule?

S3 Lifecycle doesn't support including multiple prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see [the section called "Archiving all objects within one day after creation"](#).

However, if you have one or more prefixes that start with the same characters, you can include all of those prefixes in your rule by specifying a partial prefix with no trailing slash (/) in the filter. For example, suppose that you have these prefixes:

```
sales1999/  
sales2000/  
sales2001/
```

To include all three prefixes in your rule, specify <Prefix>sales</Prefix> in your lifecycle rule.

Logging and monitoring in Amazon S3

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. We recommend collecting monitoring data from all of the parts of your AWS solution so that you can more easily debug a multipoint failure if one occurs. Before you start monitoring Amazon S3, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

For more information about logging and monitoring in Amazon S3, see the following topics.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon S3 resources and responding to potential incidents.

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon S3. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

Amazon GuardDuty

[Amazon GuardDuty](#) is a threat detection service that continuously monitors your accounts, containers, workloads, and the data within your AWS environment to identify potential threats or security risks to your S3 buckets. GuardDuty also provides rich context about the threats that it detects. GuardDuty monitors AWS CloudTrail management logs for threats and surfaces security relevant information. For example, GuardDuty will include factors of an API request, such as the user that made the request, the location the request was made from, and the specific API requested, that could be unusual in your environment. [GuardDuty S3 Protection](#) monitors the S3 data events collected by CloudTrail and identifies potentially anomalous and malicious behavior in all the S3 buckets in your environment.

Amazon S3 Access Logs

Server access logs provide detailed records about requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. For more information, see [Logging requests with server access logging](#).

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon S3-related checks:

- Logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that don't have versioning enabled, or have versioning suspended.

For more information, see [AWS Trusted Advisor](#) in the *Support User Guide*.

Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads.

S3 Storage Lens aggregates your metrics and displays the information in the Account snapshot section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. For more information, see [Understanding Amazon S3 Storage Lens](#).

Amazon S3 Inventory

Amazon S3 Inventory generates a list of objects and metadata that you can use to query and manage your objects. You can use this inventory report to generate granular data such as object size, last modified date, encryption status and other fields. Those reports are available daily or weekly to automatically give the latest list.

For example, you can use Amazon S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also use Amazon S3 Inventory to simplify and speed up business workflows and big data jobs, which provides a scheduled alternative to the Amazon S3 synchronous List API operations. Amazon S3 Inventory doesn't use the List API operations to audit your objects and does not affect the request rate of your bucket. For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

Amazon S3 Event Notifications

With the Amazon S3 Event Notifications feature, you receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that identifies the events that you want Amazon S3 to publish. For more information, see [Amazon S3 Event Notifications](#).

Amazon S3 and AWS X-Ray

AWS X-Ray integrates with Amazon S3 to trace upstream requests to update your application's S3 buckets. If a service traces requests by using the X-Ray SDK, Amazon S3 can send the tracing headers to downstream event subscribers such as Lambda, Amazon SQS, and Amazon SNS. X-Ray enables trace messages for Amazon S3 event notifications. You can use the X-Ray trace map to view the connections between Amazon S3 and other services that your application uses. For more information, see [Amazon S3 and X-Ray](#).

The following security best practices also address logging and monitoring:

- [Identify and audit all your Amazon S3 buckets](#)
- [Implement monitoring using Amazon Web Services monitoring tools](#)
- [Enable AWS Config](#)
- [Enable Amazon S3 server access logging](#)
- [Use CloudTrail](#)
- [Monitor Amazon Web Services security advisories](#)

Topics

- [Monitoring tools](#)
- [Logging options for Amazon S3](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)
- [Logging requests with server access logging](#)
- [Monitoring metrics with Amazon CloudWatch](#)
- [Amazon S3 Event Notifications](#)
- [Monitoring your storage activity and usage with Amazon S3 Storage Lens](#)
- [Cataloging and analyzing your data with S3 Inventory](#)

Monitoring tools

AWS provides various tools that you can use to monitor Amazon S3. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon S3 and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring metrics with Amazon CloudWatch](#).
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

Manual monitoring tools

Another important part of monitoring Amazon S3 involves manually monitoring those items that the CloudWatch alarms don't cover. The Amazon S3, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. You might want to enable *server access logging*, which tracks requests for access to your bucket. Each access log record provides details about a single access request, such as the requester, bucket name, request time, request action, response status, and error code, if any. For more information, see [Logging requests with server access logging](#).

- The Amazon S3 dashboard shows the following:
 - Your buckets and the objects and properties they contain
- The CloudWatch home page shows the following:
 - Current alarms and status
 - Graphs of alarms and resources
 - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services you care about.

- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.
- AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see [AWS Trusted Advisor](#).

Trusted Advisor has these checks that relate to Amazon S3:

- Checks of the logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that do not have versioning enabled, or have versioning suspended.

Logging options for Amazon S3

You can record the actions that are taken by users, roles, or AWS services on Amazon S3 resources and maintain log records for auditing and compliance purposes. To do this, you can use server-access logging, AWS CloudTrail logging, or a combination of both. We recommend that you use CloudTrail for logging bucket-level and object-level actions for your Amazon S3 resources. For more information about each option, see the following sections:

- [Logging requests with server access logging](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)

The following table lists the key properties of CloudTrail logs and Amazon S3 server-access logs. To make sure that CloudTrail meets your security requirements, review the table and notes.

Log properties	AWS CloudTrail	Amazon S3 server logs
Can be forwarded to other systems (Amazon CloudWatch Logs, Amazon CloudWatch Events)	Yes	No

Log properties	AWS CloudTrail	Amazon S3 server logs
Deliver logs to more than one destination (for example, send the same logs to two different buckets)	Yes	No
Turn on logs for a subset of objects (prefix)	Yes	No
Cross-account log delivery (target and source bucket owned by different accounts)	Yes	No
Integrity validation of log file by using digital signature or hashing	Yes	No
Default or choice of encryption for log files	Yes	No
Object operations (by using Amazon S3 APIs)	Yes	Yes
Bucket operations (by using Amazon S3 APIs)	Yes	Yes
Searchable UI for logs	Yes	No
Fields for Object Lock parameters, Amazon S3 Select properties for log records	Yes	No
Fields for Object Size, Total Time, Turn-Around Time, and HTTP Referer for log records	No	Yes

Log properties	AWS CloudTrail	Amazon S3 server logs
Lifecycle transitions, expiration, restores	No	Yes
Logging of keys in a batch delete operation	Yes	Yes
Authentication failures ¹	No	Yes
Accounts where logs get delivered	Bucket owner ² , and requester	Bucket owner only
Performance and Cost	AWS CloudTrail	Amazon S3 Server Logs
Price	Management events (first delivery) are free; data events incur a fee, in addition to storage of logs	No other cost in addition to storage of logs
Speed of log delivery	Data events every 5 minutes; management events every 15 minutes	Within a few hours
Log format	JSON	Log file with space-separated, newline-delimited records

Notes

- CloudTrail does not deliver logs for requests that fail authentication (in which the provided credentials are not valid) or that fail due to redirection (error code 301 Moved Permanently). However, it does include logs for requests in which authorization fails (AccessDenied) and requests that are made by anonymous users.
- The S3 bucket owner receives CloudTrail logs when the account does not have full access to the object in the request. For more information, see [Amazon S3 object-level actions in cross-account scenarios](#).

3. S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them or for requests that fail before the VPC policy is evaluated.

Logging Amazon S3 API calls using AWS CloudTrail

[AWS CloudTrail](#) is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. The calls captured include calls from the Amazon S3 console and code calls to the Amazon S3 API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see [Working with CloudTrail Event history](#) in the [AWS CloudTrail User Guide](#). There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a [CloudTrail Lake](#) event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see [Creating a](#)

[trail for your AWS account](#) and [Creating a trail for an organization](#) in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#). For information about Amazon S3 pricing, see [Amazon S3 Pricing](#).

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to [Apache ORC](#) format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying [advanced event selectors](#). The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see [Working with AWS CloudTrail Lake](#) in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the [pricing option](#) you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

You can store your log files in your bucket for as long as you want, but you can also define Amazon S3 Lifecycle rules to archive or delete log files automatically. By default, your log files are encrypted by using Amazon S3 server-side encryption (SSE).

Using CloudTrail logs with Amazon S3 server access logs and CloudWatch Logs

AWS CloudTrail logs provide a record of actions taken by a user, role, or an AWS service in Amazon S3, while Amazon S3 server access logs provide detailed records for the requests that are made to an S3 bucket. For more information about how the different logs work, and their properties, performance, and costs, see [the section called “Logging options”](#).

You can use AWS CloudTrail logs together with server access logs for Amazon S3. CloudTrail logs provide you with detailed API tracking for Amazon S3 bucket-level and object-level operations. Server access logs for Amazon S3 provide you with visibility into object-level operations on your

data in Amazon S3. For more information about server access logs, see [Logging requests with server access logging](#).

You can also use CloudTrail logs together with Amazon CloudWatch for Amazon S3. CloudTrail integration with CloudWatch Logs delivers S3 bucket-level API activity captured by CloudTrail to a CloudWatch log stream in the CloudWatch log group that you specify. You can create CloudWatch alarms for monitoring specific API activity and receive email notifications when the specific API activity occurs. For more information about CloudWatch alarms for monitoring specific API activity, see the [AWS CloudTrail User Guide](#). For more information about using CloudWatch with Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

 **Note**

S3 does not support delivery of CloudTrail logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them.

CloudTrail tracking with Amazon S3 SOAP API calls

CloudTrail tracks Amazon S3 SOAP API calls. Amazon S3 SOAP support over HTTP is deprecated, but it is still available over HTTPS. For more information about Amazon S3 SOAP support, see [Appendix: SOAP API](#) in the *Amazon S3 API Reference*.

 **Important**

Newer Amazon S3 features are not supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.

The following table shows Amazon S3 SOAP actions tracked by CloudTrail logging.

SOAP API name	API event name used in CloudTrail log
ListAllMyBuckets	ListBuckets
CreateBucket	CreateBucket
DeleteBucket	DeleteBucket

SOAP API name	API event name used in CloudTrail log
GetBucketAccessControlPolicy	GetBucketAcl
SetBucketAccessControlPolicy	PutBucketAcl
GetBucketLoggingStatus	GetBucketLogging
SetBucketLoggingStatus	PutBucketLogging

For more information about CloudTrail and Amazon S3, see the following topics:

Topics

- [Amazon S3 CloudTrail events](#)
- [CloudTrail log file entries for Amazon S3 and S3 on Outposts](#)
- [Enabling CloudTrail event logging for S3 buckets and objects](#)
- [Identifying Amazon S3 requests using CloudTrail](#)

Amazon S3 CloudTrail events

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

This section provides information about the events that S3 logs to CloudTrail.

Amazon S3 data events in CloudTrail

[Data events](#) provide information about the resource operations performed on or in a resource (for example, reading or writing to an Amazon S3 object). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail doesn't log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

You can log data events for the Amazon S3 resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see [Logging data events with the AWS Management Console](#) and [Logging data events with the AWS Command Line Interface](#) in the *AWS CloudTrail User Guide*.

The following table lists the Amazon S3 resource types for which you can log data events. The **Data event type (console)** column shows the value to choose from the **Data event type** list on the CloudTrail console. The **resources.type value** column shows the `resources.type` value, which you would specify when configuring advanced event selectors using the AWS CLI or CloudTrail APIs. The **Data APIs logged to CloudTrail** column shows the API calls logged to CloudTrail for the resource type.

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3	AWS::S3::Object	<ul style="list-style-type: none">• AbortMultipartUpload• CompleteMultipartUpload• CopyObject• CreateMultipartUpload• DeleteObject• DeleteObjectTagging• DeleteObjects• GetObject• GetObjectAcl• GetObjectAttributes• GetObjectLegalHold

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
		<ul style="list-style-type: none">• GetObjectRetention• GetObjectTagging• GetObjectTorrent• HeadObject• HeadBucket• ListObjectVersions• ListObjects• ListParts• PutObject• PutObjectAcl• PutObjectLegalHold• PutObjectRetention• PutObjectTagging• RestoreObject• SelectObjectContent• UploadPart• UploadPartCopy

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Express One Zone	AWS::S3Express::Object	<ul style="list-style-type: none">• AbortMultipartUpload• CompleteMultipartUpload• CreateSession• CopyObject• CreateMultipartUpload• DeleteObject• DeleteObjects• GetObject• GetObjectAttributes• HeadBucket• HeadObject• ListObjectsV2• ListParts• PutObject• UploadPart• UploadPartCopy

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Access Point	AWS::S3::Access Point	<ul style="list-style-type: none">• AbortMultipartUpload• CompleteMultipartUpload• CopyObject (same-region copies only)• CreateMultipartUpload• DeleteObject• DeleteObjectTagging• GetObject• GetObjectAcl• GetObjectAttributes• GetObjectLegalHold• GetObjectRetention• GetObjectTagging• HeadBucket• HeadObject• ListObjects• ListObjectsV2• ListObjectVersions• ListParts• Presign• PutObject• PutObjectLegalHold• PutObjectRetention• PutObjectAcl• PutObjectTagging• RestoreObject• UploadPart

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Object Lambda	AWS::S3ObjectLambda::AccessPoint	<ul style="list-style-type: none">• UploadPartCopy (same-region copies only)• AbortMultipartUpload• CompleteMultipartUpload• CopyObject (same-region copies only)• CreateMultipartUpload• DeleteObject• DeleteObjectTagging• GetObject• GetObjectAcl• GetObjectLegalHold• GetObjectRetention• GetObjectTagging• HeadObject• ListObjects• ListObjectVersions• ListParts• PutObject• PutObjectLegalHold• PutObjectRetention• PutObjectAcl• PutObjectTagging• RestoreObject• UploadPart• WriteGetObjectResponse

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Outposts	AWS::S3Outposts::Object	<ul style="list-style-type: none"> • AbortMultipartUpload • CompleteMultipartUpload • CopyObject (same-region copies only) • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • GetObject • GetObjectTagging • HeadObject • ListObjects • ListObjectsV2 • ListParts • PutObject • PutObjectTagging • UploadPart • UploadPartCopy

You can configure advanced event selectors to filter on the `eventName`, `readOnly`, and `resourcesARN` fields to log only those events that are important to you. For more information about these fields, see [AdvancedFieldSelector](#) in the *AWS CloudTrail API Reference*.

Amazon S3 management events in CloudTrail

Amazon S3 logs all control plane operations as management events. For more information about S3 API operations, see the [Amazon S3 API Reference](#).

How CloudTrail captures requests made to Amazon S3

By default, CloudTrail logs S3 bucket-level API calls that were made in the last 90 days, but not log requests made to objects. Bucket-level calls include events such as `CreateBucket`,

`DeleteBucket`, `PutBucketLifecycle`, `PutBucketPolicy`, and so on. You can see bucket-level events on the CloudTrail console. However, you can't view data events (Amazon S3 object-level calls) there—you must parse or query CloudTrail logs for them.

If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 `DeleteObjects` data event includes both the `DeleteObjects` event and a `DeleteObject` event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see [AWS CLI examples for filtering data events](#) in the *AWS CloudTrail User Guide*.

Amazon S3 account-level actions tracked by CloudTrail logging

CloudTrail logs account-level actions. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

The tables in this section list the Amazon S3 account-level actions that are supported for logging by CloudTrail.

Amazon S3 account-level API actions tracked by CloudTrail logging appear as the following event names. The CloudTrail event names differ from the API action name. For example, `DeletePublicAccessBlock` is `DeleteAccountPublicAccessBlock`.

- [DeleteAccountPublicAccessBlock](#)
- [GetAccountPublicAccessBlock](#)
- [PutAccountPublicAccessBlock](#)

Amazon S3 bucket-level actions that are tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for general purpose buckets. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

This section lists the Amazon S3 bucket-level actions that are supported for logging by CloudTrail.

Amazon S3 bucket-level API actions tracked by CloudTrail logging appear as the following event names. In some cases, the CloudTrail event name differs from the API action name. For example, `PutBucketLifecycleConfiguration` is `PutBucketLifecycle`.

- [CreateBucket](#)
- [CreateBucketMetadataConfiguration](#) (V2 API operation)
- [CreateBucketMetadataTableConfiguration](#) (V1 API operation)
- [DeleteBucket](#)
- [DeleteBucketAnalyticsConfiguration](#)
- [DeleteBucketCors](#)
- [DeleteBucketEncryption](#)
- [DeleteBucketIntelligentTieringConfiguration](#)
- [DeleteBucketInventoryConfiguration](#)
- [DeleteBucketLifecycle](#)
- [DeleteBucketMetadataConfiguration](#) (V2 API operation)
- [DeleteBucketMetadataTableConfiguration](#) (V1 API operation)
- [DeleteBucketMetricsConfiguration](#)
- [DeleteBucketOwnershipControls](#)
- [DeleteBucketPolicy](#)
- [DeleteBucketPublicAccessBlock](#)
- [DeleteBucketReplication](#)
- [DeleteBucketTagging](#)
- [GetAccelerateConfiguration](#)
- [GetBucketAcl](#)
- [GetBucketAnalyticsConfiguration](#)
- [GetBucketCors](#)
- [GetBucketEncryption](#)
- [GetBucketIntelligentTieringConfiguration](#)
- [GetBucketInventoryConfiguration](#)
- [GetBucketLifecycle](#)
- [GetBucketLocation](#)
- [GetBucketLogging](#)
- [GetBucketMetadataConfiguration](#) (V2 API operation)
- [GetBucketMetadataTableConfiguration](#) (V1 API operation)

- [GetBucketMetricsConfiguration](#)
- [GetBucketNotification](#)
- [GetBucketObjectLockConfiguration](#)
- [GetBucketOwnershipControls](#)
- [GetBucketPolicy](#)
- [GetBucketPolicyStatus](#)
- [GetBucketPublicAccessBlock](#)
- [GetBucketReplication](#)
- [GetBucketRequestPayment](#)
- [GetBucketTagging](#)
- [GetBucketVersioning](#)
- [GetBucketWebsite](#)
- [HeadBucket](#)
- [ListBuckets](#)
- [PutAccelerateConfiguration](#)
- [PutBucketAcl](#)
- [PutBucketAnalyticsConfiguration](#)
- [PutBucketCors](#)
- [PutBucketEncryption](#)
- [PutBucketIntelligentTieringConfiguration](#)
- [PutBucketInventoryConfiguration](#)
- [PutBucketLifecycle](#)
- [PutBucketLogging](#)
- [PutBucketMetricsConfiguration](#)
- [PutBucketNotification](#)
- [PutBucketObjectLockConfiguration](#)
- [PutBucketOwnershipControls](#)
- [PutBucketPolicy](#)
- [PutBucketPublicAccessBlock](#)

- [PutBucketReplication](#)
- [PutBucketRequestPayment](#)
- [PutBucketTagging](#)
- [PutBucketVersioning](#)
- [PutBucketWebsite](#)
- [UpdateBucketMetadataJournalTableConfiguration](#)
- [UpdateBucketMetadataInventoryTableConfiguration](#)

In addition to these API operations, you can also use the [OPTIONS object](#) object-level action. This action is treated like a bucket-level action in CloudTrail logging because the action checks the CORS configuration of a bucket.

 **Note**

The HeadBucket API is supported as an Amazon S3 data event in CloudTrail.

Amazon S3 Express One Zone bucket-level (Regional API endpoint) actions tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for directory buckets as management events. The eventsource for CloudTrail management events for S3 Express One Zone is `s3express.amazonaws.com`.

These following Regional endpoint API operations are logged to CloudTrail.

- [CreateBucket](#)
- [DeleteBucket](#)
- [DeleteBucketPolicy](#)
- [GetBucketPolicy](#)
- [PutBucketPolicy](#)
- [ListDirectoryBuckets](#)
- [PutBucketEncryption](#)
- [GetBucketEncryption](#)

- [DeleteBucketEncryption](#)

For more information, see [Logging with AWS CloudTrail for S3 Express One Zone](#)

Amazon S3 object-level actions in cross-account scenarios

The following are special use cases involving the object-level API calls in cross-account scenarios and how CloudTrail logs are reported. CloudTrail delivers logs to the requester (the account that made the API call), except in some access denied cases where log entries are redacted or omitted. When setting up cross-account access, consider the examples in this section.

 **Note**

The examples assume that CloudTrail logs are appropriately configured.

Example 1: CloudTrail delivers logs to the bucket owner

CloudTrail delivers logs to the bucket owner even if the bucket owner does not have permissions for the same object API operation. Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) tries to access an object in that bucket.
- Account C owns the object. Account C might or might not be the same account as Account A.

 **Note**

CloudTrail always delivers object-level API logs to the requester (Account B). In addition, CloudTrail also delivers the same logs to the bucket owner (Account A) even when the bucket owner does not own the object (Account C) or have permissions for those same API operations on that object.

Example 2: CloudTrail does not proliferate email addresses that are used in setting object ACLs

Consider the following cross-account scenario:

- Account A owns the bucket.

- Account B (the requester) sends a request to set an object ACL grant by using an email address. For more information about ACLs, see [Access control list \(ACL\) overview](#).

The requester gets the logs along with the email information. However, the bucket owner—if they are eligible to receive logs, as in example 1—gets the CloudTrail log reporting the event. However, the bucket owner doesn't get the ACL configuration information, specifically the grantee email address and the grant. The only information that the log tells the bucket owner is that an ACL API call was made by Account B.

CloudTrail log file entries for Amazon S3 and S3 on Outposts

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

Note

To view CloudTrail log file examples for Amazon S3 Express One Zone, see [CloudTrail log file examples for S3 Express One Zone](#).

For more information, see the following examples.

Enabling CloudTrail event logging for S3 buckets and objects

You can use CloudTrail data events to get information about bucket and object-level requests in Amazon S3. To enable CloudTrail data events for all of your buckets or for a list of specific buckets, you must [create a trail manually in CloudTrail](#).

Note

- The default setting for CloudTrail is to find only management events. Check to ensure that you have the data events enabled for your account.
- With an S3 bucket that is generating a high workload, you could quickly generate thousands of logs in a short amount of time. Be mindful of how long you choose to enable CloudTrail data events for a busy bucket.

CloudTrail stores Amazon S3 data event logs in an S3 bucket of your choosing. Consider using a bucket in a separate AWS account to better organize events from multiple buckets that you might own into a central place for easier querying and analysis. AWS Organizations helps you create an AWS account that is linked to the account that owns the bucket that you're monitoring. For more information, see [What is AWS Organizations?](#) in the *AWS Organizations User Guide*.

When you log data events for a trail in CloudTrail, you can choose to use advanced event selectors or basic event selectors to log data events for objects stored in general purpose buckets. To log

data events for objects stored in directory buckets, you must use advanced event selectors. For more information, see [Logging with AWS CloudTrail for S3 Express One Zone](#).

When you create a trail in the CloudTrail console using advanced event selectors, in the data events section, you can choose **Log all events** for the **Log selector template** to log all object-level events. When you create a trail in the CloudTrail console using basic event selectors, in the data events section, you can select the **Select all S3 buckets in your account** check box to log all object-level events.

Note

- It's a best practice to create a lifecycle configuration for your AWS CloudTrail data event bucket. Configure the lifecycle configuration to periodically remove log files after the period of time you believe you need to audit them. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see [Setting an S3 Lifecycle configuration on a bucket](#).
- For more information about logging format, see [Logging Amazon S3 API calls using AWS CloudTrail](#).
- For examples of how to query CloudTrail logs, see the *AWS Big Data Blog* post [Analyze Security, Compliance, and Operational Activity Using AWS CloudTrail and Amazon Athena](#).

Enable logging for objects in a bucket using the console

You can use the AWS CloudTrail console to configure a CloudTrail trail to log data events for objects in an S3 bucket. CloudTrail supports logging Amazon S3 object-level API operations such as `GetObject`, `DeleteObject`, and `PutObject`. These events are called *data events*.

By default, CloudTrail trails don't log data events, but you can configure trails to log data events for S3 buckets that you specify, or to log data events for all the Amazon S3 buckets in your AWS account. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

CloudTrail does not populate data events in the CloudTrail event history. Additionally, not all bucket-level actions are populated in the CloudTrail event history. For more information about the Amazon S3 bucket-level API actions tracked by CloudTrail logging, see [Amazon S3 bucket-level actions that are tracked by CloudTrail logging](#). For more information about how to query CloudTrail

logs, see the AWS Knowledge Center article about [using Amazon CloudWatch Logs filter patterns and Amazon Athena to query CloudTrail logs](#).

 **Note**

If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 DeleteObjects data event includes both the DeleteObjects event and a DeleteObject event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see [AWS CLI examples for filtering data events](#) in the *AWS CloudTrail User Guide*.

To enable CloudTrail data events logging for objects in an S3 general purpose bucket or an S3 directory bucket see [Creating a trail with the CloudTrail console](#) in the *AWS CloudTrail User Guide*.

For more information about logging objects in an S3 directory bucket, see [Logging with AWS CloudTrail for directory buckets](#).

For information about using the CloudTrail console to configure a trail to log S3 data events, see [Logging data events](#) in the *AWS CloudTrail User Guide*.

To disable CloudTrail data events logging for objects in an S3 bucket, see [Deleting a trail with the CloudTrail console](#) in the *AWS CloudTrail User Guide*.

 **Important**

Additional charges apply for data events. For more information, see [AWS CloudTrail pricing](#).

For more information about CloudTrail logging with S3 buckets, see the following topics:

- [Creating a general purpose bucket](#)
- [Viewing the properties for an S3 general purpose bucket](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)
- [Working with CloudTrail log files](#) in the *AWS CloudTrail User Guide*

Identifying Amazon S3 requests using CloudTrail

In Amazon S3, you can identify requests using an AWS CloudTrail event log. AWS CloudTrail is the preferred way of identifying Amazon S3 requests, but if you are using Amazon S3 server access logs, see [the section called “Identifying S3 requests”](#).

Topics

- [Identifying requests made to Amazon S3 in a CloudTrail log](#)
- [Identifying Amazon S3 Signature Version 2 requests by using CloudTrail](#)
- [Identifying access to S3 objects by using CloudTrail](#)

Identifying requests made to Amazon S3 in a CloudTrail log

After you set up CloudTrail to deliver events to a bucket, you should start to see objects go to your destination bucket on the Amazon S3 console. These are formatted as follows:

`s3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/Region/yyyy/mm/dd`

Events logged by CloudTrail are stored as compressed, gzipped JSON objects in your S3 bucket. To efficiently find requests, you should use a service like Amazon Athena to index and query the CloudTrail logs.

For more information about CloudTrail and Athena, see [Creating the table for AWS CloudTrail logs in Athena using partition projection](#) in the *Amazon Athena User Guide*.

Identifying Amazon S3 Signature Version 2 requests by using CloudTrail

You can use a CloudTrail event log to identify which API signature version was used to sign a request in Amazon S3. This capability is important because support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use *Signature Version 4* signing.

We *strongly* recommend that you use CloudTrail to help determine whether any of your workflows are using Signature Version 2 signing. Remediate them by upgrading your libraries and code to use Signature Version 4 instead to prevent any impact to your business.

For more information, see [Announcement: AWS CloudTrail for Amazon S3 adds new fields for enhanced security auditing](#) in AWS re:Post.

Note

CloudTrail events for Amazon S3 include the signature version in the request details under the key name of 'additionalEventData'. To find the signature version on requests made for objects in Amazon S3 such as GET, PUT, and DELETE requests, you must enable CloudTrail data events. (This feature is turned off by default.)

AWS CloudTrail is the preferred method for identifying Signature Version 2 requests. If you're using Amazon S3 server-access logs, see [Identifying Signature Version 2 requests by using Amazon S3 access logs](#).

Topics

- [Athena query examples for identifying Amazon S3 Signature Version 2 requests](#)
- [Partitioning Signature Version 2 data](#)

Athena query examples for identifying Amazon S3 Signature Version 2 requests**Example — Select all Signature Version 2 events, and print only EventTime, S3_Action, Request_Parameters, Region, SourceIP, and UserAgent**

In the following Athena query, replace `s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table` with your Athena details, and increase or remove the limit as needed.

```
SELECT EventTime, EventName as S3_Action, requestParameters as Request_Parameters,  
awsregion as AWS_Region, sourceipaddress as Source_IP, useragent as User_Agent  
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE eventsource='s3.amazonaws.com'  
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'  
LIMIT 10;
```

Example — Select all requesters that are sending Signature Version 2 traffic

```
SELECT useridentity.arn, Count(requestid) as RequestCount  
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE eventsource='s3.amazonaws.com'
```

```
    and json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'  
Group by useridentity.arn
```

Partitioning Signature Version 2 data

If you have a large amount of data to query, you can reduce the costs and running time of Athena by creating a partitioned table.

To do this, create a new table with partitions as follows.

```
CREATE EXTERNAL TABLE s3_cLOUDTRAIL_EVENTS_DB.cLOUDTRAIL_TABLE_partitioned(  
    eventversion STRING,  
    userIdentity STRUCT<  
        type:STRING,  
        principalId:STRING,  
        arn:STRING,  
        accountId:STRING,  
        invokedBy:STRING,  
        accessKeyId:STRING,  
        userName:STRING,  
        sessionContext:STRUCT<  
            attributes:STRUCT<  
                mfaAuthenticated:STRING,  
                creationDate:STRING>,  
            sessionIssuer:STRUCT<  
                type:STRING,  
                principalId:STRING,  
                arn:STRING,  
                accountId:STRING,  
                userName:STRING>  
        >  
    >,  
    eventTime STRING,  
    eventSource STRING,  
    eventName STRING,  
    awsRegion STRING,  
    sourceIpAddress STRING,  
    userAgent STRING,  
    errorCode STRING,  
    errorMessage STRING,  
    requestParameters STRING,  
    responseElements STRING,
```

```
additionalEventData STRING,  
requestId STRING,  
eventId STRING,  
resources ARRAY<STRUCT<ARN:STRING,accountId: STRING,type:STRING>>,  
eventType STRING,  
apiVersion STRING,  
readOnly STRING,  
recipientAccountId STRING,  
serviceEventDetails STRING,  
sharedEventID STRING,  
vpcEndpointId STRING  
)  
PARTITIONED BY (region string, year string, month string, day string)  
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'  
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'  
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'  
LOCATION 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/';
```

Then, create the partitions individually. You can't get results from dates that you haven't created.

```
ALTER TABLE s3_cLOUDTRAIL_EVENTS_DB.cLOUDTRAIL_TABLE_partitioned ADD  
PARTITION (region= 'us-east-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-east-1/2019/02/19/'  
PARTITION (region= 'us-west-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-1/2019/02/19/'  
PARTITION (region= 'us-west-2', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-2/2019/02/19/'  
PARTITION (region= 'ap-southeast-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-1/2019/02/19/'  
PARTITION (region= 'ap-southeast-2', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-2/2019/02/19/'  
PARTITION (region= 'ap-northeast-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-northeast-1/2019/02/19/'  
PARTITION (region= 'eu-west-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/eu-west-1/2019/02/19/'  
PARTITION (region= 'sa-east-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/sa-east-1/2019/02/19';
```

You can then make the request based on these partitions, and you don't need to load the full bucket.

```
SELECT useridentity.arn,
Count(requestid) AS RequestCount
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table_partitioned
WHERE eventsource='s3.amazonaws.com'
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
AND region='us-east-1'
AND year='2019'
AND month='02'
AND day='19'
Group by useridentity.arn
```

Identifying access to S3 objects by using CloudTrail

You can use your AWS CloudTrail event logs to identify Amazon S3 object access requests for data events such as GetObject, DeleteObject, and PutObject, and discover additional information about those requests.

Note

If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 DeleteObjects data event includes both the DeleteObjects event and a DeleteObject event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see [AWS CLI examples for filtering data events](#) in the *AWS CloudTrail User Guide*.

The following example shows how to get all PUT object requests for Amazon S3 from an AWS CloudTrail event log.

Topics

- [Athena query examples for identifying Amazon S3 object access requests](#)

Athena query examples for identifying Amazon S3 object access requests

In the following Athena query examples, replace *s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table* with your Athena details, and modify the date range as needed.

Example — Select all events that have PUT object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table
WHERE
  eventName = 'PutObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all events that have GET object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table
WHERE
  eventName = 'GetObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all anonymous requester events to a bucket in a certain period and print only EventTime, EventName, EventSource, SourceIP, UserAgent, BucketName, UserARN, and AccountID

```
SELECT
```

```
eventTime,  
eventName,  
eventSource,  
sourceIpAddress,  
userAgent,  
json_extract_scalar(requestParameters, '$.bucketName') as bucketName,  
userIdentity.arn as userArn,  
userIdentity.accountId  
FROM  
s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE  
userIdentity.accountId = 'anonymous'  
AND eventTime BETWEEN '2019-07-05T00:00:00Z' AND '2019-07-06T00:00:00Z'
```

Example — Identify all requests that required an ACL for authorization

The following Amazon Athena query example shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. If the request required an ACL for authorization, the `aclRequired` value in `additionalEventData` is Yes. If no ACLs were required, `aclRequired` is not present. You can use this information to migrate those ACL permissions to the appropriate bucket policies. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see [Prerequisites for disabling ACLs](#).

```
SELECT  
eventTime,  
eventName,  
eventSource,  
sourceIpAddress,  
userAgent,  
userIdentity.arn as userArn,  
json_extract_scalar(requestParameters, '$.bucketName') as bucketName,  
json_extract_scalar(requestParameters, '$.key') as object,  
json_extract_scalar(additionalEventData, '$.aclRequired') as aclRequired  
FROM  
s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE  
json_extract_scalar(additionalEventData, '$.aclRequired') = 'Yes'  
AND eventTime BETWEEN '2022-05-10T00:00:00Z' AND '2022-08-10T00:00:00Z'
```

Note

- These query examples can also be useful for security monitoring. You can review the results for PutObject or GetObject calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.

If you are using Amazon S3 server access logs, see [Identifying object access requests by using Amazon S3 access logs](#).

Logging requests with server access logging

Server access logging provides detailed records for the requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

Note

Server access logs don't record information about wrong-Region redirect errors for Regions that launched after March 20, 2019. Wrong-Region redirect errors occur when a request for an object or bucket is made outside the Region in which the bucket exists.

How do I enable log delivery?

To enable log delivery, perform the following basic steps. For details, see [Enabling Amazon S3 server access logging](#).

1. **Provide the name of the destination bucket** (also known as a *target bucket*). This bucket is where you want Amazon S3 to save the access logs as objects. Both the source and destination buckets must be in the same AWS Region and owned by the same account. The destination bucket must not have an S3 Object Lock default retention period configuration. The destination bucket must also not have Requester Pays enabled.

You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. But for simpler log management, we recommend that you save access logs in a different bucket.

When your source bucket and destination bucket are the same bucket, additional logs are created for the logs that are written to the bucket, which creates an infinite loop of logs. We do not recommend doing this because it could result in a small increase in your storage billing. In addition, the extra logs about logs might make it harder to find the log that you are looking for.

If you choose to save access logs in the source bucket, we recommend that you specify a destination prefix (also known as a *target prefix*) for all log object keys. When you specify a prefix, all the log object names begin with a common string, which makes the log objects easier to identify.

2. **(Optional) Assign a destination prefix to all Amazon S3 log object keys.** The destination prefix (also known as a *target prefix*) makes it simpler for you to locate the log objects. For example, if you specify the prefix value logs/, each log object that Amazon S3 creates begins with the logs/ prefix in its key, for example:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

If you specify the prefix value logs, the log object appears as follows:

```
logs2013-11-01-21-32-16-E568B2907131C0C0
```

Prefixes are also useful to distinguish between source buckets when multiple buckets log to the same destination bucket.

This prefix can also help when you delete the logs. For example, you can set a lifecycle configuration rule for Amazon S3 to delete objects with a specific prefix. For more information, see [Deleting Amazon S3 log files](#).

3. **(Optional) Set permissions so that others can access the generated logs.** By default, only the bucket owner always has full access to the log objects. If your destination bucket uses the Bucket owner enforced setting for S3 Object Ownership to disable access control lists (ACLs), you can't grant permissions in destination grants (also known as *target grants*) that use ACLs. However, you can update your bucket policy for the destination bucket to grant access to others.

For more information, see [Identity and Access Management for Amazon S3](#) and [Permissions for log delivery](#).

4. (Optional) Set a log object key format for the log files. You have two options for the log object key format (also known as the *target object key format*):

- **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

```
[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For example, if you specify logs/ as the prefix, your log objects are named like this:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

If you choose date-based partitioning, the log file key format appears as follows:

```
[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For example, if you specify logs/ as the target prefix, your log objects are named like this:

```
logs/123456789012/us-west-2/amzn-s3-demo-source-bucket/2023/03/01/2023-03-01-21-32-16-E568B2907131C0C0
```

For delivery time delivery, the time in the log file names corresponds to the delivery time for the log files.

For event time delivery, the year, month, and day correspond to the day on which the event occurred, and the hour, minutes and seconds are set to 00 in the key. The logs delivered in these log files are for a specific day only.

If you're configuring your logs through the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, use TargetObjectKeyFormat to specify the log object key format.

To specify non-date-based partitioning, use SimplePrefix. To specify data-based partitioning,

use `PartitionedPrefix`. If you use `PartitionedPrefix`, use `PartitionDataSource` to specify either `EventTime` or `DeliveryTime`.

For `SimplePrefix`, the log file key format appears as follows:

```
[TargetPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For `PartitionedPrefix` with event time or delivery time, the log file key format appears as follows:

```
[TargetPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/  
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

Log object key format

Amazon S3 uses the following object key formats for the log objects that it uploads in the destination bucket:

- **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

```
[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

If you choose date-based partitioning, the log file key format appears as follows:

```
[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/  
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

In the log object key, `YYYY`, `MM`, `DD`, `hh`, `mm`, and `ss` are the digits of the year, month, day, hour, minute, and seconds (respectively). These dates and times are in Coordinated Universal Time (UTC).

A log file delivered at a specific time can contain records written at any point before that time. There is no way to know whether all log records for a certain time interval have been delivered or not.

The UniqueString component of the key is there to prevent overwriting of files. It has no meaning, and log processing software should ignore it.

How are logs delivered?

Amazon S3 periodically collects access log records, consolidates the records in log files, and then uploads log files to your destination bucket as log objects. If you enable logging on multiple source buckets that identify the same destination bucket, the destination bucket will have access logs for all those source buckets. However, each log object reports access log records for a specific source bucket.

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. We recommend that you update the bucket policy on the destination bucket to grant access to the logging service principal (`logging.s3.amazonaws.com`) for access log delivery. You can also grant access for access log delivery to the S3 log delivery group through your bucket access control list (ACL). However, granting access to the S3 log delivery group by using your bucket ACL is not recommended.

When you enable server access logging and grant access for access log delivery through your destination bucket policy, you must update the policy to allow `s3:PutObject` access for the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the destination bucket policy to grant these permissions to the logging service principal. For more information about granting permissions for server access log delivery, see [Permissions for log delivery](#).

 **Note**

S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them or for requests that fail before the VPC policy is evaluated.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. You must update the bucket policy on the destination bucket to grant access to the logging service principal. For more information about Object Ownership, see [Grant access to the S3 log delivery group for server access logging](#).

Best-effort server log delivery

Server access log records are delivered on a best-effort basis. Most requests for a bucket that is properly configured for logging result in a delivered log record. Most log records are delivered within a few hours of the time that they are recorded, but they can be delivered more frequently.

The completeness and timeliness of server logging is not guaranteed. The log record for a particular request might be delivered long after the request was actually processed, or *it might not be delivered at all*. It is possible that you might even see a duplication of a log record. The purpose of server logs is to give you an idea of the nature of traffic against your bucket. Although log records are rarely lost or duplicated, be aware that server logging is not meant to be a complete accounting of all requests.

Because of the best-effort nature of server logging, your usage reports might include one or more access requests that do not appear in a delivered server log. You can find these usage reports under **Cost & usage reports** in the AWS Billing and Cost Management console.

Bucket logging status changes take effect over time

Changes to the logging status of a bucket take time to actually affect the delivery of log files. For example, if you enable logging for a bucket, some requests made in the following hour might be logged, and others might not. Suppose that you change the destination bucket for logging from bucket A to bucket B. For the next hour, some logs might continue to be delivered to bucket A, whereas others might be delivered to the new destination bucket B. In all cases, the new settings eventually take effect without any further action on your part.

For more information about logging and log files, see the following sections:

Topics

- [Enabling Amazon S3 server access logging](#)
- [Amazon S3 server access log format](#)
- [Deleting Amazon S3 log files](#)
- [Using Amazon S3 server access logs to identify requests](#)
- [Troubleshoot server access logging](#)

Enabling Amazon S3 server access logging

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

By default, Amazon S3 doesn't collect server access logs. When you enable logging, Amazon S3 delivers access logs for a source bucket to a destination bucket (also known as a *target bucket*) that you choose. The destination bucket must be in the same AWS Region and AWS account as the source bucket.

An access log record contains details about the requests that are made to a bucket. This information can include the request type, the resources that are specified in the request, and the time and date that the request was processed. For more information about logging basics, see [Logging requests with server access logging](#).

Important

- There is no extra charge for enabling server access logging on an Amazon S3 bucket. However, any log files that the system delivers to you will accrue the usual charges for storage. (You can delete the log files at any time.) We do not assess data-transfer charges for log file delivery, but we do charge the normal data-transfer rate for accessing the log files.
- Your destination bucket should not have server access logging enabled. You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. However, delivering logs to the source bucket will cause an infinite loop of logs and is not recommended. For simpler log management, we recommend that you save access logs in a different bucket. For more information, see [How do I enable log delivery?](#)
- S3 buckets that have S3 Object Lock enabled can't be used as destination buckets for server access logs. Your destination bucket must not have a default retention period configuration.
- The destination bucket must not have Requester Pays enabled.

You can enable or disable server access logging by using the Amazon S3 console, Amazon S3 API, the AWS Command Line Interface (AWS CLI), or AWS SDKs.

Permissions for log delivery

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. For access log delivery, you must grant the logging service principal (`logging.s3.amazonaws.com`) access to your destination bucket.

To grant permissions to Amazon S3 for log delivery, you can use either a bucket policy or bucket access control lists (ACLs), depending on your destination bucket's S3 Object Ownership settings. However, we recommend that you use a bucket policy instead of ACLs.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. In this case, you must update the bucket policy for the destination bucket to grant access to the logging service principal. You can't update your bucket ACL to grant access to the S3 log delivery group. You also can't include destination grants (also known as *target grants*) in your [PutBucketLogging](#) configuration.

For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see [Grant access to the S3 log delivery group for server access logging](#). For more information about Object Ownership, see [Controlling ownership of objects and disabling ACLs for your bucket](#). When you create new buckets, ACLs are disabled by default.

Granting access by using a bucket policy

To grant access by using the bucket policy on the destination bucket, update the bucket policy to grant the `s3:PutObject` permission to the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the bucket policy on the destination bucket to grant this permission to the logging service principal. If you enable server access logging programmatically, you must manually update the bucket policy for the destination bucket to grant access to the logging service principal.

For an example bucket policy that grants access to the logging service principal, see [the section called "Grant permissions to the logging service principal by using a bucket policy"](#).

Granting access by using bucket ACLs

You can alternately use bucket ACLs to grant access for access log delivery. You add a grant entry to the bucket ACL that grants WRITE and READ_ACP permissions to the S3 log delivery group. However, granting access to the S3 log delivery group by using bucket ACLs is not recommended. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#). For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see [Grant access to the S3 log delivery group for server access logging](#). For an example ACL that grants access to the logging service principal, see [the section called “Grant permissions to the log delivery group by using a bucket ACL”](#).

Grant permissions to the logging service principal by using a bucket policy

This example bucket policy grants the s3:PutObject permission to the logging service principal (logging.s3.amazonaws.com). To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, *amzn-s3-demo-destination-bucket* is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-bucket* is the source bucket. *EXAMPLE-LOGGING-PREFIX* is the optional destination prefix (also known as a *target prefix*) that you want to use for your log objects. *SOURCE-ACCOUNT-ID* is the AWS account that owns the source bucket.

Note

If there are Deny statements in your bucket policy, make sure that they don't prevent Amazon S3 from delivering access logs.

```

Grant permissions to the log delivery group by using a bucket ACL

Note

As a security best practice, Amazon S3 disables access control lists (ACLs) by default in all new buckets. For more information about ACL permissions in the Amazon S3 console, see [Configuring ACLs](#).

Although we do not recommend this approach, you can grant permissions to the log delivery group by using a bucket ACL. However, if the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination grants (also known as *target grants*) in your [PutBucketLogging](#) configuration. Instead, you must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see [Permissions for log delivery](#).

In the bucket ACL, the log delivery group is represented by the following URL:

```
http://acs.amazonaws.com/groups/s3/LogDelivery
```

To grant WRITE and READ_ACP (ACL read) permissions, add the following grants to the destination bucket ACL:

```
<Grant>  
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
```

```
<URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
</Grantee>
<Permission>WRITE</Permission>
</Grant>
<Grant>
<Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
</Grantee>
<Permission>READ_ACP</Permission>
</Grant>
```

For examples of adding ACL grants programmatically, see [Configuring ACLs](#).

Important

When you enable Amazon S3 server access logging by using AWS CloudFormation on a bucket and you're using ACLs to grant access to the S3 log delivery group, you must also add "AccessControl": "LogDeliveryWrite" to your CloudFormation template. Doing so is important because you can grant those permissions only by creating an ACL for the bucket, but you can't create custom ACLs for buckets in CloudFormation. You can use only canned ACLs with CloudFormation.

To enable server access logging

To enable server access logging by using the Amazon S3 console, Amazon S3 REST API, AWS SDKs, and AWS CLI, use the following procedures.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable server access logging for.
4. Choose **Properties**.
5. In the **Server access logging** section, choose **Edit**.
6. Under **Server access logging**, choose **Enable**.

7. Under **Destination bucket**, specify a bucket and an optional prefix. If you specify a prefix, we recommend including a forward slash (/) after the prefix to make it easier to find your logs.

 **Note**

Specifying a prefix with a slash (/) makes it simpler for you to locate the log objects.

For example, if you specify the prefix value logs/, each log object that Amazon S3 creates begins with the logs/ prefix in its key, as follows:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

If you specify the prefix value logs, the log object appears as follows:

```
logs2013-11-01-21-32-16-E568B2907131C0C0
```

8. Under **Log object key format**, do one of the following:

- To choose non-date-based partitioning, choose **[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**.
- To choose date-based partitioning, choose **[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**, then choose **S3 event time** or **Log file delivery time**.

9. Choose **Save changes**.

When you enable server access logging on a bucket, the console both enables logging on the source bucket and updates the bucket policy for the destination bucket to grant the s3:PutObject permission to the logging service principal (logging.s3.amazonaws.com). For more information about this bucket policy, see [Grant permissions to the logging service principal by using a bucket policy](#).

You can view the logs in the destination bucket. After you enable server access logging, it might take a few hours before the logs are delivered to the target bucket. For more information about how and when logs are delivered, see [How are logs delivered?](#)

For more information, see [Viewing the properties for an S3 general purpose bucket](#).

Using the REST API

To enable logging, you submit a [PutBucketLogging](#) request to add the logging configuration on the source bucket. The request specifies the destination bucket (also known as a *target bucket*) and, optionally, the prefix to be used with all log object keys.

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket and *Logs/* as the prefix.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>Logs/</TargetPrefix>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket, *Logs/* as the prefix, and EventTime as the log object key format.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>Logs/</TargetPrefix>
    <TargetObjectKeyFormat>
      <PartitionedPrefix>
        <PartitionDataSource>EventTime</PartitionDataSource>
      </PartitionedPrefix>
    </TargetObjectKeyFormat>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The log objects are written and owned by the S3 log delivery account, and the bucket owner is granted full permissions on the log objects. You can optionally use destination grants (also known as *target grants*) to grant permissions to other users so that they can access the logs. For more information, see [PutBucketLogging](#).

Note

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't use destination grants to grant permissions to other users. To grant permissions to

others, you can update the bucket policy on the destination bucket. For more information, see [Permissions for log delivery](#).

To retrieve the logging configuration on a bucket, use the [GetBucketLogging](#) API operation.

To delete the logging configuration, you send a PutBucketLogging request with an empty BucketLoggingStatus:

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
</BucketLoggingStatus>
```

To enable logging on a bucket, you can use either the Amazon S3 API or the AWS SDK wrapper libraries.

Using the AWS SDKs

The following examples enable logging on a bucket. You must create two buckets, a source bucket and a destination (target) bucket. The examples update the bucket ACL on the destination bucket first. They then grant the log delivery group the necessary permissions to write logs to the destination bucket, and then they enable logging on the source bucket.

These examples won't work on destination buckets that use the Bucket owner enforced setting for Object Ownership.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your [PutBucketLogging](#) configuration. You must use a bucket policy to grant access to the logging service principal (logging.s3.amazonaws.com). For more information, see [Permissions for log delivery](#).

.NET

SDK for .NET

        .build();
    BucketLoggingStatus bucketLoggingStatus = BucketLoggingStatus.builder()
        .loggingEnabled(loggingEnabled)
```

```
        .build();
    s3Client.putBucketLogging(PutBucketLoggingRequest.builder()
        .bucket(sourceBucketName)
        .bucketLoggingStatus(bucketLoggingStatus)
        .build());
}

}
```

Using the AWS CLI

We recommend that you create a dedicated logging bucket in each AWS Region that you have S3 buckets in. Then have your Amazon S3 access logs delivered to that S3 bucket. For more information and examples, see [put-bucket-logging](#) in the *AWS CLI Reference*.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your [PutBucketLogging](#) configuration. You must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see [Permissions for log delivery](#).

Example — Enable access logs with five buckets across two Regions

In this example, you have the following five buckets:

- `amzn-s3-demo-source-bucket-us-east-1`
- `amzn-s3-demo-source-bucket1-us-east-1`
- `amzn-s3-demo-source-bucket2-us-east-1`
- `amzn-s3-demo-bucket1-us-west-2`
- `amzn-s3-demo-bucket2-us-west-2`

Note

The final step of the following procedure provides example bash scripts that you can use to create your logging buckets and enable server access logging on these buckets. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in the following procedure.

1. Create two logging destination buckets in the US West (Oregon) and US East (N. Virginia) Regions and give them the following names:
 - *amzn-s3-demo-destination-bucket-logs-us-east-1*
 - *amzn-s3-demo-destination-bucket1-logs-us-west-2*
2. Later in these steps, you will enable server access logging as follows:
 - *amzn-s3-demo-source-bucket-us-east-1* logs to the S3 bucket *amzn-s3-demo-destination-bucket-logs-us-east-1* with the prefix *amzn-s3-demo-source-bucket-us-east-1*
 - *amzn-s3-demo-source-bucket1-us-east-1* logs to the S3 bucket *amzn-s3-demo-destination-bucket-logs-us-east-1* with the prefix *amzn-s3-demo-source-bucket1-us-east-1*
 - *amzn-s3-demo-source-bucket2-us-east-1* logs to the S3 bucket *amzn-s3-demo-destination-bucket-logs-us-east-1* with the prefix *amzn-s3-demo-source-bucket2-us-east-1*
 - *amzn-s3-demo-bucket1-us-west-2* logs to the S3 bucket *amzn-s3-demo-destination-bucket1-logs-us-west-2* with the prefix *amzn-s3-demo-bucket1-us-west-2*
 - *amzn-s3-demo-bucket2-us-west-2* logs to the S3 bucket *amzn-s3-demo-destination-bucket1-logs-us-west-2* with the prefix *amzn-s3-demo-bucket2-us-west-2*
3. For each destination logging bucket, grant permissions for server access log delivery by using a bucket ACL or a bucket policy:
 - **Update the bucket policy** (Recommended) – To grant permissions to the logging service principal, use the following `put-bucket-policy` command. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination bucket.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-destination-bucket-logs --  
policy file://policy.json
```

`Policy.json` is a JSON document in the current folder that contains the following bucket policy. To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, *amzn-s3-demo-destination-bucket-logs* is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-*

bucket is the source bucket. **SOURCE-ACCOUNT-ID** is the AWS account that owns the source bucket.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "S3ServerAccessLogsPolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "logging.s3.amazonaws.com"  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket-logs/*",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-  
bucket"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "SOURCE-ACCOUNT-ID"  
                }  
            }  
        }  
    ]  
}
```

- **Update the bucket ACL** – To grant permissions to the S3 log delivery group, use the following put-bucket-acl command. Replace **amzn-s3-demo-destination-bucket-logs** with the name of your destination (target) bucket.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-destination-bucket-logs --  
grant-write URI=http://acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp  
URI=http://acs.amazonaws.com/groups/s3/LogDelivery
```

4. Then, create a `logging.json` file that contains your logging configuration (based on one of the three examples that follow). After you create the `logging.json` file, you can apply the logging configuration by using the following `put-bucket-logging` command. Replace `amzn-s3-demo-destination-bucket-logs` with the name of your destination (target) bucket.

```
aws s3api put-bucket-logging --bucket amzn-s3-demo-destination-bucket-logs --  
bucket-logging-status file://logging.json
```

 **Note**

Instead of using this `put-bucket-logging` command to apply the logging configuration on each destination bucket, you can use one of the bash scripts provided in the next step. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in this procedure.

The `logging.json` file is a JSON document in the current folder that contains your logging configuration. If a destination bucket uses the Bucket owner enforced setting for Object Ownership, your logging configuration can't contain destination (target) grants. For more information, see [Permissions for log delivery](#).

Example – `logging.json` without destination (target) grants

The following example `logging.json` file doesn't contain destination (target) grants. Therefore, you can apply this configuration to a destination (target) bucket that uses the Bucket owner enforced setting for Object Ownership.

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",  
        "TargetPrefix": "amzn-s3-demo-destination-bucket/"  
    }  
}
```

Example – logging.json with destination (target) grants

The following example logging.json file contains destination (target) grants.

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't include destination (target) grants in your [PutBucketLogging](#) configuration. For more information, see [Permissions for log delivery](#).

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",  
        "TargetPrefix": "amzn-s3-demo-destination-bucket/",  
        "TargetGrants": [  
            {  
                "Grantee": {  
                    "Type": "CanonicalUser",  
                    "ID": "79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be"  
                },  
                "Permission": "FULL_CONTROL"  
            }  
        ]  
    }  
}
```

Grantee values

You can specify the person (grantee) to whom you're assigning access rights (by using request elements) in the following ways:

- By the person's ID:

```
{  
    "Grantee": {  
        "Type": "CanonicalUser",  
        "ID": "ID"  
    }  
}
```

{

- By URI:

```
{  
  "Grantee": {  
    "Type": "Group",  
    "URI": "http://acs.amazonaws.com/groups/global/AuthenticatedUsers"  
  }  
}
```

Example – logging.json with the log object key format set to S3 event time

The following logging.json file changes the log object key format to S3 event time. For more information about setting the log object key format, see [the section called “How do I enable log delivery?”](#)

```
{  
  "LoggingEnabled": {  
    "TargetBucket": "amzn-s3-demo-destination-bucket-logs",  
    "TargetPrefix": "amzn-s3-demo-destination-bucket/",  
    "TargetObjectKeyFormat": {  
      "PartitionedPrefix": {  
        "PartitionDataSource": "EventTime"  
      }  
    }  
  }  
}
```

5. Use one of the following bash scripts to add access logging for all the buckets in your account. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket, and replace *us-west-2* with the name of the Region that your buckets are located in.

 **Note**

This script works only if all of your buckets are in the same Region. If you have buckets in multiple Regions, you must adjust the script.

Example – Grant access with bucket policies and add logging for the buckets in your account

```
loggingBucket='amzn-s3-demo-destination-bucket-logs'
region='us-west-2'

# Create the logging bucket.
aws s3 mb s3://$loggingBucket --region $region

aws s3api put-bucket-policy --bucket $loggingBucket --policy file://policy.json

# List the buckets in this account.
buckets=$(aws s3 ls | awk '{print $3}')

# Put a bucket logging configuration on each bucket.
for bucket in $buckets
do
    # This if statement excludes the logging bucket.
    if [ "$bucket" == "$loggingBucket" ] ; then
        continue;
    fi
    printf '{
        "LoggingEnabled": {
            "TargetBucket": "%s",
            "TargetPrefix": "%s/"
        }
    }' "$loggingBucket" "$bucket" > logging.json
    aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
    echo "$bucket done"
done

rm logging.json

echo "Complete"
```

Example – Grant access with bucket ACLs and add logging for the buckets in your account

```
loggingBucket='amzn-s3-demo-destination-bucket-logs'
region='us-west-2'

# Create the logging bucket.
aws s3 mb s3://$loggingBucket --region $region

aws s3api put-bucket-acl --bucket $loggingBucket --grant-write URI=http://
acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp URI=http://
acs.amazonaws.com/groups/s3/LogDelivery

# List the buckets in this account.
buckets=$(aws s3 ls | awk '{print $3}')

# Put a bucket logging configuration on each bucket.
for bucket in $buckets
do
    # This if statement excludes the logging bucket.
    if [ "$bucket" == "$loggingBucket" ] ; then
        continue;
    fi
    printf '%{
    "LoggingEnabled": {
        "TargetBucket": "%s",
        "TargetPrefix": "%s/"
    }
}' "$loggingBucket" "$bucket" > logging.json
    aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
    echo "$bucket done"
done

rm logging.json

echo "Complete"
```

Verifying your server access logs setup

After you enable server access logging, complete the following steps:

- Access the destination bucket and verify that the log files are being delivered. After the access logs are set up, Amazon S3 immediately starts capturing requests and logging them. However,

it might take a few hours before the logs are delivered to the destination bucket. For more information, see [the section called “Bucket logging status changes take effect over time”](#) and [the section called “Best-effort server log delivery”](#).

You can also automatically verify log delivery by using Amazon S3 request metrics and setting up Amazon CloudWatch alarms for these metrics. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

- Verify that you are able to open and read the contents of the log files.

For server access logging troubleshooting information, see [Troubleshoot server access logging](#).

Amazon S3 server access log format

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. You can use server access logs for the following purposes:

- Performing security and access audits
- Learning about your customer base
- Understanding your Amazon S3 bill

This section describes the format and other details about Amazon S3 server access log files.

Server access log files consist of a sequence of newline-delimited log records. Each log record represents one request and consists of space-delimited fields.

The following is an example log consisting of five log records.

 **Note**

Any field can be set to - to indicate that the data was unknown or unavailable, or that the field was not applicable to this request.

- [Programming considerations for extensible server access log format](#)

Log record fields

The following list describes the log record fields.

Bucket Owner

The canonical user ID of the owner of the source bucket. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see [AWS account identifiers](#) in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see [Finding the canonical user ID for your AWS account](#).

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that the request was processed against. If the system receives a malformed request and cannot determine the bucket, the request will not appear in any server access log.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: [%d/%b/%Y:%H:%M:%S %z]

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a - for unauthenticated requests. If the requester was an IAM user, this field returns the requester's IAM user name along with the AWS account that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request. For **Compute checksum** job requests, the **Request ID** field displays the associated job ID. For more information, see [Compute checksums](#).

Example entry

```
3E57427F33A59F07
```

Operation

The operation listed here is declared as SOAP.*operation*,
REST.*HTTP_method.resource_type*, WEBSITE.*HTTP_method.resource_type*, or

BATCH.DELETE.OBJECT, or S3.action.resource_type for [S3 Lifecycle and logging](#). For [Compute checksum](#) job requests, the operation is listed as S3.COMPUTE.OBJECT.CHECKSUM.

Example entry

```
REST.PUT.OBJECT  
S3.COMPUTE.OBJECT.CHECKSUM
```

Key

The key (object name) part of the request.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The Request-URI part of the HTTP request message.

Example Entry

```
"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar HTTP/1.1"
```

HTTP status

The numeric HTTP status code of the response.

Example entry

```
200
```

Error Code

The Amazon S3 [Error responses](#), or - if no error occurred.

Example entry

```
NoSuchBucket
```

Bytes Sent

The number of response bytes sent, excluding HTTP protocol overhead, or - if zero.

Example entry

2662992

Object Size

The total size of the object in question.

Example entry

3462992

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

70

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

10

Referer

The value of the HTTP Referer header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP User-Agent header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID in the request, or - if the operation doesn't take a `versionId` parameter.

Example entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The `x-amz-id-2` or Amazon S3 extended request ID.

Example entry

```
s91zHYrFp76ZVxRcpX9+5cjAnEH2R0uNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request or a - for unauthenticated requests.

Example entry

```
SigV2
```

Cipher Suite

The Transport Layer Security (TLS) cipher that was negotiated for an HTTPS request or a - for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: AuthHeader for authentication headers, QueryString for query string (presigned URL), or a - for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see [Legacy endpoints](#). For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: TLSv1.1, TLSv1.2, TLSv1.3, or - if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a -. For more information about access points, see

[Using Amazon S3 access points for general purpose buckets.](#) For more information about ARNs, see [Amazon Resource Name \(ARN\)](#) in the [AWS Reference Guide](#).

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is Yes. If no ACLs were required, the string is -. For more information about ACLs, see [Access control list \(ACL\) overview](#). For more information about using the aclRequired field to disable ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Example entry

```
Yes
```

Additional logging for copy operations

A copy operation involves a GET and a PUT. For that reason, we log two records when performing a copy operation. The previous section describes the fields related to the PUT part of the operation. The following list describes the fields in the record that relate to the GET part of the copy operation.

Bucket Owner

The canonical user ID of the bucket that stores the object being copied. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see [AWS account identifiers](#) in the [AWS General Reference](#). For information about how to find the canonical user ID for your account, see [Finding the canonical user ID for your AWS account](#).

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that stores the object that's being copied.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: [%d/%B/%Y:%H:%M:%S %z]

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a - for unauthenticated requests. If the requester was an IAM user, this field will return the requester's IAM user name along with the AWS account root user that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request. For **Compute checksum** job requests, the **Request ID** field displays the associated job ID. For more information, see [Compute checksums](#).

Example entry

```
3E57427F33A59F07
```

Operation

The operation listed here is declared as SOAP.*operation*, REST.*HTTP_method.resource_type*, WEBSITE.*HTTP_method.resource_type*, or BATCH.DELETE.OBJECT.

Example entry

```
REST.COPY.OBJECT_GET
```

Key

The key (object name) of the object being copied, or - if the operation doesn't take a key parameter.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The Request-URI part of the HTTP request message.

Example entry

```
"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar"
```

HTTP status

The numeric HTTP status code of the GET portion of the copy operation.

Example entry

200

Error Code

The Amazon S3 [Error responses](#) of the GET portion of the copy operation, or - if no error occurred.

Example entry

NoSuchBucket

Bytes Sent

The number of response bytes sent, excluding the HTTP protocol overhead, or - if zero.

Example entry

2662992

Object Size

The total size of the object in question.

Example entry

3462992

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

70

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

```
10
```

Referer

The value of the HTTP Referer header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP User-Agent header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID of the object being copied, or - if the x-amz-copy-source header didn't specify a versionId parameter as part of the copy source.

Example Entry

```
3HL4kqtJvjVBH40Nrjkfd
```

Host Id

The x-amz-id-2 or Amazon S3 extended request ID.

Example entry

```
s9lzMHyxFp76ZVxRcpX9+5cjAnEH2R0uNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request, or a `-` for unauthenticated requests.

Example entry

```
SigV4
```

Cipher Suite

The Transport Layer Security (TLS) cipher that was negotiated for an HTTPS request, or a `-` for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: `AuthHeader` for authentication headers, `QueryString` for query strings (presigned URLs), or a `-` for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint that was used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see [Legacy endpoints](#). For a complete

list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: TLSv1.1, TLSv1.2, TLSv1.3, or - if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a -. For more information about access points, see [Using Amazon S3 access points for general purpose buckets](#). For more information about ARNs, see [Amazon Resource Name \(ARN\)](#) in the *AWS Reference Guide*.

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is Yes. If no ACLs were required, the string is -. For more information about ACLs, see [Access control list \(ACL\) overview](#). For more information about using the aclRequired field to disable ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Example entry

```
Yes
```

Custom access log information

You can include custom information to be stored in the access log record for a request. To do this, add a custom query-string parameter to the URL for the request. Amazon S3 ignores query-string

parameters that begin with x-, but includes those parameters in the access log record for the request, as part of the Request-URI field of the log record.

For example, a GET request for "s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-user=johndoe" works the same as the request for "s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg", except that the "x-user=johndoe" string is included in the Request-URI field for the associated log record. This functionality is available in the REST interface only.

Programming considerations for extensible server access log format

Occasionally, we might extend the access log record format by adding new fields to the end of each line. Therefore, make sure that any of your code that parses server access logs can handle trailing fields that it might not understand.

Deleting Amazon S3 log files

An Amazon S3 bucket with server access logging enabled can accumulate many server log objects over time. Your application might need these access logs for a specific period after they are created, and after that, you might want to delete them. You can use Amazon S3 Lifecycle configuration to set rules so that Amazon S3 automatically queues these objects for deletion at the end of their life.

You can define a lifecycle configuration for a subset of objects in your S3 bucket by using a shared prefix. If you specified a prefix in your server access logging configuration, you can set a lifecycle configuration rule to delete log objects that have that prefix.

For example, suppose that your log objects have the prefix logs/. You can set a lifecycle configuration rule to delete all objects in the bucket that have the prefix logs/ after a specified period of time.

For more information about lifecycle configuration, see [Managing the lifecycle of objects](#).

For general information about server access logging, see [Logging requests with server access logging](#).

Using Amazon S3 server access logs to identify requests

You can identify Amazon S3 requests by using Amazon S3 server access logs.

Note

- To identify Amazon S3 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information. For more information, see [Identifying Amazon S3 requests using CloudTrail](#).
- Depending on how many access requests you get, analyzing your logs might require more resources or time than using CloudTrail data events.

Topics

- [Querying access logs for requests by using Amazon Athena](#)
- [Identifying Signature Version 2 requests by using Amazon S3 access logs](#)
- [Identifying object access requests by using Amazon S3 access logs](#)

Querying access logs for requests by using Amazon Athena

You can identify Amazon S3 requests with Amazon S3 access logs by using Amazon Athena.

Amazon S3 stores server access logs as objects in an S3 bucket. It is often easier to use a tool that can analyze the logs in Amazon S3. Athena supports analysis of S3 objects and can be used to query Amazon S3 access logs.

Example

The following example shows how you can query Amazon S3 server access logs in Amazon Athena. Replace the *user input placeholders* used in the following examples with your own information.

Note

To specify an Amazon S3 location in an Athena query, you must provide an S3 URI for the bucket where your logs are delivered to. This URI must include the bucket name and prefix in the following format: `s3://amzn-s3-demo-bucket1-logs/prefix/`

1. Open the Athena console at <https://console.aws.amazon.com/athena/>.

2. In the Query Editor, run a command similar to the following. Replace `s3_access_logs_db` with the name that you want to give to your database.

```
CREATE DATABASE s3_access_logs_db
```

 **Note**

It's a best practice to create the database in the same AWS Region as your S3 bucket.

3. In the Query Editor, run a command similar to the following to create a table schema in the database that you created in step 2. Replace `s3_access_logs_db.mybucket_logs` with the name that you want to give to your table. The STRING and BIGINT data type values are the access log properties. You can query these properties in Athena. For LOCATION, enter the S3 bucket and prefix path as noted earlier.

Date-based partitioning

```
CREATE EXTERNAL TABLE s3_access_logs_db.mybucket_logs(  
    `bucketowner` STRING,  
    `bucket_name` STRING,  
    `requestdatetime` STRING,  
    `remoteip` STRING,  
    `requester` STRING,  
    `requestid` STRING,  
    `operation` STRING,  
    `key` STRING,  
    `request_uri` STRING,  
    `httpstatus` STRING,  
    `errorcode` STRING,  
    `bytessent` BIGINT,  
    `objectsize` BIGINT,  
    `totaltime` STRING,  
    `turnaroundtime` STRING,  
    `referrer` STRING,  
    `useragent` STRING,  
    `versionid` STRING,  
    `hostid` STRING,  
    `sigv` STRING,  
    `ciphersuite` STRING,  
    `authtype` STRING,  
    `endpoint` STRING,
```

```

`tlsversion` STRING,
`accesspointarn` STRING,
`aclrequired` STRING)
PARTITIONED BY (
    `timestamp` string)
ROW FORMAT SERDE
    'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
    'input.regex'='([^\n]* ([^\n]*) \\[.*?]\\] ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n"]*\"| -) (-|[0-9]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*) ([^\n]*)(?: ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*))?.*?$')
STORED AS INPUTFORMAT
    'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
    'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
's3://bucket-name/prefix-name/account-id/region/source-bucket-name/'
TBLPROPERTIES (
    'projection.enabled'='true',
    'projection.timestamp.format'='yyyy/MM/dd',
    'projection.timestamp.interval'='1',
    'projection.timestamp.interval.unit'='DAYS',
    'projection.timestamp.range'='2024/01/01,NOW',
    'projection.timestamp.type'='date',
    'storage.location.template'='s3://bucket-name/prefix-name/account-id/region/
source-bucket-name/${timestamp}')

```

Non-date-based partitioning

```

CREATE EXTERNAL TABLE `s3_access_logs_db.mybucket_logs`(
    `bucketowner` STRING,
    `bucket_name` STRING,
    `requestdatetime` STRING,
    `remoteip` STRING,
    `requester` STRING,
    `requestid` STRING,
    `operation` STRING,
    `key` STRING,
    `request_uri` STRING,
    `httpstatus` STRING,
    `errorcode` STRING,
    `bytessent` BIGINT,

```

4. In the navigation pane, under **Database**, choose your database.
 5. Under **Tables**, choose **Preview table** next to your table name.

In the **Results** pane, you should see data from the server access logs, such as bucketowner, bucket, requestdatetime, and so on. This means that you successfully created the Athena table. You can now query the Amazon S3 server access logs.

Example — Show who deleted an object and when (timestamp, IP address, and IAM user)

```
SELECT requestdatetime, remoteip, requester, key  
FROM s3_access_logs_db.mybucket_logs  
WHERE key = 'images/picture.jpg' AND operation like '%DELETE%';
```

Example — Show all operations that were performed by an IAM user

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE requester='arn:aws:iam::123456789123:user/user_name';
```

Example — Show all operations that were performed on an object in a specific time period

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE Key='prefix/images/picture.jpg'
AND parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2017-02-18:07:00:00', 'yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2017-02-18:08:00:00', 'yyyy-MM-dd:HH:mm:ss');
```

Example — Show how much data was transferred to a specific IP address in a specific time period

```
SELECT coalesce(SUM(bytessent), 0) AS bytessenttotal
FROM s3_access_logs_db.mybucket_logs
WHERE remoteip='192.0.2.1'
AND parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2022-06-01', 'yyyy-MM-dd')
AND parse_datetime('2022-07-01', 'yyyy-MM-dd');
```

Example — Find request IDs for HTTP 5xx errors in a specific time period

```
SELECT requestdatetime, key, httpstatus, errorcode, requestid, hostid
FROM s3_access_logs_db.mybucket_logs
WHERE httpstatus like '5%' AND timestamp
BETWEEN '2024/01/29'
AND '2024/01/30'
```

Note

To reduce the time that you retain your logs, you can create an S3 Lifecycle configuration for your server access logs bucket. Create lifecycle configuration rules to remove log files periodically. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see [Setting an S3 Lifecycle configuration on a bucket](#).

Identifying Signature Version 2 requests by using Amazon S3 access logs

Amazon S3 support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use Signature Version 4 signing. You can identify Signature Version 2 access requests by using Amazon S3 access logs.

Note

To identify Signature Version 2 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information than server access logs. For more information, see [Identifying Amazon S3 Signature Version 2 requests by using CloudTrail](#).

Example — Show all requesters that are sending Signature Version 2 traffic

```
SELECT requester, sigv, Count(sigv) as sigcount
FROM s3_access_logs_db.mybucket_logs
GROUP BY requester, sigv;
```

Identifying object access requests by using Amazon S3 access logs

You can use queries on Amazon S3 server access logs to identify Amazon S3 object access requests, for operations such as GET, PUT, and DELETE, and discover further information about those requests.

The following Amazon Athena query example shows how to get all PUT object requests for Amazon S3 from a server access log.

Example — Show all requesters that are sending PUT object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE operation='REST.PUT.OBJECT'
AND parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2019-07-02:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all GET object requests for Amazon S3 from the server access log.

Example — Show all requesters that are sending GET object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE operation='REST.GET.OBJECT'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2019-07-02:00:42:42','yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all anonymous requests to your S3 buckets from the server access log.

Example — Show all anonymous requesters that are making requests to a bucket during a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE requester IS NULL
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2019-07-02:00:42:42','yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. You can use this information to migrate those ACL permissions to the appropriate bucket policies and disable ACLs. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see [Prerequisites for disabling ACLs](#).

Example — Identify all requests that required an ACL for authorization

```
SELECT bucket_name, requester, key, operation, aclrequired, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE aclrequired = 'Yes'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2022-05-10:00:00:00','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2022-08-10:00:00:00','yyyy-MM-dd:HH:mm:ss')
```

Note

- You can modify the date range as needed to suit your needs.
- These query examples might also be useful for security monitoring. You can review the results for PutObject or GetObject calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.
- If you are using AWS CloudTrail logs, see [Identifying access to S3 objects by using CloudTrail](#).

Troubleshoot server access logging

The following topics can help you troubleshoot issues that you might encounter when setting up logging with Amazon S3.

Topics

- [Common error messages when setting up logging](#)
- [Troubleshooting delivery failures](#)

Common error messages when setting up logging

The following common error messages can appear when you're enabling logging through the AWS Command Line Interface (AWS CLI) and AWS SDKs:

Error: Cross S3 location logging not allowed

If the destination bucket (also known as a *target bucket*) is in a different Region than the source bucket, a Cross S3 location logging not allowed error occurs. To resolve this error, make sure that the destination bucket configured to receive the access logs is in the same AWS Region and AWS account as the source bucket.

Error: The owner for the bucket to be logged and the target bucket must be the same

When you're enabling server access logging, this error occurs if the specified destination bucket belongs to a different account. To resolve this error, make sure that the destination bucket is in the same AWS account as the source bucket.

Note

We recommend that you choose a destination bucket that's different from the source bucket. When the source bucket and destination bucket are the same, additional logs are created for the logs that are written to the bucket, which can increase your storage bill. These extra logs about logs can also make it difficult to find the particular logs that you're looking for. For simpler log management, we recommend saving access logs in a different bucket. For more information, see [the section called "How do I enable log delivery?"](#).

Error: The target bucket for logging does not exist

The destination bucket must exist prior to setting the configuration. This error indicates that the destination bucket doesn't exist or can't be found. Make sure that the bucket name is spelled correctly, and then try again.

Error: Target grants not allowed for bucket owner enforced buckets

This error indicates that the destination bucket uses the Bucket owner enforced setting for S3 Object Ownership. The Bucket owner enforced setting doesn't support destination (target) grants. For more information, see [Permissions for log delivery](#).

Troubleshooting delivery failures

To avoid server access logging issues, make sure that you're following these best practices:

- **The S3 log delivery group has write access to the destination bucket** – The S3 log delivery group delivers server access logs to the destination bucket. A bucket policy or bucket access control list (ACL) can be used to grant write access to the destination bucket. However, we recommend that you use a bucket policy instead of an ACL. For more information about how to grant write access to your destination bucket, see [Permissions for log delivery](#).

Note

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, be aware of the following:

- ACLs are disabled and no longer affect permissions. This means that you can't update your bucket ACL to grant access to the S3 log delivery group. Instead, to grant access

to the logging service principal, you must update the bucket policy for the destination bucket.

- You can't include destination grants in your PutBucketLogging configuration.

- **The bucket policy for the destination bucket allows access to the logs** – Check the bucket policy of the destination bucket. Search the bucket policy for any statements that contain "Effect": "Deny". Then, verify that the Deny statement isn't preventing access logs from being written to the bucket.
- **S3 Object Lock isn't enabled on the destination bucket** – Check if the destination bucket has Object Lock enabled. Object Lock blocks server access log delivery. You must choose a destination bucket that doesn't have Object Lock enabled.
- **Amazon S3 managed keys (SSE-S3) is selected if default encryption is enabled on the destination bucket** – You can use default bucket encryption on the destination bucket only if you use server-side encryption with Amazon S3 managed keys (SSE-S3). Default server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) is not supported for server access logging destination buckets. For more information about how to enable default encryption, see [Configuring default encryption](#).
- **The destination bucket does not have Requester Pays enabled** – Using a Requester Pays bucket as the destination bucket for server access logging is not supported. To allow delivery of server access logs, disable the Requester Pays option on the destination bucket.
- **Review your AWS Organizations service control policies (SCPs) and resource control policies (RCPs)** – When you're using AWS Organizations, check the service control policies and resource control policies to make sure that Amazon S3 access is allowed. These policies specify the maximum permissions for principals and resources in the affected accounts. Search the policies for any statements that contain "Effect": "Deny" and verify that Deny statements aren't preventing any access logs from being written to the bucket. For more information, see [Authorization policies in AWS Organizations](#) in the *AWS Organizations User Guide*.
- **Allow some time for recent logging configuration changes to take effect** – Enabling server access logging for the first time, or changing the destination bucket for logs, requires time to fully take effect. It might take longer than an hour for all requests to be properly logged and delivered.

To check for log delivery failures, enable request metrics in Amazon CloudWatch. If the logs are not delivered within a few hours, look for the 4xxErrors metric, which can indicate log delivery failures. For more information about enabling request metrics, see [the section called “Creating a metrics configuration for all objects”](#).

Monitoring metrics with Amazon CloudWatch

Amazon CloudWatch metrics for Amazon S3 can help you understand and improve the performance of applications that use Amazon S3. There are several ways that you can use CloudWatch with Amazon S3.

Daily storage metrics for buckets

Monitor bucket storage using CloudWatch, which collects and processes storage data from Amazon S3 into readable, daily metrics. These storage metrics for Amazon S3 are reported once per day and are provided to all customers at no additional cost.

Request metrics

Monitor Amazon S3 requests to quickly identify and act on operational issues. The metrics are available at 1-minute intervals after some latency for processing. These CloudWatch metrics are billed at the same rate as the Amazon CloudWatch custom metrics. For information about CloudWatch pricing, see [Amazon CloudWatch pricing](#). To learn how to opt in to getting these metrics, see [CloudWatch metrics configurations](#).

When enabled, request metrics are reported for all object operations. By default, these 1-minute metrics are available at the Amazon S3 bucket level. You can also define a filter for the metrics using a shared prefix, object tag, or access point:

- **Access point** – Access points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. With the access point filter, you can gain insights into your access point usage. For more information about access points, see [Monitoring and logging access points](#).
- **Prefix** – Although the Amazon S3 data model is a flat structure, you can use prefixes to infer a hierarchy. A prefix is similar to a directory name that enables you to group similar objects together in a bucket. The S3 console supports prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see [Organizing objects using prefixes](#).
- **Tags** – Tags are key-value name pairs that you can add to objects. Tags help you find and organize objects easily. You can also use tags as a filter for metrics configurations so that only objects with those tags are included in the metrics configuration. For more information about object tags, see [Categorizing your objects using tags](#).

To align these metrics to specific business applications, workflows, or internal organizations, you can filter on a shared prefix, object tag, or access point.

Replication metrics

Monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination AWS Region, and the total number of operations that failed replication. Replication rules that have S3 Replication Time Control (S3 RTC) or S3 Replication metrics enabled will publish replication metrics.

For more information, see [Monitoring replication with metrics, event notifications, and statuses](#) or [Meeting compliance requirements with S3 Replication Time Control](#).

Amazon S3 Storage Lens metrics

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). S3 Storage Lens metrics are available in the AWS/S3/Storage-Lens namespace. The CloudWatch publishing option is available for S3 Storage Lens dashboards upgraded to *advanced metrics and recommendations*. You can enable the CloudWatch publishing option for a new or existing dashboard configuration in S3 Storage Lens.

For more information, see [Monitor S3 Storage Lens metrics in CloudWatch](#).

All CloudWatch statistics are retained for a period of 15 months so that you can access historical information and gain a better perspective on how your web application or service is performing. For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*. You may need some additional configurations to your CloudWatch alarms, depending on your use cases. For example, you can use metric math expression to create an alarm. For more information, see [Use CloudWatch metrics](#), [Use metric math](#), [Using Amazon CloudWatch alarms](#), and [Create a CloudWatch alarm based on a metric math expression](#) in the *Amazon CloudWatch User Guide*.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the

nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the [Billing & Cost Management Dashboard](#) might include one or more access requests that do not appear in the bucket metrics.

For more information, see the following topics.

Topics

- [Metrics and dimensions](#)

Amazon S3 daily storage metrics for buckets in CloudWatch

The AWS/S3 namespace includes the following daily storage metrics for buckets.

Metric	Description
BucketSizeBytes	<p>The amount of data in bytes that is stored in a bucket in the following storage classes:</p> <ul style="list-style-type: none">• Reduced Redundancy Storage (RRS) (REDUCED_REDUNDANCY)• S3 Express One Zone (EXPRESS_ONEZONE)• S3 Glacier Deep Archive (DEEP_ARCHIVE)• S3 Glacier Flexible Retrieval (GLACIER)• S3 Glacier Instant Retrieval (GLACIER_IR)• S3 Intelligent-Tiering (INTELLIGENT_TIERING)• S3 One Zone-Infrequent Access (ONEZONE_IA)• S3 Standard (STANDARD)• S3 Standard-Infrequent Access (STANDARD_IA) <p>This value is calculated by summing the size of all objects and metadata (such as bucket names) in the bucket (both current and noncurrent objects), including the size of all parts for all incomplete multipart uploads to the bucket.</p>

Metric	Description
	<p>Note</p> <p>The S3 Express One Zone storage class is available only for directory buckets.</p>
	<p>Valid storage-type filters (see the <code>StorageType</code> dimension):</p> <ul style="list-style-type: none">• Reduced Redundancy Storage (RRS): <code>ReducedRedundancyStorage</code>• S3 Express One Zone: <code>ExpressOneZoneStorage</code>• S3 Glacier Deep Archive: <code>DeepArchiveObjectOverhead</code> , <code>DeepArchiveS3ObjectOverhead</code> , <code>DeepArchiveStagingStorage</code> , <code>DeepArchiveStorage</code>• S3 Glacier Flexible Retrieval: <code>GlacierObjectOverhead</code> , <code>GlacierS3ObjectOverhead</code> , <code>GlacierStagingStorage</code> , <code>GlacierStorage</code>• S3 Glacier Instant Retrieval: <code>GlacierInstantRetrievalStorage</code> , <code>GlacierIRSizeOverhead</code>• S3 Intelligent-Tiering: <code>IntelligentTieringAAStorage</code> , <code>IntelligentTieringAIAStorage</code> , <code>IntelligentTieringDAAStorage</code> , <code>IntelligentTieringFAStorage</code> , <code>IntelligentTieringIAStorage</code>• S3 One Zone-Infrequent Access: <code>OneZoneIASizeOverhead</code> , <code>OneZoneIAStorage</code>• S3 Standard: <code>StandardStorage</code>• S3 Standard-Infrequent Access: <code>StandardIAObjectOverhead</code> , <code>StandardIASizeOverhead</code> , <code>StandardIAStorage</code>
	<p>Units: Bytes</p>
	<p>Valid statistics: Average</p>

Metric	Description
	<p>For more information about the <code>StorageType</code> dimensions, see the section called “Amazon S3 dimensions in CloudWatch”.</p>
NumberOfObjects	<p>The total number of objects stored in a general purpose bucket for all storage classes. This value is calculated by counting all objects in the bucket, which includes current and noncurrent objects, delete markers, and the total number of parts for all incomplete multipart uploads to the bucket. For directory buckets with objects in the S3 Express One Zone storage class, this value is calculated by counting all objects in the bucket, but it doesn't include incomplete multipart uploads to the bucket.</p> <p>Valid storage type filters: <code>AllStorageTypes</code> (see the <code>StorageType</code> dimension)</p> <p>Units: Count</p> <p>Valid statistics: Average</p>

Amazon S3 request metrics in CloudWatch

The AWS/S3 namespace includes the following request metrics. These metrics include non-billable requests (in the case of GET requests from CopyObject and Replication).

 **Note**

Amazon S3 request metrics in CloudWatch aren't supported for directory buckets.

Metric	Description
AllRequests	The total number of HTTP requests made to an Amazon S3 bucket, regardless of type. If you're using a metrics configuration with a filter, then this metric returns only the HTTP requests that meet the filter's requirements.

Metric	Description
	<p>Units: Count</p> <p>Valid statistics: Sum</p>
GetRequests	<p>The number of HTTP GET requests made for objects in an Amazon S3 bucket. This doesn't include list operations. This metric is incremented for the source of each <code>CopyObject</code> request.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
	<p>Note</p> <p>Paginated list-oriented requests, such as ListMultipartUploads, ListParts, ListObjectVersions, and others, are not included in this metric.</p>
PutRequests	<p>The number of HTTP PUT requests made for objects in an Amazon S3 bucket. This metric is incremented for the destination of each <code>CopyObject</code> request.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
DeleteRequests	<p>The number of HTTP DELETE requests made for objects in an Amazon S3 bucket. This metric also includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
HeadRequests	<p>The number of HTTP HEAD requests made to an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
PostRequests	<p>The number of HTTP POST requests made to an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
	<p> Note</p> <p>DeleteObjects and SelectObjectContent requests are not included in this metric.</p>
SelectRequests	<p>The number of Amazon S3 SelectObjectContent requests made for objects in an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
SelectBytesScanned	<p>The number of bytes of data scanned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
SelectBytesReturned	<p>The number of bytes of data returned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
ListRequests	<p>The number of HTTP requests that list the contents of a bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
BytesDownloaded	<p>The number of bytes downloaded for requests made to an Amazon S3 bucket, where the response includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
BytesUploaded	<p>The number of bytes uploaded for requests made to an Amazon S3 bucket, where the request includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
4xxErrors	<p>The number of HTTP 4xx client error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
5xxErrors	<p>The number of HTTP 5xx server error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
FirstByteLatency	<p>The per-request time from the complete request being received by an Amazon S3 bucket to when the response starts to be returned.</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
TotalRequestLatency	<p>The elapsed per-request time from the first byte received to the last byte sent to an Amazon S3 bucket. This metric includes the time taken to receive the request body and send the response body, which is not included in FirstByteLatency .</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>

S3 Replication metrics in CloudWatch

You can monitor the progress of replication with S3 Replication metrics by tracking bytes pending, operations pending, and replication latency. For more information, see [Monitoring progress with replication metrics](#).

 **Note**

You can enable alarms for your replication metrics in Amazon CloudWatch. When you set up alarms for your replication metrics, set the **Missing data treatment** field to **Treat missing data as ignore (maintain the alarm state)**.

Metric	Description
Replicati onLatency	The maximum number of seconds by which the replication destination AWS Region is behind the source AWS Region for a given replication rule. Units: Seconds Valid statistics: Max
BytesPend ingReplicatio n	The total number of bytes of objects pending replication for a given replication rule. Units: Bytes Valid statistics: Max
Operation sPendingR eplication	The number of operations pending replication for a given replication rule. Units: Count Valid statistics: Max
Operation sFailedRe plication	The number of operations that failed to replicate for a given replication rule.

Metric	Description
	Units: Count Valid statistics: Sum (total number of failed operations), Average (failure rate), Sample Count (total number of replication operations)

S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). S3 Storage Lens metrics are published to the AWS/S3/Storage-Lens namespace in CloudWatch. The CloudWatch publishing option is available for S3 Storage Lens dashboards that have been upgraded to advanced metrics and recommendations.

For a list of S3 Storage Lens metrics that are published to CloudWatch, see [Amazon S3 Storage Lens metrics glossary](#). For a complete list of dimensions, see [Dimensions](#).

S3 Object Lambda request metrics in CloudWatch

S3 Object Lambda includes the following request metrics.

Metric	Description
AllRequests	The total number of HTTP requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
GetRequests	The number of HTTP GET requests made for objects by using an Object Lambda Access Point. This metric does not include list operations. Units: Count Valid statistics: Sum
BytesUploaded	The number of bytes uploaded to an Amazon S3 bucket by using an Object Lambda Access Point, where the request includes a body.

Metric	Description
	<p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
PostRequests	<p>The number of HTTP POST requests made to an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
PutRequests	<p>The number of HTTP PUT requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
DeleteRequests	<p>The number of HTTP DELETE requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point. This metric includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
BytesDownloaded	<p>The number of bytes downloaded for requests made to an Amazon S3 bucket by using an Object Lambda Access Point, where the response includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
FirstByteLatency	<p>The per-request time from the complete request being received by an Amazon S3 bucket through an Object Lambda Access Point to when the response starts to be returned. This metric is dependent on the AWS Lambda function's running time to transform the object before the function returns the bytes to the Object Lambda Access Point.</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
TotalRequestLatency	<p>The elapsed per-request time from the first byte received to the last byte sent to an Object Lambda Access Point. This metric includes the time taken to receive the request body and send the response body, which is not included in FirstByteLatency .</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
HeadRequests	<p>The number of HTTP HEAD requests made to an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
ListRequests	<p>The number of HTTP GET requests that list the contents of an Amazon S3 bucket. This metric includes both ListObjects and ListObjectsV2 operations.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
4xxErrors	<p>The number of HTTP 4xx client error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
5xxErrors	<p>The number of HTTP 5xx server error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
ProxiedRequests	<p>The number of HTTP requests to an Object Lambda Access Point that return the standard Amazon S3 API response. (Such requests do not have a Lambda function configured.)</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
InvokedLambda	<p>The number of HTTP requests to an S3 object where a Lambda function was invoked.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
LambdaResponseRequests	The number of <code>WriteGetObjectResponse</code> requests made by the Lambda function. This metric applies only to <code>GetObject</code> requests.
LambdaResponse4xx	The number of HTTP 4xx client errors that occur when calling <code>WriteGetObjectResponse</code> from a Lambda function. This metric provides the same information as <code>4xxErrors</code> , but only for <code>WriteGetObjectResponse</code> calls.
LambdaResponse5xx	The number of HTTP 5xx server errors that occur when calling <code>WriteGetObjectResponse</code> from a Lambda function. This metric provides the same information as <code>5xxErrors</code> , but only for <code>WriteGetObjectResponse</code> calls.

Amazon S3 dimensions in CloudWatch

The following dimensions are used to filter Amazon S3 metrics.

Dimension	Description
BucketName	This dimension filters the data that you request for the identified bucket only.
StorageType	This dimension filters the data that you have stored in a bucket by the following types of storage: <ul style="list-style-type: none"> • <code>DeepArchiveObjectOverhead</code> – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive rates for this additional storage. • <code>DeepArchiveS3ObjectOverhead</code> – For each object archived to S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage.

Dimension	Description
	<ul style="list-style-type: none"> • DeepArchiveStagingStorage – The number of bytes used for parts of multipart upload objects before the CompleteMultipartUpload request is completed on objects in the S3 Glacier Deep Archive storage class. • DeepArchiveStorage – The number of bytes used for objects in the S3 Glacier Deep Archive storage class. • ExpressOneZoneStorage – The number of bytes used for objects in the S3 Express One Zone storage class. • GlacierInstantRetrievalStorage – The number of bytes used for objects in the S3 Glacier Instant Retrieval storage class. • GlacierIRSizeOverhead – For objects smaller than 128 KB stored in the S3 Glacier Instant Retrieval storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • GlacierObjectOverhead – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage. • GlacierS3ObjectOverhead – For each object archived to S3 Glacier Flexible Retrieval, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage. • GlacierStagingStorage – The number of bytes used for parts of multipart upload objects before the CompleteMultipartUpload request is completed on objects in the S3 Glacier Flexible Retrieval storage class. • GlacierStorage – The number of bytes used for objects in the S3 Glacier Flexible Retrieval storage class. • IntAAObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Archive Access tier, S3 Glacier adds 32 KB of storage for index and

Dimension	Description
	<p>related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage.</p> <ul style="list-style-type: none">• IntAAS3ObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Archive Access tier, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage.• IntDAAObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Deep Archive Access tier, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive storage rates for this additional storage.• IntDAAS3ObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Deep Archive Access tier, Amazon S3 adds 8 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Standard rates for this additional storage.• IntelligentTieringAAStorage – The number of bytes used for objects in the Archive Access tier of the INTELLIGENT_TIERING storage class.• IntelligentTieringAIASStorage – The number of bytes used for objects in the Archive Instant Access tier of the INTELLIGENT_TIERING storage class.• IntelligentTieringDAAStorage – The number of bytes used for objects in the Deep Archive Access tier of the INTELLIGENT_TIERING storage class.• IntelligentTieringFAStorage – The number of bytes used for objects in the Frequent Access tier of the INTELLIGENT_TIERING storage class.

Dimension	Description
	<ul style="list-style-type: none"> • IntelligentTieringIAStorage – The number of bytes used for objects in the Infrequent Access tier of the INTELLIGENT_TIERING storage class. • OneZoneIASizeOverhead – For objects smaller than 128 KB stored in the S3 One Zone-Infrequent Access (ONEZONE_IA) storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • OneZoneIAStorage – The number of bytes used for objects in the S3 One Zone-Infrequent Access (ONEZONE_I A) storage class. • ReducedRedundancyStorage – The number of bytes used for objects in the Reduced Redundancy Storage (RRS) class. • StandardIASizeOverhead – For objects smaller than 128 KB stored in the STANDARD_IA storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • StandardIAStorage – The number of bytes used for objects in the S3 Standard-Infrequent Access (STANDARD_ IA) storage class. • StandardStorage – The number of bytes used for objects in the STANDARD storage class.
FilterId	<p>This dimension filters metrics configurations that you specify for the request metrics on a bucket. When you create a metrics configuration, you specify a filter ID (for example, a prefix, a tag, or an access point). For more information, see Creating a metrics configuration.</p>

S3 Replication dimensions in CloudWatch

The following dimensions are used to filter S3 Replication metrics.

Dimension	Description
SourceBucket	The name of the bucket objects are replicated from.
DestinationBucket	The name of the bucket objects are replicated to.
RuleId	A unique identifier for the rule that triggered this replication metric to update.

S3 Storage Lens dimensions in CloudWatch

For a list of dimensions that are used to filter S3 Storage Lens metrics in CloudWatch, see [Dimensions](#).

S3 Object Lambda request dimensions in CloudWatch

The following dimensions are used to filter data from an Object Lambda Access Point.

Dimension	Description
AccessPointName	The name of the access point of which requests are being made.
DataSourceARN	The source the Object Lambda Access Point is retrieving the data from. If the request invokes a Lambda function this refers to the Lambda Amazon Resource Name (ARN). Otherwise this refers to the access point ARN.

Amazon S3 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon S3 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see [AWS usage metrics in the Amazon CloudWatch User Guide](#).

Amazon S3 publishes the following metrics in the AWS/Usage namespace.

Metric	Description
ResourceCount	The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric.

The following dimensions are used to refine the usage metrics that are published by Amazon S3.

Dimension	Description
Service	The name of the AWS service containing the resource. For Amazon S3 usage metrics, the value for this dimension is S3.
Type	The type of entity that is being reported. Currently, the only valid value for Amazon S3 usage metrics is Resource.
Resource	The type of resource that is running. Currently, the only valid value for Amazon S3 usage metrics is GeneralPurposeBuckets , which returns the number of general purpose buckets in an AWS account. General purpose buckets allow objects that are stored across all storage classes, except S3 Express One Zone.

Accessing CloudWatch metrics

You can use the following procedures to view the storage metrics for Amazon S3. To get the Amazon S3 metrics involved, you must set a start and end timestamp. For metrics for any given 24-hour period, set the time period to 86400 seconds, the number of seconds in a day. Also, remember to set the BucketName and StorageType dimensions.

Using the AWS CLI

For example, if you want to use the AWS CLI to get the average of a specific bucket's size in bytes, you could use the following command:

```
aws cloudwatch get-metric-statistics --metric-name BucketSizeBytes --namespace AWS/S3  
--start-time 2016-10-19T00:00:00Z --end-time 2016-10-20T00:00:00Z --statistics Average
```

```
--unit Bytes --region us-west-2 --dimensions Name=BucketName,Value=amzn-s3-demo-bucket
Name=StorageType,Value=StandardStorage --period 86400 --output json
```

This example produces the following output.

```
{
  "Datapoints": [
    {
      "Timestamp": "2016-10-19T00:00:00Z",
      "Average": 1025328.0,
      "Unit": "Bytes"
    }
  ],
  "Label": "BucketSizeBytes"
}
```

Using the S3 console

To view metrics by using the Amazon CloudWatch console

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the left navigation pane, choose **Metrics**.
3. Choose the **S3** namespace.
4. (Optional) To view a metric, enter the metric name in the search box.
5. (Optional) To filter by the **StorageType** dimension, enter the name of the storage class in the search box.

To view a list of valid metrics stored for your AWS account by using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/S3"
```

For more information about the permissions required to access CloudWatch dashboards, see [Amazon CloudWatch dashboard permissions](#) in the *Amazon CloudWatch User Guide*.

CloudWatch metrics configurations

With Amazon CloudWatch request metrics for Amazon S3, you can receive 1-minute CloudWatch metrics, set CloudWatch alarms, and access CloudWatch dashboards to view near-real-time operations and performance of your Amazon S3 storage. For applications that depend on cloud storage, these metrics let you quickly identify and act on operational issues. When enabled, these 1-minute metrics are available at the Amazon S3 bucket-level, by default.

If you want to get the CloudWatch request metrics for the objects in a bucket, you must create a metrics configuration for the bucket. For more information, see [Creating a CloudWatch metrics configuration for all the objects in your bucket](#).

You can also use a shared prefix, object tags, or an access point to define a filter for the metrics collected. This method of defining a filter allows you to align metrics filters to specific business applications, workflows, or internal organizations. For more information, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#). For more information about the CloudWatch metrics that are available and the differences between storage and request metrics, see [Monitoring metrics with Amazon CloudWatch](#).

Keep the following in mind when using metrics configurations:

- You can have a maximum of 1,000 metrics configurations per bucket.
- You can choose which objects in a bucket to include in metrics configurations by using filters. You can filter on a shared prefix, object tag, or access point to align metrics filters to specific business applications, workflows, or internal organizations. To request metrics for the entire bucket, create a metrics configuration without a filter.
- Metrics configurations are necessary only to enable request metrics. Bucket-level daily storage metrics are always turned on, and are provided at no additional cost. Currently, it's not possible to get daily storage metrics for a filtered subset of objects.
- Each metrics configuration enables the full set of [available request metrics](#). Operation-specific metrics (such as PostRequests) are reported only if there are requests of that type for your bucket or your filter.
- Request metrics are reported for object-level operations. They are also reported for operations that list bucket contents, like [GET Bucket \(List Objects\)](#), [GET Bucket Object Versions](#), and [List Multipart Uploads](#), but they are not reported for other operations on buckets.
- Request metrics support filtering by prefix, object tags, or access point, but storage metrics do not.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the [Billing & Cost Management Dashboard](#) might include one or more access requests that do not appear in the bucket metrics.

For more information about working with CloudWatch metrics in Amazon S3, see the following topics.

Topics

- [Creating a CloudWatch metrics configuration for all the objects in your bucket](#)
- [Creating a metrics configuration that filters by prefix, object tag, or access point](#)
- [Deleting a metrics filter](#)

Creating a CloudWatch metrics configuration for all the objects in your bucket

When you configure request metrics, you can create a CloudWatch metrics configuration for all the objects in your bucket, or you can filter by prefix, object tag, or access point. The procedures in this topic show you how to create a configuration for all the objects in your bucket. To create a configuration that filters by object tag, prefix, or access point, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. [S3 Replication metrics](#) provide detailed metrics for the replication rules in your replication configuration. With

replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

You can add metrics configurations to a bucket using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the objects you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

Names can only contain letters, numbers, periods, dashes, and underscores. We recommend using the name `EntireBucket` for a filter that applies to all objects.

9. Under **Filter scope**, choose **This filter applies to all objects in the bucket**.

You can also define a filter so that the metrics are only collected and reported on a subset of objects in the bucket. For more information, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

10. Choose **Save changes**.
11. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

After about 15 minutes, CloudWatch begins tracking these request metrics. You can see them on the **Request metrics** tab. You can see graphs for the metrics on the Amazon S3 or CloudWatch console. Request metrics are billed at the standard CloudWatch rate. For more information, see [Amazon CloudWatch pricing](#).

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see [Installing, updating, and uninstalling the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. Run the following command to add a metrics configuration.

```
aws s3api put-bucket-metrics-configuration --endpoint https://s3.us-west-2.amazonaws.com --bucket bucket-name --id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'}'
```

Creating a metrics configuration that filters by prefix, object tag, or access point

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. [S3 Replication metrics](#) provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

When you configure CloudWatch metrics, you can create a filter for all the objects in your bucket, or you can filter the configuration into groups of related objects within a single bucket. You can filter objects in a bucket for inclusion in a metrics configuration based on one or more of the following filter types:

- **Object key name prefix** – Although the Amazon S3 data model is a flat structure, you can infer a hierarchy by using a prefix. The Amazon S3 console supports these prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see [Organizing objects using prefixes](#).
- **Tag** – You can add tags, which are key-value name pairs, to objects. Tags help you find and organize objects easily. You can also use tags as filters for metrics configurations. For more information about object tags, see [Categorizing your objects using tags](#).
- **Access point** – S3 Access Points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. When you create an access point filter, Amazon S3 includes requests to the access point that you specify in the metrics configuration. For more information, see [Monitoring and logging access points](#).

 **Note**

When you create a metrics configuration that filters by access point, you must use the access point Amazon Resource Name (ARN), not the access point alias. Make sure that you use the ARN for the access point itself, not the ARN for a specific object. For more information about access point ARNs, see [Using Amazon S3 access points for general purpose buckets](#).

If you specify a filter, only requests that operate on single objects can match the filter and be included in the reported metrics. Requests like [DeleteObjects](#) and [ListObjects](#) requests don't return any metrics for configurations with filters.

To request more complex filtering, choose two or more elements. Only objects that have all of those elements are included in the metrics configuration. If you don't set filters, all of the objects in the bucket are included in the metrics configuration.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **General purpose buckets**
3. In the buckets list, choose the name of the bucket that contains the objects that you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

Names can contain only letters, numbers, periods, dashes, and underscores.
9. Under **Filter scope**, choose **Limit the scope of this filter using a prefix, object tags, and an S3 Access Point, or a combination of all three**.
10. Under **Filter type**, choose at least one filter type: **Prefix**, **Object tags**, or **Access Point**.
11. To define a prefix filter and limit the scope of the filter to a single path, in the **Prefix** box, enter a prefix.
12. To define an object tags filter, under **Object tags**, choose **Add tag**, and then enter a tag **Key** and **Value**.
13. To define an access point filter, in the **S3 Access Point** field, enter the access point ARN, or choose **Browse S3** to navigate to the access point.

⚠ Important

You cannot enter an access point alias. You must enter the ARN for the access point itself, not the ARN for a specific object.

14. Choose **Save changes**.

Amazon S3 creates a filter that uses the prefix, tags, or access point that you specified.

15. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

You have now created a filter that limits the request metrics scope by prefix, object tags, or access point. About 15 minutes after CloudWatch begins tracking these request metrics, you can see charts for the metrics on both the Amazon S3 and CloudWatch consoles. Request metrics are billed at the standard CloudWatch rate. For more information, see [Amazon CloudWatch pricing](#).

You can also configure request metrics at the bucket level. For information, see [Creating a CloudWatch metrics configuration for all the objects in your bucket](#).

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see [Installing, updating, and uninstalling the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. To add a metrics configuration, run one of the following commands:

Example : To filter by prefix

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"Prefix":"'prefix1'"}' '
```

Example : To filter by tags

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"Tag": {"Key": "string", "Value": "string"} }' '
```

Example : To filter by access point

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"AccessPointArn":":arn:aws:s3:Region:account-id:accesspoint/access-point-name"} }' '
```

Example : To filter by prefix, tags, and access point

```
aws s3api put-bucket-metrics-configuration --endpoint https://  
s3.Region.amazonaws.com --bucket amzn-s3-demo-bucket --id metrics-config-id --  
metrics-configuration '  
{  
    "Id": "metrics-config-id",  
    "Filter": {  
        "And": {  
            "Prefix": "string",
```

```
"Tags": [  
    {  
        "Key": "string",  
        "Value": "string"  
    }  
,  
    "AccessPointArn": "arn:aws:s3:Region:account-id:accesspoint/access-point-name"  
}  
}  
}'
```

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Deleting a metrics filter

You can delete an Amazon CloudWatch request metrics filter if you no longer need it. When you delete a filter, you are no longer charged for request metrics that use that *specific filter*. However, you will continue to be charged for any other filter configurations that exist.

When you delete a filter, you can no longer use the filter for request metrics. Deleting a filter cannot be undone.

For information about creating a request metrics filter, see the following topics:

- [Creating a CloudWatch metrics configuration for all the objects in your bucket](#)
- [Creating a metrics configuration that filters by prefix, object tag, or access point](#)

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket you want to delete a request metrics filter for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Manage filters**.
8. Choose your filter.

 **Important**

Deleting a filter cannot be undone.

9. Choose **Delete**.

Amazon S3 deletes your filter.

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Amazon S3 Event Notifications

You can use the Amazon S3 Event Notifications feature to receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that

identifies the events that you want Amazon S3 to publish. Make sure that it also identifies the destinations where you want Amazon S3 to send the notifications. You store this configuration in the *notification* subresource that's associated with a bucket. For more information, see [General purpose buckets configuration options](#). Amazon S3 provides an API for you to manage this subresource.

 **Important**

Amazon S3 event notifications are designed to be delivered at least once. Typically, event notifications are delivered in seconds but can sometimes take a minute or longer.

Overview of Amazon S3 Event Notifications

Currently, Amazon S3 can publish notifications for the following events:

- New object created events
- Object removal events
- Restore object events
- Reduced Redundancy Storage (RRS) object lost events
- Replication events
- S3 Lifecycle expiration events
- S3 Lifecycle transition events
- S3 Intelligent-Tiering automatic archival events
- Object tagging events
- Object ACL PUT events

For full descriptions of all the supported event types, see [Supported event types for SQS, SNS, and Lambda](#).

Amazon S3 can send event notification messages to the following destinations. You specify the Amazon Resource Name (ARN) value of these destinations in the notification configuration.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda function

- Amazon EventBridge

For more information, see [Supported event destinations](#).

 **Note**

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

 **Warning**

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.

For more information and an example of using Amazon S3 notifications with AWS Lambda, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

For more information about the number of event notification configurations that you can create per bucket, see [Amazon S3 service quotas](#) in *AWS General Reference*.

For more information about event notifications, see the following sections.

Topics

- [Event notification types and destinations](#)
- [Using Amazon SQS, Amazon SNS, and Lambda](#)
- [Using EventBridge](#)

Event notification types and destinations

Amazon S3 supports several event notification types and destinations where the notifications can be published. You can specify the event type and destination when configuring your event

notifications. Only one destination can be specified for each event notification. Amazon S3 event notifications send one event entry for each notification message.

Topics

- [Supported event destinations](#)
- [Supported event types for SQS, SNS, and Lambda](#)
- [Supported event types for Amazon EventBridge](#)
- [Event ordering and duplicate events](#)

Supported event destinations

Amazon S3 can send event notification messages to the following destinations.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda
- Amazon EventBridge

However, only one destination type can be specified for each event notification.

Note

You must grant Amazon S3 permissions to post messages to an Amazon SNS topic or an Amazon SQS queue. You must also grant Amazon S3 permission to invoke an AWS Lambda function on your behalf. For instructions on how to grant these permissions, see [Granting permissions to publish event notification messages to a destination](#).

Amazon SNS topic

Amazon SNS is a flexible, fully managed push messaging service. You can use this service to push messages to mobile devices or distributed services. With SNS, you can publish a message once, and deliver it one or more times. Currently, Standard SNS is only allowed as an S3 event notification destination, whereas SNS FIFO is not allowed.

Amazon SNS both coordinates and manages sending and delivering messages to subscribing endpoints or clients. You can use the Amazon SNS console to create an Amazon SNS topic that your notifications can be sent to.

The topic must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SNS topic, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide* and the [Amazon SNS FAQ](#).

Before you can use the Amazon SNS topic that you created as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SNS topic
- A valid Amazon SNS topic subscription. With it, topic subscribers are notified when a message is published to your Amazon SNS topic.

Amazon SQS queue

Amazon SQS offers reliable and scalable hosted queues for storing messages as they travel between computers. You can use Amazon SQS to transmit any volume of data without requiring other services to be always available. You can use the Amazon SQS console to create an Amazon SQS queue that your notifications can be sent to.

The Amazon SQS queue must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SQS queue, see [What is Amazon Simple Queue Service](#) and [Getting started with Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.

Before you can use the Amazon SQS queue as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SQS queue

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Lambda function

You can use AWS Lambda to extend other AWS services with custom logic, or create your own backend that operates at AWS scale, performance, and security. With Lambda, you can create discrete, event-driven applications that run only when needed. You can also use it to scale these applications automatically from a few requests a day to thousands a second.

Lambda can run custom code in response to Amazon S3 bucket events. You upload your custom code to Lambda and create what's called a Lambda function. When Amazon S3 detects an event of a specific type, it can publish the event to AWS Lambda and invoke your function in Lambda. In response, Lambda runs your function. One event type it might detect, for example, is an object created event.

You can use the AWS Lambda console to create a Lambda function that uses the AWS infrastructure to run the code on your behalf. The Lambda function must be in the same Region as your S3 bucket. You must also have the name or the ARN of a Lambda function to set up the Lambda function as an event notification destination.

Warning

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.

For more information and an example of using Amazon S3 notifications with AWS Lambda, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Amazon EventBridge

Amazon EventBridge is a serverless event bus, which receives events from AWS services. You can set up rules to match events and deliver them to targets, such as an AWS service or an HTTP endpoint. For more information, see [What is EventBridge](#) in the *Amazon EventBridge User Guide*.

Unlike other destinations, you can either enable or disable events to be delivered to EventBridge for a bucket. If you enable delivery, all events are sent to EventBridge. Moreover, you can use EventBridge rules to route events to additional targets.

Supported event types for SQS, SNS, and Lambda

Amazon S3 can publish events of the following types. You specify these event types in the notification configuration.

Event types	Description
s3:TestEvent	<p>When a notification is enabled, Amazon S3 publishes a test notification. This is to ensure that the topic exists and that the bucket owner has permission to publish the specified topic.</p> <p>If enabling the notification fails, you don't receive a test notification.</p>
s3:ObjectCreated:*	<p>Amazon S3 API operations such as PUT, POST, and COPY can create an object. With these event types, you can enable notifications when an object is created using a specific API operation. Alternatively, you can use the s3:ObjectCreated: * event type to request notification regardless of the API that was used to create an object.</p> <p>s3:ObjectCreated:CompleteMultipartUpload includes objects that are created using UploadPartCopy for Copy operations.</p>
s3:ObjectRemoved:*	<p>By using the ObjectRemoved event types, you can enable notification when an object or a batch of objects is removed from a bucket.</p> <p>You can request notification when an object is deleted or a versioned object is permanently deleted by using the s3:ObjectRemoved:Delete event type. Alternatively, you can request notification when a delete marker is created for a versioned object using s3:ObjectRemoved:DeleteMarkerCreated. For instructions on how to delete versioned objects, see Deleting</p>

Event types	Description
	<p>object versions from a versioning-enabled bucket. You can also use a wildcard <code>s3:ObjectRemoved:*</code> to request notification anytime an object is deleted.</p> <p>These event notifications don't alert you for automatic deletes from lifecycle configurations or from failed operations.</p>
<code>s3:ObjectRestore:*</code> <code>s3:ObjectRestore:Post</code> <code>s3:ObjectRestore:Completed</code> <code>s3:ObjectRestore:Delete</code>	<p>By using the <code>ObjectRestore</code> event types, you can receive notifications for event initiation and completion when restoring objects from the S3 Glacier Flexible Retrieval storage class, S3 Glacier Deep Archive storage class, S3 Intelligent-Tiering Archive Access tier, and S3 Intelligent-Tiering Deep Archive Access tier. You can also receive notifications for when the restored copy of an object expires.</p> <p>The <code>s3:ObjectRestore:Post</code> event type notifies you of object restoration initiation. The <code>s3:ObjectRestore:Completed</code> event type notifies you of restoration completion. The <code>s3:ObjectRestore:Delete</code> event type notifies you when the temporary copy of a restored object expires.</p>
<code>s3:ReducedRedundancyLostObject</code>	You receive this notification event when Amazon S3 detects that an object of the RRS storage class is lost.

Event types	Description
<p>s3:Replication:*</p> <p>s3:Replication:OperationFailedReplication</p> <p>s3:Replication:OperationMissedThreshold</p> <p>s3:Replication:OperationReplicatedAfterThreshold</p> <p>s3:Replication:OperationNotTracked</p>	<p>By using the Replication event types, you can receive notifications for replication configurations that have S3 Replication metrics or S3 Replication Time Control (S3 RTC) enabled. You can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For information about replication metrics, see Monitoring replication with metrics, event notifications, and statuses.</p> <ul style="list-style-type: none">The s3:Replication:OperationFailedReplication event type notifies you when an object that was eligible for replication failed to replicate.The s3:Replication:OperationMissedThreshold event type notifies you when an object that was eligible for replication that uses S3 RTC exceeds the 15-minute threshold for replication.The s3:Replication:OperationReplicatedAfterThreshold event type notifies you when an object that was eligible for replication that uses S3 RTC replicates after the 15-minute threshold.The s3:Replication:OperationNotTracked event type notifies you when an object that was eligible for live replication (either Same-Region Replication [SRR] or Cross-Region Replication [CRR]) is no longer being tracked by replication metrics.

Event types	Description
<p>s3:LifecycleExpiration:*</p> <p>s3:LifecycleExpiration:Delete</p> <p>s3:LifecycleExpiration:DeleteMarkerCreated</p>	<p>By using the LifecycleExpiration event types, you can receive a notification when Amazon S3 deletes an object based on your S3 Lifecycle configuration.</p> <p>The s3:LifecycleExpiration:Delete event type notifies you when an object in an unversioned bucket is deleted. It also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration.</p> <p>The s3:LifecycleExpiration:DeleteMarkerCreated event type notifies you when S3 Lifecycle creates a delete marker when a current version of an object in versioned bucket is deleted.</p>
<p>s3:LifecycleTransition</p>	<p>You receive this notification event when an object is transitioned to another Amazon S3 storage class by an S3 Lifecycle configuration.</p>
<p>s3:IntelligentTiering</p>	<p>You receive this notification event when an object within the S3 Intelligent-Tiering storage class moved to the Archive Access tier or Deep Archive Access tier.</p>
<p>s3:ObjectTagging:*</p> <p>s3:ObjectTagging:Put</p> <p>s3:ObjectTagging:Delete</p>	<p>By using the ObjectTagging event types, you can enable notification when an object tag is added or deleted from an object.</p> <p>The s3:ObjectTagging:Put event type notifies you when a tag is PUT on an object or an existing tag is updated. The s3:ObjectTagging:Delete event type notifies you when a tag is removed from an object.</p>
<p>s3:ObjectAcl:Put</p>	<p>You receive this notification event when an ACL is PUT on an object or when an existing ACL is changed. An event is not generated when a request results in no change to an object's ACL.</p>

Supported event types for Amazon EventBridge

For a list of event types Amazon S3 will send to Amazon EventBridge, see [Using EventBridge](#).

Event ordering and duplicate events

Amazon S3 Event Notifications is designed to deliver notifications at least once, but they aren't guaranteed to arrive in the same order that the events occurred. On rare occasions, Amazon S3's retry mechanism might cause duplicate S3 Event Notifications for the same object event. For more about handling duplicate or out of order events, see [Manage event ordering and duplicate events with Amazon S3 Event Notifications](#) on the [AWS Storage Blog](#).

Using Amazon SQS, Amazon SNS, and Lambda

Enabling notifications is a bucket-level operation. You store notification configuration information in the *notification* subresource that's associated with a bucket. After you create or change the bucket notification configuration, it usually takes about five minutes for the changes to take effect. When the notification is first enabled, an s3:TestEvent occurs. You can use any of the following methods to manage notification configuration:

- **Using the Amazon S3 console** — You can use the console UI to set a notification configuration on a bucket without having to write any code. For more information, see [Enabling and configuring event notifications using the Amazon S3 console](#).
- **Programmatically using the AWS SDKs** — Internally, both the console and the SDKs call the Amazon S3 REST API to manage *notification* subresources that are associated with the bucket. For examples of notification configurations that use AWS SDK, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

 **Note**

You can also make the Amazon S3 REST API calls directly from your code. However, this can be cumbersome because to do so you must write code to authenticate your requests.

Regardless of the method that you use, Amazon S3 stores the notification configuration as XML in the *notification* subresource that's associated with a bucket. For information about bucket subresources, see [General purpose buckets configuration options](#).

Note

If you have multiple failed event notifications due to deleted destinations you may receive the **Unable to validate the following destination configurations** when trying to delete them. You can resolve this in the S3 console by deleting all the failed notifications at the same time.

Topics

- [Granting permissions to publish event notification messages to a destination](#)
- [Enabling and configuring event notifications using the Amazon S3 console](#)
- [Configuring event notifications programmatically](#)
- [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#)
- [Configuring event notifications using object key name filtering](#)
- [Event message structure](#)

Granting permissions to publish event notification messages to a destination

You must grant the Amazon S3 principal the necessary permissions to call the relevant API to publish messages to an SNS topic, an SQS queue, or a Lambda function. This is so that Amazon S3 can publish event notification messages to a destination.

To troubleshoot publishing event notification messages to a destination, see [Troubleshoot to publish Amazon S3 event notifications to an Amazon Simple Notification Service topic](#).

Topics

- [Granting permissions to invoke an AWS Lambda function](#)
- [Granting permissions to publish messages to an SNS topic or an SQS queue](#)

Granting permissions to invoke an AWS Lambda function

Amazon S3 publishes event messages to AWS Lambda by invoking a Lambda function and providing the event message as an argument.

When you use the Amazon S3 console to configure event notifications on an Amazon S3 bucket for a Lambda function, the console sets up the necessary permissions on the Lambda function. This is

so that Amazon S3 has permissions to invoke the function from the bucket. For more information, see [Enabling and configuring event notifications using the Amazon S3 console](#).

You can also grant Amazon S3 permissions from AWS Lambda to invoke your Lambda function. For more information, see [Tutorial: Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Granting permissions to publish messages to an SNS topic or an SQS queue

To grant Amazon S3 permissions to publish messages to the SNS topic or SQS queue, attach an AWS Identity and Access Management (IAM) policy to the destination SNS topic or SQS queue.

For an example of how to attach a policy to an SNS topic or an SQS queue, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#). For more information about permissions, see the following topics:

- [Example cases for Amazon SNS access control in the Amazon Simple Notification Service Developer Guide](#)
- [Identity and access management in Amazon SQS in the Amazon Simple Queue Service Developer Guide](#)

IAM policy for a destination SNS topic

The following is an example of an AWS Identity and Access Management (IAM) policy that you attach to the destination SNS topic. For instructions on how to use this policy to set up a destination Amazon SNS topic for event notifications, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "Example SNS topic policy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            }  
        }  
    ]  
}
```

```
        },
        "Action": [
            "SNS:Publish"
        ],
        "Resource": "arn:aws:sns:us-east-1:11122223333:example-sns-topic",
        "Condition": {
            "ArnEquals": {
                "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
            },
            "StringEquals": {
                "aws:SourceAccount": "bucket-owner-account-id"
            }
        }
    ]
}
```

IAM policy for a destination SQS queue

The following is an example of an IAM policy that you attach to the destination SQS queue. For instructions on how to use this policy to set up a destination Amazon SQS queue for event notifications, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

To use this policy, you must update the Amazon SQS queue ARN, bucket name, and bucket owner's AWS account ID.

JSON

```
{
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "SQS:SendMessage"
            ],

```

```
"Resource": "arn:aws:sqs:us-east-1:111122223333:queue-name",
"Condition": {
    "ArnLike": {
        "aws:SourceArn": "arn:aws:s3::*:*:amzn-s3-demo-bucket"
    },
    "StringEquals": {
        "aws:SourceAccount": "bucket-owner-account-id"
    }
}
]
```

For both the Amazon SNS and Amazon SQS IAM policies, you can specify the `StringLike` condition in the policy instead of the `ArnLike` condition.

When `ArnLike` is used, the partition, service, account ID, resource type, and partial resource ID portions of the ARN must exactly match to the ARN in the request context. Only the Region and resource path allow partial matching.

When `StringLike` is used instead of `ArnLike`, matching ignores the ARN structure and allows partial matching, regardless of the portion that's replaced by the wildcard character. For more information, see [IAM JSON policy elements](#) in the *IAM User Guide*.

```
"Condition": {
    "StringLike": { "aws:SourceArn": "arn:aws:s3::*:*:amzn-s3-demo-bucket" }
}
```

AWS KMS key policy

If the SQS queue or SNS topics are encrypted with an AWS Key Management Service (AWS KMS) customer managed key, you must grant the Amazon S3 service principal permission to work with the encrypted topics or queue. To grant the Amazon S3 service principal permission, add the following statement to the key policy for the customer managed key.

JSON

```
{
    "Version": "2012-10-17",
```

```
"Id": "example-ID",
"Statement": [
    {
        "Sid": "example-statement-ID",
        "Effect": "Allow",
        "Principal": {
            "Service": "s3.amazonaws.com"
        },
        "Action": [
            "kms:GenerateDataKey",
            "kms:Decrypt"
        ],
        "Resource": "*"
    }
]
```

For more information about AWS KMS key policies, see [Using key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

For more information about using server-side encryption with AWS KMS for Amazon SQS and Amazon SNS, see the following:

- [Key management](#) in the *Amazon Simple Notification Service Developer Guide*.
- [Key management](#) in the *Amazon Simple Queue Service Developer Guide*.
- [Encrypting messages published to Amazon SNS with AWS KMS](#) in the *AWS Compute Blog*.

Enabling and configuring event notifications using the Amazon S3 console

You can enable certain Amazon S3 general purpose bucket events to send a notification message to a destination whenever those events occur. This section explains how to use the Amazon S3 console to enable event notifications. For information about how to use event notifications with the AWS SDKs and the Amazon S3 REST APIs, see [Configuring event notifications programmatically](#).

Prerequisites: Before you can enable event notifications for your bucket, you must set up one of the destination types and then configure permissions. For more information, see [Supported event destinations](#) and [Granting permissions to publish event notification messages to a destination](#).

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Topics

- [Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console](#)

Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console**To enable and configure event notifications for an S3 bucket**

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable events for.
4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and choose **Create event notification**.
6. In the **General configuration** section, specify descriptive event name for your event notification. Optionally, you can also specify a prefix and a suffix to limit the notifications to objects with keys ending in the specified characters.
 - a. Enter a description for the **Event name**.
If you don't enter a name, a globally unique identifier (GUID) is generated and used for the name.

- b. (Optional) To filter event notifications by prefix, enter a **Prefix**.
For example, you can set up a prefix filter so that you receive notifications only when files are added to a specific folder (for example, `images/`).
 - c. (Optional) To filter event notifications by suffix, enter a **Suffix**.

For more information, see [Configuring event notifications using object key name filtering](#).

7. In the **Event types** section, select one or more event types that you want to receive notifications for.

For a list of the different event types, see [Supported event types for SQS, SNS, and Lambda](#).

8. In the **Destination** section, choose the event notification destination.

 **Note**

Before you can publish event notifications, you must grant the Amazon S3 principal the necessary permissions to call the relevant API. This is so that it can publish notifications to a Lambda function, SNS topic, or SQS queue.

- a. Select the destination type: **Lambda Function**, **SNS Topic**, or **SQS Queue**.
- b. After you choose your destination type, choose a function, topic, or queue from the list.
- c. Or, if you prefer to specify an Amazon Resource Name (ARN), select **Enter ARN** and enter the ARN.

For more information, see [Supported event destinations](#).

9. Choose **Save changes**, and Amazon S3 sends a test message to the event notification destination.

Configuring event notifications programmatically

By default, notifications aren't enabled for any type of event. Therefore, the *notification* subresource initially stores an empty configuration.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</NotificationConfiguration>
```

To enable notifications for events of specific types, you replace the XML with the appropriate configuration that identifies the event types you want Amazon S3 to publish and the destination where you want the events published. For each destination, you add a corresponding XML configuration.

To publish event messages to an SQS queue

To set an SQS queue as the notification destination for one or more event types, add the QueueConfiguration.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>optional-id-string</Id>
    <Queue>sqs-queue-arn</Queue>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </QueueConfiguration>
  ...
</NotificationConfiguration>
```

To publish event messages to an SNS topic

To set an SNS topic as the notification destination for specific event types, add the TopicConfiguration.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Id>optional-id-string</Id>
    <Topic>sns-topic-arn</Topic>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </TopicConfiguration>
  ...
</NotificationConfiguration>
```

To invoke the AWS Lambda function and provide an event message as an argument

To set a Lambda function as the notification destination for specific event types, add the CloudFunctionConfiguration.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
    <Id>optional-id-string</Id>
    <CloudFunction>cloud-function-arn</CloudFunction>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </CloudFunctionConfiguration>
</NotificationConfiguration>
```

```
</CloudFunctionConfiguration>  
...  
</NotificationConfiguration>
```

To remove all notifications configured on a bucket

To remove all notifications configured on a bucket, save an empty `<NotificationConfiguration/>` element in the *notification* subresource.

When Amazon S3 detects an event of the specific type, it publishes a message with the event information. For more information, see [Event message structure](#).

For more information about configuring event notifications, see the following topics:

- [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).
- [Configuring event notifications using object key name filtering](#)

Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue)

You can receive Amazon S3 notifications using Amazon Simple Notification Service (Amazon SNS) or Amazon Simple Queue Service (Amazon SQS). In this walkthrough, you add a notification configuration to your bucket using an Amazon SNS topic and an Amazon SQS queue.

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Topics

- [Walkthrough summary](#)
- [Step 1: Create an Amazon SQS queue](#)
- [Step 2: Create an Amazon SNS topic](#)
- [Step 3: Add a notification configuration to your bucket](#)
- [Step 4: Test the setup](#)

Walkthrough summary

This walkthrough helps you do the following:

- Publish events of the s3:ObjectCreated:* type to an Amazon SQS queue.
- Publish events of the s3:ReducedRedundancyLostObject type to an Amazon SNS topic.

For information about notification configuration, see [Using Amazon SQS, Amazon SNS, and Lambda](#).

You can do all these steps using the console, without writing any code. In addition, code examples using AWS SDKs for Java and .NET are also provided to help you add notification configurations programmatically.

The procedure includes the following steps:

1. Create an Amazon SQS queue.

Using the Amazon SQS console, create an SQS queue. You can access any messages Amazon S3 sends to the queue programmatically. But, for this walkthrough, you verify notification messages in the console.

You attach an access policy to the queue to grant Amazon S3 permission to post messages.

2. Create an Amazon SNS topic.

Using the Amazon SNS console, create an SNS topic and subscribe to the topic. That way, any events posted to it are delivered to you. You specify email as the communications protocol. After you create a topic, Amazon SNS sends an email. You use the link in the email to confirm the topic subscription.

You attach an access policy to the topic to grant Amazon S3 permission to post messages.

3. Add notification configuration to a bucket.

Step 1: Create an Amazon SQS queue

Follow the steps to create and subscribe to an Amazon Simple Queue Service (Amazon SQS) queue.

1. Using the Amazon SQS console, create a queue. For instructions, see [Getting Started with Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.

2. Replace the access policy that's attached to the queue with the following policy.
 - a. In the Amazon SQS console, in the **Queues** list, choose the queue name.
 - b. On the **Access policy** tab, choose **Edit**.
 - c. Replace the access policy that's attached to the queue. In it, provide your Amazon SQS ARN, source bucket name, and bucket owner account ID.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "SQS:SendMessage"  
            ],  
            "Resource": "arn:aws:sqs:us-west-2:111122223333:s3-  
notification-queue",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::*::awsexamplebucket1"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "bucket-owner-account-id"  
                }  
            }  
        }  
    ]  
}
```

- d. Choose **Save**.
3. (Optional) If the Amazon SQS queue or the Amazon SNS topic is server-side encryption enabled with AWS Key Management Service (AWS KMS), add the following policy to the associated symmetric encryption customer managed key.

You must add the policy to a customer managed key because you cannot modify the AWS managed key for Amazon SQS or Amazon SNS.

JSON

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "kms:GenerateDataKey",  
                "kms:Decrypt"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

For more information about using SSE for Amazon SQS and Amazon SNS with AWS KMS, see the following:

- [Key management in the Amazon Simple Notification Service Developer Guide](#).
- [Key management in the Amazon Simple Queue Service Developer Guide](#).

4. Note the queue ARN.

The SQS queue that you created is another resource in your AWS account. It has a unique Amazon Resource Name (ARN). You need this ARN in the next step. The ARN is of the following format:

```
arn:aws:sqs:aws-region:account-id:queue-name
```

Step 2: Create an Amazon SNS topic

Follow the steps to create and subscribe to an Amazon SNS topic.

1. Using Amazon SNS console, create a topic. For instructions, see [Creating an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.
2. Subscribe to the topic. For this exercise, use email as the communications protocol. For instructions, see [Subscribing to an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.

You get an email requesting you to confirm your subscription to the topic. Confirm the subscription.

3. Replace the access policy attached to the topic with the following policy. In it, provide your SNS topic ARN, bucket name, and bucket owner's account ID.
4. Note the topic ARN.

The SNS topic you created is another resource in your AWS account, and it has a unique ARN. You will need this ARN in the next step. The ARN will be of the following format:

```
arn:aws:sns:aws-region:account-id:topic-name
```

Step 3: Add a notification configuration to your bucket

You can enable bucket notifications either by using the Amazon S3 console or programmatically by using AWS SDKs. Choose any one of the options to configure notifications on your bucket. This section provides code examples using the AWS SDKs for Java and .NET.

Option A: Enable notifications on a bucket using the console

Using the Amazon S3 console, add a notification configuration requesting Amazon S3 to do the following:

- Publish events of the **All object create events** type to your Amazon SQS queue.
- Publish events of the **Object in RRS lost** type to your Amazon SNS topic.

After you save the notification configuration, Amazon S3 posts a test message, which you get via email.

For instructions, see [Enabling and configuring event notifications using the Amazon S3 console](#).

Option B: Enable notifications on a bucket using the AWS SDKs

.NET

The following C# code example provides a complete code listing that adds a notification configuration to a bucket. You must update the code and provide your bucket name and SNS topic ARN. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class EnableNotificationsTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string snsTopic = "*** SNS topic ARN ***";
        private const string sqsQueue = "*** SQS topic ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            EnableNotificationAsync().Wait();
        }

        static async Task EnableNotificationAsync()
        {
            try
            {
                PutBucketNotificationRequest request = new
PutBucketNotificationRequest
                {

```

```
        BucketName = bucketName
    };

    TopicConfiguration c = new TopicConfiguration
    {
        Events = new List<EventType> { EventType.ObjectCreatedCopy },
        Topic = snsTopic
    };
    request.TopicConfigurations = new List<TopicConfiguration>();
    request.TopicConfigurations.Add(c);
    request.QueueConfigurations = new List<QueueConfiguration>();
    request.QueueConfigurations.Add(new QueueConfiguration()
    {
        Events = new List<EventType> { EventType.ObjectCreatedPut },
        Queue = sqsQueue
    });
}

PutBucketNotificationResponse response = await
client.PutBucketNotificationAsync(request);
}
catch (AmazonS3Exception e)
{
    Console.WriteLine("Error encountered on server. Message:'{0}' ", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown error encountered on server. Message:'{0}' ", e.Message);
}
}
```

Java

For examples of how to configure bucket notifications with the AWS SDK for Java, see [Process S3 event notifications](#) in the *Amazon S3 API Reference*.

Step 4: Test the setup

Now, you can test the setup by uploading an object to your bucket and verifying the event notification in the Amazon SQS console. For instructions, see [Receiving a Message](#) in the *Amazon Simple Queue Service Developer Guide "Getting Started"* section.

Configuring event notifications using object key name filtering

When configuring an Amazon S3 event notification, you must specify which supported Amazon S3 event types cause Amazon S3 to send the notification. If an event type that you didn't specify occurs in your S3 bucket, Amazon S3 doesn't send the notification.

You can configure notifications to be filtered by the prefix and suffix of the key name of objects. For example, you can set up a configuration where you're sent a notification only when image files with a ".jpg" file name extension are added to a bucket. Or, you can have a configuration that delivers a notification to an Amazon SNS topic when an object with the prefix "images/" is added to the bucket, while having notifications for objects with a "logs/" prefix in the same bucket delivered to an AWS Lambda function.

Note

A wildcard character ("*") can't be used in filters as a prefix or suffix. If your prefix or suffix contains a space, you must replace it with the "+" character. If you use any other special characters in the value of the prefix or suffix, you must enter them in [URL-encoded \(percent-encoded\) format](#). For a complete list of special characters that must be converted to URL-encoded format when used in a prefix or suffix for event notifications, see [Safe characters](#).

You can set up notification configurations that use object key name filtering in the Amazon S3 console. You can do so by using Amazon S3 APIs through the AWS SDKs or the REST APIs directly. For information about using the console UI to set a notification configuration on a bucket, see [Enabling and configuring event notifications using the Amazon S3 console](#).

Amazon S3 stores the notification configuration as XML in the *notification* subresource associated with a bucket as described in [Using Amazon SQS, Amazon SNS, and Lambda](#). You use the Filter XML structure to define the rules for notifications to be filtered by the prefix or suffix of an object key name. For information about the Filter XML structure, see [PUT Bucket notification](#) in the *Amazon Simple Storage Service API Reference*.

Notification configurations that use `Filter` cannot define filtering rules with overlapping prefixes, overlapping suffixes, or prefix and suffix overlapping. The following sections have examples of valid notification configurations with object key name filtering. They also contain examples of notification configurations that are not valid because of prefix and suffix overlapping.

Topics

- [Examples of valid notification configurations with object key name filtering](#)
- [Examples of notification configurations with invalid prefix and suffix overlapping](#)

Examples of valid notification configurations with object key name filtering

The following notification configuration contains a queue configuration identifying an Amazon SQS queue for Amazon S3 to publish events to of the `s3:ObjectCreated:Put` type. The events are published whenever an object that has a prefix of `images/` and a `.jpg` suffix is PUT to a bucket.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>images/</Value>
        </FilterRule>
        <FilterRule>
          <Name>suffix</Name>
          <Value>.jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
    <Queue>arn:aws:sqs:us-west-2:44445556666:s3notificationqueue</Queue>
    <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping prefixes. The configuration defines that notifications for PUT requests in the `images/` folder go to queue-A, while notifications for PUT requests in the `logs/` folder go to queue-B.

```
<NotificationConfiguration>
```

```
<QueueConfiguration>
  <Id>1</Id>
  <Filter>
    <S3Key>
      <FilterRule>
        <Name>prefix</Name>
        <Value>images/</Value>
      </FilterRule>
    </S3Key>
  </Filter>
  <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-A</Queue>
  <Event>s3:ObjectCreated:Put</Event>
</QueueConfiguration>
<QueueConfiguration>
  <Id>2</Id>
  <Filter>
    <S3Key>
      <FilterRule>
        <Name>prefix</Name>
        <Value>logs/</Value>
      </FilterRule>
    </S3Key>
  </Filter>
  <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-B</Queue>
  <Event>s3:ObjectCreated:Put</Event>
</QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping suffixes. The configuration defines that all .jpg images newly added to the bucket are processed by Lambda cloud-function-A, and all newly added .png images are processed by cloud-function-B. The .png and .jpg suffixes aren't overlapping even though they have the same last letter. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can't end with both .png and .jpg, so the suffixes in the example configuration aren't overlapping suffixes.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>suffix</Name>
```

```
<Value>.jpg</Value>
</FilterRule>
</S3Key>
</Filter>
<CloudFunction>arn:aws:lambda:us-west-2:44445556666:cloud-function-A</
CloudFunction>
<Event>s3:ObjectCreated:Put</Event>
</CloudFunctionConfiguration>
<CloudFunctionConfiguration>
<Id>2</Id>
<Filter>
<S3Key>
<FilterRule>
<Name>suffix</Name>
<Value>.png</Value>
</FilterRule>
</S3Key>
</Filter>
<CloudFunction>arn:aws:lambda:us-west-2:44445556666:cloud-function-B</
CloudFunction>
<Event>s3:ObjectCreated:Put</Event>
</CloudFunctionConfiguration>
</NotificationConfiguration>
```

Your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes for the same event types. They can only do so, if the overlapping prefixes that are used with suffixes that don't overlap. The following example configuration shows how objects created with a common prefix but non-overlapping suffixes can be delivered to different destinations.

```
<NotificationConfiguration>

Examples of notification configurations with invalid prefix and suffix overlapping

For the most part, your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes, overlapping suffixes, or overlapping combinations of prefixes and suffixes for the same event types. You can have overlapping prefixes as long as the suffixes don't overlap. For an example, see [Configuring event notifications using object key name filtering](#).

You can use overlapping object key name filters with different event types. For example, you can create a notification configuration that uses the prefix `image/` for the `ObjectCreated:Put` event type and the prefix `image/` for the `ObjectRemoved:*` event type.

You get an error if you try to save a notification configuration that has invalid overlapping name filters for the same event types when using the Amazon S3 console or API. This section shows examples of notification configurations that aren't valid because of overlapping name filters.

Any existing notification configuration rule is assumed to have a default prefix and suffix that match any other prefix and suffix, respectively. The following notification configuration isn't valid

because it has overlapping prefixes. Specifically, the root prefix overlaps with any other prefix. The same thing is true if you use a suffix instead of a prefix in this example. The root suffix overlaps with any other suffix.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:44445556666:sns-notification-one</Topic>
    <Event>s3:ObjectCreated:*</Event>
  </TopicConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:44445556666:sns-notification-two</Topic>
    <Event>s3:ObjectCreated:*</Event>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>images</Value>
        </FilterRule>
      </S3Key>
    </Filter>
  </TopicConfiguration>
</NotificationConfiguration>
```

The following notification configuration isn't valid because it has overlapping suffixes. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can end with jpg and pg. So, the suffixes overlap. The same is true for prefixes. If a given string can begin with both prefixes, the two prefixes are considered overlapping.

```

        </FilterRule>
      </S3Key>
    </Filter>
  </TopicConfiguration>
</NotificationConfiguration>
```

```
</TopicConfiguration>
</NotificationConfiguration>
```

Event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format.

For a general overview and instructions on configuring event notifications, see [Amazon S3 Event Notifications](#).

This example shows *version 2.1* of the event notification JSON structure. Amazon S3 uses *versions 2.1, 2.2, and 2.3* of this event structure. Amazon S3 uses version 2.2 for cross-Region replication event notifications. It uses version 2.3 for S3 Lifecycle, S3 Intelligent-Tiering, object ACL, object tagging, and object restoration delete events. These versions contain extra information specific to these operations. Versions 2.2 and 2.3 are otherwise compatible with version 2.1, which Amazon S3 currently uses for all other event notification types.

```
{
    "Records": [
        {
            "eventVersion": "2.1",
            "eventSource": "aws:s3",
            "awsRegion": "us-west-2",
            "eventTime": "The time, in ISO-8601 format (for example, 1970-01-01T00:00:00.000Z) when Amazon S3 finished processing the request",
            "eventName": "The event type",
            "userIdentity": {
                "principalId": "The unique ID of the IAM resource that caused the event"
            },
            "requestParameters": {
                "sourceIPAddress": "The IP address where the request came from"
            },
            "responseElements": {
                "x-amz-request-id": "The Amazon S3 generated request ID",
                "x-amz-id-2": "The Amazon S3 host that processed the request"
            },
            "s3": {
                "s3SchemaVersion": "1.0",
                "configurationId": "The ID found in the bucket notification configuration",
                "bucket": {
                    "name": "The name of the bucket, for example, amzn-s3-demo-bucket",
                    "ownerIdentity": {

```

```
        "principalId": "The Amazon retail customer ID of the bucket owner",
    },
    "arn": "The bucket Amazon Resource Name (ARN)",
},
"object": {
    "key": "The object key name",
    "size": "The object size in bytes (as a number)",
    "eTag": "The object entity tag (ETag)",
    "versionId": "The object version if the bucket is versioning-enabled; null or not present if the bucket isn't versioning-enabled",
    "sequencer": "A string representation of a hexadecimal value used to determine event sequence; only used with PUT and DELETE requests"
}
},
"glacierEventData": {
    "restoreEventData": {
        "lifecycleRestorationExpiryTime": "The time, in ISO-8601 format (for example, 1970-01-01T00:00:00.000Z), when the temporary copy of the restored object expires",
        "lifecycleRestoreStorageClass": "The source storage class for restored objects"
    }
}
]
}
```

Note the following about the event message structure:

- The eventVersion key value contains a major and minor version in the form *major.minor*.

The major version is incremented if Amazon S3 makes a change to the event structure that's not backward compatible. This includes removing a JSON field that's already present or changing how the contents of a field are represented (for example, a date format).

The minor version is incremented if Amazon S3 adds new fields to the event structure. This might occur if new information is provided for some or all existing events. This might also occur if new information is provided only for newly introduced event types. To stay compatible with new minor versions of the event structure, we recommend that your applications ignore new fields.

If new event types are introduced, but the structure of the event is otherwise unmodified, the event version doesn't change.

To ensure that your applications can parse the event structure correctly, we recommend that you do an equal-to comparison on the major version number. To ensure that the fields that are expected by your application are present, we also recommend doing a greater-than-or-equal-to comparison on the minor version.

- The `eventName` key value references the list of [event notification types](#) but doesn't contain the `s3:` prefix.
- The `userIdentity` key value references the unique ID of the AWS Identity and Access Management (IAM) resource (a user, role, group, and so on) that caused the event. For a definition of each IAM identification prefix (for example, AIDA, AROA, AGPA) and information about how to get the unique identifier, see [Unique identifiers](#) in the *IAM User Guide*.
- The `responseElements` key value is useful if you want to trace a request by following up with AWS Support. Both `x-amz-request-id` and `x-amz-id-2` help Amazon S3 trace an individual request. These values are the same as those that Amazon S3 returns in the response to the request that initiates the events. Therefore, you can use these values to match the event to the request.
- The `s3` key value provides information about the bucket and object involved in the event. The object key name value is URL encoded. For example, `red flower.jpg` becomes `red +flower.jpg`. (Amazon S3 returns "application/x-www-form-urlencoded" as the content type in the response.)

The `ownerIdentity` key value corresponds to the Amazon retail (Amazon.com) customer ID of the bucket owner. This ID value is no longer used and is maintained only for backward compatibility.

- The `sequencer` key value provides a way to determine the sequence of events. Event notifications aren't guaranteed to arrive in the same order that the events occurred. However, notifications from events that create objects (PUT requests) and delete objects contain a `sequencer`. You can use this value to determine the order of events for a given object key.

If you compare the `sequencer` strings from two event notifications on the same object key, the event notification with the greater `sequencer` hexadecimal value is the event that occurred later. If you're using event notifications to maintain a separate database or index of your Amazon S3 objects, we recommend that you compare and store the `sequencer` values as you process each event notification.

Note the following:

- You can't use the sequencer key value to determine the order for events on different object keys.
- The sequencer strings can be of different lengths. So, to compare these values, first left-pad the shorter value with zeros, and then do a lexicographical comparison.
- The glacierEventData key value is only visible for s3:ObjectRestore:Completed events.
- The restoreEventData key value contains attributes that are related to your restore request.
- The replicationEventData key value is only visible for replication events.
- The intelligentTieringEventData key value is only visible for S3 Intelligent-Tiering events.
- The lifecycleEventData key value is only visible for S3 Lifecycle transition events.

Example messages

The following are examples of Amazon S3 event notification messages.

Amazon S3 test message

After you configure an event notification on a bucket, Amazon S3 sends the following test message.

```
{  
    "Service": "Amazon S3",  
    "Event": "s3:TestEvent",  
    "Time": "2014-10-13T15:57:02.089Z",  
    "Bucket": "amzn-s3-demo-bucket",  
    "RequestId": "5582815E1AEA5ADF",  
    "HostId": "8cLeGAmw098X5cv4Zkwcmo8vvZa3eH3eKxsPzbB9wrR+YstdA6Knx4Ip8EXAMPLE"  
}
```

Note

The s3:TestEvent message uses a different format than regular S3 event notifications. Unlike other event notifications that use the Records array structure shown earlier, the test event uses a simplified format with direct fields. When implementing event handling, ensure your code can distinguish between and properly handle both message formats.

Example message when an object is created using a PUT request

The following is an example of a message that Amazon S3 sends to publish an s3:ObjectCreated:Put event.

```
{  
  "Records": [  
    {  
      "eventVersion": "2.1",  
      "eventSource": "aws:s3",  
      "awsRegion": "us-west-2",  
      "eventTime": "1970-01-01T00:00:00.000Z",  
      "eventName": "ObjectCreated:Put",  
      "userIdentity": {  
        "principalId": "AIDAJDPLRKLG7UEXAMPLE"  
      },  
      "requestParameters": {  
        "sourceIPAddress": "172.16.0.1"  
      },  
      "responseElements": {  
        "x-amz-request-id": "C3D13FE58DE4C810",  
        "x-amz-id-2": "FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/  
JRWeUWerMUE5JgHvAN0jpD"  
      },  
      "s3": {  
        "s3SchemaVersion": "1.0",  
        "configurationId": "testConfigRule",  
        "bucket": {  
          "name": "amzn-s3-demo-bucket",  
          "ownerIdentity": {  
            "principalId": "A3NL1K0ZZKExample"  
          },  
          "arn": "arn:aws:s3:::amzn-s3-demo-bucket"  
        },  
        "object": {  
          "key": "HappyFace.jpg",  
          "size": 1024,  
          "eTag": "d41d8cd98f00b204e9800998ecf8427e",  
          "versionId": "096fKKXTRTt13on89fV0.nfljtsv6qko",  
          "sequencer": "0055AED6DCD90281E5"  
        }  
      }  
    }  
  ]
```

}

Using EventBridge

Amazon S3 can send events to Amazon EventBridge whenever certain events happen in your bucket. Unlike other destinations, you don't need to select which event types you want to deliver. After EventBridge is enabled, all events below are sent to EventBridge. You can use EventBridge rules to route events to additional targets. The following lists the events Amazon S3 sends to EventBridge.

Event type	Description
<i>Object Created</i>	<p>An object was created.</p> <p>The reason field in the event message structure indicates which S3 API was used to create the object: PutObject, POST Object, CopyObject, or CompleteMultipartUpload.</p>
<i>Object Deleted (DeleteObject)</i>	An object was deleted.
<i>Object Deleted (Lifecycle expiration)</i>	When an object is deleted using an S3 API call, the reason field is set to DeleteObject. When an object is deleted by an S3 Lifecycle expiration rule, the reason field is set to Lifecycle Expiration. For more information, see Expiring objects .
	When an unversioned object is deleted, or a versioned object is permanently deleted, the deletion-type field is set to Permanently Deleted. When a delete marker is created for a versioned object, the deletion-type field is set to Delete Marker Created. For more information, see Deleting object versions from a versioning-enabled bucket .
<i>Object Restore Initiated</i>	An object restore was initiated from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class or from S3 Intelligent-Tiering Archive Access or Deep Archive

Event type	Description
	Access tier. For more information, see Working with archived objects .
<i>Object Restore Completed</i>	An object restore was completed.
<i>Object Restore Expired</i>	The temporary copy of an object restored from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive expired and was deleted.
<i>Object Storage Class Changed</i>	An object was transitioned to a different storage class. For more information, see Transitioning objects using Amazon S3 Lifecycle .
<i>Object Access Tier Changed</i>	An object was transitioned to the S3 Intelligent-Tiering Archive Access tier or Deep Archive Access tier. For more information, see Managing storage costs with Amazon S3 Intelligent-Tiering .
<i>Object ACL Updated</i>	An object's access control list (ACL) was set using <code>PutObjectAcl</code> . An event is not generated when a request results in no change to an object's ACL. For more information, see Access control list (ACL) overview .
<i>Object Tags Added</i>	A set of tags was added to an object using <code>PutObjectTagging</code> . For more information, see Categorizing your objects using tags .
<i>Object Tags Deleted</i>	All tags were removed from an object using <code>DeleteObjectTagging</code> . For more information, see Categorizing your objects using tags .

 **Note**

For more information about how Amazon S3 event types map to EventBridge event types, see [Amazon EventBridge mapping and troubleshooting](#).

You can use Amazon S3 Event Notifications with EventBridge to write rules that take actions when an event occurs in your bucket. For example, you can have it send you a notification. For more information, see [What is EventBridge?](#) in the *Amazon EventBridge User Guide*.

For more information about the actions and data types you can interact with using the EventBridge API, see the [Amazon EventBridge API Reference](#) in the *Amazon EventBridge API Reference*.

For information about pricing, see [Amazon EventBridge pricing](#).

Topics

- [Amazon EventBridge permissions](#)
- [Enabling Amazon EventBridge](#)
- [EventBridge event message structure](#)
- [Amazon EventBridge mapping and troubleshooting](#)

Amazon EventBridge permissions

Amazon S3 does not require any additional permissions to deliver events to Amazon EventBridge.

Enabling Amazon EventBridge

You can enable Amazon EventBridge by using the S3 console, AWS Command Line Interface (AWS CLI), or Amazon S3 REST API.

Note

After you enable EventBridge, it takes around five minutes for the changes to take effect.

Using the S3 console

To enable EventBridge event delivery in the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable events for.

4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and find the **Amazon EventBridge** subsection. Choose **Edit**.
6. Under **Send notifications to Amazon EventBridge for all events in this bucket** choose **On**.

Using the AWS CLI

The following example creates a bucket notification configuration for bucket *amzn-s3-demo-bucket1* with Amazon EventBridge enabled.

```
aws s3api put-bucket-notification-configuration --bucket amzn-s3-demo-bucket1 --  
notification-configuration='{"EventBridgeConfiguration": {} }'
```

Using the REST API

You can programmatically enable Amazon EventBridge on a bucket by calling the Amazon S3 REST API. For more information, see [PutBucketNotificationConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

The following example shows the XML used to create a bucket notification configuration with Amazon EventBridge enabled.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">  
  <EventBridgeConfiguration>  
  </EventBridgeConfiguration>  
</NotificationConfiguration>
```

Creating EventBridge rules

Once enabled you can create Amazon EventBridge rules for certain tasks. For example, you can send email notifications when an object is created. For a full tutorial, see [Tutorial: Send a notification when an Amazon S3 object is created](#) in the *Amazon EventBridge User Guide*.

EventBridge event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format. When Amazon S3 sends an event to Amazon EventBridge, the following fields are present.

- **version** – Currently 0 (zero) for all events.

- **id** – A UUID generated for every event.
 - **detail-type** – The type of event that's being sent. See [Using EventBridge](#) for a list of event types.
 - **source** – Identifies the service that generated the event.
 - **account** – The 12-digit AWS account ID of the bucket owner.
 - **time** – The time the event occurred.
 - **region** – Identifies the AWS Region of the bucket.
 - **resources** – A JSON array that contains the Amazon Resource Name (ARN) of the bucket.
 - **detail** – A JSON object that contains information about the event. For more information about what can be included in this field, see [Event message detail field](#).

Event message structure examples

The following are examples of some of the Amazon S3 event notification messages that can be sent to Amazon EventBridge.

Object created

```
"version-id": "IYV3p45BT0ac8hjHg1houSdS1a.Mro8e",

        "size": 5,
        "etag": "b1946ac92492d2347c6235b4d2611184",
        "version-id": "KKsjUC1.6gIjqtvhfg5AdMI0eCePIiT3"
    },
    "request-id": "189F19CB7FB1B6A4",
    "requester": "s3.amazonaws.com",
    "restore-expiry-time": "2021-11-13T00:00:00Z",
    "source-storage-class": "GLACIER"
}
}
```

Event message detail field

The detail field contains a JSON object with information about the event. The following fields may be present in the detail field.

- **version** – Currently 0 (zero) for all events.
- **bucket** – Information about the Amazon S3 bucket involved in the event.
- **object** – Information about the Amazon S3 object involved in the event.
- **request-id** – Request ID in S3 response.
- **requester** – AWS account ID or AWS service principal of requester.
- **source-ip-address** – Source IP address of S3 request. Only present for events triggered by an S3 request.
- **reason** – For **Object Created** events, the S3 API used to create the object: [PutObject](#), [POST Object](#), [CopyObject](#), or [CompleteMultipartUpload](#). For **Object Deleted** events, this is set to **DeleteObject** when an object is deleted by an S3 API call, or **Lifecycle Expiration** when an object is deleted by an S3 Lifecycle expiration rule. For more information, see [Expiring objects](#).
- **deletion-type** – For **Object Deleted** events, when an unversioned object is deleted, or a versioned object is permanently deleted, this is set to **Permanently Deleted**. When a delete

marker is created for a versioned object, this is set to **Delete Marker Created**. For more information, see [Deleting object versions from a versioning-enabled bucket](#).

 **Note**

Some object attributes (such as etag and size) are present only when a delete marker is created.

- `restore-expiry-time` – For **Object Restore Completed** events, the time when the temporary copy of the object will be deleted from S3. For more information, see [Working with archived objects](#).
- `source-storage-class` – For **Object Restore Initiated** and **Object Restore Completed** events, the storage class of the object being restored. For more information, see [Working with archived objects](#).
- `destination-storage-class` – For **Object Storage Class Changed** events, the new storage class of the object. For more information, see [Transitioning objects using Amazon S3 Lifecycle](#).
- `destination-access-tier` – For **Object Access Tier Changed** events, the new access tier of the object. For more information, see [Managing storage costs with Amazon S3 Intelligent-Tiering](#).

Amazon EventBridge mapping and troubleshooting

The following table describes how Amazon S3 event types are mapped to Amazon EventBridge event types.

S3 event type	Amazon EventBridge detail type
ObjectCreated:Put	Object Created
ObjectCreated:Post	
ObjectCreated:Copy	
ObjectCreated:CompleteMultiPartUpload	
ObjectRemoved:Delete	Object Deleted

S3 event type	Amazon EventBridge detail type
ObjectRemoved:DeleteMarkerCreated	
LifecycleExpiration:Delete	
LifecycleExpiration:DeleteMarkerCreated	
<u>ObjectRestore:Post</u>	Object Restore Initiated
ObjectRestore:Completed	Object Restore Completed
ObjectRestore:Delete	Object Restore Expired
LifecycleTransition	Object Storage Class Changed
IntelligentTiering	Object Access Tier Changed
<u>ObjectTagging:Put</u>	Object Tags Added
<u>ObjectTagging:Delete</u>	Object Tags Deleted
<u>ObjectAcl:Put</u>	Object ACL Updated

Amazon EventBridge troubleshooting

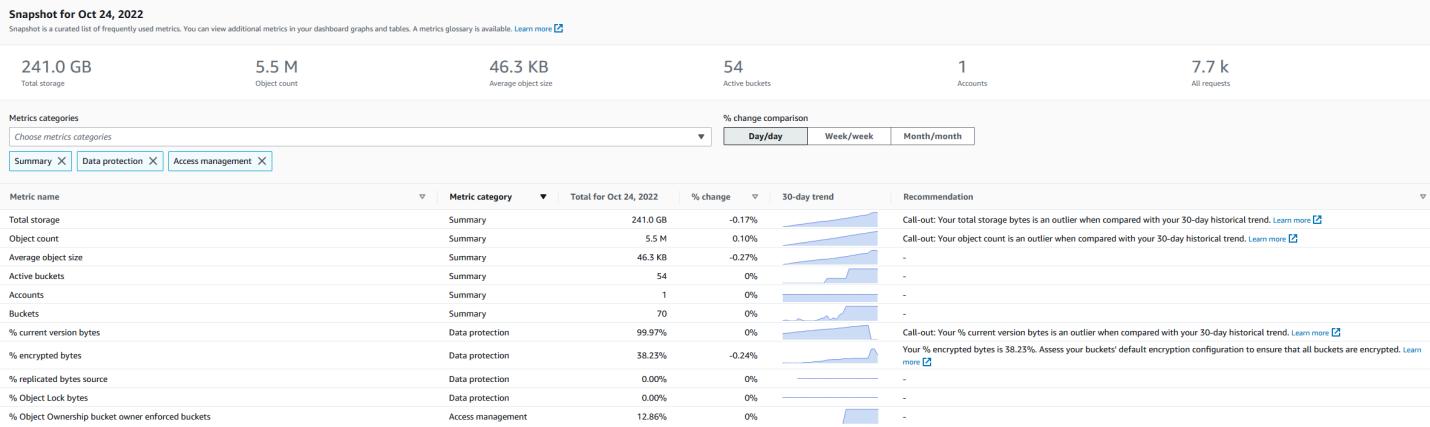

For information about how to troubleshoot EventBridge, see [Troubleshooting Amazon EventBridge](#) in the *Amazon EventBridge User Guide*.

Monitoring your storage activity and usage with Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object storage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

You can use S3 Storage Lens metrics to generate summary insights. For example, you can find out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost optimization opportunities, implement data protection and access management best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules set up to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data protection best practices, such as using S3 Replication or S3 Versioning.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

S3 Storage Lens metrics and features

S3 Storage Lens provides an interactive *default dashboard* that is updated daily. S3 Storage Lens preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. Metrics from this dashboard are also summarized in your account snapshot on the **Buckets** page. For more information, see [Default dashboard](#).

To create other dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations), you create an S3 Storage Lens dashboard configuration. You can create and manage S3 Storage Lens dashboard configurations by using the Amazon S3 console, AWS

Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

S3 Storage Lens offers free tier metrics and advanced tier metrics, which you can upgrade to for an additional charge. With the advanced tier, you can access additional metrics and features for gaining insight into your storage. These features include advanced metric categories, prefix aggregation, contextual recommendations, expanded prefixes metrics reports, and Amazon CloudWatch publishing. Prefix aggregation and contextual recommendations are available only in the Amazon S3 console. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

Metrics categories

Within the free and advanced tiers, metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to the advanced tier, you can enable advanced cost optimization and data protection metrics. You can use these advanced metrics to further reduce your S3 storage costs and improve your data protection stance. You can also enable activity metrics and detailed status-code metrics to improve the performance of application workloads that are accessing your S3 buckets. For more information about the free and advanced metrics categories, see [Metrics selection](#).

You can assess your storage based on S3 best practices, such as analyzing the percentage of your buckets that have encryption or S3 Object Lock or S3 Versioning enabled. You can also identify potential cost-savings opportunities. For example, you can use S3 Lifecycle rule count metrics to identify buckets that are missing lifecycle expiration or transition rules. You can also analyze your request activity per bucket to find buckets where objects could be transitioned to a lower-cost storage class. For more information, see [Amazon S3 Storage Lens metrics use cases](#).

Metrics export

Default metrics report

The default metrics report in S3 Storage Lens includes free metrics and advanced tier metrics covering object storage usage and activity trends across your AWS accounts. The report includes prefix aggregation for prefixes whose objects comprise at least 1% of the total data stored in the bucket, and supports up to 10 levels of prefix depth. The report can be exported daily in CSV or Parquet format to an S3 general purpose bucket. The report can also be sent to an AWS-managed S3 table bucket (with name aws-s3) making it easy to query using AWS analytics services or third-party tools.

With the default metrics report, you can identify cost optimization opportunities like buckets without S3 Lifecycle rules for incomplete multipart uploads and buckets not following data protection best practices such as S3 Replication or S3 Versioning. The default metrics report also provides contextual recommendations for optimizing storage costs and applying data protection best practices, at no additional charge beyond standard S3 storage costs.

Expanded prefixes metrics report

The Storage Lens expanded prefixes metrics report provides comprehensive prefix-level analytics across your entire S3 storage data, expanding coverage to support billions of prefixes in your bucket. This report delivers metrics for all prefixes in your buckets, including storage usage, bytes transferred, request counts by status code, and data protection compliance metrics, which you can export daily in CSV or Parquet format to S3 general purpose bucket. You can also export the metrics directly to the aws-s3 AWS-managed S3 table bucket.

Note

The report processes metrics for prefixes up to 50 levels deep and excludes prefix-level metrics for any bucket where the prefix and storage class combinations exceed twice the object count.

With the expanded prefixes metrics report, you can identify performance optimization opportunities, such as high error rates, small objects, or sub-optimal request patterns, across billions of prefixes in your bucket. Unlike the default metrics report, the expanded prefixes metrics report delivers metrics for granular prefixes in your bucket. For example, you can identify prefixes with large numbers of objects of size less than 128KB to quickly isolate such datasets for compaction that will improve application performance. This report is available in all AWS Regions as an opt-in feature in the Storage Lens advanced tier dashboard configuration.

Metrics publishing

Amazon CloudWatch publishing

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics.

The CloudWatch publishing option is available for dashboards that are upgraded to the S3 Storage Lens advanced tier. For more information about support for S3 Storage Lens metrics in CloudWatch, see [Monitor S3 Storage Lens metrics in CloudWatch](#).

For more information about using S3 Storage Lens, see the following topics.

Understanding Amazon S3 Storage Lens

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security

best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket. You can create and manage S3 Storage Lens dashboards by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

S3 Storage Lens concepts and terminology

This section contains the terminology and concepts that are essential for successfully understanding and using Amazon S3 Storage Lens.

Topics

- [Dashboard configuration](#)
- [Default dashboard](#)
- [Dashboards](#)
- [Account snapshot](#)
- [Metrics export](#)
- [Metrics export destinations](#)
- [Home Region](#)
- [Retention period](#)
- [Metrics categories](#)
- [Recommendations](#)
- [Metrics selection](#)

- [Prefix delimiter](#)
- [S3 Storage Lens and AWS Organizations](#)

Dashboard configuration

S3 Storage Lens requires a dashboard configuration that contains the properties required to aggregate metrics on your behalf for a single dashboard or export. When you create a configuration, you choose the dashboard name and the home Region, which you can't change after you create the dashboard. You can optionally add tags and configure a metrics export in CSV or Parquet format.

In the dashboard configuration, you also define the dashboard scope and the metrics selection. The scope can include all the storage for your organization account or sections that are filtered by Region, bucket, and account. When you configure the metrics selection, you choose between free tier metrics and advanced tier metrics, which you can upgrade to for an additional charge. With the advanced tier, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

Default dashboard

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. S3 preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from free tier metrics to advanced tier metrics. You can configure the optional metrics export or even disable the dashboard. However, you can't delete the default dashboard.

Note

If you disable your default dashboard, it's no longer updated. You'll no longer receive any new daily metrics in your S3 Storage Lens dashboard, your metrics export, or the account snapshot on the **S3 Buckets** page. If your dashboard uses advanced metrics, you'll no longer be charged. You can still see historic data in the dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics. To access historic data, you can re-enable the dashboard within the expiration period.

Dashboards

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations). When you create or edit a S3 Storage Lens dashboard, you define your dashboard scope and metrics selection. S3 Storage Lens offers free tier metrics and advanced tier metrics, which you can upgrade to for an additional charge. With advanced metrics, you can access additional metrics and features for gaining insight into your storage. These include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

You can also disable or delete dashboards. If you disable a dashboard, it's no longer updated, and you will no longer receive any new daily metrics. You can still see historic data until the 14-day expiration period. If you enabled advanced metrics for that dashboard, this period is 15 months. To access historic data, you can re-enable the dashboard within the expiration period.

If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

Note

- You can use S3 Storage Lens to create up to 50 dashboards per home Region.
- Organization-level dashboards can be limited only to a Regional scope.

Account snapshot

The S3 Storage Lens **Account snapshot** summarizes metrics from your default dashboard and displays your total storage, object count, and average object size on the S3 console **Buckets** page. This account snapshot gives you quick access to insights about your storage without having to leave the **Buckets** page. The account snapshot also provides one-click access to your interactive S3 Storage Lens dashboard.

You can use your dashboard to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate insights at the organization, account, bucket, object,

or prefix level. You can also send a once-daily metrics export to an S3 bucket in CSV or Parquet format.

You can't modify the dashboard scope of the **default-account dashboard** because it's linked to the **Account snapshot**. However, you can upgrade the metrics selection in your **default-account-dashboard** from free metrics to paid advanced metrics. After upgrading, you can then display all requests, bytes uploaded, and bytes downloaded in the S3 Storage Lens **Account snapshot**.

 **Note**

If you disable your default dashboard, your **Account snapshot** is no longer updated. To continue displaying metrics in the **Account snapshot**, you can re-enable the **default-account-dashboard**.

Metrics export

An S3 Storage Lens metrics export is a file that contains all the metrics identified in your S3 Storage Lens configuration. This information is generated daily in CSV or Parquet format and is sent to a general purpose S3 bucket. You can also export the metrics directly to the aws-s3 AWS-managed S3 table bucket making it easy to query using AWS analytics services or third-party tools. You can use the metrics export for further analysis by using the metrics tool of your choice. The bucket specified for your metrics export must be in the same Region as your S3 Storage Lens configuration. You can generate an S3 Storage Lens metrics export from the S3 console by editing your dashboard configuration. You can also configure a metrics export by using the AWS CLI and AWS SDKs.

There are two types of metric exports available in Storage Lens:

- **Default metrics report** – The default metrics report in S3 Storage Lens includes free metrics and activity trends across your AWS account and aggregates usage metrics for top prefixes.
- **Expanded prefixes metrics report** – The Storage Lens expanded prefixes metrics report provides granular storage and activity metrics (such as storage usage, bytes transferred, and request counts by status code) at the prefix level for every prefix in your bucket. This report is available as an opt-in feature in all AWS Regions, through the advanced pricing tier in your Storage Lens dashboard configuration. For information about S3 Storage Lens feature pricing, see [Amazon S3 pricing](#).

Note

Storage Lens only generates metrics for [S3 general purpose buckets](#).

Metrics export destinations

When exporting Storage Lens metrics data, you can choose both an S3 general purpose bucket or an S3 table bucket as your destination. General purpose buckets provide broad compatibility with existing tools and applications, offering flexibility to process data within your account, using your preferred analytics services. This option supports standard S3 access patterns and integrations for data analysis within individual buckets in your Region. In contrast, S3 table bucket lets you run immediate queries across multiple accounts and regions, create custom dashboards with Amazon Quick Suite, and join data with other AWS services or third-party tools, without the need for additional processing infrastructure. For example, you can combine Storage Lens metrics with S3 Metadata to analyze object activity patterns across your organization.

S3 general purpose bucket

Exporting Storage Lens metrics to an S3 general purpose bucket offers flexibility and continuity for storing your Storage Lens data. You can maintain existing workflows and operational consistency by continuing to use your current infrastructure and existing extract, transform, and load (ETL) processes, analytics tools, or automated workflows. General purpose buckets also work with the full range of AWS services and third-party tools that support standard S3 APIs. This gives you maximum flexibility in how you process, analyze, or visualize your Storage Lens insights. Additionally, you can implement S3 lifecycle policies to automatically manage data retention, transitioning older metrics to lower-cost storage classes or deleting them after specified periods to optimize costs. Therefore, if operational continuity and workflow flexibility are your priorities for Storage Lens implementation, then consider choosing an S3 general purpose bucket for exporting your Storage Lens data. For more information about S3 general purpose buckets pricing, see [Amazon S3 pricing](#).

S3 table bucket

When exporting Storage Lens metrics to S3 table bucket, you can easily analyze your storage usage and activity metrics without building data pipelines. Your metrics are organized in S3 Tables that are created in an AWS-managed S3 table bucket called aws-s3 for optimal query performance, with customizable retention periods and encryption settings to meet your data management

needs. With your metrics in S3 Tables, you can run queries across multiple accounts and Regions using SQL tools and AWS analytics services (like Amazon Athena, Amazon Quick Suite, Amazon EMR, and Amazon Redshift) to create custom dashboards and generate deeper insights. For example, you can join S3 Storage Lens metrics with S3 Metadata to identify objects in prefixes that aren't showing any recent activity. Any data stored in an S3 table bucket incurs S3 Tables costs. For more information about S3 Tables pricing, see [Amazon S3 pricing](#).

Permissions for metrics export to S3 Tables

To create and work with S3 Storage Lens tables and table buckets, you must have certain `s3tables` permissions. At a minimum, to configure S3 Storage Lens to S3 Tables, you must have the following `s3tables` permissions:

- `s3tables:CreateTableBucket` – This permission allows you to create an AWS-managed table bucket. All S3 Storage Lens metrics in your account are stored in a single AWS-managed table bucket named `aws-s3`.
- `s3tables:PutTableBucketPolicy` – S3 Storage Lens uses this permission to set a table bucket policy that allows `systemtables.s3.amazonaws.com` access to the bucket so that logs can be delivered.

Important

If you remove permissions for the service principal `systemtables.s3.amazonaws.com`, S3 Storage Lens will not be able to update the S3 tables with data based on your configuration. We recommend adding other access control policies in addition to the policy already provided, instead of editing the canned policy that is added when your table bucket is set up.

Note

A separate S3 table for each type of metric export is created for each Storage Lens configuration. If you have multiple Storage Lens configurations in the Region, separate tables are created for additional configurations. For example, there are three types of tables available for your S3 table bucket.

Home Region

The home Region is the AWS Region where all S3 Storage Lens metrics for a given dashboard configuration are stored. You must choose a home Region when you create your S3 Storage Lens dashboard configuration. After you choose a home Region, you can't change it. Also, if you're creating a Storage Lens group, we recommend that you choose the same home Region as your Storage Lens dashboard.

Note

You can choose one of the following Regions as your home Region:

- US East (N. Virginia) – us-east-1
- US East (Ohio) – us-east-2
- US West (N. California) – us-west-1
- US West (Oregon) – us-west-2
- Asia Pacific (Mumbai) – ap-south-1
- Asia Pacific (Seoul) – ap-northeast-2
- Asia Pacific (Singapore) – ap-southeast-1
- Asia Pacific (Sydney) – ap-southeast-2
- Asia Pacific (Tokyo) – ap-northeast-1
- Canada (Central) – ca-central-1
- China (Beijing) – cn-north-1
- China (Ningxia) – cn-northwest-1
- Europe (Frankfurt) – eu-central-1
- Europe (Ireland) – eu-west-1
- Europe (London) – eu-west-2
- Europe (Paris) – eu-west-3
- Europe (Stockholm) – eu-north-1
- South America (São Paulo) – sa-east-1

Retention period

S3 Storage Lens metrics are retained so that you can see historical trends and compare differences in your storage and activity over time. You can use Amazon S3 Storage Lens metrics for queries so that you can see historical trends and compare differences in your storage usage and activity over time.

All S3 Storage Lens metrics are retained for a period of 15 months. However, metrics are only available for queries for a specific duration, which depends on your [metrics selection](#). This duration can't be modified. Free metrics are available for queries for a 14-day period, and advanced metrics are available for queries for a 15-month period.

Metrics categories

Within the free and advanced tiers, S3 Storage Lens metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics, you can enable additional cost optimization and data protection metrics that you can use to further reduce your S3 storage costs and ensure your data is protected. You can also enable activity metrics and detailed status-code metrics that you can use to improve the performance of application workflows.

The following list shows all of the free and advanced metric categories. For a complete list of the individual metrics included in each category, see [Amazon S3 Storage Lens metrics glossary](#).

Summary metrics

Summary metrics provide general insights about your S3 storage, including your total storage bytes and object count.

Cost optimization metrics

Cost optimization metrics provide insights that you can use to manage and optimize your storage costs. For example, you can identify buckets that have incomplete multipart uploads that are more than 7-days old.

With advanced metrics, you can enable advanced cost optimization metrics. These metrics include S3 Lifecycle rule count metrics that you can use to get per-bucket expiration and transition S3 Lifecycle rule counts.

Data-protection metrics

Data-protection metrics provide insights for data protection features, such as encryption and S3 Versioning. You can use these metrics to identify buckets that are not following data protection best practices. For example, you can identify buckets that are not using default encryption with AWS Key Management Service keys (SSE-KMS) or S3 Versioning.

With advanced metrics, you can enable advanced data protection metrics. These metrics include per-bucket replication rule count metrics.

Access management metrics

Access management metrics provide insights for S3 Object Ownership. You can use these metrics to see which Object Ownership settings your buckets use.

Event metrics

Event metrics provide insights for S3 Event Notifications. With event metrics, you can see which buckets have S3 Event Notifications configured.

Performance metrics

Performance metrics provide insights for S3 Transfer Acceleration. With performance metrics, you can see which buckets have Transfer Acceleration enabled.

Activity metrics (advanced)

If you upgrade your dashboard to the **Advanced tier**, you can enable activity metrics. Activity metrics provide details about how your storage is requested (for example, all requests, Get requests, Put requests), bytes uploaded or downloaded, and errors.

Prefix-level activity metrics can be used to help you determine which prefixes are being used infrequently, so that you can [transition to a more optimal storage class using S3 Lifecycle](#).

Detailed status code metrics (advanced)

If you upgrade your dashboard to the **Advanced tier**, you can enable detailed status code metrics. Detailed status code metrics provide insights for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable, that you can use to troubleshoot access or performance issues. For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied.

Prefix-level detailed status code metrics can be used to gain a better understanding of the HTTP status code occurrences by prefix. For example, 503 error count metrics enable you to identify prefixes receiving throttling requests during data ingestion.

Advanced cost optimization metrics

Advanced cost optimization metrics provide detailed insights into your S3 lifecycle management configurations to help you optimize storage costs through automated data transitions and deletions. These metrics track the number of lifecycle rules configured across different lifecycle rule types. You can use these metrics to ensure comprehensive lifecycle rule coverage across your buckets and identify opportunities to implement additional cost optimization strategies through automated data management.

Advanced data protection metrics

Advanced data protection metrics help you protect your data by providing insights into replication rule counts, SSE-KMS encryption usage, and security vulnerabilities such as unsupported signature and TLS requests. (**Note:** Replication rule count metrics aren't available for prefixes.)

This visibility enables you to ensure proper data redundancy, validate encryption compliance, identify security risks from outdated protocols, troubleshoot replication misconfigurations, and maintain robust data protection strategies at the organization, account, and bucket levels.

Advanced performance metrics

Advanced performance metrics reveal how your applications interact with data in S3 and can help identify opportunities to optimize application performance such as inefficient I/O patterns, cross-region access, and unique object access count. Storage Lens advanced performance metrics eliminates the need for expensive custom monitoring tools and enables customers to implement S3 best practices more effectively, particularly benefiting performance sensitive applications such as machine learning training, data analytics, and other high-performance compute workloads.

Recommendations

S3 Storage Lens provides automated recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the S3 Storage Lens dashboard. Historical data is not eligible for recommendations because recommendations are relevant to what is happening in the most recent period. Recommendations appear only when they are relevant.

S3 Storage Lens recommendations come in the following forms:

- **Suggestions**

Suggestions alert you to trends within your storage and activity that might indicate a storage-cost optimization opportunity or a data protection best practice. You can use the suggested topics in the *Amazon S3 User Guide* and the S3 Storage Lens dashboard to drill down for more details about the specific Regions, buckets, or prefixes.

- **Call-outs**

Call-outs are recommendations that alert you to interesting anomalies within your storage and activity over a period that might need further attention or monitoring.

- **Outlier call-outs**

S3 Storage Lens provides call-outs for metrics that are outliers, based on your recent 30-day trend. The outlier is calculated by using a standard score, also known as a *z-score*. In this score, the current day's metric is subtracted from the average of the last 30 days for that metric. The current day's metric is then divided by the standard deviation for that metric over the last 30 days. The resulting score is usually between -3 and +3. This number represents the number of standard deviations that the current day's metric is from the mean.

S3 Storage Lens considers metrics with a score >2 or <-2 to be outliers because they are higher or lower than 95 percent of normally distributed data.

- **Significant change call-outs**

The significant change call-out applies to metrics that are expected to change less frequently. Therefore, it's set to a higher sensitivity than the outlier calculation, which is typically in the range of $+/- 20$ percent versus the prior day, week, or month.

Addressing call-outs in your storage and activity – If you receive a significant change call-out, it's not necessarily a problem. The call-out could be the result of an anticipated change in your storage. For example, you might have recently added a large number of new objects, deleted a large number of objects, or made similar planned changes.

If you see a significant change call-out on your dashboard, take note of it and determine whether it can be explained by recent circumstances. If not, use the S3 Storage Lens dashboard to drill down for more details to understand the specific Regions, buckets, or prefixes that are driving the fluctuation.

- **Reminders**

Reminders provide insights into how Amazon S3 works. They can help you learn more about ways to use S3 features to reduce storage costs or apply data protection best practices.

Metrics selection

S3 Storage Lens offers two metrics selections that you can choose for your dashboard and export: *free tier* and *advanced tier*.

- **Free tier**

S3 Storage Lens offers free metrics for all dashboards and configurations. Free metrics contain metrics that are relevant to your storage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics (for example, cost optimization and data protection metrics) that you can use to investigate whether your storage is configured according to S3 best practices. All free tier metrics are collected daily and can be exported to either an S3 general purpose bucket (CSV or Parquet format) or S3 table bucket (Parquet format only). Data is available for queries for 14 days in the Amazon S3 console. For more information about which metrics are available with free metrics, see the [Amazon S3 Storage Lens metrics glossary](#).

- **Advanced tier**

S3 Storage Lens offers free metrics for all dashboards and configurations with the option to upgrade to advanced metrics. Additional charges apply. For more information, see [Amazon S3 pricing](#).

Advanced tier metrics include all the metrics in free metrics along with additional metrics, such as advanced data protection and cost optimization metrics, activity metrics, and detailed status-code metrics. Advanced tier metrics also provide recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the dashboard.

Advanced tier includes the following features:

- **Advanced metrics categories** – Generate additional metrics. For a complete list of advanced metric categories, see [Metrics categories](#). For a complete list of metrics, see the [Amazon S3 Storage Lens metrics glossary](#).
- **Amazon CloudWatch publishing** – Publishes S3 Storage Lens metrics to CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). You can also use CloudWatch API operations and features, such as alarms and triggered actions, metric math,

and anomaly detection, to monitor and take action on S3 Storage Lens metrics. For more information, see [Monitor S3 Storage Lens metrics in CloudWatch](#).

- **Default metrics report** – The default metrics report in S3 Storage Lens includes free metrics and prefix aggregation capabilities for top prefixes for object storage usage and activity trends across your AWS accounts. With the default metrics report, you can identify cost optimization opportunities at no additional charge beyond standard S3 storage costs.
- **Expanded prefixes metrics report** – The Storage Lens expanded prefixes metrics report provides comprehensive prefix-level analytics across your entire S3 storage data, expanding coverage to support up to billions of prefixes per bucket.
- **Additional metrics aggregation**
 - **Prefix aggregation** – Collects metrics at the [prefix](#) level. This setting specifies the prefixes aggregated as part of the default metrics report, which is displayed in the Storage Lens dashboard. Note that metrics that are applicable at the prefix level are available with **Prefix aggregation**, except for bucket-level settings and rule count metrics. Prefix-level metrics don't apply to the expanded prefixes metrics export and aren't published to CloudWatch.
 - **Storage Lens group aggregation** – Collects metrics at the Storage Lens group level. After you enable the advanced tier metrics and Storage Lens group aggregation, you can specify which Storage Lens groups to include or exclude from your Storage Lens dashboard. At least one Storage Lens group must be specified. Storage Lens groups that are specified must also reside within the designated home Region in the dashboard account. Storage Lens group-level metrics are not published to CloudWatch.

All advanced metrics are collected daily. Data is available for querying for up to 15 months in the Amazon S3 console. For more information about the storage metrics that are aggregated by S3 Storage Lens, see [Amazon S3 Storage Lens metrics glossary](#).

Prefix delimiter

Prefix delimiters determine how Storage Lens counts prefix depth, by separating the hierarchical levels within object keys. You can only specify a single character to indicate each level within your prefixes. If the prefix delimiter is undefined, Amazon S3 uses "/" as the default delimiter.

Note

When you're updating your Storage Lens dashboard configuration via API, the *delimiter* and the updated *prefix delimiter* must be defined in the same way, or you'll receive an error.

The delimiter only applies to prefix-level metrics that are exported to the default metrics report. The prefix delimiter applies to all prefixes that are exported to the expanded prefixes metrics report.

S3 Storage Lens and AWS Organizations

AWS Organizations is an AWS service that helps you aggregate all of your AWS accounts under one organization hierarchy. Amazon S3 Storage Lens works with AWS Organizations to provide a single view of object storage and activity across your Amazon S3 storage.

For more information, see [Using Amazon S3 Storage Lens with AWS Organizations](#).

- **Trusted access**

Using your organization's management account, you must enable trusted access for S3 Storage Lens to aggregate storage metrics and usage data for all member accounts in your organization. You can then create dashboards or exports for your organization by using your management account or by giving delegated administrator access to other accounts in your organization.

You can disable trusted access for S3 Storage Lens at any time, which stops S3 Storage Lens from aggregating metrics for your organization.

- **Delegated administrator**

You can create dashboards and metrics for S3 Storage Lens for your organization by using your AWS Organizations management account, or by giving *delegated administrator* access to other accounts in your organization. You can deregister delegated administrators at any time. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

For more information, see [Amazon S3 Storage Lens and AWS Organizations](#) in the *AWS Organizations User Guide*.

Amazon S3 Storage Lens service-linked roles

Along with AWS Organizations trusted access, Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that's linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens

and include all the permissions that it requires to collect daily storage and activity metrics from member accounts in your organization.

For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

Amazon S3 Storage Lens metrics glossary

The Amazon S3 Storage Lens metrics glossary provides a complete list of free and advanced metrics for S3 Storage Lens.

S3 Storage Lens offers free metrics for all dashboards and configurations, with the option to upgrade to advanced metrics.

- **Free metrics** contain metrics that are relevant to your storage usage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics, such as cost-optimization and data-protection metrics. All free metrics are collected daily, and data is available for queries for up to 14 days.
- **Advanced metrics** include all the metrics in free metrics along with additional metrics, such as advanced performance, advanced data protection, and advanced cost optimization metrics. Advanced metrics also include additional metric categories, such as activity metrics and detailed status-code metrics. Advanced metrics data is available for queries for 15 months.

There are additional charges when you use S3 Storage Lens with advanced metrics and recommendations. For more information, see [Amazon S3 pricing](#). For more information about advanced metrics and recommendations features, see [Metrics selection](#).

 **Note**

For Storage Lens groups, only free tier storage metrics are available. Advanced tier metrics are not available at the Storage Lens group level.

Metric names

The **Metric name** column in the following table provides the name of each S3 Storage Lens in the S3 console. The **CloudWatch and export** column provides the name of each metric in Amazon CloudWatch and the metrics export file that you can configure in your S3 Storage Lens dashboard.

Derived metric formulas

Derived metrics are not available for the metrics export and the CloudWatch publishing option. However, you can use the metrics formulas shown in the **Derived metrics formula** column to compute them.

Interpreting the Amazon S3 Storage Lens prefix symbols for metrics unit multiples (K, M, G, and so on)

S3 Storage Lens metrics unit multiples are written with prefix symbols. These prefix symbols match the International System of Units (SI) symbols that are standardized by the International Bureau of Weights and Measures (BIPM). These symbols are also used in the Unified Code for Units of Measure (UCUM). For more information, see [List of SI prefix symbols](#).

Note

- The unit of measurement for S3 storage bytes is in binary gigabytes (GB), where 1 GB is 2^{30} bytes, 1 TB is 2^{40} bytes, and 1 PB is 2^{50} bytes. This unit of measurement is also known as a gibibyte (GiB), as defined by the International Electrotechnical Commission (IEC).
- When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. S3 Storage Lens doesn't include metrics for objects that have expired but haven't been removed. For more information about expiration actions in S3 Lifecycle, see [Expiring objects](#).
- Amazon S3 stores metadata (object key, timestamps, etc.) for every object, which requires minimum storage even for 0KB data files. This is why 0KB objects appear in the [0KB-128KB] size range in S3 Storage Lens.
- S3 Storage Lens provides best-effort tracking of cross-region data transfers, primarily focusing on requests from customer-managed resources like EC2 instances. Requests made through AWS PrivateLink or certain in-Region requests are unclassified.

The following table shows the S3 Storage Lens metrics glossary.

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Detailed metric form
Total storage	StorageBytes	Total storage, inclusive of incomplete multipart uploads, object metadata, and delete markers	Free	Sum	N	-
Object count	ObjectCount	Total object count	Free	Sum	N	-
Average object size	-	Average object size	Free	Sum	Y	$\text{sum(StorageBytes)}/\text{sum(ObjectCount)}$
Active buckets	-	Number of buckets with storage > 0 bytes	Free	Sum	Y	-
Buckets	-	Number of buckets	Free	Sum	Y	-
Accounts	-	Number of accounts whose storage is in scope	Free	Sum	Y	-
Current version bytes	CurrentVersionStorageBytes	Number of bytes that are a current version of an object	Free	Cost optimization	N	-
% current version bytes	-	Percentage of bytes in scope that are current	Free	Cost optimization	Y	$\text{sum(CurrentVersionStorageBytes)}/\text{sum(StorageBytes)}$

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
		versions of objects				tes)/sum(StorageBytes)	
Current version object count	CurrentVersionObjectCount	Number of current version objects	Free	Data protection	N	-	
% current version objects	-	Percentage of objects in scope that are a current version	Free	Cost optimization	Y	sum(CurrentVersionObjectCount)/sum(ObjectCount)	
Noncurrent version bytes	NonCurrentVersionStorageBytes	Number of noncurrent version bytes	Free	Cost optimization	N	-	
% noncurrent version bytes	-	Percentage of bytes in scope that are noncurrent versions	Free	Cost optimization	Y	sum(NonCurrentVersionStorageBytes)/sum(StorageBytes)	
Noncurrent version object count	NonCurrentVersionObjectCount	Number of the noncurrent object versions	Free	Cost optimization	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
% noncurrent version objects	-	Percentage of objects in scope that are a noncurrent version	Free	Cost optimization	Y	sum(NonCurrentVersionObjectCount)/sum(ObjectCount)	
Delete marker bytes	DeleteMarkerStorageBytes	Number of bytes in scope that are delete markers	Free	Cost optimization	N	-	
% delete marker bytes	-	Percentage of bytes in scope that are delete markers	Free	Cost optimization	Y	sum(DeleteMarkerStorageBytes)/sum(StorageBytes)	
Delete marker object count	DeleteMarkerObjectCount	Number of objects with a delete marker	Free	Cost optimization	N	-	
% delete marker objects	-	Percentage of objects in scope with a delete marker	Free	Cost optimization	Y	sum(DeleteMarkerObjectCount)/sum(ObjectCount)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
Incomplete multipart upload bytes	IncompleteMultipartUploadStorageBytes	Total bytes in scope for incomplete multipart uploads	Free	Cost optimization	N	-	
% incomplete multipart upload bytes	-	Percentage of bytes in scope that are the result of incomplete multipart uploads	Free	Cost optimization	Y	sum(IncompleteMultipartUploadStorageBytes)/sum(StorageBytes)	
Incomplete multipart upload object count	IncompleteMultipartUploadObjectCount	Number of objects in scope that are incomplete multipart uploads	Free	Cost optimization	N	-	
% incomplete multipart upload objects	-	Percentage of objects in scope that are incomplete multipart uploads	Free	Cost optimization	Y	sum(IncompleteMultipartUploadObjectCount)/sum(ObjectCount)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Incomplete multipart upload storage bytes greater than 7 days old	IncompleteMPUStorageBytesOlderThan7Days	Total bytes in scope for incomplete multipart uploads that are more than 7 days old	Free	Cost optimization	N	-	
% incomplete multipart upload storage bytes greater than 7 days old	-	Percentage of bytes for incomplete multipart uploads that are more than 7 days old	Free	Cost optimization	Y	sum(IncompleteMPUStorageBytesOlderThan7Days)/sum(StorageBytes)	
Incomplete multipart upload object count greater than 7 days old	IncompleteMPUObjectCountOlderThan7Days	Number of objects that are incomplete multipart uploads more than 7 days old	Free	Cost optimization	N	-	
% incomplete multipart upload object count greater than 7 days old	-	Percentage of objects that are incomplete multipart uploads more than 7 days old	Free	Cost optimization	Y	sum(IncompleteMPUObjectCountOlderThan7Days)/sum(ObjectCount)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Transition lifecycle rule count	TransitionLifecycleRuleCount	Number of lifecycle rules to transition objects to another storage class	Advanced	Cost optimization	No	-	
Average transition lifecycle rules per bucket	-	Average number of lifecycle rules to transition objects to another storage class	Advanced	Cost optimization	Yes	sum(TransitionLifecycleRuleCount)/sum(DistinctNumberOfBuckets)	
Expiration lifecycle rule count	ExpirationLifecycleRuleCount	Number of lifecycle rules to expire objects	Advanced	Cost optimization	No	-	
Average expiration lifecycle rules per bucket	-	Average number of lifecycle rules to expire objects	Advanced	Cost optimization	Yes	sum(ExpirationLifecycleRuleCount)/sum(DistinctNumberOfBuckets)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric form
Noncurrent version transition lifecycle rule count	NoncurrentVersionTransitionLifecycleRuleCount	Number of lifecycle rules to transition noncurrent object versions to another storage class	Advanced	Cost optimization	N	
Average noncurrent version transition lifecycle rules per bucket	-	Average number of lifecycle rules to transition noncurrent object versions to another storage class	Advanced	Cost optimization	Y	sum(NoncurrentVersionTransitionLifecycleRuleCount)/sum(Distinct NumberOfBuckets)
Noncurrent version expiration lifecycle rule count	NoncurrentVersionExpirationLifecycleRuleCount	Number of lifecycle rules to expire noncurrent object versions	Advanced	Cost optimization	N	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric form
Average noncurrent expiration lifecycle rules per bucket	-	Average number of lifecycle rules to expire noncurrent object versions	Advanced	Cost optimization	Y	sum(NoncurrentVersionExpirationLifecycleRuleCount)/sum(DistinctNumberOfBuckets)
Abort incomplete multipart upload lifecycle rule count	AbortIncompleteMPULifecycleRuleCount	Number of lifecycle rules to delete incomplete multipart uploads	Advanced	Cost optimization	N	-
Average abort incomplete multipart upload lifecycle rules per bucket	-	Average number of lifecycle rules to delete incomplete multipart uploads	Advanced	Cost optimization	Y	sum(AbortIncompleteMPULifecycleRuleCount)/sum(DistinctNumberOfBuckets)
Expired object delete marker lifecycle rule count	ExpiredObjectDeleteMarkerLifecycleRuleCount	Number of lifecycle rules to remove expired object delete markers	Advanced	Cost optimization	N	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Average expired object delete marker lifecycle rules per bucket	-	Average number of lifecycle rules to remove expired object delete markers	Advanced	Cost optimization	Y	sum(ExpiredObjectDeleteMarkerLifecycleRuleCount)/sum(DistinctNumberOfWorkers)	
Total lifecycle rule count	TotalLifecycleRuleCount	Number of lifecycle rules	Advanced	Cost optimization	N	-	
Average lifecycle rule count per bucket	-	Average number of lifecycle rules	Advanced	Cost optimization	Y	sum(TotalLifecycleRuleCount)/sum(DistinctNumberOfWorkers)	
Encrypted bytes	EncryptedStorageBytes	Number of encrypted bytes	Free	Data protection	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivation metric
% encrypted bytes	-	Percentage of total bytes that are encrypted	Free	Data protection	Y	$\text{sum}(\text{EncryptedObjectCount}) / \text{sum}(\text{StorageBytes})$
Encrypted object count	Encrypted ObjectCount	Number of objects that are encrypted	Free	Data protection	N	-
% encrypted objects	-	Percentage of objects that are encrypted	Free	Data protection	Y	$\text{sum}(\text{EncryptedStorageBytes}) / \text{sum}(\text{ObjectCount})$
Unencrypted bytes	UnencryptedStorageBytes	Number of bytes that are unencrypted	Free	Data protection	Y	$\text{sum}(\text{StorageBytes}) - \text{sum}(\text{EncryptedStorageBytes})$
% unencrypted bytes	-	Percentage of bytes that are unencrypted	Free	Data protection	Y	$\text{sum}(\text{UnencryptedStorageBytes}) / \text{sum}(\text{StorageBytes})$

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
Unencrypted object count	UnencryptedObjectCount	Number of objects that are unencrypted	Free	Data protection	Y	sum(ObjectCount)	- sum(EncryptedObjectCount)
% unencrypted objects	-	Percentage of unencrypted objects	Free	Data protection	Y	sum(UnencryptedObjectCount)	/ sum(ObjectCount)
Replicated storage bytes source	ReplicatedStorageBytesSource	Number of bytes that are replicated from the source bucket	Free	Data protection	N	-	
% replicated bytes source	-	Percentage of total bytes that are replicated from the source bucket	Free	Data protection	Y	sum(ReplicatedStorageBytesSource)	/ sum(StorageBytes)
Replicated object count source	ReplicatedObjectCountSource	Number of replicated objects from the source bucket	Free	Data protection	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
% replicated objects source	-	Percentage of total objects that are replicated from the source bucket	Free	Data protection	Y	sum(ReplicatedStorageObjectCount) / sum(ObjectCount)	
Replicated storage bytes destination	Replicate dStorageBytes	Number of bytes that are replicated to the destination bucket	Free	Data protection	N	-	
% replicated bytes destination	-	Percentage of total bytes that are replicated to the destination bucket	Free	Data protection	Y	sum(ReplicatedStorageBytes) / sum(StorageBytes)	
Replicated object count destination	Replicate dObjectCount	Number of objects that are replicated to the destination bucket	Free	Data protection	N	-	
% replicated objects destination	-	Percentage of total objects that are replicated to the destination bucket	Free	Data protection	Y	sum(ReplicatedObjectCount) / sum(ObjectCount)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Data type	Derivation	Metrics from
Object Lock bytes	ObjectLockEnabledStorageBytes	Number of Object Lock enabled storage bytes	Free	Data protection	N	sum(UnencryptedStorageBytes) / sum(ObjectLockEnabledStorageCount)	-
% Object Lock bytes	-	Percentage of Object Lock enabled storage bytes	Free	Data protection	Y	sum(ObjectLockEnabledStorageBytes) / sum(StorageBytes)	-
Object Lock object count	ObjectLockEnabledObjectCount	Number of Object Lock objects	Free	Data protection	N	-	-
% Object Lock objects	-	Percentage of total objects that have Object Lock enabled	Free	Data protection	Y	sum(ObjectLockEnabledObjectCount) / sum(ObjectCount)	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Versioning-enabled bucket count	VersioningEnabledBucketCount	Number of buckets that have S3 Versioning enabled	Free	Data protection	N	-	
% versioning-enabled buckets	-	Percentage of buckets that have S3 Versioning enabled	Free	Data protection	Y	sum(VersioningEnabledBucketCount)/sum(DistinctNumberOfBuckets)	
MFA delete-enabled bucket count	MFADeleteEnabledBucketCount	Number of buckets that have MFA (multi-factor authentication) delete enabled	Free	Data protection	N	-	
% MFA delete-enabled buckets	-	Percentage of buckets that have MFA (multi-factor authentication) delete enabled	Free	Data protection	Y	sum(MFADeleteEnabledBucketCount)/sum(DistinctNumberOfBuckets)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
SSE-KMS enabled bucket count	SSEKMSEnabledBucketCount	Number of buckets that use server-side encryption with AWS Key Management Service keys (SSE-KMS) for default bucket encryption	Free	Data protection	No	-	
% SSE-KMS enabled buckets	-	Percentage of buckets that SSE-KMS for default bucket encryption	Free	Data protection	Yes	$\text{sum}(\text{SSEKMSEnabledBucketCount}) / \text{sum}(\text{DistinctNumberOfBuckets})$	
All unsupported signature requests	AllUnsupportedSignatureRequests	Total number of requests that use unsupported AWS signature versions	Advanced protection	Data protection	No	-	
% all unsupported signature requests	-	Percentage of requests that use unsupported AWS signature versions	Advanced protection	Data protection	Yes	$\text{sum}(\text{AllUnsupportedSignatureRequests}) / \text{sum}(\text{AllRequests})$	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
All unsupported TLS requests	AllUnsupportedTLSRequests	Total number of requests that use unsupported Transport Layer Security (TLS) versions	Advanced	Data protection	No	-	
% all unsupported TLS requests	-	Percentage of requests that use unsupported TLS versions	Advanced	Data protection	Yes	$\text{sum}(\text{AllUnsupportedTLSRequests}) / \text{sum}(\text{AllRequests})$	
All SSE-KMS requests	AllSSEKMSRequests	Total number of requests that specify SSE-KMS	Advanced	Data protection	No	-	
% all SSE-KMS requests	-	Percentage of requests that specify SSE-KMS	Advanced	Data protection	Yes	$\text{sum}(\text{AllSSEKMSRequests}) / \text{sum}(\text{AllRequests})$	
Same-Region Replication rule count	SameRegionReplicationRuleCount	Number of replication rules for Same-Region Replication (SRR)	Advanced	Data protection	No	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Average Same-Region Replication rules per bucket	-	Average number of replication rules for SRR	Advanced	Data protection	Y	sum(SameRegionReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Cross-Region Replication rule count	CrossRegionReplicationRuleCount	Number of replication rules for Cross-Region Replication (CRR)	Advanced	Data protection	N	-	
Average Cross-Region Replication rules per bucket	-	Average number of replication rules for CRR	Advanced	Data protection	Y	sum(CrossRegionReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Same-account replication rule count	SameAccountReplicationRuleCount	Number of replication rules for replication within the same account	Advanced	Data protection	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Average same-account replication rules per bucket	-	Average number of replication rules for replication within the same account	Advanced	Data protection	Y	sum(SameAccountReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Cross-account replication rule count	CrossAccountReplicationRuleCount	Number of replication rules for cross-account replication	Advanced	Data protection	N	-	
Average cross-account replication rules per bucket	-	Average number of replication rules for cross-account replication	Advanced	Data protection	Y	sum(CrossAccountReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Invalid destination replication rule count	InvalidDestinationReplicationRuleCount	Number of replication rules with a replication destination that's not valid	Advanced	Data protection	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
Average invalid destination replication rules per bucket	-	Average number of replication rules with a replication destination that's not valid	Advanced	Data protection	Y	sum(InvalidReplicaCount)/sum(DistinctNumberOfBuckets)	
Total replication rule count	-	Total replication rule count	Advanced	Data protection	Y	-	
Average replication rule count per bucket	-	Average total replication rule count	Advanced	Data protection	Y	sum(all replication rule count metrics)/sum(DistinctNumberOfBuckets)	
Object Ownership bucket owner enforced bucket count	ObjectOwnershipBucketOwnerEnforcedBucketCount	Number of buckets that have access control lists (ACLs) disabled by using the bucket owner enforced setting for Object Ownership	Free	Access management	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derived metric	Definition
% Object Ownership bucket owner enforced buckets	-	Percentage of buckets that have ACLs disabled by using the bucket owner enforced setting for Object Ownership	Free	Access management	Y	sum(ObjectOwnershipBucketOwnerEnforcedBucketCount) / sum(DistinctNumberOfBuckets)	sum(DistinctNumberOfBuckets)
Object Ownership bucket owner preferred bucket count	ObjectOwnershipBucketOwnerPreferredBucketCount	Number of buckets that use the bucket owner preferred setting for Object Ownership	Free	Access management	N	-	-

500 Internal Server Error count	500InternalServerErrorCount	Number of 500 Internal Server Error status codes	Advanced	Detail	Number	-	-
% 500 Internal Server Errors	-	Number of 500 Internal Server Error status codes as a percentage of total requests	Advanced	Detail	Y	sum(500InternalServerErrorCount)/sum(AllRequests)	-
503 Service Unavailable error count	503ServiceUnavailableCount	Number of 503 Service Unavailable status codes	Advanced	Detail	Number	-	-
% 503 Service Unavailable errors	-	Number of 503 Service Unavailable status codes as a percentage of total requests	Advanced	Detail	Y	sum(503ServiceUnavailableCount)/sum(AllRequests)	-

¹ All free tier storage metrics are available at the Storage Lens group level. Advanced tier metrics are not available at the Storage Lens group level.

² Rule count metrics and bucket settings metrics aren't available at the prefix level.

The following table shows the performance metrics available in S3 Storage Lens and their availability in CloudWatch:

Met nan	CloudWatch and export	Description	Tier	Category	Derive	Derived metric formula
Ave Firs Byt Lat	AverageFirstByteLa tency	Average per-request time between when an Amazon S3 bucket receives a complete request and when it starts returning the response, measured over the past 24 hours	Advanced	Performance	N	-
Ave Tot Req Lat	AverageTotalReques tLatency	Average elapsed per-request time between the first byte received and the last byte sent to an Amazon S3 bucket, measured over the past 24 hours	Advanced	Performance	N	-

Metric name	CloudWatch and nan export	Description	Tier	Category	Derived	Derived metric formula
ReadOKBRequestCount*	ReadOKBRequestCount*	Number of GetObject requests with data sizes of 0KB, including both range-based requests and whole object requests	Advanced	Performance	N	-
ReadOKBTo128KBRequestCount*	ReadOKBTo128KBRequestCount*	Number of GetObject requests with data sizes greater than 0KB and up to 128KB, including both range-based requests and whole object requests	Advanced	Performance	N	-
Read128KBT0256KBRequestCount*	Read128KBT0256KBRequestCount*	Number of GetObject requests with data sizes greater than 128KB and up to 256KB, including both range-based requests and whole object requests	Advanced	Performance	N	-

Met nan	CloudWatch and export	Description	Tier	Category	Derived	Derived metric formula
Rea 256 to 512 req cou	Read256KB To512KBRequestCount*	Number of GetObject requests with data sizes greater than 256KB and up to 512KB, including both range-bas ed requests and whole object requests	Advanced	Performan ce	N	-
Rea 512 to 1MI req cou	Read512KB To1MBRequestCount*	Number of GetObject requests with data sizes greater than 512KB and up to 1MB, including both range-bas ed requests and whole object requests	Advanced	Performan ce	N	-

Met nan	CloudWatch and export	Description	Tier	Category	Derived	Derived metric formula
Rea 1MI to 2MI req cou	Read1MBTo 1MBRequestCount*	Number of GetObject requests with data sizes greater than 1MB and up to 2MB, including both range-bas ed requests and whole object requests	Advanced	Performan ce	N	-
Rea 2MI to 4MI req cou	Read2MBTo 2MBRequestCount*	Number of GetObject requests with data sizes greater than 2MB and up to 4MB, including both range-bas ed requests and whole object requests	Advanced	Performan ce	N	-

Met nan	CloudWatch and export	Description	Tier	Category	Derived	Derived metric formula
Rea 4MI to 8MI req cou	Read4MBTo 8MBRequestCount*	Number of GetObject requests with data sizes greater than 4MB and up to 8MB, including both range-bas ed requests and whole object requests	Advanced	Performan ce	N	-
Rea 8MI to 16M req cou	Read8MBTo 16MBRequestCount*	Number of GetObject requests with data sizes greater than 8MB and up to 16MB, including both range-bas ed requests and whole object requests	Advanced	Performan ce	N	-

Setting Amazon S3 Storage Lens permissions

Amazon S3 Storage Lens requires new permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to enable or disable S3 Storage Lens, or to access any S3 Storage Lens dashboard or configuration.

The IAM user or role must belong to the account that created or owns the dashboard or configuration, unless both of the following conditions are true:

- Your account is a member of AWS Organizations.
- You were given access to create organization-level dashboards by your management account as a delegated administrator.

Note

- You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required IAM permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see [Security best practices in IAM](#) in the *IAM User Guide*.
- Using S3 Storage Lens on the Amazon S3 console can require multiple permissions. For example, to edit a dashboard on the console, you need the following permissions:
 - `s3>ListStorageLensConfigurations`

- `s3:GetStorageLensConfiguration`
- `s3:PutStorageLensConfiguration`

Topics

- [Setting account permissions to use S3 Storage Lens](#)
- [Setting account permissions to use S3 Storage Lens groups](#)
- [Setting permissions to use S3 Storage Lens with AWS Organizations](#)

Setting account permissions to use S3 Storage Lens

To create and manage S3 Storage Lens dashboards and Storage Lens dashboard configurations, you must have the following permissions, depending on which actions you want to perform:

The following table shows Amazon S3 Storage Lens related IAM permissions.

Action	IAM permissions
Create or update an S3 Storage Lens dashboard in the Amazon S3 console.	<code>s3>ListStorageLensConfigurations</code> <code>s3:GetStorageLensConfiguration</code> <code>s3:GetStorageLensConfigurationTagging</code> <code>s3:PutStorageLensConfiguration</code> <code>s3:PutStorageLensConfigurationTagging</code>
Get the tags of an S3 Storage Lens dashboard on the Amazon S3 console.	<code>s3>ListStorageLensConfigurations</code> <code>s3:GetStorageLensConfigurationTagging</code>
View an S3 Storage Lens dashboard on the Amazon S3 console.	<code>s3>ListStorageLensConfigurations</code> <code>s3:GetStorageLensConfiguration</code>

Action	IAM permissions
	s3:GetStorageLensDashboard
Delete an S3 Storage Lens dashboard on Amazon S3 console.	s3>ListStorageLensConfigurations s3:GetStorageLensConfiguration s3>DeleteStorageLensConfiguration
Create or update an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3:PutStorageLensConfiguration s3:PutStorageLensConfigurationTagging
Get the tags of an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3:GetStorageLensConfigurationTagging
View an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3:GetStorageLensConfiguration
Delete an S3 Storage Lens configuration by using the AWS CLI or AWS SDK.	s3>DeleteStorageLensConfiguration

Note

- You can use resource tags in an IAM policy to manage permissions.
- An IAM user or role with these permissions can see metrics from buckets and prefixes that they might not have direct permission to read or list objects from.
- For S3 Storage Lens dashboards with prefix-level metrics enabled, if a selected prefix path matches with an object key, the dashboard might display the object key as another prefix.
- For metrics exports, which are stored in a bucket in your account, permissions are granted by using the existing s3:GetObject permission in the IAM policy. Similarly, for an AWS Organizations entity, the organization's management account or delegated administrator

accounts can use IAM policies to manage access permissions for organization-level dashboard and configurations.

Setting account permissions to use S3 Storage Lens groups

You can use S3 Storage Lens groups to understand the distribution of your storage within buckets based on prefix, suffix, object tag, object size, or object age. You can attach Storage Lens groups to your dashboards to view their aggregated metrics.

To work with Storage Lens groups, you need certain permissions. For more information, see [the section called “Storage Lens groups permissions”](#).

Setting permissions to use S3 Storage Lens with AWS Organizations

You can use Amazon S3 Storage Lens to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. The following table shows the actions and permissions related to using S3 Storage Lens with Organizations.

Action	IAM Permissions
Enable trusted access for S3 Storage Lens for your organization.	organizations:EnableAWSServiceAccess
Disable trusted access for S3 Storage Lens for your organization.	organizations:DisableAWSServiceAccess
Register a delegated administrator to create S3 Storage Lens dashboards or configurations for your organization.	organizations:RegisterDelegatedAdministrator
Deregister a delegated administrator so that they can no longer create S3 Storage Lens dashboards or configurations for your organization.	organizations:DeregisterDelegatedAdministrator
Additional permissions to create S3 Storage Lens organization-wide configurations.	organizations:DescribeOrganization

Action	IAM Permissions
	organizations>ListAccounts
	organizations>ListAWSServiceAccessForOrganization
	organizations>ListDelegatedAdministrators
	iam>CreateServiceLinkedRole

Table naming for S3 Storage Lens export to S3 Tables

Overview

When you export S3 Storage Lens metrics to S3 Tables, the tables are organized using Apache Iceberg catalog conventions with specific naming patterns to ensure compatibility and organization.

Table location structure

The complete table location follows this pattern:

```
s3tablescatalog/aws-s3/<namespace>/<table-name>
```

Table bucket name

Table Bucket: aws-s3

The S3 Storage Lens export uses the aws-s3 table bucket, which is the designated bucket for AWS S3-related system tables.

Catalog name

Catalog: s3tablescatalog/aws-s3

S3 Storage Lens tables are stored in the S3 catalog because Storage Lens provides insights about three types of S3 resources:

- Storage metrics

- Bucket properties
- API usage metrics

Namespace naming convention

Namespaces organize tables within the catalog. For S3 Storage Lens, the namespace is derived from your Storage Lens configuration ID.

Standard namespace format

For Storage Lens configuration IDs without dots (.):

```
lens_<configuration-id>_exp
```

Example: If your configuration ID is my-lens-config, the namespace will be:

```
lens_my-lens-config_exp
```

Namespace format with dot character handling

Storage Lens configuration IDs can contain dots (.), but S3 Tables namespaces only support lowercase letters, numbers, hyphens (-), and underscores (_). When your configuration ID contains dots, they are converted to hyphens and a hash suffix is added for uniqueness:

```
lens_<configuration-id-with-dots-replaced>_exp_<7-char-hash>
```

Example: If your configuration ID is my.lens.config, the namespace will be:

```
lens_my-lens-config_exp_a1b2c3d
```

Where a1b2c3d is the first 7 characters of the SHA-1 hash of the original configuration ID.

Namespace naming rules

- Length: 1-127 characters
- Allowed characters: lowercase letters (a-z), numbers (0-9), hyphens (-), underscores (_)
- Pattern: [a-z0-9_-]{1,127}
- Must be unique within the table bucket

Storage Lens configuration ID requirements

Your Storage Lens configuration ID must follow these rules:

- Length: 1-64 characters
- Allowed characters: letters (a-z, A-Z), numbers (0-9), hyphens (-), underscores (_), dots (.)
- Pattern: [a-zA-Z0-9\-_\.\.]+

Complete examples

For a Storage Lens configuration with ID `production-metrics`:

- **Table Bucket:** `aws-s3`
- **Catalog:** `s3tablescatalog/aws-s3`
- **Namespace:** `lens_production-metrics_exp`
- **Full Path:** `s3tablescatalog/aws-s3/lens_production-metrics_exp/<table-name>`

For a Storage Lens configuration with ID `prod.us.east.metrics`:

- **Table Bucket:** `aws-s3`
- **Catalog:** `s3tablescatalog/aws-s3`
- **Namespace:** `lens_prod-us-east-metrics_exp_f8e9a1b` (with hash)
- **Full Path:** `s3tablescatalog/aws-s3/lens_prod-us-east-metrics_exp_f8e9a1b/<table-name>`

Table types

The following table shows the different types of tables created for S3 Storage Lens exports:

Bucket name	Namespace	S3 table name	Description
<code>s3tablescatalog/ aws-s3</code>	<code>lens_<conf_name>_exp[<hash>]</code>	<code>default_storage_metrics</code>	This table contains the storage metrics for your Storage Lens configuration.

Bucket name	Namespace	S3 table name	Description
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	default_activity_metrics	This table contains the activity metrics for your Storage Lens configuration.
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	expanded_prefixes_storage_metrics	This table contains the storage metrics for all the prefixes in your Storage Lens configuration.
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	expanded_prefixes_activity_metrics	This table contains the activity metrics for all of your prefixes in your Storage Lens configuration.
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	bucket_property_metrics	This table contains the bucket property metrics for all the buckets in your Storage Lens configuration.

 **Note**

There is no extra charge for export S3 Storage Lens metrics to AWS-managed S3 Tables bucket. You pay the usual charges for table storage and management in table bucket. You can enable or disable export to S3 Tables by using the Amazon S3 console, Amazon S3 API, the AWS CLI, or AWS SDKs.

Working with Amazon S3 Storage Lens by using the console and API

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that

are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

 **Note**

Storage Lens only aggregates metrics for [S3 general purpose buckets](#).

The following sections contain examples of creating, updating, and viewing S3 Storage Lens configurations and performing operations related to the feature. If you are using S3 Storage Lens with AWS Organizations, these examples also cover those use cases. In the examples, replace any placeholder values.

Topics

- [Create an Amazon S3 Storage Lens dashboard](#)
- [Update an Amazon S3 Storage Lens dashboard](#)
- [Disable an Amazon S3 Storage Lens dashboard](#)
- [Delete an Amazon S3 Storage Lens dashboard](#)
- [List Amazon S3 Storage Lens dashboards](#)
- [View an Amazon S3 Storage Lens dashboard configuration details](#)
- [Managing AWS resource tags with S3 Storage Lens](#)
- [Helper files for using Amazon S3 Storage Lens](#)

Create an Amazon S3 Storage Lens dashboard

You can create additional S3 Storage Lens custom dashboards that can be scoped to your organization in AWS Organizations or to specific AWS Regions or buckets within an account.

Note

Any updates to your dashboard configuration can take up to 48 hours to accurately display or visualize.

Using the S3 console

Use the following steps to create an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Configure general settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, under **S3 Storage Lens**, choose **Dashboards**.
4. Choose **Create dashboard**.
5. On the **Dashboard** page, in the **General** section, do the following:
 - a. View the **Home Region** for your dashboard. The home Region is the AWS Region where the configuration and metrics for this Storage Lens dashboard are stored.
 - b. Enter a dashboard name.

Dashboard names must be fewer than 65 characters and must not contain special characters or spaces.

Note

You can't change this dashboard name after the dashboard is created.

- c. Choose **Enabled** to display updated daily metrics in your dashboard.

- d. (Optional) You can choose to add **Tags** to your dashboard. You can use tags to manage permissions for your dashboard and track costs for S3 Storage Lens. For more information, see [Controlling access to AWS resources using tags](#) in the *IAM User Guide* and [Using AWS-generated tags](#) in the *AWS Billing User Guide*.

 **Note**

You can add up to 50 tags to your dashboard configuration.

6. Choose **Next** to save your changes and proceed.

Step 2: Define the dashboard scope

1. In the **Dashboard scope** section, choose the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.
2. Choose the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option isn't available when you create organization-level dashboards.

 **Note**

- You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
- You can choose up to 50 buckets to include or exclude.

3. Choose **Next** to save your changes and proceed.

Step 3: Choose your Storage Lens tier

1. In the **Storage Lens tier** section, choose the tier of features that you want to aggregate for this dashboard.
 - a. To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free tier**.

- b. To enable advanced metrics, choose **Advanced tier**. These options include prefix or Storage Lens groups aggregation, Amazon CloudWatch publishing, the expanded prefixes report, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see [Amazon S3 pricing](#).

For more information about advanced metrics and free metrics, see [Metrics selection](#).

2. Under **Advanced metric categories**, select the category of metrics that you want to enable:
 - **Activity metrics**
 - **Detailed status code metrics**
 - **Cost optimization metrics**
 - **Data protection metrics**
 - **Performance metrics**

To preview which metrics are included in each category, use the drop-down arrow button below the metrics category checkbox list. For more information about metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

3. Choose or specify a **Prefix delimiter** to distinguish levels within each prefix. This value is used to identify each prefix level. The default value in Amazon S3 is the "/" character, but your storage structure might use other delimiter characters.
4. Choose **Next** to save your changes and proceed.

Step 4: (Optional) Choose your metrics aggregation

1. Under **Additional metrics aggregation**, choose which metrics you want to aggregate:
 - Prefix aggregation
 - Storage Lens group aggregation
2. If you've enabled **Prefix aggregation**, specify the minimum **Prefix threshold** for your dashboard and **Prefix depth**. Then, choose **Next** to save and proceed.

Note

The **Prefix depth** setting determines how many hierarchical levels deep S3 Storage Lens will analyze your object prefixes, with a maximum limit of 10 levels. The **Prefix threshold** specifies the minimum percentage of total storage that a prefix must represent before it's included in Storage Lens metrics.

3. If you've enabled **Storage Lens group aggregation**, choose one of the following:
 - **Include Storage Lens groups**
 - **Exclude Storage Lens groups**
4. When you include Storage Lens groups in your aggregation, you can either **Include all Storage Lens groups in your home Region** or specify Storage Lens groups to include.
5. Choose **Next** to save your changes and proceed.

Step 5: (Optional) Choose your metrics export and publishing settings

1. Under **Metrics publishing**, choose **CloudWatch publishing** if you want to access your Storage Lens metrics in your CloudWatch dashboard.

Note

Prefix-level metrics aren't available in CloudWatch.

2. Under **Metrics export**, choose which Storage Lens dashboard data you want exported daily:
 - **Default metrics report**
 - **Expanded prefixes metrics report**
3. (Optional) If you chose **Default metrics report**, in the **Default metrics report** settings, choose the bucket type. You can export the report to either a general purpose Amazon S3 bucket or AWS-managed S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings** options.

Note

The **default metrics report** only includes prefixes within the set threshold and depth set in prefix aggregation settings.

If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#).

4. (Optional) If you chose **Expanded prefixes metrics report**, in the **Expanded prefixes metrics report** settings, choose the bucket type. You can export the report to either a general purpose Amazon S3 bucket or a read-only S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings**.

Note

The **Expanded prefixes metrics report** includes all prefixes up to prefix depth 50 in all selected buckets that are specified in your dashboard scope.

If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#).

5. Choose **Next** to save your changes and proceed.
6. Review everything on the **Review and Create** page. If there are no additional changes, choose **Next** to save your changes and to create your dashboard.

Step 6: Review your dashboard configuration and create your dashboard

1. In the **General** section, review your settings. Choose **Edit** to make any changes.
2. In the **Dashboard scope** section, review your settings. Choose **Edit** to make any changes.
3. In the **Storage Lens tier** section, review your settings. Choose **Edit** to make any changes.
4. In the **Metrics aggregation** section, review your settings. Choose **Edit** to make any changes.

5. In the **Metrics export** section, review your settings. Choose **Edit** to make any changes.
6. After reviewing and confirming all your dashboard configuration settings, choose **Submit** to create your dashboard.

After you've successfully created your new Storage Lens dashboard, you can view your new dashboard listed under your Storage Lens **Dashboard** page.

Using the AWS CLI

Example

The following example command creates a Amazon S3 Storage Lens configuration with tags. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json --tags=file://./tags.json
```

Example

The following example command creates a Amazon S3 Storage Lens configuration without tags. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=222222222222 --config-id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json
```

Using the AWS SDK for Java

Example – Create and update an Amazon S3 Storage Lens configuration

The following example creates and updates an Amazon S3 Storage Lens configuration in SDK for Java:

```
package aws.example.s3control;

import software.amazon.awssdk.awscore.exception.AwsServiceException;
import software.amazon.awssdk.core.exception.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.AccountLevel;
import software.amazon.awssdk.services.s3control.model.ActivityMetrics;
import software.amazon.awssdk.services.s3control.model.AdvancedCostOptimizationMetrics;
import software.amazon.awssdk.services.s3control.model.AdvancedDataProtectionMetrics;
import software.amazon.awssdk.services.s3control.model.AdvancedPerformanceMetrics;
import software.amazon.awssdk.services.s3control.model.BucketLevel;
import software.amazon.awssdk.services.s3control.model.CloudWatchMetrics;
import software.amazon.awssdk.services.s3control.model.DetailedStatusCodesMetrics;
import software.amazon.awssdk.services.s3control.model.Format;
import software.amazon.awssdk.services.s3control.model.Include;
import software.amazon.awssdk.services.s3control.model.OutputSchemaVersion;
import software.amazon.awssdk.services.s3control.model.PrefixLevel;
import software.amazon.awssdk.services.s3control.model.PrefixLevelStorageMetrics;
import
software.amazon.awssdk.services.s3control.model.PutStorageLensConfigurationRequest;
import software.amazon.awssdk.services.s3control.model.S3BucketDestination;
import software.amazon.awssdk.services.s3control.model.SSES3;
import software.amazon.awssdk.services.s3control.model.SelectionCriteria;
import software.amazon.awssdk.services.s3control.model.StorageLensAwsOrg;
import software.amazon.awssdk.services.s3control.model.StorageLensConfiguration;
import software.amazon.awssdk.services.s3control.model.StorageLensDataExport;
import software.amazon.awssdk.services.s3control.model.StorageLensDataExportEncryption;
import
software.amazon.awssdk.services.s3control.model.StorageLensExpandedPrefixesDataExport;
import software.amazon.awssdk.services.s3control.model.StorageLensTableDestination;
import software.amazon.awssdk.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

public class CreateAndUpdateDashboard {

    public static void main(String[] args) {

    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

For access to S3 Storage Lens groups or expanded prefixes, you must upgrade your dashboard to use the advanced tier. Additional charges apply. For more information about the free and advanced tiers, see [Metrics selection](#). For more information about S3 Storage Lens groups, see [the section called "Working with Storage Lens groups"](#).

Update an Amazon S3 Storage Lens dashboard

The Amazon S3 Storage Lens default dashboard is default-account-dashboard. This dashboard is preconfigured by Amazon S3 to help you visualize summarized insights and trends for your entire account's aggregated free and advanced metrics on the console. You can't modify the default dashboard's configuration scope, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations, configure the optional metrics export, or even disable the default dashboard. The default dashboard can't be deleted, and can only be disabled. For more information, see [Using the S3 console](#).

Using the S3 console

Use the following steps to update an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Update your dashboard and configure your general settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit.
4. Choose **View dashboard configuration**.
5. Choose **Edit**. You can now review the dashboard configuration, step by step. To make changes to any of the steps, you can click directly on the step using the left navigation. For instructions on how to update those steps,

 **Note**

You can't change the following:

- The dashboard name
- The home Region

6. On the **Dashboard** page, in the **General** section, you can make changes to the following:
 - Choose **Enabled** or **Disabled** to update whether you're receiving daily metrics in your dashboard.

- (Optional) You can choose to add **Tags** to your dashboard. You can use tags to manage permissions for your dashboard and track costs for S3 Storage Lens. For more information, see [Controlling access to AWS resources using tags](#) in the *IAM User Guide* and [Using AWS-generated tags](#) in the *AWS Billing User Guide*.

 **Note**

You can add up to 50 tags to your dashboard configuration.

7. Choose **Next** to save your changes and proceed.

Step 2: Update the dashboard scope

1. In the **Dashboard scope** section, update the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.

 **Note**

- You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
- You can choose up to 50 buckets to include or exclude.

2. Choose the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option isn't available when you create organization-level dashboards.

 **Note**

- You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
- You can choose up to 50 buckets to include or exclude.

3. Choose **Next** to save your changes and proceed.

Step 3: Update your Storage Lens tier Configure the metrics selection

1. In the **Storage Lens tier Metrics selection** section, update the tier of metrics that you want to aggregate for this dashboard.

Note

- If you're updating from the **Free tier** to the **Advanced tier**, you'll need to update your **Metrics aggregation** settings. To update your **Metrics aggregation settings**, see [Step 4: Update your metrics aggregation](#).
- If you're updating your Storage Lens tier from the **Advanced tier** to the **Free tier**, you won't need to update any **Metrics aggregation** settings. The **Metrics aggregation** feature only applies to **Advanced tier** metric categories.

2. To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free tier**.
3. To enable advanced metrics, choose **Advanced tier**. These options include prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see [Amazon S3 pricing](#).

For more information about advanced metrics and free metrics, see [Metrics selection](#).

4. Under **Advanced metric categories**, choose the category of metrics that you want to enable:
 - **Activity metrics**
 - **Detailed status code metrics**
 - **Cost optimization metrics**
 - **Data protection metrics**
 - **Performance metrics**

To preview which metrics are included in each category, use the drop-down arrow button below the metrics category checkbox list. For more information about metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

5. Choose or specify a **Prefix delimiter** to distinguish levels within each prefix. This value is used to identify each prefix level. The default value in Amazon S3 is the "/" character, but your storage structure might use other delimiter characters.
6. Choose **Next** to save your changes and proceed.

Step 4: (Optional) Update your metrics aggregation

1. Under **Additional metrics aggregation**, update which metrics you want to aggregate by choosing one of the following:
 - Prefix aggregation
 - Storage Lens group aggregation
2. If you've enabled **Prefix aggregation**, specify the minimum **Prefix threshold** for your dashboard and **Prefix depth**. Then, choose **Next** to save and proceed.
3. If you've enabled **Storage Lens group aggregation**, choose one of the following:
 - **Include Storage Lens groups**
 - **Exclude Storage Lens groups**
4. When you include Storage Lens groups in your aggregation, you can either **Include all Storage Lens groups in your home Region** or specify Storage Lens groups to include.
5. Choose **Next** to save your changes and proceed.

Step 5: (Optional) Update your metrics export and publishing settings

1. Under **Metrics publishing**, choose **CloudWatch publishing** if you want to access your Storage Lens metrics in your CloudWatch dashboard.

 **Note**

Prefix-level metrics aren't available in CloudWatch.

2. Under **Metrics export**, choose which Storage Lens dashboard data you want exported daily:
 - **Default metrics report**
 - **Expanded prefixes metrics report**

3. (Optional) If you chose **Default metrics report**, in the **Default metrics report** settings, choose the bucket type. You can export the report to either a general purpose S3 bucket or a read-only S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings** options.

 **Note**

- The **default metrics report** only includes prefixes within the set threshold and depth set in prefix aggregation settings. If your prefix aggregation isn't already configured, the threshold includes up to the 100 largest prefixes by size.
- If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#).

4. Choose **Next** to save your changes and proceed.
5. (Optional) If you chose **Expanded prefixes metrics report**, in the **Expanded prefixes metrics report** settings, choose the bucket type. You can export the report to either a general purpose S3 bucket or a read-only S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings**.

 **Note**

- The **Expanded prefixes metrics report** includes prefixes in all buckets that are specified in your dashboard scope.
- If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#).

6. Choose **Next** to save your changes and proceed.

Step 6: Review and update your dashboard configuration

1. In the **General** section, review your settings. Choose **Edit** to make any changes.
2. In the **Dashboard scope** section, review your settings. Choose **Edit** to make any changes.
3. In the **Storage Lens tier** section, review your settings. Choose **Edit** to make any changes.
4. In the **Metrics aggregation** section, review your settings. Choose **Edit** to make any changes.
5. In the **Metrics export** section, review your settings. Choose **Edit** to make any changes.
6. After reviewing and confirming all your dashboard configuration settings, choose **Submit** to update your dashboard.

After you've successfully updated your new Storage Lens dashboard, you can view your updated dashboard configuration listed under your Storage Lens **Dashboard** page.

Using the AWS CLI

Example

The following example command updates a Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --  
config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-  
configuration=file://./config.json --tags=file://./tags.json
```

Using the AWS SDK for Java

Example – Update a Amazon S3 Storage Lens configuration with advanced metrics and recommendations

The following examples shows you how to update the default S3 Storage Lens configuration with advanced metrics and recommendations in SDK for Java:

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import com.amazonaws.auth.profile.ProfileCredentialsProvider;  
import com.amazonaws.services.s3control.AWS3Control;  
import com.amazonaws.services.s3control.AWS3ControlClient;  
import com.amazonaws.services.s3control.model.AccountLevel;
```

```
import com.amazonaws.services.s3control.model.ActivityMetrics;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.Format;
import com.amazonaws.services.s3control.model.Include;
import com.amazonaws.services.s3control.model.OutputSchemaVersion;
import com.amazonaws.services.s3control.model.PrefixLevel;
import com.amazonaws.services.s3control.model.PrefixLevelStorageMetrics;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.S3BucketDestination;
import com.amazonaws.services.s3control.model.SSES3;
import com.amazonaws.services.s3control.model.SelectionCriteria;
import com.amazonaws.services.s3control.model.StorageLensAwsOrg;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensDataExport;
import com.amazonaws.services.s3control.model.StorageLensDataExportEncryption;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class UpdateDefaultConfigWithPaidFeatures {

    public static void main(String[] args) {
        String configurationId = "default-account-dashboard"; // This configuration ID
cannot be modified.
        String sourceAccountId = "111122223333";

        try {
            SelectionCriteria selectionCriteria = new SelectionCriteria()
                .withDelimiter("/")
                .withMaxDepth(5)
                .withMinStorageBytesPercentage(10.0);
            PrefixLevelStorageMetrics prefixStorageMetrics = new
PrefixLevelStorageMetrics()
                .withEnabled(true)
                .withSelectionCriteria(selectionCriteria);
            BucketLevel bucketLevel = new BucketLevel()
                .withActivityMetrics(new ActivityMetrics().withEnabled(true))
                .withPrefixLevel(new
PrefixLevel().withStorageMetrics(prefixStorageMetrics));
            AccountLevel accountLevel = new AccountLevel()
                .withActivityMetrics(new ActivityMetrics().withEnabled(true))
        }
    }
}
```

```
        .withBucketLevel(bucketLevel);

    StorageLensConfiguration configuration = new StorageLensConfiguration()
        .withId(configurationId)
        .withAccountLevel(accountLevel)
        .withIsEnabled(true);

    AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
        .withCredentials(new ProfileCredentialsProvider())
        .withRegion(US_WEST_2)
        .build();

    s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
        .withAccountId(sourceAccountId)
        .withConfigId(configurationId)
        .withStorageLensConfiguration(configuration)
    );

} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

For access to S3 Storage Lens groups or expanded prefixes, you must upgrade your dashboard to use the advanced tier. Additional charges apply. For more information about the free and advanced tiers, see [Metrics selection](#). For more information about S3 Storage Lens groups, see [the section called “Working with Storage Lens groups”](#).

Disable an Amazon S3 Storage Lens dashboard

You can disable an Amazon S3 Storage Lens dashboard from the Amazon S3 console. Disabling a dashboard prevents it from generating metrics in the future. A disabled dashboard still retains its configuration information, so that it can be easily resumed when re-enabled. A disabled dashboard retains its historical data until it's no longer available for queries.

Using the S3 console

Use the following steps to disable an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

To disable an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to disable, and then choose **Disable** at the top of the list.
4. On the confirmation page, confirm that you want to disable the dashboard by entering the name of dashboard in the text field, and then choose **Confirm**.

Delete an Amazon S3 Storage Lens dashboard

You can't delete the default dashboard. However, you can disable it. Before deleting a dashboard that you've created, consider the following:

- As an alternative to deleting a dashboard, you can *disable* the dashboard so that it is available to be re-enabled in the future. For more information, see [Using the S3 console](#).
- Deleting the dashboard deletes all the configuration settings that are associated with it.
- Deleting a dashboard makes all the historic metrics data unavailable. This historical data is still retained for 15 months. If you want to access this data again, create a dashboard with the same name in the same home Region as the one that was deleted.

Using the S3 console

You can delete an Amazon S3 Storage Lens dashboard from the Amazon S3 console. However, deleting a dashboard prevents it from generating metrics in the future.

Deleting an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.

3. In the **Dashboards** list, choose the dashboard that you want to delete, and then choose **Delete** at the top of the list.
4. On the **Delete dashboards** page, confirm that you want to delete the dashboard by entering the name of dashboard in the text field. Then choose **Confirm**.

Using the AWS CLI

Example

The following example deletes a S3 Storage Lens configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control delete-storage-lens-configuration --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id
```

Using the AWS SDK for Java

Example – Delete an Amazon S3 Storage Lens dashboard configuration

The following example shows you how to delete an S3 Storage Lens configuration using SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();
            DeleteStorageLensConfigurationRequest request =
                new DeleteStorageLensConfigurationRequest()
                    .withConfigurationId(configurationId)
                    .withSourceAccountId(sourceAccountId);
            s3ControlClient.deleteStorageLensConfiguration(request);
        } catch (AmazonServiceException e) {
            System.out.println("Error deleting storage lens configuration " +
                configurationId + ": " + e.getMessage());
        }
    }
}
```

```
        .withRegion(US_WEST_2)
        .build();

    s3ControlClient.deleteStorageLensConfiguration(new
DeleteStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)

);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

List Amazon S3 Storage Lens dashboards

Using the S3 console

To list S3 Storage Lens dashboards

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**. You can now view the dashboards in your AWS account.

Using the AWS CLI

Example

The following example command lists the S3 Storage Lens dashboards in your AWS account. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1 --next-token=abcdefghijkl1234
```

Example

The following example lists S3 Storage Lens configurations without a next token. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1
```

Using the AWS SDK for Java

Example – List S3 Storage Lens dashboard configurations

The following examples shows you how to list S3 Storage Lens configurations in SDK for Java. To use this example, replace the *user input placeholders* with your own information." to each example description.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationEntry;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationsRequest;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class ListDashboard {

    public static void main(String[] args) {
        String sourceAccountId = "11122223333";
        String nextToken = "nextToken";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();
        }
    }
}
```

```
        final List<ListStorageLensConfigurationEntry> configurations =
            s3ControlClient.listStorageLensConfigurations(new
ListStorageLensConfigurationsRequest()
                .withAccountId(sourceAccountId)
                .withNextToken(nextToken)
            ).getStorageLensConfigurationList();

        System.out.println(configurations.toString());
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
}
```

View an Amazon S3 Storage Lens dashboard configuration details

You can view a Amazon S3 Storage Lens dashboard from the Amazon S3 console, AWS CLI, and SDK for Java.

Using the S3 console

To view S3 Storage Lens dashboard configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. From the **Dashboards** list, click on the dashboard that you want to view. You can now view the details of your Storage Lens dashboard.

Using the AWS CLI

Example

The following example retrieves an S3 Storage Lens configuration so that you can view the configuration details. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-configuration --account-id=222222222222 --config-id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

Example – Retrieve and view an S3 Storage Lens configuration

The following example shows you how to retrieve an S3 Storage Lens configuration in SDK for Java so that you can view the configuration details. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWS3ControlClient;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationResult;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            AWSS3Control s3ControlClient = AWS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();
        }
    }
}
```

```
final StorageLensConfiguration configuration =
    s3ControlClient.getStorageLensConfiguration(new
GetStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
).getStorageLensConfiguration();

System.out.println(configuration.toString());
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Managing AWS resource tags with S3 Storage Lens

Each Amazon S3 Storage Lens dashboard is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens dashboard, you can optionally add AWS resource tags to the dashboard. You can add up to 50 tags for each Storage Lens dashboard. To create a Storage Lens dashboard with tags, you must have the following [S3 Storage Lens permissions](#):

- `s3>ListStorageLensConfigurations`
- `s3:GetStorageLensConfiguration`
- `s3:GetStorageLensConfigurationTagging`
- `s3:PutStorageLensConfiguration`
- `s3:PutStorageLensConfigurationTagging`

You can use AWS resource tags to categorize resources according to department, line of business, or project. This is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific S3 Storage Lens dashboard based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens dashboard, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes such as tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with aws :) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens dashboard.

Topics

- [Add AWS resource tags to a Storage Lens dashboard](#)
- [Retrieve AWS resource tags for a Storage Lens dashboard](#)
- [Updating Storage Lens dashboard tags](#)
- [Deleting AWS resource tags from a S3 Storage Lens dashboard](#)

Add AWS resource tags to a Storage Lens dashboard

The following examples demonstrate how to add AWS resource tags to an S3 Storage Lens dashboard. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add AWS resource tags to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, navigate to **Storage Lens** on the left navigation panel.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard that you want to update. Then, choose **Edit**.
5. Under **General**, choose **Add tag**.
6. On the **Add tag** page, add the new key-value pair.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens dashboard.
8. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
9. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds tags to a S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

The following example adds tags to an Amazon S3 Storage Lens configuration in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

Example – Add tags to an S3 Storage Lens configuration

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;
```

```
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            List<StorageLensTag> tags = Arrays.asList(
                new StorageLensTag().withKey("key-1").withValue("value-1"),
                new StorageLensTag().withKey("key-2").withValue("value-2")
            );

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.putStorageLensConfigurationTagging(new
PutStorageLensConfigurationTaggingRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
                .withTags(tags)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

```
    }  
}  
}
```

Retrieve AWS resource tags for a Storage Lens dashboard

The following examples demonstrate how to retrieve AWS resource tags for a S3 Storage Lens dashboard. You can get resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To retrieve the AWS resource tags for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command retrieves tags for a S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-configuration-tagging --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

Example – Get tags for an S3 Storage Lens dashboard configuration

The following example shows you how to retrieve tags for an S3 Storage Lens dashboard configuration in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;
import
com.amazonaws.services.s3control.model.GetStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "11122223333";
        try {
            AWSS3Control s3ControlClient = AWS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())

```

```
        .withRegion(US_WEST_2)
        .build();

    final List<StorageLensTag> s3Tags = s3ControlClient
        .getStorageLensConfigurationTagging(new
GetStorageLensConfigurationTaggingRequest()
            .withAccountId(sourceAccountId)
            .withConfigId(configurationId)
        ).getTags();

    System.out.println(s3Tags.toString());
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Updating Storage Lens dashboard tags

The following examples demonstrate how to update Storage Lens dashboard tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

Note

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds or replaces tags on an existing Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=111122223333 --config-id=example-dashboard-configuration-id --region=us-east-1 --config-id=your-configuration-id
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates the AWS resource tags on an existing Storage Lens dashboard. To use this example, replace the *user input placeholders* with your own information.

Example – Update tags on an existing Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;
```

```
import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            List<StorageLensTag> tags = Arrays.asList(
                new StorageLensTag().withKey("key-1").withValue("value-1"),
                new StorageLensTag().withKey("key-2").withValue("value-2")
            );

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.putStorageLensConfigurationTagging(new
PutStorageLensConfigurationTaggingRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
                .withTags(tags)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Deleting AWS resource tags from a S3 Storage Lens dashboard

The following examples demonstrate how to delete AWS resource tags from an existing Storage Lens dashboard. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete AWS resource tags from an existing Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. Choose **Remove** next to the tag that you want to remove.
7. Choose **Save changes**.

Using the AWS CLI

The following AWS CLI command deletes AWS resource tags from an existing Storage Lens dashboard. To use this example command, replace the *user input placeholders* with your own information.

Example

```
aws s3control delete-storage-lens-configuration-tagging --account-id=222222222222 --config-id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes an AWS resource tag from the Storage Lens dashboard using the Amazon Resource Name (ARN) that you specify in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

Example – Delete tags for an S3 Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationTaggingRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.deleteStorageLensConfigurationTagging(new
DeleteStorageLensConfigurationTaggingRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Helper files for using Amazon S3 Storage Lens

Use the following JSON files and its key inputs for your examples.

S3 Storage Lens example configuration in JSON

Example config.json

The config.json file contains the details of a S3 Storage Lens Organizations-level *advanced metrics and recommendations* configuration. To use the following example, replace the *user input placeholders* with your own information.

Note

Additional charges apply for advanced metrics and recommendations. For more information, see [advanced metrics and recommendations](#).

S3 Storage Lens example configuration with Storage Lens groups in JSON

Example config.json

The config.json file contains the details that you want to apply to your Storage Lens configuration when using Storage Lens groups. To use the example, replace the *user input placeholders* with your own information.

To attach all Storage Lens groups to your dashboard, update your Storage Lens configuration with the following syntax:

```
{
    "Id": "ExampleS3StorageLensConfiguration",
    "AccountLevel": {
        "ActivityMetrics": {
            "Enabled": true
        },
        "AdvancedCostOptimizationMetrics": {
            "Enabled": true
        },
        "AdvancedDataProtectionMetrics": {
            "Enabled": true
        },
        "BucketLevel": {
            "ActivityMetrics": {
                "Enabled": true
            },
            "StorageLensGroupLevel": {}
        },
        "Enabled": true
    }
}
```

To include only two Storage Lens groups in your Storage Lens dashboard configuration (*slg-1* and *slg-2*), use the following syntax:

```
{
    "Id": "ExampleS3StorageLensConfiguration",
    "AccountLevel": {
```

```
"ActivityMetrics": {  
    "Enabled":true  
},  
"AdvancedCostOptimizationMetrics": {  
    "Enabled":true  
},  
"AdvancedDataProtectionMetrics": {  
    "Enabled":true  
},  
"BucketLevel": {  
    "ActivityMetrics": {  
        "Enabled":true  
    },  
"StorageLensGroupLevel": {  
    "SelectionCriteria": {  
        "Include": [  
            "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slg-1",  
            "arn:aws:s3:us-east-1:44445556666:storage-lens-group/slg-2"  
        ]  
    },  
    "Enabled": true  
}  
}
```

To exclude only certain Storage Lens groups from being attached to your dashboard configuration, use the following syntax:

```
{  
    "Id": "ExampleS3StorageLensConfiguration",  
    "AccountLevel": {  
        "ActivityMetrics": {  
            "Enabled":true  
        },  
        "AdvancedCostOptimizationMetrics": {  
            "Enabled":true  
        },  
        "AdvancedDataProtectionMetrics": {  
            "Enabled":true  
        },  
        "BucketLevel": {  
            "ActivityMetrics": {  
                "Enabled":true  
            },  
"StorageLensGroupLevel": {  
    }
```

```
"SelectionCriteria": {  
    "Exclude": [  
        "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slgl-1",  
        "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slgl-2"  
    ]  
},  
"IsEnabled": true  
}
```

S3 Storage Lens example tags configuration in JSON

Example tags.json

The tags.json file contains the tags that you want to apply to your S3 Storage Lens configuration. To use this example, replace the *user input placeholders* with your own information.

```
[  
    {  
        "Key": "key1",  
        "Value": "value1"  
    },  
    {  
        "Key": "key2",  
        "Value": "value2"  
    }  
]
```

S3 Storage Lens example configuration IAM permissions

Example permissions.json – Specific dashboard name

This example policy shows an S3 Storage Lens IAM permissions.json file with a specific dashboard name specified. Replace *value1*, *us-east-1*, *your-dashboard-name*, and *example-account-id* with your own values.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [
```

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:GetStorageLensConfiguration",  
        "s3>DeleteStorageLensConfiguration",  
        "s3:PutStorageLensConfiguration"  
    ],  
    "Condition": {  
        "StringEquals": {  
            "aws:ResourceTag/key1": "value1"  
        }  
    },  
    "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens/your-  
dashboard-name"  
}  
]  
}
```

Example permissions.json – No specific dashboard name

This example policy shows an S3 Storage Lens IAM permissions.json file without a specific dashboard name specified. Replace *value1*, *us-east-1*, and *example-account-id* with your own values.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetStorageLensConfiguration",  
                "s3>DeleteStorageLensConfiguration",  
                "s3:PutStorageLensConfiguration"  
            ],  
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/key1": "value1"  
                }  
            },  
        },  
    ]  
}
```

```
        "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens/*"
    }
}
```

Viewing metrics with Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

By default, all dashboards are configured with free metrics, which include metrics that you can use to understand usage and activity across your S3 storage, optimize your storage costs, and implement data-protection and access-management best practices. Free metrics are aggregated down to the bucket level. With free metrics, data is available for queries for up to 14 days.

Advanced metrics and recommendations include the following additional features that you can use to gain further insight into usage and activity across your storage and best practices for optimizing your storage:

- Contextual recommendations (available only in the dashboard)
- Advanced metrics (including activity metrics aggregated by bucket)
- Prefix aggregation
- Storage Lens group aggregation
- Storage Lens group aggregation
- Amazon CloudWatch publishing

Advanced metrics data is available for queries for 15 months. There are additional charges for using S3 Storage Lens with advanced metrics. For more information, see [Amazon S3 pricing](#). For more information about free and advanced metrics, see [Metrics selection](#).

Topics

- [Viewing S3 Storage Lens metrics on the dashboards](#)

- [Amazon S3 Storage Lens metrics use cases](#)

Viewing S3 Storage Lens metrics on the dashboards

In the Amazon S3 console, S3 Storage Lens provides an interactive default dashboard that you can use to visualize insights and trends in your data. You can also use this dashboard to flag outliers and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the account, bucket, AWS Region, prefix, or Storage Lens group level. If you've enabled S3 Storage Lens to work with AWS Organizations, you can also generate insights at the organization level (such as data for all accounts that are part of your AWS Organizations hierarchy). The dashboard always loads for the latest date that has metrics available.

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. Amazon S3 pre-configures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing.

You can disable the default dashboard, but you can't delete it. If you disable your default dashboard, it is no longer updated. You also will no longer receive any new daily metrics in S3 Storage Lens or in the **Account snapshot** section on the **Buckets** page. You can still see historic data in the default dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access this data, you can re-enable the default dashboard within the expiration period.

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts. You can also scope your dashboards by organization if you've enabled Storage Lens to work with AWS Organizations. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

You can disable or delete any additional dashboards that you create.

- If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data for free metrics until the 14-day expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access this data, you can re-enable the dashboard within the expiration period.
- If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

- [Understanding your S3 Storage Lens dashboard](#)

Viewing an Amazon S3 Storage Lens dashboard

The following procedure shows how to view an S3 Storage Lens dashboard in the S3 console. For use-case based walkthroughs that show how to use your dashboard to optimize costs, implement best practices, and improve the performance of applications that access your S3 buckets, see [Amazon S3 Storage Lens metrics use cases](#).

Note

You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required AWS Identity and Access Management (IAM) permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see [Setting Amazon S3 Storage Lens permissions](#) and [Security best practices in IAM](#) in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

Your dashboard opens in S3 Storage Lens. The **Snapshot for date** section shows the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads the latest date that has metrics available.

4. (Optional) To change the date for your S3 Storage Lens dashboard, in the top-right date selector, choose a new date.
5. (Optional) To apply temporary filters to further limit the scope of your dashboard data, do the following:
 - a. Expand the **Filters** section.
 - b. To filter by specific accounts, AWS Regions, storage classes, buckets, prefixes, or Storage Lens groups, choose the options to filter by.

 **Note**

The **Prefixes** filter and the **Storage Lens groups** filter can't be applied at the same time.

- c. To update a filter, choose **Apply**.
- d. To remove a filter, click on the **X** next to the filter.
6. In any section in your S3 Storage Lens dashboard, to see data for a specific metric, for **Metric**, choose the metric name.
7. In any chart or visualization in your S3 Storage Lens dashboard, you can drill down into deeper levels of aggregation by using the **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes**, or **Storage Lens groups** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

Understanding your S3 Storage Lens dashboard

Your S3 Storage Lens dashboard has a primary **Overview** tab, and up to five additional tabs that represent each aggregation level:

- **Accounts**
- **AWS Regions**
- **Storage classes**
- **Buckets**
- **Prefixes**

• Storage Lens groups

On the **Overview** tab, your dashboard data is aggregated into three different sections: **Snapshot for date**, **Trends and distributions**, and **Top N overview**.

For more information about your S3 Storage Lens dashboard, see the following sections.

Snapshot

The **Snapshot for date** section shows summary metrics that S3 Storage Lens has aggregated for the date selected. These summary metrics include the following metrics:

- **Total storage** – The total amount of storage used in bytes.
- **Object count** – The total number of objects in your AWS account.
- **Average object size** – The average object size.
- **Active buckets** – The total number of active buckets in active usage with storage > 0 bytes in your account.
- **Accounts** – The number of accounts whose storage is in scope. This value is **1** unless you are using AWS Organizations and your S3 Storage Lens has trusted access with a valid service-linked role. For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).
- **Buckets** – The total number of buckets in your account.

Metric data

For each metric that appears in the snapshot, you can see the following data:

- **Metric name** – The name of the metric.
- **Metric category** – The category that the metric is organized into.
- **Total for date** – The total count for the date selected.
- **% change** – The percentage change from the last snapshot date.
- **30-day trend** – A trend-line showing the changes for the metric over a 30-day period.
- **Recommendation** – A contextual recommendation based on the data that's provided in the snapshot. Recommendations are available with advanced metrics and recommendations. For more information, see [Recommendations](#).

Metrics categories

You can optionally update your dashboard **Snapshot for date** section to display metrics for other categories. If you want to see snapshot data for additional metrics, you can choose from the following **Metrics categories**:

- **Cost optimization**
- **Data protection**
- **Activity** (available with advanced metrics)
- **Access management**
- **Performance**
- **Events**

The **Snapshot for date** section displays only a selection of metrics for each category. To see all metrics for a specific category, choose the metric in the **Trends and distributions** or **Top N overview** sections. For more information about metric categories, see [Metrics categories](#). For a complete list of S3 Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Trends and distributions

The second section of the **Overview** tab is **Trends and distributions**. In the **Trends and distributions** section, you can choose two metrics to compare over a date range that you define. The **Trends and distributions** section shows the relationship between two metrics over time. This section displays charts that you can use to see the **Storage class** and **Region** distribution between the two trends that you are tracking. You can optionally drill down into a data point in one of the charts for deeper analysis.

For a walkthrough that uses the **Trends and distributions** section, see [Identify buckets that don't use server-side encryption with AWS KMS for default encryption \(SSE-KMS\)](#).

Top N overview

The third section of the S3 Storage Lens dashboard is **Top N overview** (sorted in ascending or descending order). This section displays your selected metrics across the top number of accounts, AWS Regions, buckets, prefixes, or Storage Lens groups. If you enabled S3 Storage Lens to work with AWS Organizations, you can also see your selected metrics across your organization.

For a walkthrough that uses the **Top N overview** section, see [Identify your largest S3 buckets](#).

Drill down and analyze by options

To provide a fluid experience for analysis, the S3 Storage Lens dashboard provides an action menu, which appears when you choose any chart value. To use this menu, choose any chart value to see the associated metrics values, and then choose from two options in the box that appears:

- The **Drill down** action applies the selected value as a filter across all tabs of your dashboard. You can then drill down into that value for deeper analysis.
- The **Analyze by** action takes you to the **Dimension** tab that you select and applies that tab value as a filter. These tabs include **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes** (for dashboards that have **Advanced metrics** and **Prefix aggregation** enabled), and **Storage Lens groups** (for dashboards that have **Advanced metrics** and **Storage Lens group aggregation** enabled). With **Analyze by**, you can view the data in the context of the new dimension for deeper analysis.

The **Drill down** and **Analyze by** actions might be disabled if the outcome would yield illogical results or would not have any value. Both the **Drill down** and **Analyze by** actions apply filters on top of any existing filters across all tabs of the dashboard. You can also remove the filters as needed.

Tabs

The dimension-level tabs provide a detailed view of all values within a particular dimension. For example, the **AWS Regions** tab shows metrics for all AWS Regions, and the **Buckets** tab shows metrics for all buckets. Each dimension tab contains an identical layout consisting of four sections:

- A trend chart that displays your top N items within the dimension over the last 30 days for the selected metric. By default, this chart displays the top 10 items, but you can decrease it to at least 3 items or increase it up to 50 items.
- A histogram chart that shows a vertical bar chart for the selected date and metric. If you have a large number of items to display in this chart, you might need to scroll horizontally.
- A bubble analysis chart that plots all items within the dimension. This chart represents the first metric on the x axis and the second metric on the y axis. The third metric is represented by the size of the bubble.
- A metric grid view that contains each item in the dimension listed in rows. The columns represent each available metric, arranged in metrics category tabs for easier navigation.

Viewing Amazon S3 Storage Lens metrics using a data export

Amazon S3 Storage Lens metrics are generated daily in CSV or Apache Parquet-formatted metrics export files and placed in an S3 general purpose bucket in your account. From there, you can ingest the metrics export into the analytics tools of your choice, such as Amazon Quick Suite and Amazon Athena, where you can analyze storage usage and activity trends. You can also send daily metric exports to an AWS-managed S3 table bucket for immediate querying, using AWS analytics services or third-party tools.

Topics

- [Using an AWS KMS key to encrypt your metrics exports](#)
- [What is an S3 Storage Lens export manifest?](#)
- [Understanding the Amazon S3 Storage Lens export schemas](#)

Using an AWS KMS key to encrypt your metrics exports

To grant Amazon S3 Storage Lens permission to encrypt your metrics exports by using a customer managed key, you must use a key policy. To update your key policy so that you can use a KMS key to encrypt your S3 Storage Lens metrics exports, follow these steps.

To grant S3 Storage Lens permissions to encrypt data by using your KMS key

1. Sign into the AWS Management Console by using the AWS account that owns the customer managed key.
2. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the **Region selector** in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the key that you want to use to encrypt the metrics exports. AWS KMS keys are Region-specific and must be in the same Region as the metrics export destination S3 bucket.
6. Under **Key policy**, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. Under **Edit key policy**, add the following key policy to the existing key policy. To use this policy, replace the *user input placeholders* with your information.

{

```
"Sid": "Allow Amazon S3 Storage Lens use of the KMS key",
"Effect": "Allow",
"Principal": {
    "Service": "storage-lens.s3.amazonaws.com"
},
>Action": [
    "kms:GenerateDataKey"
],
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:SourceArn": "arn:aws:s3:us-east-1:source-account-id:storage-
lens/your-dashboard-name",
        "aws:SourceAccount": "source-account-id"
    }
}
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following topics in the *AWS Key Management Service Developer Guide*:

- [Create a KMS key](#)
- [Key policies in AWS KMS](#)

You can also use the AWS KMS PUT key policy API operation ([PutKeyPolicy](#)) to copy the key policy to the customer managed keys that you want to use to encrypt the metrics exports by using the REST API, AWS CLI, and SDKs.

Additional permissions for S3 table bucket exports

All data in S3 tables including S3 Storage Lens metrics are encrypted with SSE-S3 encryption by default. You can choose to encrypt your Storage Lens metrics report with AWS KMS keys (SSE-KMS). If you choose to encrypt your S3 Storage Lens metric reports with KMS keys, you must have additional permissions.

1. The user or IAM role needs the following permissions. You can grant these permissions by using the IAM console at <https://console.aws.amazon.com/iam/>.

- kms:DescribeKey on the AWS KMS key used

2. On the key policy for the AWS KMS key, you need the following permissions. You can grant these permissions by using the AWS KMS console at <https://console.aws.amazon.com/kms>. To use this policy, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "EnableSystemTablesKeyUsage",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "systemtables.s3.amazonaws.com"  
            },  
            "Action": [  
                "kms:DescribeKey",  
                "kms:GenerateDataKey",  
                "kms:Decrypt"  
            ],  
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id",  
            "Condition": {  
                "StringEquals": {  
                    "aws:SourceAccount": "111122223333"  
                }  
            }  
        },  
        {  
            "Sid": "EnableKeyUsage",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "maintenance.s3tables.amazonaws.com"  
            },  
            "Action": [  
                "kms:GenerateDataKey",  
                "kms:Decrypt"  
            ],  
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id",  
            "Condition": {  
                "StringLike": {  
                    "kms:EncryptionContext:aws:s3:arn": "<table-bucket-arn>/*"  
                }  
            }  
        }  
    ]  
}
```

{

What is an S3 Storage Lens export manifest?

S3 Storage Lens daily metrics exports in general-purpose buckets may be split into multiple files due to the large amount of data aggregated. The manifest file `manifest.json` describes where the metrics export files for that day are located. Whenever a new export is delivered, it's accompanied by a new manifest. Each manifest contained in the `manifest.json` file provides metadata and other basic information about the export.

The manifest information includes the following properties:

- `sourceAccountId` – The account ID of the configuration owner.
- `configId` – A unique identifier for the dashboard.
- `destinationBucket` – The destination bucket Amazon Resource Name (ARN) that the metrics export is placed in.
- `reportVersion` – The version of the export.
- `reportDate` – The date of the report.
- `reportFormat` – The format of the report.
- `reportSchema` – The schema of the report.
- `reportFiles` – The actual list of the export report files that are in the destination bucket.

Manifest destination path example:

```
user-defined-prefix/StorageLens/111122223333/example-dashboard-configuration-id/V_1/manifests/dt=2025-03-18/manifest.json
```

The following example shows a `manifest.json` file for a CSV-formatted Storage Lens default metrics report:

```
{  
  "sourceAccountId": "111122223333",  
  "configId": "example-dashboard-configuration-id",  
  "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
  "reportVersion": "V_1",  
  "reportDate": "2025-07-15",  
  "reportFormat": "CSV",
```

```
"reportSchema":  
"version_number,configuration_id,report_date,aws_account_number,aws_region,storage_class,recor  
  
"reportFiles": [  
    {  
        "key": "DestinationPrefix/StorageLens/111122223333/example-dashboard-  
configuration-id/V_1/reports/dt=2025-07-15/12345678-1234-1234-1234-123456789012.csv",  
        "size": 1603959,  
        "md5Checksum": "2177e775870def72b8d84febe1ad3574"  
    }  
]  
}
```

The following example shows a `manifest.json` file for a CSV-formatted Storage Lens expanded prefixes metrics report:

```
{  
    "sourceAccountId": "111122223333",  
    "configId": "example-dashboard-configuration-id",

You can configure your metrics export to be generated as part of your dashboard configuration in the Amazon S3 console or by using the Amazon S3 REST API, AWS CLI, and SDKs.

Understanding the Amazon S3 Storage Lens export schemas

S3 Storage Lens export schemas vary depending on your export destination. Choose the appropriate schema based on whether you're exporting to S3 general purpose buckets or S3 tables.

Topics

- [Export schema for S3 general purpose buckets](#)
- [Export schemas for S3 tables](#)

Export schema for S3 general purpose buckets

The following table contains the schema of your S3 Storage Lens metrics export when exporting to S3 general purpose buckets.

Attribute name	Data type	Column name	Description
VersionNumber	String	version_number	The version of the S3 Storage Lens metrics being used.
ConfigurationId	String	configuration_id	The configuration_id of your S3 Storage Lens configuration.
ReportDate	String	report_date	The date that the metrics were tracked.
AwsAccountNumber	String	aws_account_number	Your AWS account number.

Attribute name	Data type	Column name	Description
AwsRegion	String	aws_region	The AWS Region for which the metrics are being tracked.
StorageClass	String	storage_class	The storage class of the bucket in question.
RecordType	ENUM	record_type	The type of artifact that is being reported (ACCOUNT, BUCKET, or PREFIX).
RecordValue	String	record_value	The value of the RecordType artifact. <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> i Note The record_value is URL-encoded. </div>
BucketName	String	bucket_name	The name of the bucket that is being reported.
MetricName	String	metric_name	The name of the metric that is being reported.
MetricValue	Long	metric_value	The value of the metric that is being reported.

Example of an S3 Storage Lens metrics export

The following is an example of an S3 Storage Lens metrics export based on this schema.

Note

You can identify metrics for Storage Lens groups by looking for the STORAGE_LENS_GROUP_BUCKET or STORAGE_LENS_GROUP_ACCOUNT values in the record_type column. The record_value column will display the Amazon Resource Name (ARN) for the Storage Lens group, for example, arn:aws:s3:us-east-1:123456789012:storage-lens-group/slg-1.

version_r	configuration_id	report_date	aws_account_number	aws_region	storage_class	record_type	record_value	bucket_name	metric_name	metric_value

Export schemas for S3 tables

When exporting S3 Storage Lens metrics to S3 tables, the data is organized into three separate table schemas: storage metrics, bucket property metrics, and activity metrics.

Topics

- [Storage metrics table schema](#)
- [Bucket property metrics table schema](#)
- [Activity metrics table schema](#)

Storage metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamp tz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to

Name	Type	Description
aws_region	string	Region
storage_class	string	Storage Class
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX, LENS GROUP.
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix
bucket_name	string	Bucket name
object_count	long	Number of objects stored for the current referenced item
storage_bytes	DECIMAL(3 8,0)	Number of bytes stored for the current referenced item
bucket_ke y_sse_kms _object_count	long	Number of objects encrypted with a customer managed key stored for the current referenced item
bucket_ke y_sse_kms _storage_bytes	DECIMAL(3 8,0)	Number of bytes encrypted with a customer managed key stored for the current referenced item
current_v ersion_ob ject_count	long	Number of current version objects stored for the current referenced item
current_v ersion_st orage_bytes	DECIMAL(3 8,0)	Number of current version bytes stored for the current referenced item

Name	Type	Description
delete_marker_object_count	long	Number of delete marker objects stored for the current referenced item
delete_marker_storage_bytes	DECIMAL(38,0)	Number of delete marker bytes stored for the current referenced item
encrypted_object_count	long	Number of encrypted objects stored for the current referenced item
encrypted_storage_bytes	DECIMAL(38,0)	Number of encrypted bytes stored for the current referenced item
incomplete_mpu_object_older_than_7_days_count	long	Number of incomplete multipart upload objects older than 7 days stored for the current referenced item
incomplete_mpu_storage_older_than_7_days_bytes	DECIMAL(38,0)	Number of incomplete multipart upload bytes stored older than 7 days for the current referenced item
incomplete_mpu_object_count	long	Number of incomplete multipart upload objects stored for the current referenced item
incomplete_mpu_storage_bytes	DECIMAL(38,0)	Number of incomplete multipart upload bytes stored for the current referenced item

Name	Type	Description
non_current_version_object_count	long	Number of non-current version objects stored for the current referenced item
non_current_version_storage_bytes	DECIMAL(38,0)	Number of non-current version bytes stored for the current referenced item
object_lock_enabled_object_count	long	Number of objects stored for objects with lock enabled in the current referenced item
object_lock_enabled_storage_bytes	DECIMAL(38,0)	Number of bytes stored for objects with lock enabled in the current referenced item
replicated_object_count	long	Number of objects replicated for the current referenced item
replicated_storage_bytes	DECIMAL(38,0)	Number of bytes replicated for the current referenced item
replicated_object_source_count	long	Number of objects replicated as source stored for the current referenced item
replicated_storage_source_bytes	DECIMAL(38,0)	Number of bytes replicated as source for the current referenced item
sse_kms_object_count	long	Number of objects encrypted with SSE key stored for the current referenced item

Name	Type	Description
sse_kms_storage_bytes	DECIMAL(38,0)	Number of bytes encrypted with SSE key stored for the current referenced item
object_0kb_count	long	Number of objects with sizes equal to 0KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_0kb_to_128kb_count	long	Number of objects with sizes greater than 0KB and less than equal to 128KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_128kb_to_256kb_count	long	Number of objects with sizes greater than 128KB and less than equal to 256KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_256kb_to_512kb_count	long	Number of objects with sizes greater than 256KB and less than equal to 512KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_512kb_to_1mb_count	long	Number of objects with sizes greater than 512KB and less than equal to 1MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_1mb_to_2mb_count	long	Number of objects with sizes greater than 1MB and less than equal to 2MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_2mb_to_4mb_count	long	Number of objects with sizes greater than 2MB and less than equal to 4MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Name	Type	Description
object_4m b_to_8mb_count	long	Number of objects with sizes greater than 4MB and less than equal to 8MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_8m b_to_16mb _count	long	Number of objects with sizes greater than 8MB and less than equal to 16MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_16 mb_to_32m b_count	long	Number of objects with sizes greater than 16MB and less than equal to 32MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_32 mb_to_64m b_count	long	Number of objects with sizes greater than 32MB and less than equal to 64MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_64 mb_to_128 mb_count	long	Number of objects with sizes greater than 64MB and less than equal to 128MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_12 8mb_to_25 6mb_count	long	Number of objects sizes greater than 128MB and less than equal to 256MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_25 6mb_to_51 2mb_count	long	Number of objects sizes greater than 256MB and less than equal to 512MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Name	Type	Description
object_51_2mb_to_1gb_count	long	Number of objects sizes greater than 512MB and less than equal to 1GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_1gb_to_2gb_count	long	Number of objects sizes greater than 1GB and less than equal to 2GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_2gb_to_4gb_count	long	Number of objects sizes greater than 2GB and less than equal to 4GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_larger_than_4gb_count	long	Number of objects sizes greater than 4GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Bucket property metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamp_tz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX, LENS GROUP.

Name	Type	Description
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix.
aws_region	string	Region
storage_class	string	Storage Class
bucket_name	string	Bucket name
versioning_enabled_bucket_count	long	Number of buckets with versioning enabled for the current referenced item
mfa_delete_enabled_bucket_count	long	Number of buckets with MFA delete enabled for the current referenced item
sse_kms_enabled_bucket_count	long	Number of buckets with KMS enabled for the current referenced item
object_ownership_bucket_owner_enforced_bucket_count	long	Number of buckets with Object Ownership bucket owner enforced for the current referenced item
object_ownership_bucket_owner_preferred_bucket_count	long	Number of buckets with Object Ownership bucket owner preferred for the current referenced item

Name	Type	Description
object_ownership_object_writer_bucket_count	long	Number of buckets with Object Ownership object writer for the current referenced item
transfer_acceleration_enabled_bucket_count	long	Number of buckets with transfer acceleration enabled for the current referenced item
event_notification_enabled_bucket_count	long	Number of buckets with event notification enabled for the current referenced item
transition_lifecycle_rule_count	long	Number of transition lifecycle rules for the current referenced item
expiration_lifecycle_rule_count	long	Number of expiration lifecycle rules for the current referenced item
non_current_version_transition_lifecycle_rule_count	long	Number of noncurrent version transition lifecycle rules for the current referenced item

Name	Type	Description
non_current_version_expiration_lifecycle_rule_count	long	Number of noncurrent version expiration lifecycle rules for the current referenced item
abort_incomplete_multipart_upload_lifecycle_rule_count	long	Number of abort incomplete multipart upload lifecycle rules for the current referenced item
expired_object_delete_marker_lifecycle_rule_count	long	Number of expire object delete marker lifecycle rules for the current referenced item
same_region_replication_rule_count	long	Number of Same-Region Replication rule count for the current referenced item
cross_region_replication_rule_count	long	Number of Cross-Region Replication rule count for the current referenced item
same_account_replication_rule_count	long	Number of Same-account replication rule count for the current referenced item

Name	Type	Description
cross_account_replication_rule_count	long	Number of Cross-account replication rule count for the current referenced item
invalid_destination_replication_rule_count	long	Number of buckets with Invalid destination replication for the current referenced item

Activity metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamp tz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to
aws_region	string	Region
storage_class	string	Storage Class
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX.
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix
bucket_name	string	Bucket name

Name	Type	Description
all_request_count	long	Number of _all_ requests for the current referenced item
all_sse_kms_encrypted_request_count	long	Number of KMS encrypted requests for the current referenced item
all_unsupported_sig_request_count	long	Number of unsupported sig requests for the current referenced item
all_unsupported_tls_request_count	long	Number of unsupported TLS requests for the current referenced item
bad_request_error_400_count	long	Number of 400 bad request errors for the current referenced item
delete_request_count	long	Number of delete requests for the current referenced item
downloaded_bytes	decimal(0,0)	Number of downloaded bytes for the current referenced item
error_4xx_count	long	Number of 4xx errors for the current referenced item
error_5xx_count	long	Number of 5xx errors for the current referenced item
forbidden_error_403_count	long	Number of 403 forbidden errors for the current referenced item

Name	Type	Description
get_request_count	long	Number of get requests for the current referenced item
head_request_count	long	Number of head requests for the current referenced item
internal_server_error_500_count	long	Number of 500 internal server errors for the current referenced item
list_request_count	long	Number of list requests for the current referenced item
not_found_error_404_count	long	Number of 404 not found errors for the current referenced item
ok_status_200_count	long	Number of 200 OK requests for the current referenced item
partial_content_status_206_count	long	Number of 206 partial content requests for the current referenced item
post_request_count	long	Number of post requests for the current referenced item
put_request_count	long	Number of put requests for the current referenced item
select_request_count	long	Number of select requests for the current referenced item
select_returned_bytes	decimal(0,0)	Number of bytes returned by select requests for the current referenced item

Name	Type	Description
select_scanned_bytes	decimal(0,0)	Number of bytes scanned by select requests for the current referenced item
service_unavailable_error_503_count	long	Number of 503 service unavailable errors for the current referenced item
uploaded_bytes	decimal(0,0)	Number of uploaded bytes for the current referenced item
average_first_byte_latency	long	Average per-request time between when an S3 bucket receives a complete request and when it starts returning the response, measured over the past 24 hours
average_total_request_latency	long	Average elapsed per-request time between the first byte received and the last byte sent to an S3 bucket, measured over the past 24 hours
read_0kb_request_count	long	Number of GetObject requests with data sizes of 0KB, including both range-based requests and whole object requests
read_0kb_to_128kb_request_count	long	Number of GetObject requests with data sizes greater than 0KB and up to 128KB, including both range-based requests and whole object requests
read_128kb_to_256kb_request_count	long	Number of GetObject requests with data sizes greater than 128KB and up to 256KB, including both range-based requests and whole object requests
read_256kb_to_512kb_request_count	long	Number of GetObject requests with data sizes greater than 256KB and up to 512KB, including both range-based requests and whole object requests

Name	Type	Description
read_512k_b_to_1mb_request_count	long	Number of GetObject requests with data sizes greater than 512KB and up to 1MB, including both range-based requests and whole object requests
read_1mb_to_2mb_request_count	long	Number of GetObject requests with data sizes greater than 1MB and up to 2MB, including both range-based requests and whole object requests
read_2mb_to_4mb_request_count	long	Number of GetObject requests with data sizes greater than 2MB and up to 4MB, including both range-based requests and whole object requests
read_4mb_to_8mb_request_count	long	Number of GetObject requests with data sizes greater than 4MB and up to 8MB, including both range-based requests and whole object requests
read_8mb_to_16mb_request_count	long	Number of GetObject requests with data sizes greater than 8MB and up to 16MB, including both range-based requests and whole object requests
read_16mb_to_32mb_request_count	long	Number of GetObject requests with data sizes greater than 16MB and up to 32MB, including both range-based requests and whole object requests
read_32mb_to_64mb_request_count	long	Number of GetObject requests with data sizes greater than 32MB and up to 64MB, including both range-based requests and whole object requests
read_64mb_to_128mb_request_count	long	Number of GetObject requests with data sizes greater than 64MB and up to 128MB, including both range-based requests and whole object requests
read_128mb_to_256mb_request_count	long	Number of GetObject requests with data sizes greater than 128MB and up to 256MB, including both range-based requests and whole object requests

Name	Type	Description
read_256m_b_to_512m_b_request_count	long	Number of GetObject requests with data sizes greater than 256MB and up to 512MB, including both range-based requests and whole object requests
read_512m_b_to_1gb_request_count	long	Number of GetObject requests with data sizes greater than 512MB and up to 1GB, including both range-based requests and whole object requests
read_1gb_to_2gb_request_count	long	Number of GetObject requests with data sizes greater than 1GB and up to 2GB, including both range-based requests and whole object requests
read_2gb_to_4gb_request_count	long	Number of GetObject requests with data sizes greater than 2GB and up to 4GB, including both range-based requests and whole object requests
read_larger_than_4gb_request_count	long	Number of GetObject requests with data sizes greater than 4GB, including both range-based requests and whole object requests
write_0kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes of 0KB
write_0kb_to_128kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 0KB and up to 128KB
write_128kb_to_256kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 128KB and up to 256KB

Name	Type	Description
write_256_kb_to_512_kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 256KB and up to 512KB
write_512_kb_to_1mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 512KB and up to 1MB
write_1mb_to_2mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 1MB and up to 2MB
write_2mb_to_4mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 2MB and up to 4MB
write_4mb_to_8mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 4MB and up to 8MB
write_8mb_to_16mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 8MB and up to 16MB
write_16mb_to_32mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 16MB and up to 32MB
write_32mb_to_64mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 32MB and up to 64MB

Name	Type	Description
write_64m b_to_128m b_request _count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 64MB and up to 128MB
write_128 mb_to_256 mb_reques t_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 128MB and up to 256MB
write_256 mb_to_512 mb_reques t_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 256MB and up to 512MB
write_512 mb_to_1gb _request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 512MB and up to 1GB
write_1gb _to_2gb_r equest_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 1GB and up to 2GB
write_2gb _to_4gb_r equest_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 2GB and up to 4GB
write_lar ger_than_ 4gb_reque st_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 4GB
concurren t_put_503 _error_count	long	Number of 503 errors that are generated due to concurrent writes to the same object

Name	Type	Description
cross_region_request_count	long	Number of requests that originate from a client in different Region than bucket's home Region
cross_region_transferred_bytes	decimal(0,0)	Number of bytes that are transferred from calls in different Region than bucket's home Region
cross_region_withinout_replication_request_count	long	Number of requests that originate from a client in different Region than bucket's home Region, excluding cross-region replication requests
cross_region_withinout_replication_transferred_bytes	decimal(0,0)	Number of bytes that are transferred from calls in different Region than bucket's home Region, excluding cross-region replication bytes
inregion_request_count	long	Number of requests that originate from a client in same Region as bucket's home Region
inregion_transferred_bytes	decimal(0,0)	Number of bytes that are transferred from calls from same Region as bucket's home Region
unique_objects_accessed_dAILY_count	long	Number of objects that were accessed at least once in last 24 hrs

Monitor S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features,

such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, and AWS SDKs. Dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations can use the CloudWatch publishing option. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see [Amazon CloudWatch pricing](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

After you enable the CloudWatch publishing option, you can use the following CloudWatch features to monitor and analyze your S3 Storage Lens data:

- [Dashboards](#) – Use CloudWatch dashboards to create customized S3 Storage Lens dashboards. Share your CloudWatch dashboard with people who don't have direct access to your AWS account, across teams, with stakeholders, and with people external to your organizations.
- [Alarms and triggered actions](#) – Configure alarms that watch metrics and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS

notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.

- **Anomaly detection** – Enable anomaly detection to continuously analyze metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on the expected value of a metric. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.
- **Metric math** – You can also use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric to get the average object size by dividing `StorageBytes` by `ObjectCount`.

For more information about the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

Topics

- [S3 Storage Lens metrics and dimensions](#)
- [Enabling CloudWatch publishing for S3 Storage Lens](#)
- [Working with S3 Storage Lens metrics in CloudWatch](#)

S3 Storage Lens metrics and dimensions

To send S3 Storage Lens metrics to CloudWatch, you must enable the CloudWatch publishing option within S3 Storage Lens advanced metrics. After advanced metrics are enabled, you can use [CloudWatch dashboards](#) to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. You can use dimensions to filter your S3 Storage Lens metrics in CloudWatch by organization, account, bucket, storage class, Region, and metrics configuration ID.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must

be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

For more information about S3 Storage Lens metrics and dimensions in CloudWatch, see the following topics.

Topics

- [Metrics](#)
- [Dimensions](#)

Metrics

S3 Storage Lens metrics are available as metrics within CloudWatch. S3 Storage Lens metrics are published to the AWS/S3/Storage-Lens namespace. This namespace is only for S3 Storage Lens metrics. Amazon S3 bucket, request, and replication metrics are published to the AWS/S3 namespace.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

In S3 Storage Lens, metrics are aggregated and stored only in the designated home Region. S3 Storage Lens metrics are also published to CloudWatch in the home Region that you specify in the S3 Storage Lens configuration.

For a complete list of S3 Storage Lens metrics, including a list of those metrics available in CloudWatch, see [Amazon S3 Storage Lens metrics glossary](#).

Note

The valid statistic for S3 Storage Lens metrics in CloudWatch is Average. For more information about statistics in CloudWatch, see [CloudWatch statistics definitions](#) in the *Amazon CloudWatch User Guide*.

Granularity of S3 Storage Lens metrics in CloudWatch

S3 Storage Lens offers metrics at organization, account, bucket, and prefix granularity. S3 Storage Lens publishes organization, account, and bucket-level S3 Storage Lens metrics to CloudWatch. Prefix-level S3 Storage Lens metrics are not available in CloudWatch.

For more information about the granularity of S3 Storage Lens metrics available in CloudWatch, see the following list:

- **Organization** – Metrics aggregated across the member accounts in your organization. S3 Storage Lens publishes metrics for member accounts to CloudWatch in the management account.
 - **Organization and account** – Metrics for the member accounts in your organization.
 - **Organization and bucket** – Metrics for Amazon S3 buckets in the member accounts of your organization.
- **Account** (Non-organization level) – Metrics aggregated across the buckets in your account.
- **Bucket** (Non-organization level) – Metrics for a specific bucket. In CloudWatch, S3 Storage Lens publishes these metrics to the AWS account that created the S3 Storage Lens configuration. S3 Storage Lens publishes these metrics only for non-organization configurations.

Dimensions

When S3 Storage Lens sends data to CloudWatch, dimensions are attached to each metric. Dimensions are categories that describe the characteristics of metrics. You can use dimensions to filter the results that CloudWatch returns.

For example, all S3 Storage Lens metrics in CloudWatch have the `configuration_id` dimension. You can use this dimension to differentiate between metrics associated with a specific S3 Storage Lens configuration. The `organization_id` identifies organization-level metrics. For more information about dimensions in CloudWatch, see [Dimensions](#) in the *CloudWatch User Guide*.

Different dimensions are available for S3 Storage Lens metrics depending on the granularity of the metrics. For example, you can use the `organization_id` dimension to filter organization-level metrics by the AWS Organizations ID. However, you can't use this dimension for bucket and account-level metrics. For more information, see [Filtering metrics using dimensions](#).

To see which dimensions are available for your S3 Storage Lens configuration, see the following table.

Dimension	Description	Bucket	Account	Organization	Region	Granularity
<code>configuration_id</code>	The dashboard name for the S3 Storage Lens configuration reported in the metrics	•	•	•	•	•
<code>metrics_version</code>	The version of the S3 Storage Lens metrics. The metrics version has a fixed value of <code>1.0</code> .	•	•	•	•	•
<code>organization_id</code>	The AWS Organizations ID for the metrics	•	•	•	•	•
<code>aws_account_number</code>	The AWS account that's associated with the metrics	•	•	•	•	•
<code>aws_region</code>	The AWS Region for the metrics	•	•	•	•	•
<code>bucket_name</code>	The name of the S3 bucket that's reported in the metrics	•	•	•	•	•
<code>storage_class</code>	The storage class for the bucket that's reported in the metrics	•	•	•	•	•
<code>record_type</code>	The granularity of the metrics: <code>ORGANIZATION</code> , <code>ACCOUNT</code> , <code>BUCKET</code>	BUCKET	BUCKET	ACCOUNT	REGION	ORGANIZATION

Enabling CloudWatch publishing for S3 Storage Lens

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

You can enable CloudWatch support for new or existing dashboard configurations by using the S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply.

To enable the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

Using the S3 console

When you update an S3 Storage Lens dashboard, you can't change the dashboard name or home Region. You also can't change the scope of the default dashboard, which is scoped to your entire account's storage.

To update an S3 Storage Lens dashboard to enable CloudWatch publishing

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **S3 Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit**.
4. Under **Metrics selection**, choose **Advanced metrics and recommendations**.

Advanced metrics and recommendations are available for an additional charge. Advanced metrics and recommendations include a 15-month period for data queries, usage metrics aggregated at the prefix level, activity metrics aggregated by bucket, the CloudWatch publishing option, and contextual recommendations that help you optimize storage costs and apply data-protection best practices. For more information, see [Amazon S3 pricing](#).

5. Under **Select Advanced metrics and recommendations features**, select **CloudWatch publishing**.

 **Important**

If your configuration enables prefix aggregation for usage metrics, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

6. Choose **Save changes**.

To create a new S3 Storage Lens dashboard that enables CloudWatch support

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose **Create dashboard**.
4. Under **General**, define the following configuration options:

- a. For **Dashboard name**, enter your dashboard name.

Dashboard names must be fewer than 65 characters and must not contain special characters or spaces. You can't change the dashboard name after you create your dashboard.

- b. Choose the **Home Region** for your dashboard.

Metrics for all Regions included in this dashboard scope are stored centrally in the designated home Region. In CloudWatch, S3 Storage Lens metrics are also available in the home Region. You can't change the home Region after you create your dashboard.

5. (Optional) To add tags, choose **Add tag** and enter the tag **Key** and **Value**.

 **Note**

You can add up to 50 tags to your dashboard configuration.

6. Define the scope for your configuration:

- a. If you're creating an organization-level configuration, choose the accounts to include in the configuration: **Include all accounts in your configuration** or **Limit the scope to your signed-in account**.

 **Note**

When you create an organization-level configuration that includes all accounts, you can include or exclude only Regions, not buckets.

- b. Choose the Regions and buckets that you want S3 Storage Lens to include in the dashboard configuration by doing the following:
 - To include all Regions, choose **Include Regions and buckets**.
 - To include specific Regions, clear **Include all Regions**. Under **Choose Regions to include**, choose the Regions that you want S3 Storage Lens to include in the dashboard.
 - To include specific buckets, clear **Include all buckets**. Under **Choose buckets to include**, choose the buckets that you want S3 Storage Lens to include in the dashboard.

Note

You can choose up to 50 buckets.

7. For Metrics selection, choose Advanced metrics and recommendations.

For more information about advanced metrics and recommendations pricing, see [Amazon S3 pricing](#).

8. Under Advanced metrics and recommendations features, select the options that you want to enable:

- **Advanced metrics**
- **CloudWatch publishing**

⚠ Important

If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

- **Prefix aggregation**

Note

For more information about advanced metrics and recommendations features, see [Metrics selection](#).

9. If you enabled Advanced metrics, select the Advanced metrics categories that you want to display in your S3 Storage Lens dashboard:

- **Activity metrics**
- **Detailed status code metrics**
- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information about metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

10. (Optional) Configure your metrics export.

For more information about how to configure a metrics export, see step [Using the S3 console](#).

11. Choose **Create dashboard**.

Using the AWS CLI

The following AWS CLI example enables the CloudWatch publishing option by using a S3 Storage Lens organization-level advanced metrics and recommendations configuration. To use this example, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=555555555555 --config-id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json

config.json
{
    "Id": "SampleS3StorageLensConfiguration",
    "AwsOrg": {
        "Arn": "arn:aws:organizations::123456789012:organization/o-abcdefg"
    },
    "AccountLevel": {
        "ActivityMetrics": {
            "Enabled": true
        },
        "AdvancedCostOptimizationMetrics": {
            "Enabled": true
        },
        "AdvancedDataProtectionMetrics": {
            "Enabled": true
        },
        "DetailedStatusCodesMetrics": {
            "Enabled": true
        },
        "BucketLevel": {
            "ActivityMetrics": {
                "Enabled": true
            }
        }
    }
}
```

```
"AdvancedCostOptimizationMetrics": {  
    "Enabled": true  
},  
"DetailedStatusCodesMetrics": {  
    "Enabled": true  
},

Using the REST API

To enable the CloudWatch publishing option by using the Amazon S3 REST API, you can use [PutStorageLensConfiguration](#).

Next steps

After you enable the CloudWatch publishing option, you can access your S3 Storage Lens metrics in CloudWatch. You also can leverage CloudWatch features to monitor and analyze your S3 Storage Lens data in CloudWatch. For more information, see the following topics:

- [S3 Storage Lens metrics and dimensions](#)
- [Working with S3 Storage Lens metrics in CloudWatch](#)

Working with S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see [Amazon CloudWatch pricing](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day.

When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

For more information about working with S3 Storage Lens metrics in CloudWatch, see the following topics.

Topics

- [Working with CloudWatch dashboards](#)
- [Setting alarms, triggering actions, and using anomaly detection](#)
- [Filtering metrics using dimensions](#)
- [Calculating new metrics with metric math](#)
- [Using search expressions in graphs](#)

Working with CloudWatch dashboards

You can use CloudWatch dashboards to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view.

CloudWatch has broad permissions control that doesn't support limiting access to a specific set of metrics or dimensions. Users in your account or organization who have access to CloudWatch will have access to metrics for all S3 Storage Lens configurations where the CloudWatch support option is enabled. You can't manage permissions for specific dashboards as you can in S3 Storage Lens. For more information about CloudWatch permissions, see [Managing access permissions to your CloudWatch resources](#) in the *Amazon CloudWatch User Guide*.

For more information about using CloudWatch dashboards and configuring permissions, see [Using Amazon CloudWatch dashboards](#) and [Sharing CloudWatch dashboards](#) in the *Amazon CloudWatch User Guide*.

Setting alarms, triggering actions, and using anomaly detection

You can configure CloudWatch alarms that watch S3 Storage Lens metrics in CloudWatch and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.

You can also enable anomaly detection to continuously analyze your S3 Storage Lens metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on a metric's expected value. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.

For more information and examples, see [Using Amazon CloudWatch alarms](#) and [Creating an alarm from a metric on a graph](#) in the *Amazon CloudWatch User Guide*.

Filtering metrics using dimensions

You can use dimensions to filter S3 Storage Lens metrics in the CloudWatch console. For example, you can filter by `configuration_id`, `aws_account_number`, `aws_region`, `bucket_name`, and more.

S3 Storage Lens supports multiple dashboard configurations per account. This means that different configurations can include the same bucket. When these metrics are published to CloudWatch, the bucket will have duplicate metrics within CloudWatch. To view metrics only for a specific S3 Storage Lens configuration in CloudWatch, you can use the `configuration_id` dimension. When you filter by `configuration_id`, you see only the metrics that are associated with the configuration that you identify.

For more information about filtering by configuration ID, see [Searching for available metrics](#) in the *Amazon CloudWatch User Guide*.

Calculating new metrics with metric math

You can use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric for unencrypted objects by subtracting Encrypted Objects from Object Count. You can also create a

metric to get the average object size by dividing `StorageBytes` by `ObjectCount` or the number bytes accessed on one day by dividing `BytesDownloaded` by `StorageBytes`.

For more information, see [Using metric math](#) in the *Amazon CloudWatch User Guide*.

Using search expressions in graphs

With S3 Storage Lens metrics, you can create a search expression. For example, you can create a search expression for all metrics that are named `IncompleteMultipartUploadStorageBytes` and add `SUM` to the expression. With this search expression, you can see your total incomplete multipart upload bytes across all dimensions of your storage in a single metric.

This example shows the syntax that you would use to create a search expression for all metrics named `IncompleteMultipartUploadStorageBytes`.

```
SUM(SEARCH( '{AWS/S3/Storage-  
Lens,aws_account_number,aws_region,configuration_id,metrics_version,record_type,storage_class}  
MetricName="IncompleteMultipartUploadStorageBytes"', 'Average',86400))
```

For more information about this syntax, see [CloudWatch search expression syntax](#) in the *Amazon CloudWatch User Guide*. To create a CloudWatch graph with a search expression, see [Creating a CloudWatch graph with a search expression](#) in the *Amazon CloudWatch User Guide*.

Amazon S3 Storage Lens metrics use cases

You can use your Amazon S3 Storage Lens dashboard to visualize insights and trends, flag outliers, and receive recommendations. S3 Storage Lens metrics are organized into categories that align with key use cases. You can use these metrics to do the following:

- Identify cost-optimization opportunities
- Apply data-protection best practices
- Apply access-management best practices
- Improve the performance of application workloads

For example, with cost-optimization metrics, you can identify opportunities to reduce your Amazon S3 storage costs. You can identify buckets with multipart uploads that are more than 7-days old or buckets that are accumulating noncurrent versions.

Similarly, you can use data-protection metrics to identify buckets that aren't following data-protection best practices within your organization. For example, you can identify buckets that

don't use AWS Key Management Service keys (SSE-KMS) for default encryption or don't have S3 Versioning enabled.

With S3 Storage Lens access-management metrics, you can identify bucket settings for S3 Object Ownership so that you can migrate access control list (ACL) permissions to bucket policies and disable ACLs.

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use detailed status-code metrics to get counts for successful or failed requests that you can use to troubleshoot access or performance issues.

With advanced metrics, you can also access additional cost-optimization and data-protection metrics that you can use to identify opportunities to further reduce your overall S3 storage costs and better align with best practices for protecting your data. For example, advanced cost-optimization metrics include lifecycle rule counts that you can use to identify buckets that don't have lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. Advanced data-protection metrics include replication rule counts.

For more information about metrics categories, see [Metrics categories](#). For a complete list of S3 Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Topics

- [Using Amazon S3 Storage Lens to optimize your storage costs](#)
- [Using S3 Storage Lens to protect your data](#)
- [Using S3 Storage Lens to audit Object Ownership settings](#)
- [Using S3 Storage Lens metrics to improve performance](#)

Using Amazon S3 Storage Lens to optimize your storage costs

You can use S3 Storage Lens cost-optimization metrics to reduce the overall cost of your S3 storage. Cost-optimization metrics can help you confirm that you've configured Amazon S3 cost effectively and according to best practices. For example, you can identify the following cost-optimization opportunities:

- Buckets with incomplete multipart uploads older than 7 days
- Buckets that are accumulating numerous noncurrent versions
- Buckets that don't have lifecycle rules to abort incomplete multipart uploads
- Buckets that don't have lifecycle rules to expire noncurrent versions objects

- Buckets that don't have lifecycle rules to transition objects to a different storage class

You can then use this data to add additional lifecycle rules to your buckets.

The following examples show how you can use cost- optimization metrics in your S3 Storage Lens dashboard to optimize your storage costs.

Topics

- [Identify your largest S3 buckets](#)
- [Uncover cold Amazon S3 buckets](#)
- [Locate incomplete multipart uploads](#)
- [Reduce the number of noncurrent versions retained](#)
- [Identify buckets that don't have lifecycle rules and review lifecycle rule counts](#)

Identify your largest S3 buckets

You pay for storing objects in S3 buckets. The rate that you're charged depends on your objects' sizes, how long you store the objects, and their storage classes. With S3 Storage Lens, you get a centralized view of all the buckets in your account. To see all the buckets in all of your organization's accounts, you can configure an AWS Organizations-level S3 Storage Lens dashboard. From this dashboard view, you can identify your largest buckets.

Step 1: Identify your largest buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

When the dashboard opens, you can see the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads to the latest date that has metrics available.

4. To see a ranking of your largest buckets by the **Total storage** metric for a selected date range, scroll down to the **Top N overview for date** section.

You can toggle the sort order to show the smallest buckets. You can also adjust the **Metric** selection to rank your buckets by any of the available metrics. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line

to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

 **Note**

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For more detailed insights about your buckets, scroll up to the top of the page, and then choose the **Bucket** tab.

On the **Bucket** tab, you can see details such as the recent growth rate, the average object size, the largest prefixes, and the number of objects.

Step 2: Navigate to your buckets and investigate

After you've identified your largest S3 buckets, you can navigate to each bucket within the S3 console to view the objects in the bucket, understand its associated workload, and identify its internal owners. You can contact the bucket owners to find out whether the growth is expected or whether the growth needs further monitoring and control.

Uncover cold Amazon S3 buckets

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use [activity metrics](#) to understand how cold your S3 buckets are. A "cold" bucket is one whose storage is no longer accessed (or very rarely accessed). This lack of activity typically indicates that the bucket's objects aren't frequently accessed.

Activity metrics, such as **GET Requests** and **Download Bytes**, indicate how often your buckets are accessed each day. To understand the consistency of the access pattern and to spot buckets that are no longer being accessed at all, you can trend this data over several months. The **Retrieval rate** metric, which is computed as **Download bytes / Total storage**, indicates the proportion of storage in a bucket that is accessed daily.

 **Note**

Download bytes are duplicated in cases where the same object is downloaded multiple times during the day.

Prerequisite

To see activity metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Activity metrics**. For more information, see [Using the S3 console](#).

Step 1: Identify active buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. Choose the **Bucket** tab, and then scroll down to the **Bubble analysis by buckets for date** section.

In the **Bubble analysis by buckets for date** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

5. To find buckets that have gone cold, for **X-axis**, **Y-axis**, and **Size**, choose the **Total storage**, **% retrieval rate**, and **Average object size** metrics.
6. In the **Bubble analysis by buckets for date** section, locate any buckets with retrieval rates of zero (or near zero) and a larger relative storage size, and choose the bubble that represents the bucket.

A box will appear with choices for more granular insights. Do one of the following:

- a. To update the **Bucket** tab to display metrics only for the selected bucket, choose **Drill down**, and then choose **Apply**.
- b. To aggregate your bucket-level data to by account, AWS Region, storage class, or bucket, choose **Analyze by** and then make a choice for **Dimension**. For example, to aggregate by storage class, choose **Storage class** for **Dimension**.

To find buckets that have gone cold, do a bubble analysis using the **Total storage**, **% retrieval rate**, and **Average object size** metrics. Look for any buckets with retrieval rates of zero (or near zero) and a larger relative storage size.

The **Bucket** tab of your dashboard updates to display data for your selected aggregation or filter. If you aggregated by storage class or another dimension, that new tab opens in your dashboard (for example, the **Storage class** tab).

Step 2: Investigate cold buckets

From here, you can identify the owners of cold buckets in your account or organization and find out if that storage is still needed. You can then optimize costs by configuring [lifecycle expiration configurations](#) for these buckets or archiving the data in one of the [Amazon Glacier storage classes](#).

To avoid the problem of cold buckets going forward, you can [automatically transition your data by using S3 Lifecycle configurations](#) for your buckets, or you can enable [auto-archiving with S3 Intelligent-Tiering](#).

You can also use step 1 to identify hot buckets. Then, you can ensure that these buckets use the correct [S3 storage class](#) to ensure that they serve their requests most effectively in terms of performance and cost.

Locate incomplete multipart uploads

You can use multipart uploads to upload very large objects (up to 50 TB) as a set of parts for improved throughput and quicker recovery from network issues. In cases where the multipart upload process doesn't finish, the incomplete parts remain in the bucket (in an unusable state). These incomplete parts incur storage costs until the upload process is finished, or until the incomplete parts are removed. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).

With S3 Storage Lens, you can identify the number of incomplete multipart upload bytes in your account or across your entire organization, including incomplete multipart uploads that are more than 7 days old. For a complete list of incomplete multipart upload metrics, see [Amazon S3 Storage Lens metrics glossary](#).

As a best practice, we recommend configuring lifecycle rules to expire incomplete multipart uploads that are older than a specific number of days. When you create your lifecycle rule to expire incomplete multipart uploads, we recommend 7 days as a good starting point.

Step 1: Review overall trends for incomplete multipart uploads

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metrics categories**, choose **Cost optimization**.

The **Snapshot for date** section updates to display **Cost optimization** metrics, which include **Incomplete multipart upload bytes greater than 7 days old**.

In any chart in your S3 Storage Lens dashboard, you can see metrics for incomplete multipart uploads. You can use these metrics to further assess the impact of incomplete multipart upload bytes on your storage, including their contribution to overall growth trends. You can also drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Bucket**, or **Storage class** tabs for a deeper analysis of your data. For an example, see [Uncover cold Amazon S3 buckets](#).

Step 2: Identify buckets that have the most incomplete multipart upload bytes but don't have lifecycle rules to abort incomplete multipart uploads

Prerequisite

To see the **Abort incomplete multipart upload lifecycle rule count** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Using the S3 console](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets that are accumulating incomplete multipart uploads greater than 7 days old, go to the **Top N overview for date** section.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. You can increase or decrease the number of buckets in the **Top N** field. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. (This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.)

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For **Metric**, choose **Incomplete multipart upload bytes greater than 7 days old** in the **Cost optimization** category.

Under **Top number buckets**, you can see the buckets with the most incomplete multipart upload storage bytes that are greater than 7 days old.

6. To view more detailed bucket-level metrics for incomplete multipart uploads, scroll to the top of the page, and then choose the **Bucket** tab.
7. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

8. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
9. Clear the toggles for all cost-optimization metrics until only **Incomplete multipart upload bytes greater than 7 days old** and **Abort incomplete multipart upload lifecycle rule count** remain selected.
10. (Optional) Under **Page size**, choose the number of buckets to display in the list.
11. Choose **Confirm**.

The **Buckets** list updates to display bucket-level metrics for incomplete multipart uploads and lifecycle rule counts. You can use this data to identify buckets that have the most incomplete multipart upload bytes that are greater than 7 days old and are missing lifecycle rules to abort incomplete multipart uploads. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to delete abandoned incomplete multipart uploads.

Step 3: Add a lifecycle rule to delete incomplete multipart uploads after 7 days

To automatically manage incomplete multipart uploads, you can use the S3 console to create a lifecycle configuration to expire incomplete multipart upload bytes from a bucket after a specified number of days. For more information, see [Configuring a bucket lifecycle configuration to delete incomplete multipart uploads](#).

Reduce the number of noncurrent versions retained

When enabled, S3 Versioning retains multiple distinct copies of the same object that you can use to quickly recover data if an object is accidentally deleted or overwritten. If you've enabled S3 Versioning without configuring lifecycle rules to transition or expire noncurrent versions, a large number of previous noncurrent versions can accumulate, which can have storage-cost implications. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Step 1: Identify buckets with the most noncurrent object versions

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metric categories**, choose **Cost optimization**.

The **Snapshot for date** section updates to display **Cost optimization** metrics, which include the metric for **% noncurrent version bytes**. The **% noncurrent version bytes** metric represents the proportion of your total storage bytes that is attributed to noncurrent versions, within the dashboard scope and for the selected date.

 **Note**

If your **% noncurrent version bytes** is greater than 10 percent of your storage at the account level, you might be storing too many object versions.

5. To identify specific buckets that are accumulating a large number of noncurrent versions:
 - a. Scroll down to the **Top N overview for date** section. For **Top N**, enter the number of buckets that you would like to see data for.
 - b. For **Metric**, choose **% noncurrent version bytes**.

Under **Top number buckets**, you can see the buckets (for the number that you specified) with the highest **% noncurrent version bytes**. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

- c. To view more detailed bucket-level metrics for noncurrent object versions, scroll to the top of the page, and then choose the **Bucket** tab.

In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

- d. In the **Buckets** section, for **Metric categories**, select **Cost optimization**. Then, clear **Summary**.

You can now see the **% noncurrent version bytes** metric, along with other metrics related to noncurrent versions.

Step 2: Identify buckets that are missing transition and expiration lifecycle rules for managing noncurrent versions

Prerequisite

To see the **Noncurrent version transition lifecycle rule count** and **Noncurrent version expiration lifecycle rule count** metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Using the S3 console](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metric categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
 - **% noncurrent version bytes**
 - **Noncurrent version transition lifecycle rule count**
 - **Noncurrent version expiration lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display metrics for noncurrent version bytes and noncurrent version lifecycle rule counts. You can use this data to identify buckets that have a high percentage of noncurrent version bytes but are missing transition and expiration lifecycle rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules to transition or expire noncurrent object versions

After you've determined which buckets require further investigation, you can navigate to the buckets within the S3 console and add a lifecycle rule to expire noncurrent versions after a specified number of days. Alternatively, to reduce costs while still retaining noncurrent versions, you can configure a lifecycle rule to transition noncurrent versions to one of the Amazon Glacier storage classes. For more information, see [Specifying a lifecycle rule for a versioning-enabled bucket](#).

Identify buckets that don't have lifecycle rules and review lifecycle rule counts

S3 Storage Lens provides S3 Lifecycle rule count metrics that you can use to identify buckets that are missing lifecycle rules. To find buckets that don't have lifecycle rules, you can use the **Total buckets without lifecycle rules** metric. A bucket with no S3 Lifecycle configuration might have storage that you no longer need or can migrate to a lower-cost storage class. You can also use lifecycle rule count metrics to identify buckets that are missing specific types of lifecycle rules, such as expiration or transition rules.

Prerequisite

To see lifecycle rule count metrics and the **Total buckets without lifecycle rules** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Using the S3 console](#).

Step 1: Identify buckets without lifecycle rules

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets without lifecycle rules, scroll down to the **Top N overview for date** section.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

 **Note**

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For **Metric**, choose **Total buckets without lifecycle rules** from the **Cost optimization** category.
6. Review the following data for **Total buckets without lifecycle rules**:
 - **Top number accounts** - See which accounts that have the most buckets without lifecycle rules.
 - **Top number Regions** - View a breakdown of buckets without lifecycle rules by Region.
 - **Top number buckets** - See which buckets don't have lifecycle rules.

In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

After you identify which buckets don't have lifecycle rules, you can also review specific lifecycle rule counts for your buckets.

Step 2: Review lifecycle rule counts for your buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your S3 Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
 - **Transition lifecycle rule count**
 - **Expiration lifecycle rule count**
 - **Noncurrent version transition lifecycle rule count**
 - **Noncurrent version expiration lifecycle rule count**
 - **Abort incomplete multipart upload lifecycle rule count**
 - **Total lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display lifecycle rule count metrics for your buckets. You can use this data to identify buckets without lifecycle rules or buckets that are missing specific kinds of lifecycle rules, for example, expiration or transition rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules

After you've identified buckets with no lifecycle rules, you can add lifecycle rules. For more information, see [Setting an S3 Lifecycle configuration on a bucket](#) and [Examples of S3 Lifecycle configurations](#).

Using S3 Storage Lens to protect your data

You can use Amazon S3 Storage Lens data-protection metrics to identify buckets where data-protection best practices haven't been applied. You can use these metrics to take action and apply standard settings that align with best practices for protecting your data across the buckets in your account or organization. For example, you can use data-protection metrics to identify buckets that don't use AWS Key Management Service (AWS KMS) keys (SSE-KMS) for default encryption or requests that use AWS Signature Version 2 (SigV2).

The following use cases provide strategies for using your S3 Storage Lens dashboard to identify outliers and apply data-protection best practices across your S3 buckets.

Topics

- [Identify buckets that don't use server-side encryption with AWS KMS for default encryption \(SSE-KMS\)](#)
- [Identify buckets that have S3 Versioning enabled](#)
- [Identify requests that use AWS Signature Version 2 \(SigV2\)](#)
- [Count the total number of replication rules for each bucket](#)
- [Identify percentage of Object Lock bytes](#)

Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS)

With Amazon S3 default encryption, you can set the default encryption behavior for an S3 bucket. For more information, see [the section called "Setting default bucket encryption"](#).

You can use the **SSE-KMS enabled bucket count** and **% SSE-KMS enabled buckets** metrics to identify buckets that use server-side encryption with AWS KMS keys (SSE-KMS) for default encryption. S3 Storage Lens also provides metrics for unencrypted bytes, unencrypted objects, encrypted bytes, and encrypted objects. For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

You can analyze SSE-KMS encryption metrics in the context of general encryption metrics to identify buckets that don't use SSE-KMS. If you want to use SSE-KMS for all the buckets in your account or organization, you can then update the default encryption settings for these buckets to use SSE-KMS. In addition to SSE-KMS, you can use server-side encryption with Amazon S3 managed keys (SSE-S3) or customer-provided keys (SSE-C). For more information, see [Protecting data with encryption](#).

Step 1: Identify which buckets are using SSE-KMS for default encryption

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **% SSE-KMS enabled bucket count** for the primary metric and **% encrypted bytes** for the secondary metric.

The **Trend for date** chart updates to display trends for SSE-KMS and encrypted bytes.

5. To view more granular, bucket-level insights for SSE-KMS:
 - a. Choose a point on the chart. A box will appear with choices for more granular insights.
 - b. Choose the **Buckets** dimension. Then choose **Apply**.
6. In the **Distribution by buckets for date** chart, choose the **SSE-KMS enabled bucket count** metric.
7. You can now see which buckets have SSE-KMS enabled and which do not.

Step 2: Update bucket default encryption settings

Now that you've determined which buckets use SSE-KMS in the context of your **% encrypted bytes**, you can identify buckets that don't use SSE-KMS. You can then optionally navigate to these buckets within the S3 console and update their default encryption settings to use SSE-KMS or SSE-S3. For more information, see [Configuring default encryption](#).

Identify buckets that have S3 Versioning enabled

When enabled, the S3 Versioning feature retains multiple versions of the same object that can be used to quickly recover data if an object is accidentally deleted or overwritten. You can use the **Versioning-enabled bucket count** metric to see which buckets use S3 Versioning. Then, you can take action in the S3 console to enable S3 Versioning for other buckets.

Step 1: Identify buckets that have S3 Versioning enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **Versioning-enabled bucket count** for the primary metric and **Buckets** for the secondary metric.

The **Trend for date** chart updates to display trends for S3 Versioning enabled buckets. Right below the trends line, you can see the **Storage class distribution** and **Region distribution** subsections.

5. To view more granular insights for any of the buckets that you see in the **Trend for date** chart so that you can perform a deeper analysis, do the following:
 - a. Choose a point on the chart. A box will appear with choices for more granular insights.
 - b. Choose a dimension to apply to your data for deeper analysis: **Account**, **AWS Region**, **Storage class**, or **Bucket**. Then choose **Apply**.
6. In the **Bubble analysis by buckets for date** section, choose the **Versioning-enabled bucket count**, **Buckets**, and **Active buckets** metrics.

The **Bubble analysis by buckets for date** section updates to display data for the metrics that you selected. You can use this data to see which buckets have S3 Versioning enabled in the context of your total bucket count. In the **Bubble analysis by buckets for date** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

Step 2: Enable S3 Versioning

After you've identified buckets that have S3 Versioning enabled, you can identify buckets that have never had S3 Versioning enabled or are versioning suspended. Then, you can optionally enable versioning for these buckets in the S3 console. For more information, see [Enabling versioning on buckets](#).

Identify requests that use AWS Signature Version 2 (SigV2)

You can use the **All unsupported signature requests** metric to identify requests that use AWS Signature Version 2 (SigV2). This data can help you identify specific applications that are using SigV2. You can then migrate these applications to AWS Signature Version 4 (SigV4).

SigV4 is the recommended signing method for all new S3 applications. SigV4 provides improved security and is supported in all AWS Regions. For more information, see [Amazon S3 update - SigV2 deprecation period extended & modified](#).

Prerequisite

To see **All unsupported signature requests** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see [Using the S3 console](#).

Step 1: Examine SigV2 signing trends by AWS account, Region, and bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To identify specific buckets, accounts, and Regions with requests that use SigV2:
 - a. Under **Top N overview for date**, in **Top N**, enter the number of buckets that you would like to see data for.
 - b. For **Metric**, choose **All unsupported signature requests** from the **Data protection** category.

The **Top N overview for date** updates to display data for SigV2 requests by account, AWS Region, and bucket. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

Step 2: Identify buckets that are accessed by applications through SigV2 requests

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Data protection** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific data-protection metrics, choose the preferences icon ).
7. Clear the toggles for all data-protection metrics until only the following metrics remain selected:
 - **All unsupported signature requests**
 - **% all unsupported signature requests**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display bucket-level metrics for SigV2 requests. You can use this data to identify specific buckets that have SigV2 requests. Then, you can use this information to migrate your applications to SigV4. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

Count the total number of replication rules for each bucket

S3 Replication enables automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. For more information, see [Replicating objects within and across Regions](#).

You can use S3 Storage Lens replication rule count metrics to get detailed per-bucket information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions.

Prerequisite

To see replication rule count metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see [Using the S3 console](#).

Step 1: Count the total number of replication rules for each bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
6. To filter the **Buckets** list to display only replication rule count metrics, choose the preferences icon ).
7. Clear the toggles for all data-protection metrics until only the replication rule count metrics remain selected:
 - **Same-Region Replication rule count**
 - **Cross-Region Replication rule count**
 - **Same-account replication rule count**
 - **Cross-account replication rule count**
 - **Total replication rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

Step 2: Add replication rules

After you have a per-bucket replication rule count, you can optionally create additional replication rules. For more information, see [Examples for configuring live replication](#).

Identify percentage of Object Lock bytes

With S3 Object Lock, you can store objects by using a *write-once-read-many (WORM)* model. You can use Object Lock to help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely. You can enable Object Lock only when you create a bucket and also enable S3 Versioning. However, you can edit the retention period for individual object versions or apply legal holds for buckets that have Object Lock enabled. For more information, see [Locking objects with Object Lock](#).

You can use Object Lock metrics in S3 Storage Lens to see the **% Object Lock bytes** metric for your account or organization. You can use this information to identify buckets in your account or organization that aren't following your data-protection best practices.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot** section, under **Metrics categories**, choose **Data protection**.

The **Snapshot** section updates to display data-protection metrics, including the **% Object Lock bytes** metric. You can see the overall percentage of Object Lock bytes for your account or organization.

5. To see the **% Object Lock bytes** per bucket, scroll down to the **Top N overview** section.

To get object-level data for Object Lock, you can also use the **Object Lock object count** and **% Object Lock objects** metrics.

6. For **Metric**, choose **% Object Lock bytes** from the **Data protection** category.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

7. Review the following data for % Object Lock bytes:

- **Top *number* accounts** - See which accounts have the highest and lowest % Object Lock bytes.
- **Top *number* Regions** - View a breakdown of % Object Lock bytes by Region.
- **Top *number* buckets** - See which buckets have the highest and lowest % Object Lock bytes.

Using S3 Storage Lens to audit Object Ownership settings

Amazon S3 Object Ownership is an S3 bucket-level setting that you can use to disable access control lists (ACLs) and control ownership of the objects in your bucket. If you set Object Ownership to bucket owner enforced, you can disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket. This approach simplifies access management for data stored in Amazon S3.

By default, when another AWS account uploads an object to your S3 bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through ACLs. You can use Object Ownership to change this default behavior.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. Therefore, we recommend that you disable ACLs, except in circumstances where you must control access for each object individually. By setting Object Ownership to bucket owner enforced, you can disable ACLs and rely on policies for access control. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

With S3 Storage Lens access-management metrics, you can identify buckets that don't have disabled ACLs. After identifying these buckets, you can migrate ACL permissions to policies and disable ACLs for these buckets.

Topics

- [Step 1: Identify general trends for Object Ownership settings](#)
- [Step 2: Identify bucket-level trends for Object Ownership settings](#)

- [Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs](#)

Step 1: Identify general trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metrics categories**, choose **Access management**.

The **Snapshot for date** section updates to display the **% Object Ownership bucket owner enforced** metric. You can see the overall percentage of buckets in your account or organization that use the bucket owner enforced setting for Object Ownership to disable ACLs.

Step 2: Identify bucket-level trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To view more detailed bucket-level metrics, choose the **Bucket** tab.
5. In the **Distribution by buckets for date** section, choose the **% Object Ownership bucket owner enforced** metric.

The chart updates to show a per-bucket breakdown for **% Object Ownership bucket owner enforced**. You can see which buckets use the bucket owner enforced setting for Object Ownership to disable ACLs.

6. To view the bucket owner enforced settings in context, scroll down to the **Buckets** section. For **Metrics categories**, select **Access management**. Then clear **Summary**.

The **Buckets** list displays data for all three Object Ownership settings: bucket owner enforced, bucket owner preferred, and object writer.

7. To filter the **Buckets** list to display metrics only for a specific Object Ownership setting, choose the preferences icon

).

8. Clear the metrics that you don't want to see.
9. (Optional) Under **Page size**, choose the number of buckets to display in the list.
10. Choose **Confirm**.

Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs

After you've identified buckets that use the object writer and bucket owner preferred setting for Object Ownership, you can migrate your ACL permissions to bucket policies. When you've finished migrating your ACL permissions, you can then update your Object Ownership settings to bucket owner enforced in order to disable ACLs. For more information, see [Prerequisites for disabling ACLs](#).

Using S3 Storage Lens metrics to improve performance

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use detailed status-code metrics to get counts for successful or failed requests. You can use this information to troubleshoot access or performance issues. Detailed status-code metrics show counts for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable. You can examine overall trends for detailed status-code metrics across S3 buckets, accounts, and organizations. Then, you can drill down into bucket-level metrics to identify workloads that are currently accessing these buckets and causing errors.

For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied. After you've identified these workloads, you can do a deep dive outside of S3 Storage Lens to troubleshoot your 403 Forbidden errors.

This example shows you how to do a trend analysis for the 403 Forbidden error by using the **403 Forbidden error count** and the **% 403 Forbidden errors** metrics. You can use these metrics to identify workloads that are accessing buckets without the correct permissions applied. You can do a similar trend analysis for any of the other **Detailed status code metrics**. For more information, see [Amazon S3 Storage Lens metrics glossary](#).

Prerequisite

To see **Detailed status code metrics** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Detailed status code metrics**. For more information, see [Using the S3 console](#).

Topics

- [Step 1: Do a trend analysis for an individual HTTP status code](#)
- [Step 2: Analyze error counts by bucket](#)
- [Step 3: Troubleshoot errors](#)

Step 1: Do a trend analysis for an individual HTTP status code

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, for **Primary metric**, choose **403 Forbidden error count** from the **Detailed status codes** category. For **Secondary metric**, choose **% 403 Forbidden errors**.
5. Scroll down to the **Top N overview for date** section. For **Metrics**, choose **403 Forbidden error count** or **% 403 Forbidden errors** from the **Detailed status codes** category.

The **Top N overview for date** section updates to display the top 403 Forbidden error counts by account, AWS Region, and bucket.

Step 2: Analyze error counts by bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Detailed status code** metrics. Then clear **Summary**.

The **Buckets** list updates to display all the available detailed status code metrics. You can use this information to see which buckets have a large proportion of certain HTTP status codes and which status codes are common across buckets.

6. To filter the **Buckets** list to display only specific detailed status-code metrics, choose the preferences icon

).

7. Clear the toggles for any detailed status-code metrics that you don't want to view in the **Buckets** list.
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list displays error count metrics for the number of buckets that you specified. You can use this information to identify specific buckets that are experiencing many errors and troubleshoot errors by bucket.

Step 3: Troubleshoot errors

After you identify buckets with a high proportion of specific HTTP status codes, you can troubleshoot these errors. For more information, see the following:

- [Why am I getting a 403 Forbidden error when I try to upload files in Amazon S3?](#)
- [Why am I getting a 403 Forbidden error when I try to modify a bucket policy in Amazon S3?](#)
- [How do I troubleshoot 403 Forbidden errors from my Amazon S3 bucket where all the resources are from the same AWS account?](#)
- [How do I troubleshoot an HTTP 500 or 503 error from Amazon S3?](#)

Using Amazon S3 Storage Lens with AWS Organizations

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use Amazon S3 Storage Lens to collect storage metrics and usage data for all AWS accounts that are part of your AWS Organizations hierarchy. To do this, you must be using AWS Organizations, and you must enable S3 Storage Lens trusted access by using your AWS Organizations management account.

After enabling trusted access, add delegated administrator access to accounts in your organization. The delegated administrator accounts are used to create S3 Storage Lens configurations and dashboards that collect organization-wide storage metrics and user data. For more information about enabling trusted access, see [Amazon S3 Storage Lens and AWS Organizations](#) in the *AWS Organizations User Guide*.

Topics

- [Enabling trusted access for S3 Storage Lens](#)
- [Disabling trusted access for S3 Storage Lens](#)
- [Registering a delegated administrator for S3 Storage Lens](#)
- [Deregistering a delegated administrator for S3 Storage Lens](#)

Enabling trusted access for S3 Storage Lens

By enabling trusted access, you allow Amazon S3 Storage Lens to access your AWS Organizations hierarchy, membership, and structure through AWS Organizations API operations. S3 Storage Lens then becomes a trusted service for your entire organization's structure.

Whenever a dashboard configuration is created, S3 Storage Lens creates service-linked roles in your organization's management or delegated administrator accounts. The service-linked role grants S3 Storage Lens permission to perform the following actions:

- Describe organizations
- List accounts
- Verify a list of AWS service access for the organizations
- Get delegated administrators for the organizations

S3 Storage Lens can then ensure that it has access to collect the cross-account metrics for the accounts in your organization. For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

After enabling trusted access, you can assign delegated administrator access to accounts in your organization. When an account is marked as a delegated administrator for a service, the account receives authorization to access all read-only organization API operations. This access provides the delegated administrator visibility to the members and structures of your organization so that they too can create S3 Storage Lens dashboards.

 **Note**

- Trusted access can only be enabled by the [management account](#).
- Only the management account and delegated administrators can create S3 Storage Lens dashboards or configurations for your organization.

Using the S3 console

To enable S3 Storage Lens to have AWS Organizations trusted access

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.
4. Under **AWS Organizations trusted access**, choose **Edit**.

The **AWS Organizations access** page displays.

5. Choose **Enable** to enable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example shows you how to enable AWS Organizations trusted access for S3 Storage Lens in AWS CLI.

```
aws organizations enable-aws-service-access --service-principal storage-lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example – Enable AWS Organizations trusted access for S3 Storage Lens using SDK for Java

The following example shows you how to enable trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
```

```
import com.amazonaws.services.organizations.model.EnableAWSServiceAccessRequest;

public class EnableOrganizationsTrustedAccess {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.enableAWSServiceAccess(new
EnableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
    }
}
```

Disabling trusted access for S3 Storage Lens

Removing an account as a delegated administrator or disabling trusted access limits the account owner's S3 Storage Lens dashboard metrics to work only on an account level. Each account holder is then only be able to see the benefits of S3 Storage Lens through the limited scope of their account, and not their entire organization.

When you disable trusted access in S3 Storage Lens, any dashboards requiring trusted access are no longer updated. Any organizational dashboards that are created are also no longer updated. Instead, you're only able to query [historic data for the S3 Storage Lens dashboard](#), while the data is still available.

Note

- Disabling trusted access for S3 Storage Lens also automatically stops all organization-level dashboards from collecting and aggregating storage metrics. This is because S3 Storage Lens no longer has trusted access to the organization accounts.
- Your management and delegate administrator accounts can still see the historic data for any disabled dashboards. They can also query this historic data while it is still available.

Using the S3 console

To disable trusted access for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.
4. Under **AWS Organizations trusted access**, choose **Edit**.

The **AWS Organizations access** page displays.

5. Choose **Disable** to disable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example disables trusted access for S3 Storage Lens using the AWS CLI.

```
aws organizations disable-aws-service-access --service-principal storage-lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example – Disable AWS Organizations trusted access for S3 Storage Lens

The following example shows you how to disable AWS Organizations trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import com.amazonaws.services.organizations.model.DisableAWSServiceAccessRequest;

public class DisableOrganizationsTrustedAccess {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            // Make sure to remove any existing delegated administrator for S3 Storage
            // Lens
            // before disabling access; otherwise, the request will fail.
            organizationsClient.disableAWSServiceAccess(new
DisableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
            process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
    }
}
```

```
 }  
 }
```

Registering a delegated administrator for S3 Storage Lens

You can create organization-level dashboards by using your organization's management account or delegated administrator accounts. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can register and deregister other accounts as delegated administrators for the organization.

After enabling trusted access, you can register delegate administrator access to accounts in your organization by using the AWS Organizations REST API, AWS CLI, or SDKs from the [management account](#). (For more information, see [RegisterDelegatedAdministrator](#) in the *AWS Organizations API Reference*.) When an account is registered as a delegated administrator, the account receives authorization to access all read-only AWS Organizations API operations. This provides visibility to the members and structures of your organization so that they can create S3 Storage Lens dashboards on your behalf.

 **Note**

Before you can designate a delegated administrator by using the AWS Organizations REST API, AWS CLI, or SDKs, you must call the [EnableAWSServiceAccess](#) operation.

Using the S3 console

To register delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose **Register account**.
5. Add an AWS account ID to register the account as a delegated administrator. The delegated administrator is able to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to register Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws organizations register-delegated-administrator --service-principal storage-lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example – Register Organizations delegated administrators for S3 Storage Lens

The following example shows you how to register AWS Organizations delegated administrators for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
com.amazonaws.services.organizations.model.RegisterDelegatedAdministratorRequest;

public class RegisterOrganizationsDelegatedAdministrator {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.registerDelegatedAdministrator(new
RegisterDelegatedAdministratorRequest()
```

```
        .withAccountId(delegatedAdminAccountId)
        .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but AWS Organizations couldn't
        process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // AWS Organizations couldn't be contacted for a response, or the client
        // couldn't parse the response from AWS Organizations.
        e.printStackTrace();
    }
}
```

Deregistering a delegated administrator for S3 Storage Lens

After enabling trusted access, you can also deregister delegate administrator access to accounts in your organization. Delegated administrator accounts allow other accounts besides your [management account](#) to create organization-level dashboards. Only the management account of an organization can deregister accounts as delegated administrators for the organization.

You can deregister a delegated administrator by using the AWS Organizations AWS Management Console, REST API, AWS CLI, or AWS SDKs from the management account. For more information, see [DeregisterDelegatedAdministrator](#) in the *AWS Organizations API Reference*.

When an account is deregistered as a delegated administrator, the account loses access to the following:

- All read-only AWS Organizations API operations that provide visibility to the members and structures of your organization.
- All organization-level dashboards created by the delegated administrator. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

 **Note**

The deregistered delegated administrator will still be able to see the historic data for the disabled dashboards that they created if data is still available for querying.

Using the S3 console

To deregister delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose the account that you wish to deregister.
5. Choose **De-register account**. The deregistered account is no longer a delegated administrator and is now unable to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace **111122223333** with your own AWS account ID.

```
aws organizations deregister-delegated-administrator --service-principal storage-lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example – Deregister Organizations delegated administrators for S3 Storage Lens

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using SDK for Java. To use this example, replace the **user input placeholders** with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
```

```
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
com.amazonaws.services.organizations.model.DeregisterDelegatedAdministratorRequest;

public class DeregisterOrganizationsDelegatedAdministrator {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.deregisterDelegatedAdministrator(new
DeregisterDelegatedAdministratorRequest()
                .withAccountId(delegatedAdminAccountId)
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
    }
}
```

Working with S3 Storage Lens groups to filter and aggregate metrics

An Amazon S3 Storage Lens group aggregates metrics using custom filters based on object metadata. Storage Lens groups help you drill down into characteristics of your data, such as distribution of objects by age, your most common file types, and more. For example, you can filter metrics by object tag to identify your fastest-growing datasets, or visualize your storage based on object size and age to inform your storage archive strategy. As a result, Amazon S3 Storage Lens groups helps you to better understand and optimize your S3 storage.

When you use Storage Lens groups, you can analyze and filter S3 Storage Lens metrics using object metadata such as prefixes, suffixes, [object tags](#), object size, or object age. You can also apply a combination of these filters. After you attach your Storage Lens group to your S3 Storage Lens dashboard, you can view S3 Storage Lens metrics aggregated by Amazon S3 Storage Lens groups directly in your dashboard.

For example, you can also filter your metrics by object size or age bands to determine which portion of your storage consists of small objects. You can then use this information with S3 Intelligent-Tiering or S3 Lifecycle to transition small objects to different storage classes for cost and storage optimization.

Topics

- [How S3 Storage Lens groups work](#)
- [Using Storage Lens groups](#)

How S3 Storage Lens groups work

You can use Storage Lens groups to aggregate metrics using custom filters based on object metadata. When you define a custom filter, you can use prefixes, suffixes, object tags, object sizes, object age, or a combination of these custom filters. During Storage Lens group creation, you can also include a single filter or multiple filter conditions. To specify multiple filter conditions, you use And or Or logical operators.

When you create and configure a Storage Lens group, the Storage Lens group itself acts as a custom filter in the dashboard that you attach the group to. In your dashboard, you can then use the Storage Lens group filter to obtain storage metrics based on the custom filter that you defined in the group.

To view the data for your Storage Lens group in your S3 Storage Lens dashboard, you must attach the group to the dashboard after you've created the group. After your Storage Lens group is attached to your Storage Lens dashboard, your dashboard will collect storage usage metrics within 48 hours. You can then visualize this data in the Storage Lens dashboard or export it through a metrics export. If you forget to attach a Storage Lens group to a dashboard, your Storage Lens group data won't be captured or displayed anywhere.

Note

- When you create a S3 Storage Lens group, you're creating an AWS resource. Therefore, each Storage Lens group has its own Amazon Resource Name (ARN), which you can specify when [attaching it to or excluding it from a S3 Storage Lens dashboard](#).
- If your Storage Lens group isn't attached to a dashboard, you won't incur any additional charges for creating a Storage Lens group.
- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.

You can create a Storage Lens group at the account level in a specified home Region (from the list of supported AWS Regions). Then, you can attach your Storage Lens group to multiple Storage Lens dashboards, as long as the dashboards are in the same AWS account and home Region. You can create up to 50 Storage Lens groups per home Region in each AWS account.

You can create and manage S3 Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API.

Topics

- [Viewing Storage Lens group aggregated metrics](#)
- [Storage Lens groups permissions](#)
- [Storage Lens groups configuration](#)
- [AWS resource tags](#)
- [Storage Lens groups metrics export](#)

Viewing Storage Lens group aggregated metrics

You can view the aggregated metrics for your Storage Lens groups by attaching the groups to a dashboard. The Storage Lens groups that you want to attach must reside within the designated home Region in the dashboard account.

To attach a Storage Lens group to a dashboard, you must specify the group in the **Storage Lens group aggregation** section of your dashboard configuration. If you have several Storage Lens

groups, you can filter the **Storage Lens group aggregation** results to include or exclude only the groups that you want. For more information about attaching groups to your dashboards, see [the section called "Attach or remove a Storage Lens group"](#).

After you've attached your groups, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

 **Note**

To view aggregated metrics for your Storage Lens group, you must attach the group to an S3 Storage Lens dashboard.

Storage Lens groups permissions

Storage Lens groups require certain permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens group actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to create or delete Storage Lens groups, view their configurations, or manage their tags.

The IAM user or role that you grant permissions to must belong to the account that created or owns the Storage Lens group.

To use Storage Lens groups and to view your Storage Lens groups metrics, you must first have the appropriate permissions to use S3 Storage Lens. For more information, see [the section called "Setting permissions"](#).

To create and manage S3 Storage Lens groups, you must have the following IAM permissions, depending on which actions you want to perform:

Action	IAM permissions
Create a new Storage Lens group	s3:CreateStorageLensGroup
Create a new Storage Lens group with tags	s3:CreateStorageLensGroup , s3:TagResource
Update an existing Storage Lens group	s3:UpdateStorageLensGroup

Action	IAM permissions
Return the details of a Storage Lens group configuration	s3:GetStorageLensGroup
List all Storage Lens groups in your home Region	s3>ListStorageLensGroups
Delete a Storage Lens group	s3>DeleteStorageLensGroup
List the tags that were added to your Storage Lens group	s3>ListTagsForResource
Add or update a Storage Lens group tag for an existing Storage Lens group	s3:TagResource
Delete a tag from a Storage Lens group	s3:UntagResource

Here's an example of how to configure your IAM policy in the account that creates the Storage Lens group. To use this policy, replace *us-east-1* with the home Region that your Storage Lens group is located in. Replace *111122223333* with your AWS account ID, and replace *example-storage-lens-group* with the name of your Storage Lens group. To apply these permissions to all Storage Lens groups, replace *example-storage-lens-group* with an *.

}  
]  
}
```

For more information about S3 Storage Lens permissions, see [Setting Amazon S3 Storage Lens permissions](#). For more information about IAM policy language, see [Policies and permissions in Amazon S3](#).

Storage Lens groups configuration

S3 Storage Lens group name

We recommend giving your Storage Lens groups names that indicate their purpose so that you can easily determine which groups you want to attach to your dashboards. To [attach a Storage Lens group to a dashboard](#), you must specify the group in the **Storage Lens group aggregation** section of the dashboard configuration.

Storage Lens group names must be unique within the account. They must not exceed 64 characters, and can contain only letters (a-z, A-Z), numbers (0-9), hyphens (-), and underscores (_).

Home Region

The home Region is the AWS Region where your Storage Lens group is created and maintained. Your Storage Lens group is created in the same home Region as your Amazon S3 Storage Lens dashboard. The Storage Lens group configuration and metrics are also stored in this Region. You can create up to 50 Storage Lens groups in a home Region.

After you create your Storage Lens group, you can't edit the home Region.

Scope

To include objects in your Storage Lens group, they must be in scope for your Amazon S3 Storage Lens dashboard. The scope of your Storage Lens dashboard is determined by the buckets that you included in the **Dashboard scope** of your S3 Storage Lens dashboard configuration.

You can use different filters for your objects to define the scope of your Storage Lens group. To view these Storage Lens group metrics in your S3 Storage Lens dashboard, objects must match the filters that you include in your Storage Lens groups. For example, suppose that your Storage Lens

group includes objects with the prefix `marketing` and the suffix `.png`, but no objects match those criteria. In this case, metrics for this Storage Lens group won't be generated in your daily metrics export, and no metrics for this group will be visible in your dashboard.

Filters

You can use the following filters in an S3 Storage Lens group:

- **Prefixes** – Specifies the [prefix](#) of included objects, which is a string of characters at the beginning of the object key name. For example, a value of `images` for the **Prefixes** filter includes objects with any of the following prefixes: `images/`, `images-marketing`, and `images/production`. The maximum length of a prefix is 1,024 bytes.
- **Suffixes** – Specifies the suffix of included objects (for example, `.png`, `.jpeg`, or `.csv`). The maximum length of a suffix is 1,024 bytes.
- **Object tags** – Specifies the list of [object tags](#) that you want to filter on. A tag key can't exceed 128 Unicode characters, and a tag value can't exceed 256 Unicode characters. Note that if the object tag value field is left empty, S3 Storage Lens groups only matches the object to other objects that also have empty tag values.
- **Age** – Specifies the object age range of included objects in days. Only integers are supported.
- **Size** – Specifies the object size range of included objects in bytes. Only integers are supported. The maximum allowable value is 50 TB.

Storage Lens group object tags

You can [create a Storage Lens group](#) that includes up to 10 object tag filters. The following example includes two object tag key-value pairs as filters for a Storage Lens group that's named `Marketing-Department`. To use this example, replace `Marketing-Department` with the name of your group, and replace `object-tag-key-1`, `object-tag-value-1`, and so on with the object tag key-value pairs that you want to filter on.

```
{  
    "Name": "Marketing-Department",  
    "Filter": {  
        "MatchAnyTag": [  
            {  
                "Key": "object-tag-key-1",  
                "Value": "object-tag-value-1"  
            },  
        ]  
    }  
}
```

```
{  
    "Key": "object-tag-key-2",  
    "Value": "object-tag-value-2"  
}  
]  
}  
}
```

Logical operators (And or Or)

To include multiple filter conditions in your Storage Lens group, you can use logical operators (either And or Or). In the following example, the Storage Lens group that's named *Marketing-Department* has an And operator that contains Prefix, ObjectAge, and ObjectSize filters. Because an And operator is used, only objects that match **all** of these filter conditions will be included the Storage Lens group's scope.

To use this example, replace the *user input placeholders* with the values that you want to filter on.

```
{  
    "Name": "Marketing-Department",  
    "Filter": {  
        "And": {  
            "MatchAnyPrefix": [  
                "prefix-1",  
                "prefix-2",  
                "prefix-3/sub-prefix-1"  
            ],  
            "MatchObjectAge": {  
                "DaysGreaterThanOrEqual": 10,  
                "DaysLessThanOrEqual": 60  
            },  
            "MatchObjectSize": {  
                "BytesGreaterThanOrEqual": 10,  
                "BytesLessThanOrEqual": 60  
            }  
        }  
    }  
}
```

Note

If you want to include objects that match **any** of the conditions in the filters, replace the And logical operator with the Or logical operator in this example.

AWS resource tags

Each S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (or tags with tag keys that begin with `aws :)`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

Storage Lens groups metrics export

S3 Storage Lens group metrics are included in the [Amazon S3 Storage Lens metrics export](#) for the dashboard that the Storage Lens group is attached to. For general information about the Storage Lens metrics export feature, see [Viewing Amazon S3 Storage Lens metrics using a data export](#).

Your metrics export for Storage Lens groups includes any S3 Storage Lens metrics that are in scope for the dashboard that you attached the Storage Lens group to. The export also includes additional metrics data for Storage Lens groups.

After you create your Storage Lens group, your metrics export is sent daily to the bucket that you selected when you configured the metrics export for the dashboard that your group is attached to. It can take up to 48 hours for you to receive the first metrics export.

To generate metrics in the daily export, objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you included in your Storage Lens group, then no metrics will be generated. However, if an object matches two or more Storage Lens groups, the object is listed separately for each group when it appears in the metrics export.

You can identify metrics for Storage Lens groups by looking for one of the following values in the `record_type` column of the metrics export for your dashboard:

- `STORAGE_LENS_GROUP_BUCKET`
- `STORAGE_LENS_GROUP_ACCOUNT`

The `record_value` column displays the resource ARN for the Storage Lens group (for example, `arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department`).

Using Storage Lens groups

Amazon S3 Storage Lens groups aggregates metrics using custom filters based on object metadata. You can analyze and filter S3 Storage Lens metrics using prefixes, suffixes, object tags, object size, or object age. With Amazon S3 Storage Lens groups, you can also categorize your usage within and across Amazon S3 buckets. As a result, you'll be able to better understand and optimize your S3 storage.

To start visualizing the data for a Storage Lens group, you must first [attach your Storage Lens group to an S3 Storage Lens dashboard](#). If you need to manage Storage Lens groups in the dashboard, you can edit the dashboard configuration. To check which Storage Lens groups are

under your account, you can list them. To check which Storage Lens groups are attached to your dashboard, you can always check the **Storage Lens groups** tab in the dashboard. To review or update the scope of an existing Storage Lens group, you can view its details. You can also permanently delete a Storage Lens group.

To manage permissions, you can create and add user-defined AWS resource tags to your Storage Lens groups. You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

Creating a Storage Lens group

The following examples demonstrate how to create an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To create a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Storage Lens groups**.
4. Choose **Create Storage Lens group**.
5. Under **General**, view your **Home Region** and enter your **Storage Lens group name**.
6. Under **Scope**, choose the filter that you want to apply to your Storage Lens group. To apply multiple filters, choose your filters, and then choose the **AND** or **OR** logical operator.
 - For the **Prefixes** filter, choose **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
 - For the **Object tags** filter, choose **Object tags**, and enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
 - For the **Suffixes** filter, choose **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
 - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. Then, choose **Specify maximum object age**, and enter the maximum object age.
 - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. Choose **Specify maximum object size**, and enter the maximum object size.
7. (Optional) For AWS resource tags, add the key-value pair, and then choose **Add tag**.
8. Choose **Create Storage Lens group**.

Using the AWS CLI

The following example AWS CLI command creates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

The following example AWS CLI command creates a Storage Lens group with two AWS resource tags. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json \
--tags Key=k1,Value=v1 Key=k2,Value=v2
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Using the AWS SDK for Java

The following AWS SDK for Java example creates a Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

Example – Create a Storage Lens group with a single filter

The following example creates a Storage Lens group named *Marketing-Department*. This group has an object age filter that specifies the age range as *30* to *90* days. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithObjectAge {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupFilter objectAgeFilter = StorageLensGroupFilter.builder()
                .matchObjectAge(MatchObjectAge.builder()
                    .daysGreaterThanOrEqualTo(30)
                    .daysLessThanOrEqualTo(90)
```

```
        .build())
    .build();

    StorageLensGroup storageLensGroup = StorageLensGroup.builder()
        .name(storageLensGroupName)
        .filter(objectAgeFilter)
        .build();

    CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
    .storageLensGroup(storageLensGroup)
    .accountId(accountId).build();

    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
}
```

Example – Create a Storage Lens group with an AND operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses the AND operator to indicate that objects must match **all** of the filter conditions. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.S3Tag;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupAndOperator;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithAndFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create object tags.
            S3Tag tag1 = S3Tag.builder()
                .key("object-tag-key-1")
                .value("object-tag-value-1")
                .build();
            S3Tag tag2 = S3Tag.builder()
                .key("object-tag-key-2")
                .value("object-tag-value-2")
                .build();

            StorageLensGroupAndOperator andOperator =
            StorageLensGroupAndOperator.builder()
                .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                .matchAnySuffix(".png", ".gif", ".jpg")
                .matchAnyTag(tag1, tag2)
                .matchObjectAge(MatchObjectAge.builder()
                    .daysGreater Than(30)
                    .daysLessThan(90).build())
                .matchObjectSize(MatchObjectSize.builder()
                    .bytesGreater Than(1000L)
                    .bytesLessThan(6000L).build())
                .build();

            StorageLensGroupFilter andFilter = StorageLensGroupFilter.builder()
                .and(andOperator)
                .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                .name(storageLensGroupName)
```

```
        .filter(andFilter)
        .build();

    CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
        .storageLensGroup(storageLensGroup)
        .accountId(accountId).build();

    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Create a Storage Lens group with an OR operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses an OR operator to apply a prefix filter (*prefix-1*, *prefix-2*, *prefix3*/*sub-prefix-1*) or an object size filter with a size range between *1000* bytes and *6000* bytes. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
```

```
import software.amazon.awssdk.services.s3control.model.StorageLensGroupOrOperator;

public class CreateStorageLensGroupWithOrFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupOrOperator orOperator =
                StorageLensGroupOrOperator.builder()
                    .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                    .matchObjectSize(MatchObjectSize.builder()
                        .bytesGreaterThan(1000L)
                        .bytesLessThan(6000L)
                        .build())
                    .build();
        }

        StorageLensGroupFilter orFilter = StorageLensGroupFilter.builder()
            .or(orOperator)
            .build();

        StorageLensGroup storageLensGroup = StorageLensGroup.builder()
            .name(storageLensGroupName)
            .filter(orFilter)
            .build();

        CreateStorageLensGroupRequest createStorageLensGroupRequest =
            CreateStorageLensGroupRequest.builder()
                .storageLensGroup(storageLensGroup)
                .accountId(accountId).build();

        S3ControlClient s3ControlClient = S3ControlClient.builder()
            .region(Region.US_WEST_2)
            .credentialsProvider(ProfileCredentialsProvider.create())
            .build();
        s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

```
    }
}
}
```

Example – Create a Storage Lens group with a single filter and two AWS resource tags

The following example creates a Storage Lens group named *Marketing-Department* that has a suffix filter. This example also adds two AWS resource tags to the Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.Tag;

public class CreateStorageLensGroupWithResourceTags {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create AWS resource tags.
            Tag resourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-value-1")
                .build();
            Tag resourceTag2 = Tag.builder()
                .key("resource-tag-key-2")
                .value("resource-tag-value-2")
                .build();

            StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
                .matchAnySuffix(".png", ".gif", ".jpg")
                .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
```

```
.name(storageLensGroupName)
.filter(suffixFilter)
.build();

CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
    .storageLensGroup(storageLensGroup)
    .tags(resourceTag1, resourceTag2)
    .accountId(accountId).build();

S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();
s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Attaching or removing S3 Storage Lens groups to or from your dashboard

After you've upgraded to the advanced tier in Amazon S3 Storage Lens, you can attach a [Storage Lens group](#) to your dashboard. If you have several Storage Lens groups, you can include or exclude the groups that you want.

Your Storage Lens groups must reside within the designated home Region in the dashboard account. After you attach a Storage Lens group to your dashboard, you'll receive the additional Storage Lens group aggregation data in your metrics export within 48 hours.

Note

If you want to view aggregated metrics for your Storage Lens group, you must attach it to your Storage Lens dashboard. For examples of Storage Lens group JSON configuration files, see [S3 Storage Lens example configuration with Storage Lens groups in JSON](#).

Using the S3 console

To attach a Storage Lens group to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to attach a Storage Lens group to.
4. Choose **Edit**.
5. Under **Metrics selection**, choose **Advanced metrics and recommendations**.
6. Select **Storage Lens group aggregation**.

Note

By default, **Advanced metrics** is also selected. However, you can also deselect this setting as it's not required to aggregate Storage Lens groups data.

7. Scroll down to **Storage Lens group aggregation** and specify the Storage Lens group or groups that you either want to include or exclude in the data aggregation. You can use the following filtering options:
 - If you want to include certain Storage Lens groups, choose **Include Storage Lens groups**. Under **Storage Lens groups to include**, select your Storage Lens groups.
 - If you want to include all Storage Lens groups, select **Include all Storage Lens groups in home Region in this account**.
 - If you want to exclude certain Storage Lens groups, choose **Exclude Storage Lens groups**. Under **Storage Lens groups to exclude**, select the Storage Lens groups that you want to exclude.

8. Choose **Save changes**. If you've configured your Storage Lens groups correctly, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

To remove a Storage Lens group from an S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to remove a Storage Lens group from.
4. Choose **View dashboard configuration**.
5. Choose **Edit**.
6. Scroll down to the **Metrics selection** section.
7. Under **Storage Lens group aggregation**, choose the X next to the Storage Lens group that you want to remove. This removes your Storage Lens group.

If you included all of your Storage Lens groups in your dashboard, clear the check box next to **Include all Storage Lens groups in home Region in this account**.

8. Choose **Save changes**.

 **Note**

It will take up to 48 hours for your dashboard to reflect the configuration updates.

Using the AWS SDK for Java

Example – Attach all Storage Lens groups to a dashboard

The following SDK for Java example attaches all Storage Lens groups in the account **111122223333** to the **DashboardConfigurationId** dashboard:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3control.AWS3Control;
```

```
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWithStorageLensGroups {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel();

            AccountLevel accountLevel = new AccountLevel()
                .withBucketLevel(new BucketLevel())
                .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                .withId(configurationId)
                .withAccountLevel(accountLevel)
                .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
                .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
```

```
        // couldn't parse the response from Amazon S3.  
        e.printStackTrace();  
    }  
}  
}
```

Example – Attach two Storage Lens groups to a dashboard

The following AWS SDK for Java example attaches two Storage Lens groups (*StorageLensGroupName1* and *StorageLensGroupName2*) to the *ExampleDashboardConfigurationId* dashboard.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import com.amazonaws.auth.profile.ProfileCredentialsProvider;  
import com.amazonaws.services.s3control.AWSS3Control;  
import com.amazonaws.services.s3control.AWSS3ControlClient;  
import com.amazonaws.services.s3control.model.AccountLevel;  
import com.amazonaws.services.s3control.model.BucketLevel;  
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;  
import com.amazonaws.services.s3control.model.StorageLensConfiguration;  
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;  
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;  
  
import static com.amazonaws.regions.Regions.US_WEST_2;  
  
public class CreateDashboardWith2StorageLensGroups {  
    public static void main(String[] args) {  
        String configurationId = "ExampleDashboardConfigurationId";  
        String storageLensGroupName1 = "StorageLensGroupName1";  
        String storageLensGroupName2 = "StorageLensGroupName2";  
        String sourceAccountId = "111122223333";  
  
        try {  
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new  
            StorageLensGroupLevelSelectionCriteria()  
                .withInclude(  
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId  
+ ":storage-lens-group/" + storageLensGroupName1,  
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId  
+ ":storage-lens-group/" + storageLensGroupName2);  
        }  
    }  
}
```

```
System.out.println(selectionCriteria);
StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel()
    .withSelectionCriteria(selectionCriteria);

AccountLevel accountLevel = new AccountLevel()
    .withBucketLevel(new BucketLevel())
    .withStorageLensGroupLevel(storageLensGroupLevel);

StorageLensConfiguration configuration = new StorageLensConfiguration()
    .withId(configurationId)
    .withAccountLevel(accountLevel)
    .withIsEnabled(true);

AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(US_WEST_2)
    .build();

s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
    .withStorageLensConfiguration(configuration)
);

} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Attach all Storage Lens groups with exclusions

The following SDK for Java example attaches all Storage Lens groups to the *ExampleDashboardConfigurationId* dashboard, excluding the two specified (*StorageLensGroupName1* and *StorageLensGroupName2*):

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroupsExcluded {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
            StorageLensGroupLevelSelectionCriteria()
                .withInclude(
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName1,
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName2);

            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensLevel = new StorageLensGroupLevel()
                .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()
                .withBucketLevel(new BucketLevel())
                .withStorageLensGroupLevel(storageLensLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                .withId(configurationId)
```

```
.withAccountLevel(accountLevel)
.withIsEnabled(true);

AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(US_WEST_2)
    .build();

s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
    .withStorageLensConfiguration(configuration)
);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
}
```

Visualizing your Storage Lens groups data

You can visualize your Storage Lens groups data by [attaching the group to your Amazon S3 Storage Lens dashboard](#). After you've included the Storage Lens group in the Storage Lens group aggregation in your dashboard configuration, it can take up to 48 hours for the Storage Lens group data to display in your dashboard.

After the dashboard configuration has been updated, any newly attached Storage Lens groups appear in the list of available resources under the **Storage Lens groups** tab. You can also further analyze storage usage in your **Overview** tab by slicing the data by another dimension. For example, you can choose one of the items listed under the **Top 3** categories and choose **Analyze by** to slice the data by another dimension. You can't apply the same dimension as the filter itself.

Note

You can't apply a Storage Lens group filter along with a prefix filter, or the reverse. You also can't further analyze a Storage Lens group by using a prefix filter.

You can use the **Storage Lens groups** tab in the Amazon S3 Storage Lens dashboard to customize the data visualization for the Storage Lens groups that are attached to your dashboard. You can either visualize the data for some Storage Lens groups that are attached to your dashboard, or all of them.

When visualizing Storage Lens group data in your S3 Storage Lens dashboard, be aware of the following:

- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.
- Objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you include in your Storage Lens group, then no metrics are generated. To determine if there are any unassigned objects, check your total object count in the dashboard at the account level and bucket level.

Updating a Storage Lens group

The following examples demonstrate how to update an Amazon S3 Storage Lens group. You can update a Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **Scope**, choose **Edit**.

5. On the **Scope** page, select the filter that you want to apply to your Storage Lens group. To apply multiple filters, select your filters, and choose the **AND** or **OR** logical operator.
 - For the **Prefixes** filter, select **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
 - For the **Object tags** filter, enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
 - For the **Suffixes** filter, select **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
 - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. For **Specify maximum object age**, enter the maximum object age.
 - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. For **Specify maximum object size**, enter the maximum object size.
6. Choose **Save changes**. The details page for the Storage Lens group appears.
7. (Optional) If you want to add a new AWS resource tag, scroll to the **AWS resource tags** section, then choose **Add tags**. The **Add tags** page appears.

Add the new key-value pair, then choose **Save changes**. The details page for the Storage Lens group appears.

8. (Optional) If you want to remove an existing AWS resource tag, scroll to the **AWS resource tags** section, and select the resource tag. Then, choose **Delete**. The **Delete AWS tags** dialog box appears.

Choose **Delete** again to permanently delete the AWS resource tag.

 **Note**

After you permanently delete an AWS resource tag, it can't be restored.

Using the AWS CLI

The following AWS CLI example command returns the configuration details for a Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

The following AWS CLI example updates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control update-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the *Marketing-Department* Storage Lens group in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;

public class GetStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            GetStorageLensGroupRequest getRequest =
GetStorageLensGroupRequest.builder()
```

```
        .name(storageLensGroupName)
        .accountId(accountId).build();
    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    GetStorageLensGroupResponse response =
s3ControlClient.getStorageLensGroup(getRequest);
    System.out.println(response);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

The following example updates the Storage Lens group named *Marketing-Department* in account *111122223333*. This example updates the dashboard scope to include objects that match any of the following suffixes: *.png*, *.gif*, *.jpg*, or *.jpeg*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.UpdateStorageLensGroupRequest;

public class UpdateStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
```

```
// Create updated filter.
StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
    .matchAnySuffix(".png", ".gif", ".jpg", ".jpeg")
    .build();

StorageLensGroup storageLensGroup = StorageLensGroup.builder()
    .name(storageLensGroupName)
    .filter(suffixFilter)
    .build();

UpdateStorageLensGroupRequest updateStorageLensGroupRequest =
UpdateStorageLensGroupRequest.builder()
    .name(storageLensGroupName)
    .storageLensGroup(storageLensGroup)
    .accountId(accountId)
    .build();

S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();
s3ControlClient.updateStorageLensGroup(updateStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Managing AWS resource tags with Storage Lens groups

Each Amazon S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with aws :) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens groups.

Topics

- [Adding an AWS resource tag to a Storage Lens group](#)
- [Updating Storage Lens group tag values](#)
- [Deleting an AWS resource tag from a Storage Lens group](#)
- [Listing Storage Lens group tags](#)

Adding an AWS resource tag to a Storage Lens group

The following examples demonstrate how to add AWS resource tags to an Amazon S3 Storage Lens group. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add an AWS resource tag to a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, choose **Add tags**.
5. On the **Add tags** page, add the new key-value pair.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens group.
7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command adds two resource tags to an existing Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \  
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-  
department \  
--region us-east-1 --tags Key=k1,Value=v1 Key=k2,Value=v2
```

Using the AWS SDK for Java

The following AWS SDK for Java example adds two AWS resource tags to an existing Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class TagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag resourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-value-1")
                .build();
            Tag resourceTag2 = Tag.builder()
                .key("resource-tag-key-2")
                .value("resource-tag-value-2")
                .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tags(resourceTag1, resourceTag2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            s3ControlClient.tagResource(tagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

```
}
```

Updating Storage Lens group tag values

The following examples demonstrate how to update Storage Lens group tag values by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the tag that you want to update.
5. Add the new tag value, using the same key of the key-value pair that you want to update. Choose the checkmark icon to update the tag value.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) If you want to add new tags, choose **Add tag** to add new entries. The **Add tags** page appears.

You can add up to 50 AWS resource tags for your Storage Lens group. When you're finished adding new tags, choose **Save changes**.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove. When you're finished removing tags, choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command updates two tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
--region us-east-1 --tags Key=k1,Value=v3 Key=k2,Value=v4
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates two Storage Lens group tag values. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class UpdateTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag updatedResourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-updated-value-1")
                .build();
            Tag updatedResourceTag2 = Tag.builder()
                .key("resource-tag-key-2")
                .value("resource-tag-updated-value-2")
                .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tags(updatedResourceTag1, updatedResourceTag2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
        }
    }
}
```

```
s3ControlClient.tagResource(tagResourceRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Deleting an AWS resource tag from a Storage Lens group

The following examples demonstrate how to delete an AWS resource tag from a Storage Lens group. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete an AWS resource tag from a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the key-value pair that you want to delete.
5. Choose **Delete**. The **Delete AWS resource tags** dialog box appears.

 **Note**

If tags are used to control access, proceeding with this action can affect related resources. After you permanently delete a tag, it can't be restored.

6. Choose **Delete** to permanently delete the key-value pair.

Using the AWS CLI

The following AWS CLI command deletes two AWS resource tags from an existing Storage Lens group: To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control untag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department \
--region us-east-1 --tag-keys k1 k2
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes two AWS resource tags from the Storage Lens group Amazon Resource Name (ARN) that you specify in account **111122223333**. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;

public class UntagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            String tagKey1 = "resource-tag-key-1";
            String tagKey2 = "resource-tag-key-2";
            UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tagKeys(tagKey1, tagKey2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
        }
    }
}
```

```
        .build();
        s3ControlClient.untagResource(untagResourceRequest);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

Listing Storage Lens group tags

The following examples demonstrate how to list the AWS resource tags associated with a Storage Lens group. You can list tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To review the list of tags and tag values for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you're interested in.
4. Scroll down to the **AWS resource tags** section. All of the user-defined AWS resource tags that are added to your Storage Lens group are listed along with their tag values.

Using the AWS CLI

The following AWS CLI example command lists all the Storage Lens group tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-tags-for-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
```

```
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens group tag values for the Storage Lens group Amazon Resource Name (ARN) that you specify. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
                .resourceArn(resourceARN)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            ListTagsForResourceResponse response =
s3ControlClient.listTagsForResource(listTagsForResourceRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
        }
    }
}
```

```
        e.printStackTrace();
    }
}
}
```

Listing all Storage Lens groups

The following examples demonstrate how to list all Amazon S3 Storage Lens groups in an AWS account and home Region. These examples show how list all Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To list all Storage Lens groups in an account and home Region

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, the list of Storage Lens groups in your account is displayed.

Using the AWS CLI

The following AWS CLI example lists all of the Storage Lens groups for your account. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-groups --account-id 111122223333 \
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens groups for account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsRequest;
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsResponse;

public class ListStorageLensGroups {
    public static void main(String[] args) {
        String accountId = "111122223333";

        try {
            ListStorageLensGroupsRequest listStorageLensGroupsRequest =
ListStorageLensGroupsRequest.builder()
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            ListStorageLensGroupsResponse response =
s3ControlClient.listStorageLensGroups(listStorageLensGroupsRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Viewing Storage Lens group details

The following examples demonstrate how to view Amazon S3 Storage Lens group configuration details. You can view these details by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To view Storage Lens group configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you're interested in.
4. Choose **View details**. You can now review the details of your Storage Lens group.

Using the AWS CLI

The following AWS CLI example returns the configuration details for a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;  
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;  
  
public class GetStorageLensGroup {  
    public static void main(String[] args) {  
        String storageLensGroupName = "Marketing-Department";  
        String accountId = "111122223333";  
  
        try {  
            GetStorageLensGroupRequest getRequest =  
GetStorageLensGroupRequest.builder()  
                .name(storageLensGroupName)  
                .accountId(accountId).build();  
            S3ControlClient s3ControlClient = S3ControlClient.builder()
```

```
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    GetStorageLensGroupResponse response =
s3ControlClient.getStorageLensGroup(getRequest);
    System.out.println(response);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Deleting a Storage Lens group

The following examples demonstrate how to delete an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you want to delete.
4. Choose **Delete**. A **Delete Storage Lens group** dialog box displays.
5. Choose **Delete** again to permanently delete your Storage Lens group.

Note

After you delete a Storage Lens group, it can't be restored.

Using the AWS CLI

The following AWS CLI example deletes the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.DeleteStorageLensGroupRequest;  
  
public class DeleteStorageLensGroup {  
    public static void main(String[] args) {  
        String storageLensGroupName = "Marketing-Department";  
        String accountId = "111122223333";  
  
        try {  
            DeleteStorageLensGroupRequest deleteStorageLensGroupRequest =  
DeleteStorageLensGroupRequest.builder()  
                .name(storageLensGroupName)  
                .accountId(accountId).build();  
            S3ControlClient s3ControlClient = S3ControlClient.builder()  
                .region(Region.US_WEST_2)  
                .credentialsProvider(ProfileCredentialsProvider.create())  
                .build();  
            s3ControlClient.deleteStorageLensGroup(deleteStorageLensGroupRequest);  
        } catch (AmazonServiceException e) {  
            // The call was transmitted successfully, but Amazon S3 couldn't process  
            // it and returned an error response.  
        }  
    }  
}
```

```
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
}
```

Cataloging and analyzing your data with S3 Inventory

You can use Amazon S3 Inventory to help manage your storage. For example, you can use it to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also simplify and speed up business workflows and big data jobs by using Amazon S3 Inventory, which provides a scheduled alternative to the Amazon S3 synchronous List API operations. Amazon S3 Inventory does not use the List API operations to audit your objects and does not affect the request rate of your bucket.

Amazon S3 Inventory provides comma-separated values (CSV), [Apache optimized row columnar \(ORC\)](#) or [Apache Parquet](#) output files that list your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or objects with a shared prefix (that is, objects that have names that begin with a common string). If you set up a weekly inventory, a report is generated every Sunday (UTC time zone) after the initial report. For information about Amazon S3 Inventory pricing, see [Amazon S3 pricing](#).

You can configure multiple inventory lists for a bucket. When you're configuring an inventory list, you can specify the following:

- What object metadata to include in the inventory
- Whether to list all object versions or only current versions
- Where to store the inventory list file output
- Whether to generate the inventory on a daily or weekly basis
- Whether to encrypt the inventory list file

You can query Amazon S3 Inventory with standard SQL queries by using [Amazon Athena](#), [Amazon Redshift Spectrum](#), and other tools, such as [Presto](#), [Apache Hive](#), and [Apache Spark](#). For more information about using Athena to query your inventory files, see [the section called “Querying inventory with Athena”](#).

Note

It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

Source and destination buckets

The bucket that the inventory lists objects for is called the *source bucket*. The bucket where the inventory list file is stored is called the *destination bucket*.

Source bucket

The inventory lists the objects that are stored in the source bucket. You can get an inventory list for an entire bucket, or you can filter the list by object key name prefix.

The source bucket:

- Contains the objects that are listed in the inventory
- Contains the configuration for the inventory

Destination bucket

Amazon S3 Inventory list files are written to the destination bucket. To group all the inventory list files in a common location in the destination bucket, you can specify a destination prefix in the inventory configuration.

The destination bucket:

- Contains the inventory file lists.
- Contains the manifest files that list all the inventory list files that are stored in the destination bucket. For more information, see [Inventory manifest](#).
- Must have a bucket policy to give Amazon S3 permission to verify ownership of the bucket and permission to write files to the bucket.
- Must be in the same AWS Region as the source bucket.
- Can be the same as the source bucket.
- Can be owned by a different AWS account than the account that owns the source bucket.

Amazon S3 Inventory list

An inventory list file contains a list of the objects in the source bucket and metadata for each object. An inventory list file is stored in the destination bucket with one of the following formats:

- As a CSV file compressed with GZIP
- As an Apache optimized row columnar (ORC) file compressed with ZLIB
- As an Apache Parquet file compressed with Snappy

 **Note**

Objects in Amazon S3 Inventory reports aren't guaranteed to be sorted in any order.

An inventory list file contains a list of the objects in the source bucket and metadata for each listed object. These default fields are always included:

- **Bucket name** – The name of the bucket that the inventory is for.
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag can be an MD5 digest of the object data. Whether it is depends on how the object was created and how it is encrypted. For more information, see [Object](#) in the *Amazon Simple Storage Service API Reference*.
- **Key name** – The object key name (or key) that uniquely identifies the object in the bucket. When you're using the CSV file format, the key name is URL-encoded and must be decoded before you can use it.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Storage class** – The storage class that's used for storing the object. Set to STANDARD, REDUCED_REDUNDANCY, STANDARD_IA, ONEZONE_IA, INTELLIGENT_TIERING, GLACIER, DEEP_ARCHIVE, OUTPOSTS, GLACIER_IR, or SNOW. For more information, see [Understanding and managing Amazon S3 storage classes](#).

Note

S3 Inventory does not support S3 Express One Zone.

You can choose to include the following additional metadata fields in the report:

- **Checksum algorithm** – Indicates the algorithm that's used to create the checksum for the object. For more information, see [Using supported checksum algorithms](#).
- **Encryption status** – The server-side encryption status, depending on what kind of encryption key is used—server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). Set to SSE-S3, SSE-KMS, DSSE-KMS, SSE-C, or NOT-SSE. A status of NOT-SSE means that the object is not encrypted with server-side encryption. For more information, see [Protecting data with encryption](#).
- **S3 Intelligent-Tiering access tier** – Access tier (frequent or infrequent) of the object if it is stored in the S3 Intelligent-Tiering storage class. Set to FREQUENT, INFREQUENT, ARCHIVE_INSTANT_ACCESS, ARCHIVE, or DEEP_ARCHIVE. For more information, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).
- **S3 Object Lock retain until date** – The date until which the locked object cannot be deleted. For more information, see [Locking objects with Object Lock](#).
- **S3 Object Lock retention mode** – Set to Governance or Compliance for objects that are locked. For more information, see [Locking objects with Object Lock](#).
- **S3 Object Lock legal hold status** – Set to On if a legal hold has been applied to an object. Otherwise, it is set to Off. For more information, see [Locking objects with Object Lock](#).
- **Version ID** – The object version ID. When you enable versioning on a bucket, Amazon S3 assigns a version number to objects that are added to the bucket. For more information, see [Retaining multiple versions of objects with S3 Versioning](#). (This field is not included if the list is configured only for the current version of the objects.)
- **IsLatest** – Set to True if the object is the current version of the object. (This field is not included if the list is configured only for the current version of the objects.)

- **Delete marker** – Set to True if the object is a delete marker. For more information, see [Retaining multiple versions of objects with S3 Versioning](#). (This field is automatically added to your report if you've configured the report to include all versions of your objects).
- **Multipart upload flag** – Set to True if the object was uploaded as a multipart upload. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).
- **Object owner** – The canonical user ID of the owner of the object. For more information, see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.
- **Replication status** – Set to PENDING, COMPLETED, FAILED, or REPLICA. For more information, see [Getting replication status information](#).
- **S3 Bucket Key status** – Set to ENABLED or DISABLED. Indicates whether the object uses an S3 Bucket Key for SSE-KMS. For more information, see [Using Amazon S3 Bucket Keys](#).
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. The Object ACL field is defined in JSON format. An S3 Inventory report includes ACLs that are associated with objects in your source bucket, even when ACLs are disabled for the bucket. For more information, see [Working with the Object ACL field](#) and [Access control list \(ACL\) overview](#).

Note

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.

For example, suppose that you have the following Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {"canonicalId": "example-canonical-user-ID",  
         "type": "CanonicalUser",  
         "permission": "READ"  
     ]  
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQU1MQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2Fs
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see [Querying Amazon S3 Inventory with Amazon Athena](#).

- **Lifecycle Expiration Date** – Set to the lifecycle expiration timestamp of the object. This field will only be populated, if the object is to be expired by an applicable lifecycle rule. In other cases, the field will be empty. For more information, see [Expiring objects](#).

 **Note**

When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. The inventory report includes the objects that have expired but haven't been removed yet. For more information about expiration actions in S3 Lifecycle, see [Expiring objects](#).

The following is an example inventory report with additional metadata fields consisting of four records.

```
amzn-s3-demo-bucket1    example-object-1    EXAMPLEDC81.XJCEN1F7LePaNIIvs001    TRUE

We recommend that you create a lifecycle policy that deletes old inventory lists. For more information, see [Managing the lifecycle of objects](#).

The `s3:PutInventoryConfiguration` permission allows a user to both select all the metadata fields that are listed earlier for each object when configuring an inventory list and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory list. To restrict access to an inventory report, see [Grant permissions for S3 Inventory and S3 analytics](#).

Inventory consistency

All of your objects might not appear in each inventory list. The inventory list provides eventual consistency for PUT requests (of both new objects and overwrites) and for DELETE requests. Each inventory list for a bucket is a snapshot of bucket items. These lists are eventually consistent (that is, a list might not include recently added or deleted objects).

To validate the state of an object before you take action on the object, we recommend that you perform a `HeadObject` REST API request to retrieve metadata for the object, or to check the object's properties in the Amazon S3 console. You can also check object metadata with the AWS CLI or the AWS SDKs. For more information, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

For more information about working with Amazon S3 Inventory, see the following topics.

Configuring Amazon S3 Inventory

Amazon S3 Inventory provides a flat file list of your objects and metadata, on a schedule that you define. You can use S3 Inventory as a scheduled alternative to the Amazon S3 synchronous List API operation. S3 Inventory provides comma-separated values (CSV), [Apache optimized row columnar \(ORC\)](#), or [Apache Parquet \(Parquet\)](#) output files that list your objects and their corresponding metadata.

You can configure S3 Inventory to create inventory lists on a daily or weekly basis for an S3 bucket or for objects that share a prefix (objects that have names that begin with the same string). For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

This section describes how to configure an inventory, including details about the inventory source and destination buckets.

Topics

- [Overview](#)
- [Creating a destination bucket policy](#)
- [Granting Amazon S3 permission to use your customer managed key for encryption](#)
- [Configuring inventory by using the S3 console](#)
- [Using the REST API to work with S3 Inventory](#)

Overview

Amazon S3 Inventory helps you manage your storage by creating lists of the objects in an S3 bucket on a defined schedule. You can configure multiple inventory lists for a bucket. The inventory lists are published to CSV, ORC, or Parquet files in a destination bucket.

The easiest way to set up an inventory is by using the Amazon S3 console, but you can also use the Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs. The console performs the first step of the following procedure for you: adding a bucket policy to the destination bucket.

To set up Amazon S3 Inventory for an S3 bucket

1. Add a bucket policy for the destination bucket.

You must create a bucket policy on the destination bucket that grants permissions to Amazon S3 to write objects to the bucket in the defined location. For an example policy, see [Grant permissions for S3 Inventory and S3 analytics](#).

2. Configure an inventory to list the objects in a source bucket and publish the list to a destination bucket.

When you configure an inventory list for a source bucket, you specify the destination bucket where you want the list to be stored, and whether you want to generate the list daily or weekly. You can also configure whether to list all object versions or only current versions and what object metadata to include.

Some object metadata fields in S3 Inventory report configurations are optional, meaning that they're available by default but they can be restricted when you grant a user the `s3:PutInventoryConfiguration` permission. You can control whether users can include these optional metadata fields in their reports by using the `s3:InventoryAccessibleOptionalFields` condition key.

For more information about the optional metadata fields available in S3 Inventory, see [OptionalFields](#) in the *Amazon Simple Storage Service API Reference*. For more information about restricting access to certain optional metadata fields in an inventory configuration, see [Control S3 Inventory report configuration creation](#).

You can specify that the inventory list file be encrypted by using server-side encryption with an Amazon S3 managed key (SSE-S3) or an AWS Key Management Service (AWS KMS) customer managed key (SSE-KMS).

Note

The AWS managed key (`aws/s3`) is not supported for SSE-KMS encryption with S3 Inventory.

For more information about SSE-S3 and SSE-KMS, see [Protecting data with server-side encryption](#). If you plan to use SSE-KMS encryption, see Step 3.

- For information about how to use the console to configure an inventory list, see [Configuring inventory by using the S3 console](#).

- To use the Amazon S3 API to configure an inventory list, use the [PutBucketInventoryConfiguration](#) REST API operation or the equivalent from the AWS CLI or AWS SDKs.
- 3. To encrypt the inventory list file with SSE-KMS, grant Amazon S3 permission to use the AWS KMS key.**

You can configure encryption for the inventory list file by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, or AWS SDKs. Whichever way you choose, you must grant Amazon S3 permission to use the customer managed key to encrypt the inventory file. You [grant Amazon S3 permission by modifying the key policy for the customer managed key](#) that you want to use to encrypt the inventory file. Make sure that you've provided a KMS key ARN in the S3 Inventory configuration or the destination bucket's encryption settings. If no KMS key ARN has been specified and the default encryption settings are being used, you won't be able to access your S3 Inventory report.

The destination bucket that stores the inventory list file can be owned by a different AWS account than the account that owns the source bucket. If you use SSE-KMS encryption for the cross-account operations of Amazon S3 Inventory, we recommend that you use a fully qualified KMS key ARN when you configure S3 inventory. For more information, see [Using SSE-KMS encryption for cross-account operations](#) and [ServerSideEncryptionByDefault](#) in the *Amazon Simple Storage Service API Reference*.

 **Note**

If you can't access your S3 Inventory report, use the [GetBucketEncryption](#) API, and check whether the destination bucket has the default SSE-KMS encryption enabled. If no KMS key ARN has been specified and the default encryption settings are being used, you won't be able to access your S3 Inventory report. To access S3 Inventory reports again, either provide a KMS key ARN in the S3 Inventory configuration or in the destination bucket's encryption settings.

Creating a destination bucket policy

If you create your inventory configuration through the Amazon S3 console, Amazon S3 automatically creates a bucket policy on the destination bucket that grants Amazon S3 write permission to the bucket. However, if you create your inventory configuration through the AWS

CLI, AWS SDKs, or the Amazon S3 REST API, you must manually add a bucket policy on the destination bucket. The S3 Inventory destination bucket policy allows Amazon S3 to write data for the inventory reports to the bucket.

The following is the example bucket policy.

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "InventoryExamplePolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "s3:PutObject",  
            "Resource": [  
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"  
            ],  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "source-account-id",  
                    "s3:x-amz-acl": "bucket-owner-full-control"  
                }  
            }  
        }  
    ]  
}
```

For more information, see [Grant permissions for S3 Inventory and S3 analytics](#).

If an error occurs when you try to create the bucket policy, you are given instructions on how to fix it. For example, if you choose a destination bucket in another AWS account and don't have permissions to read and write to the bucket policy, you see an error message.

In this case, the destination bucket owner must add the bucket policy to the destination bucket. If the policy is not added to the destination bucket, you won't get an inventory report because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, the correct account ID of the source bucket owner must be substituted in the policy.

 **Note**

Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see [Why can't I generate an Amazon S3 Inventory Report?](#).

Granting Amazon S3 permission to use your customer managed key for encryption

To grant Amazon S3 permission to use your AWS Key Management Service (AWS KMS) customer managed key for server-side encryption, you must use a key policy. To update your key policy so that you can use your customer managed key, use the following procedure.

To grant Amazon S3 permissions to encrypt by using your customer managed key

1. Using the AWS account that owns the customer managed key, sign into the AWS Management Console.
2. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the customer managed key that you want to use to encrypt your inventory files.
6. In the **Key policy** section, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. On the **Edit key policy** page, add the following lines to the existing key policy. For **source-account-id** and **amzn-s3-demo-source-bucket**, supply the appropriate values for your use case.

{

```
"Sid": "Allow Amazon S3 use of the customer managed key",
"Effect": "Allow",
"Principal": {
    "Service": "s3.amazonaws.com"
},
>Action": [
    "kms:GenerateDataKey"
],
"Resource": "*",
"Condition":{
    "StringEquals":{
        "aws:SourceAccount":"source-account-id"
    },
    "ArnLike":{
        "aws:SourceARN": "arn:aws:s3:::amzn-s3-demo-source-bucket"
    }
}
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following links in the *AWS Key Management Service Developer Guide*:

- [Managing keys](#)
- [Key policies in AWS KMS](#)

Note

Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see [Why can't I generate an Amazon S3 Inventory Report?](#).

Configuring inventory by using the S3 console

Use these instructions to configure inventory by using the S3 console.

Note

It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to configure Amazon S3 Inventory for.
4. Choose the **Management** tab.
5. Under **Inventory configurations**, choose **Create inventory configuration**.
6. For **Inventory configuration name**, enter a name.
7. For **Inventory scope**, do the following:
 - Enter an optional prefix.
 - Choose which object versions to include, either **Current versions only** or **Include all versions**.
8. Under **Report details**, choose the location of the AWS account that you want to save the reports to: **This account** or **A different account**.
9. Under **Destination**, choose the destination bucket where you want the inventory reports to be saved.

The destination bucket must be in the same AWS Region as the bucket for which you are setting up the inventory. The destination bucket can be in a different AWS account. When specifying the destination bucket, you can also include an optional prefix to group your inventory reports together.

Under the **Destination** bucket field, you see the **Destination bucket permission** statement that is added to the destination bucket policy to allow Amazon S3 to place data in that bucket. For more information, see [Creating a destination bucket policy](#).

10. Under **Frequency**, choose how often the report will be generated, **Daily** or **Weekly**.
11. For **Output format**, choose one of the following formats for the report:
 - **CSV** – If you plan to use this inventory report with S3 Batch Operations or if you want to analyze this report in another tool, such as Microsoft Excel, choose **CSV**.

- Apache ORC
- Apache Parquet

12. Under **Status**, choose **Enable or Disable**.

13. To configure server-side encryption, under **Inventory report encryption**, follow these steps:

- a. Under **Server-side encryption**, choose either **Do not specify an encryption key** or **Specify an encryption key** to encrypt data.
 - To keep the bucket settings for default server-side encryption of objects when storing them in Amazon S3, choose **Do not specify an encryption key**. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies an S3 Bucket Key at the destination bucket.

 **Note**

If the bucket policy for the specified destination requires objects to be encrypted before storing them in Amazon S3, you must choose **Specify an encryption key**. Otherwise, copying objects to the destination will fail.

- b. To encrypt objects before storing them in Amazon S3, choose **Specify an encryption key**.
- c. If you chose **Specify an encryption key**, under **Encryption type**, you must choose either **Amazon S3 managed key (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. SSE-KMS provides you with more control over your key. For more information about SSE-S3, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#). For more information about SSE-KMS, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

 **Note**

To encrypt the inventory list file with SSE-KMS, you must grant Amazon S3 permission to use the customer managed key. For instructions, see [Grant Amazon S3 Permission to Encrypt Using Your KMS Keys](#).

- c. If you chose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify your AWS KMS key through one of the following options.

 **Note**

If the destination bucket that stores the inventory list file is owned by a different AWS account, make sure that you use a fully qualified KMS key ARN to specify your KMS key.

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose a symmetric encryption KMS key from the list of available keys. Make sure the KMS key is in the same Region as your bucket.

 **Note**

Both the AWS managed key (aws/s3) and your customer managed keys appear in the list. However, the AWS managed key (aws/s3) is not supported for SSE-KMS encryption with S3 Inventory.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

14. For **Additional metadata fields**, select one or more of the following to add to the inventory report:

- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **Multipart upload** – Specifies that the object was uploaded as a multipart upload. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).
- **Replication status** – The replication status of the object. For more information, see [Getting replication status information](#).

- **Encryption status** – The server-side encryption type that's used to encrypt the object. For more information, see [Protecting data with server-side encryption](#).
- **Bucket Key status** – Indicates whether a bucket-level key generated by AWS KMS applies to the object. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information about this field, see [Working with the Object ACL field](#). For more information about ACLs, see [Access control list \(ACL\) overview](#).
- **Object owner** – The owner of the object.
- **Storage class** – The storage class that's used for storing the object.
- **Intelligent-Tiering: Access tier** – Indicates the access tier (frequent or infrequent) of the object if it was stored in the S3 Intelligent-Tiering storage class. For more information, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag might or might not be an MD5 digest of the object data. Whether it is depends on how the object was created and how it is encrypted. For more information, see [Object](#) in the *Amazon Simple Storage Service API Reference*.
- **Checksum algorithm** – Indicates the algorithm that is used to create the checksum for the object. For more information, see [Using supported checksum algorithms](#).
- **All Object Lock configurations** – The Object Lock status of the object, including the following settings:
 - **Object Lock: Retention mode** – The level of protection applied to the object, either *Governance* or *Compliance*.
 - **Object Lock: Retain until date** – The date until which the locked object cannot be deleted.
 - **Object Lock: Legal hold status** – The legal hold status of the locked object.

For information about S3 Object Lock, see [How S3 Object Lock works](#).

- **Lifecycle Expiration Date** – The lifecycle expiration timestamp for objects in your Inventory report. This field will only be populated, if the object is to be expired by an applicable lifecycle rule. In other cases, the field will be empty. For more information, see [Expiring objects](#).

For more information about the contents of an inventory report, see [Amazon S3 Inventory list](#).

For more information about restricting access to certain optional metadata fields in an inventory configuration, see [Control S3 Inventory report configuration creation](#).

15. Choose **Create**.

Using the REST API to work with S3 Inventory

The following are the REST operations that you can use to work with Amazon S3 Inventory.

- [DeleteBucketInventoryConfiguration](#)
- [GetBucketInventoryConfiguration](#)
- [ListBucketInventoryConfigurations](#)
- [PutBucketInventoryConfiguration](#)

Locating your inventory list

When an inventory list is published, the manifest files are published to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/manifest.json  
destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/  
manifest.checksum  
destination-prefix/amzn-s3-demo-source-bucket/config-ID/hive/dt=YYYY-MM-DD-HH-MM/  
symlink.txt
```

- *destination-prefix* is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location within the destination bucket.
- *amzn-s3-demo-source-bucket* is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- *config-ID* is added to prevent collisions with multiple inventory reports from the same source bucket that are sent to the same destination bucket. The *config-ID* comes from the inventory report configuration, and is the name for the report that is defined during setup.

- **YYYY-MM-DDTHH-MMZ** is the timestamp that consists of the start time and the date when the inventory report generation process begins scanning the bucket; for example, 2016-11-06T21-32Z.
- `manifest.json` is the manifest file.
- `manifest.checksum` is the MD5 hash of the content of the `manifest.json` file.
- `symlink.txt` is the Apache Hive-compatible manifest file.

The inventory lists are published daily or weekly to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name.csv.gz  
...  
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name-1.csv.gz
```

- **destination-prefix** is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location in the destination bucket.
- **amzn-s3-demo-source-bucket** is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- **example-file-name.csv.gz** is one of the CSV inventory files. ORC inventory names end with the file name extension `.orc`, and Parquet inventory names end with the file name extension `.parquet`.

Inventory manifest

The manifest files `manifest.json` and `symlink.txt` describe where the inventory files are located. Whenever a new inventory list is delivered, it is accompanied by a new set of manifest files. These files might overwrite each other. In versioning-enabled buckets, Amazon S3 creates new versions of the manifest files.

Each manifest contained in the `manifest.json` file provides metadata and other basic information about an inventory. This information includes the following:

- The source bucket name
- The destination bucket name

- The version of the inventory
- The creation timestamp in the epoch date format that consists of the start time and the date when the inventory report generation process begins scanning the bucket
- The format and schema of the inventory files
- A list of the inventory files that are in the destination bucket

Whenever a `manifest.json` file is written, it is accompanied by a `manifest.checksum` file that is the MD5 hash of the content of the `manifest.json` file.

Example Inventory manifest in a `manifest.json` file

The following examples show an inventory manifest in a `manifest.json` file for CSV, ORC, and Parquet-formatted inventories.

CSV

The following is an example of a manifest in a `manifest.json` file for a CSV-formatted inventory.

```
{  
    "sourceBucket": "amzn-s3-demo-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-inventory-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "CSV",  
    "fileSchema": "Bucket, Key, VersionId, IsLatest, IsDeleteMarker,  
    Size, LastModifiedDate, ETag, StorageClass, IsMultipartUploaded,  
    ReplicationStatus, EncryptionStatus, ObjectLockRetainUntilDate, ObjectLockMode,  
    ObjectLockLegalHoldStatus, IntelligentTieringAccessTier, BucketKeyStatus,  
    ChecksumAlgorithm, ObjectAccessControlList, ObjectOwner",  
    "files": [  
        {  
            "key": "Inventory/amzn-s3-demo-source-bucket/2016-11-06T21-32Z/  
            files/939c6d46-85a9-4ba8-87bd-9db705a579ce.csv.gz",  
            "size": 2147483647,  
            "MD5checksum": "f11166069f1990abeb9c97ace9cdfabc"  
        }  
    ]  
}
```

ORC

The following is an example of a manifest in a `manifest.json` file for an ORC-formatted inventory.

```
{  
    "sourceBucket": "amzn-s3-demo-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "ORC",  
    "fileSchema":  
        "struct<bucket:string,key:string,version_id:string,is_latest:boolean,is_delete_marker:boolean>  
        "files": [  
            {  
                "key": "inventory/amzn-s3-demo-source-bucket/data/  
d794c570-95bb-4271-9128-26023c8b4900.orc",  
                "size": 56291,  
                "MD5checksum": "5925f4e78e1695c2d020b9f6eexample"  
            }  
        ]  
}
```

Parquet

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted inventory.

```
{  
    "sourceBucket": "amzn-s3-demo-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "Parquet",  
    "fileSchema": "message s3.inventory { required binary bucket (UTF8);  
    required binary key (UTF8); optional binary version_id (UTF8); optional boolean  
    is_latest; optional boolean is_delete_marker; optional int64 size; optional  
    int64 last_modified_date (TIMESTAMP_MILLIS); optional binary e_tag (UTF8);  
    optional binary storage_class (UTF8); optional boolean is.multipart_uploaded;  
    optional binary replication_status (UTF8); optional binary encryption_status  
    (UTF8); optional int64 object_lock_retain_until_date (TIMESTAMP_MILLIS); optional  
    binary object_lock_mode (UTF8); optional binary object_lock_legal_hold_status  
    (UTF8); optional binary intelligent_tiering_access_tier (UTF8); optional binary
```

```
bucket_key_status (UTF8); optional binary checksum_algorithm (UTF8); optional  
binary object_access_control_list (UTF8); optional binary object_owner (UTF8);}",  
    "files": [  
        {  
            "key": "inventory/amzn-s3-demo-source-bucket/data/  
d754c470-85bb-4255-9218-47023c8b4910.parquet",  
            "size": 56291,  
            "MD5checksum": "5825f2e18e1695c2d030b9f6eexample"  
        }  
    ]  
}
```

The `symlink.txt` file is an Apache Hive-compatible manifest file that allows Hive to automatically discover inventory files and their associated data files. The Hive-compatible manifest works with the Hive-compatible services Athena and Amazon Redshift Spectrum. It also works with Hive-compatible applications, including [Presto](#), [Apache Hive](#), [Apache Spark](#), and many others.

Important

The `symlink.txt` Apache Hive-compatible manifest file does not currently work with AWS Glue.
Reading the `symlink.txt` file with [Apache Hive](#) and [Apache Spark](#) is not supported for ORC and Parquet-formatted inventory files.

Setting up Amazon S3 Event Notifications for inventory completion

You can set up an Amazon S3 event notification to receive notice when the manifest checksum file is created, which indicates that an inventory list has been added to the destination bucket. The manifest is an up-to-date list of all the inventory lists at the destination location.

Amazon S3 can publish events to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

The following notification configuration defines that all `manifest.checksum` files newly added to the destination bucket are processed by the AWS Lambda `cloud-function-list-write`.

```
<NotificationConfiguration>
```

```
<QueueConfiguration>
  <Id>1</Id>
  <Filter>
    <S3Key>
      <FilterRule>
        <Name>prefix</Name>
        <Value>destination-prefix/source-bucket</Value>
      </FilterRule>
      <FilterRule>
        <Name>suffix</Name>
        <Value>checksum</Value>
      </FilterRule>
    </S3Key>
  </Filter>
  <CloudFunction>arn:aws:lambda:us-west-2:22223334444:cloud-function-list-write</CloudFunction>
  <Event>s3:ObjectCreated:*</Event>
</QueueConfiguration>
</NotificationConfiguration>
```

For more information, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Querying Amazon S3 Inventory with Amazon Athena

You can query Amazon S3 Inventory files with standard SQL queries by using Amazon Athena in all Regions where Athena is available. To check for AWS Region availability, see the [AWS Region Table](#).

Athena can query Amazon S3 Inventory files in [Apache optimized row columnar \(ORC\)](#), [Apache Parquet](#), or comma-separated values (CSV) format. When you use Athena to query inventory files, we recommend that you use ORC-formatted or Parquet-formatted inventory files. The ORC and Parquet formats provide faster query performance and lower query costs. ORC and Parquet are self-describing, type-aware columnar file formats designed for [Apache Hadoop](#). The columnar format lets the reader read, decompress, and process only the columns that are required for the current query. The ORC and Parquet formats for Amazon S3 Inventory are available in all AWS Regions.

To use Athena to query Amazon S3 Inventory files

1. Create an Athena table. For information about creating a table, see [Creating Tables in Amazon Athena](#) in the *Amazon Athena User Guide*.

2. Create your query by using one of the following sample query templates, depending on whether you're querying an ORC-formatted, a Parquet-formatted, or a CSV-formatted inventory report.

- When you're using Athena to query an ORC-formatted inventory report, use the following sample query as a template.

The following sample query includes all the optional fields in an ORC-formatted inventory report.

To use this sample query, do the following:

- Replace *your_table_name* with the name of the Athena table that you created.
- Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
- Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

`s3://amzn-s3-demo-bucket/config-ID/hive/`

- Replace the **2022-01-01-00-00** date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see [Partitioning data in Athena](#).

```
CREATE EXTERNAL TABLE your_table_name (
    bucket string,
    key string,
    version_id string,
    is_latest boolean,
    is_delete_marker boolean,
    size bigint,
    last_modified_date timestamp,
    e_tag string,
    storage_class string,
    is.multipart_uploaded boolean,
    replication_status string,
    encryption_status string,
    object_lock_retain_until_date bigint,
    object_lock_mode string,
    object_lock_legal_hold_status string,
    intelligent_tiering_access_tier string,
    bucket_key_status string,
```

```
        checksum_algorithm string,
        object_access_control_list string,
        object_owner string,
        lifecycle_expiration_date timestamp
    ) PARTITIONED BY (
        dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'
    STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
    OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
    LOCATION 's3://amzn-s3-demo-bucket/config-ID/hive/
TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
);
```

- When you're using Athena to query a Parquet-formatted inventory report, use the sample query for an ORC-formatted report. However, use the following Parquet SerDe in place of the ORC SerDe in the ROW FORMAT SERDE statement.

```
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe'
```

- When you're using Athena to query a CSV-formatted inventory report, use the following sample query as a template.

The following sample query includes all the optional fields in an CSV-formatted inventory report.

To use this sample query, do the following:

- Replace *your_table_name* with the name of the Athena table that you created.
- Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
- Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

s3://amzn-s3-demo-bucket/config-ID/hive/

- Replace the **2022-01-01-00-00** date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see [Partitioning data in Athena](#).

```
CREATE EXTERNAL TABLE your_table_name (
    bucket string,
    key string,
    version_id string,
    is_latest boolean,
    is_delete_marker boolean,
    size string,
    last_modified_date string,
    e_tag string,
    storage_class string,
    is_multipart_uploaded boolean,
    replication_status string,
    encryption_status string,
    object_lock_retain_until_date string,
    object_lock_mode string,
    object_lock_legal_hold_status string,
    intelligent_tiering_access_tier string,
    bucket_key_status string,
    checksum_algorithm string,
    object_access_control_list string,
    object_owner string,
    lifecycle_expiration_date string
) PARTITIONED BY (
    dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.OpenCSVSerde'
    STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
    OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
    LOCATION 's3://amzn-s3-demo-bucket/config-ID/hive/
TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
);
```

3. You can now run various queries on your inventory, as shown in the following examples. Replace each *user input placeholder* with your own information.

```
# Get a list of the latest inventory report dates available.  
SELECT DISTINCT dt FROM your_table_name ORDER BY 1 DESC limit 10;  
  
# Get the encryption status for a provided report date.  
SELECT encryption_status, count(*) FROM your_table_name WHERE dt = 'YYYY-MM-DD-HH-MM' GROUP BY encryption_status;  
  
# Get the encryption status for inventory report dates in the provided range.  
SELECT dt, encryption_status, count(*) FROM your_table_name  
WHERE dt > 'YYYY-MM-DD-HH-MM' AND dt < 'YYYY-MM-DD-HH-MM' GROUP BY dt,  
encryption_status;
```

When you configure S3 Inventory to add the Object Access Control List (Object ACL) field to an inventory report, the report displays the value for the Object ACL field as a base64-encoded string. To get the decoded value in JSON for the Object ACL field, you can query this field by using Athena. See the following query examples. For more information about the Object ACL field, see [Working with the Object ACL field](#).

```
# Get the S3 keys that have Object ACL grants with public access.  
WITH grants AS (  
    SELECT key,  
           CAST(  
               json_extract(from_utf8(from_base64(object_access_control_list)),  
'$._grants') AS ARRAY(MAP(VARCHAR, VARCHAR))  
           ) AS grants_array  
    FROM your_table_name  
)  
SELECT key,  
       grants_array,  
       grant  
FROM grants, UNNEST(grants_array) AS t(grant)  
WHERE element_at(grant, 'uri') = 'http://acs.amazonaws.com/groups/global/AllUsers'
```

```
# Get the S3 keys that have Object ACL grantees in addition to the object owner.  
WITH grants AS  
    (SELECT key,
```

```
    from_utf8(from_base64(object_access_control_list)) AS
object_access_control_list,
    object_owner,
    CAST(json_extract(from_utf8(from_base64(object_access_control_list)),
'$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))) AS grants_array
FROM your_table_name)
SELECT key,
    grant,
    objectowner
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE cardinality(grants_array) > 1 AND element_at(grant, 'canonicalId') != object_owner;
```

```
# Get the S3 keys with READ permission that is granted in the Object ACL.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
'$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
    grants_array,
    grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'permission') = 'READ';
```

```
# Get the S3 keys that have Object ACL grants to a specific canonical user ID.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
'$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
    grants_array,
    grant
```

```
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'canonicalId') = 'user-canonical-id';
```

```
# Get the number of grantees on the Object ACL.
SELECT key,
       object_access_control_list,
       json_array_length(json_extract(object_access_control_list,'$.grants')) AS grants_count
FROM your_table_name;
```

For more information about using Athena, see the [Amazon Athena User Guide](#).

Converting empty version ID strings in Amazon S3 Inventory reports to null strings

The following procedure applies only to Amazon S3 Inventory reports that include all versions, and only if the "all versions" reports are used as manifests for S3 Batch Operations on buckets that have S3 Versioning enabled. You are not required to convert strings for S3 Inventory reports that specify the current version only.

You can use S3 Inventory reports as manifests for S3 Batch Operations. However, when S3 Versioning is enabled on a bucket, S3 Inventory reports that include all versions mark any null-versioned objects with empty strings in the version ID field. When an Inventory Report includes all object version IDs, Batch Operations recognizes null strings as version IDs, but not empty strings.

When an S3 Batch Operations job uses an "all versions" S3 Inventory report as a manifest, it fails all tasks on objects that have an empty string in the version ID field. To convert empty strings in the version ID field of the S3 Inventory report to null strings for Batch Operations, use the following procedure.

Update an Amazon S3 Inventory report for use with Batch Operations

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Navigate to your S3 Inventory report. The inventory report is located in the destination bucket that you specified while configuring your inventory report. For more information about locating inventory reports, see [Locating your inventory list](#).
 - a. Choose the destination bucket.
 - b. Choose the folder. The folder is named after the original source bucket.
 - c. Choose the folder named after the inventory configuration.
 - d. Select the check box next to the folder named **hive**. At the top of the page, choose **Copy S3 URI** to copy the S3 URI for the folder.
3. Open the Amazon Athena console at <https://console.aws.amazon.com/athena/>.
4. In the query editor, choose **Settings**, then choose **Manage**. On the **Manage settings** page, for **Location of query result**, choose an S3 bucket to store your query results in.
5. In the query editor, create an Athena table to hold the data in the inventory report using the following command. Replace **table_name** with a name of your choosing, and in the LOCATION clause, insert the S3 URI that you copied earlier. Then choose **Run** to run the query.

```
CREATE EXTERNAL TABLE table_name(bucket string, key string,  
version_id string) PARTITIONED BY (dt string)ROW FORMAT SERDE  
'org.apache.hadoop.hive.serde2.OpenCSVSerde' STORED AS INPUTFORMAT  
'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat' OUTPUTFORMAT  
'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat' LOCATION 'Copied S3 URI';
```

6. To clear the query editor, choose **Clear**. Then load the inventory report into the table using the following command. Replace **table_name** with the one that you chose in the prior step. Then choose **Run** to run the query.

```
MSCK REPAIR TABLE table_name;
```

7. To clear the query editor, choose **Clear**. Run the following SELECT query to retrieve all entries in the original inventory report and replace any empty version IDs with null strings. Replace **table_name** with the one that you chose earlier, and replace **YYYY-MM-DD-HH-MM** in the WHERE clause with the date of the inventory report that you want this tool to run on. Then choose **Run** to run the query.

```
SELECT bucket as Bucket, key as Key, CASE WHEN version_id = '' THEN 'null' ELSE version_id END as VersionId FROM table_name WHERE dt = 'YYYY-MM-DD-HH-MM';
```

8. Return to the Amazon S3 console (<https://console.aws.amazon.com/s3/>), and navigate to the S3 bucket that you chose for **Location of query result** earlier. Inside, there should be a series of folders ending with the date.

For example, you should see something like `s3://amzn-s3-demo-bucket/query-result-location/Unsaved/2021/10/07/`. You should see .csv files containing the results of the SELECT query that you ran.

Choose the CSV file with the latest modified date. Download this file to your local machine for the next step.

9. The generated CSV file contains a header row. To use this CSV file as input for an S3 Batch Operations job, you must remove the header row, because Batch Operations doesn't support header rows on CSV manifests.

To remove the header row, you can run one of the following commands on the file. Replace `file.csv` with the name of your CSV file.

For macOS and Linux machines, run the tail command in a Terminal window.

```
tail -n +2 file.csv > tmp.csv && mv tmp.csv file.csv
```

For Windows machines, run the following script in a Windows PowerShell window. Replace `File-location` with the path to your file, and `file.csv` with the file name.

```
$ins = New-Object System.IO.StreamReader File-location\file.csv
$outs = New-Object System.IO.StreamWriter File-location\temp.csv
try {
    $skip = 0
    while ( !$ins.EndOfStream ) {
        $line = $ins.ReadLine();
        if ( $skip -ne 0 ) {
            $outs.WriteLine($line);
        } else {
            $skip = 1
        }
    }
}
```

```
    } finally {
        $outs.Close();
        $ins.Close();
    }
Move-Item File-location\temp.csv File-location\file.csv -Force
```

10. After removing the header row from the CSV file, you are ready to use it as a manifest in an S3 Batch Operations job. Upload the CSV file to an S3 bucket or location of your choosing, and then create a Batch Operations job using the CSV file as the manifest.

For more information about creating a Batch Operations job, see [Creating an S3 Batch Operations job](#).

Working with the Object ACL field

An Amazon S3 Inventory report contains a list of the objects in the S3 source bucket and metadata for each object. The Object access control list (ACL) field is a metadata field that is available in Amazon S3 Inventory. Specifically, the Object ACL field contains the access control list (ACL) for each object. The ACL for an object defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information, see [Access control list \(ACL\) overview](#) and [Amazon S3 Inventory list](#).

The Object ACL field in Amazon S3 Inventory reports is defined in JSON format. The JSON data includes the following fields:

- **version** – The version of the Object ACL field format in the inventory reports. It's in date format yyyy-mm-dd.
- **status** – Possible values are AVAILABLE or UNAVAILABLE to indicate whether an Object ACL is available for an object. When the status for the Object ACL is UNAVAILABLE, the value of the Object Owner field in the inventory report is also UNAVAILABLE.
- **grants** – Grantee-permission pairs that list the permission status of each grantee that is granted by the Object ACL. The available values for a grantee are CanonicalUser and Group. For more information about grantees, see [Grantees in access control lists](#).

For a grantee with the Group type, a grantee-permission pair includes the following attributes:

- **uri** – A predefined Amazon S3 group.
- **permission** – The ACL permissions that are granted on the object. For more information, see [ACL permissions on an object](#).

- type – The type Group, which denotes that the grantee is group.

For a grantee with the CanonicalUser type, a grantee-permission pair includes the following attributes:

- canonicalId – An obfuscated form of the AWS account ID. The canonical user ID for an AWS account is specific to that account. You can retrieve the canonical user ID. For more information, see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.
- permission – The ACL permissions that are granted on the object. For more information, see [ACL permissions on an object](#).
- type – The type CanonicalUser, which denotes that the grantee is an AWS account.

The following example shows possible values for the Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {  
            "uri": "http://acs.amazonaws.com/groups/global/AllUsers",  
            "permission": "READ",  
            "type": "Group"  
        }, {  
            "canonicalId": "example-canonical-id",  
            "permission": "FULL_CONTROL",  
            "type": "CanonicalUser"  
        }]  
}
```

Note

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.

For example, suppose that you have the following Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {"canonicalId": "example-canonical-user-ID",
```

```
        "type": "CanonicalUser",
        "permission": "READ"
    ]
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQU1MQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2FsSW
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see [Querying Amazon S3 Inventory with Amazon Athena](#).

Best practices design patterns: optimizing Amazon S3 performance

Your applications can easily achieve thousands of transactions per second in request performance when uploading and retrieving storage from Amazon S3. Amazon S3 automatically scales to high request rates. For example, your application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per partitioned Amazon S3 prefix. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by using parallelization. For example, if you create 10 prefixes in an Amazon S3 bucket to parallelize reads, you could scale your read performance to 55,000 read requests per second. Similarly, you can scale write operations by writing to multiple prefixes. The scaling, in the case of both read and write operations, happens gradually and is not instantaneous, and actual performance will vary based on your specific workload characteristics, usage patterns, and system configuration. While Amazon S3 is scaling to your new higher request rate, you may see some 503 (Slow Down) errors. These errors will dissipate when the scaling is complete. For more information about creating and using prefixes, see [Organizing objects using prefixes](#).

Some data lake applications on Amazon S3 scan millions or billions of objects for queries that run over petabytes of data. These data lake applications achieve single-instance transfer rates that maximize the network interface use for their [Amazon EC2](#) instance, which can be up to 100 Gb/s on a single instance. These applications then aggregate throughput across multiple instances to get multiple terabits per second.

Other applications are sensitive to latency, such as social media messaging applications. These applications can achieve consistent small object latencies (and first-byte-out latencies for larger objects) of roughly 100–200 milliseconds.

Other AWS services can also help accelerate performance for different application architectures. For example, if you want higher transfer rates over a single HTTP connection or single-digit millisecond latencies, use [Amazon CloudFront](#) or [Amazon ElastiCache](#) for caching with Amazon S3.

Additionally, if you want fast data transport over long distances between a client and an S3 bucket, use [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#). Transfer Acceleration uses the globally distributed edge locations in CloudFront to accelerate data transport over geographical distances. If your Amazon S3 workload uses server-side encryption with AWS KMS, see [AWS KMS Limits](#) in the AWS Key Management Service Developer Guide for information about the request rates supported for your use case.

The following topics describe best practice guidelines and design patterns for optimizing performance for applications that use Amazon S3. Refer to the [Performance guidelines for Amazon S3](#) and [Performance design patterns for Amazon S3](#) for the most current information about performance optimization for Amazon S3.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Topics

- [Performance guidelines for Amazon S3](#)
- [Performance design patterns for Amazon S3](#)

Performance guidelines for Amazon S3

When building applications that upload and retrieve objects from Amazon S3, follow our best practices guidelines to optimize performance. We also offer more detailed [Performance design patterns for Amazon S3](#).

To obtain the best performance for your application on Amazon S3, we recommend the following guidelines.

Topics

- [Measure performance](#)
- [Scale storage connections horizontally](#)
- [Use byte-range fetches](#)
- [Retry requests for latency-sensitive applications](#)
- [Combine Amazon S3 \(Storage\) and Amazon EC2 \(compute\) in the same AWS Region](#)
- [Use Amazon S3 Transfer Acceleration to minimize latency caused by distance](#)
- [Use the latest version of the AWS SDKs](#)

Measure performance

When optimizing performance, look at network throughput, CPU, and DRAM requirements. Depending on the mix of demands for these different resources, it might be worth evaluating different [Amazon EC2](#) instance types. For more information about instance types, see [Instance Types](#) in the *Amazon EC2 User Guide*.

It's also helpful to look at DNS lookup time, latency, and data transfer speed using HTTP analysis tools when measuring performance.

To understand the performance requirements and optimize the performance of your application, you can also monitor the 503 error responses that you receive. Monitoring certain performance metrics may incur additional expenses. For more information, see [Amazon S3 pricing](#).

Monitor the number of 503 (Slow Down) status error responses

To monitor the number of 503 status error responses that you get, you can use one of the following options:

- Use Amazon CloudWatch request metrics for Amazon S3. The CloudWatch request metrics include a metric for 5xx status responses. For more information about CloudWatch request metrics, see [Monitoring metrics with Amazon CloudWatch](#).
- Use the 503 (Service Unavailable) error count available in the advanced metrics section of Amazon S3 Storage Lens. For more information, see [Using S3 Storage Lens metrics to improve performance](#).
- Use Amazon S3 server access logging. With server access logging, you can filter and review all requests that receive 503 (Internal Error) responses. You can also use Amazon Athena to parse logs. For more information about server access logging, see [Logging requests with server access logging](#).

By monitoring the number of HTTP 503 status error code, you can often gain valuable insights into which prefixes, keys, or buckets are getting the most throttling requests.

Scale storage connections horizontally

Spreading requests across many connections is a common design pattern to horizontally scale performance. When you build high performance applications, think of Amazon S3 as a very large distributed system, not as a single network endpoint like a traditional storage server. You can achieve the best performance by issuing multiple concurrent requests to Amazon S3. Spread

these requests over separate connections to maximize the accessible bandwidth from Amazon S3. Amazon S3 doesn't have any limits for the number of connections made to your bucket.

Use byte-range fetches

Using the Range HTTP header in a [GET Object](#) request, you can fetch a byte-range from an object, transferring only the specified portion. You can use concurrent connections to Amazon S3 to fetch different byte ranges from within the same object. This helps you achieve higher aggregate throughput versus a single whole-object request. Fetching smaller ranges of a large object also allows your application to improve retry times when requests are interrupted. For more information, see [Downloading objects](#).

If objects are PUT using a multipart upload, it's a good practice to GET them in the same part sizes (or at least aligned to part boundaries) for best performance. GET requests can directly address individual parts; for example, GET ?partNumber=N.

Retry requests for latency-sensitive applications

Aggressive timeouts and retries help drive consistent latency. Given the large scale of Amazon S3, if the first request is slow, a retried request is likely to take a different path and quickly succeed. The AWS SDKs have configurable timeout and retry values that you can tune to the tolerances of your specific application.

Combine Amazon S3 (Storage) and Amazon EC2 (compute) in the same AWS Region

Although S3 bucket names are globally unique, each bucket is stored in a Region that you select when you create the bucket. To learn more about bucket naming guidelines, see [Buckets overview](#) and [Bucket naming rules](#). To optimize performance, we recommend that you access the bucket from Amazon EC2 instances in the same AWS Region when possible. This helps reduce network latency and data transfer costs.

For more information about data transfer costs, see [Amazon S3 Pricing](#).

Use Amazon S3 Transfer Acceleration to minimize latency caused by distance

[Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#) manages fast, easy, and secure transfers of files over long geographic distances between the client and an S3 bucket.

Transfer Acceleration takes advantage of the globally distributed edge locations in [Amazon CloudFront](#). As the data arrives at an edge location, it is routed to Amazon S3 over an optimized network path. Transfer Acceleration is ideal for transferring gigabytes to terabytes of data regularly across continents. It's also useful for clients that upload to a centralized bucket from all over the world.

You can use the [Amazon S3 Transfer Acceleration Speed comparison tool](#) to compare accelerated and non-accelerated upload speeds across Amazon S3 Regions. The Speed Comparison tool uses multipart uploads to transfer a file from your browser to various Amazon S3 Regions with and without using Amazon S3 Transfer Acceleration.

Use the latest version of the AWS SDKs

The AWS SDKs provide built-in support for many of the recommended guidelines for optimizing Amazon S3 performance. The SDKs provide a simpler API for taking advantage of Amazon S3 from within an application and are regularly updated to follow the latest best practices. For example, the SDKs include logic to automatically retry requests on HTTP 503 errors and are investing in code to respond and adapt to slow connections.

The SDKs also provide the [Transfer Manager](#), which automates horizontally scaling connections to achieve thousands of requests per second, using byte-range requests where appropriate. It's important to use the latest version of the AWS SDKs to obtain the latest performance optimization features.

You can also optimize performance when you are using HTTP REST API requests. When using the REST API, you should follow the same best practices that are part of the SDKs. Allow for timeouts and retries on slow requests, and multiple connections to allow fetching of object data in parallel. For information about using the REST API, see the [Amazon Simple Storage Service API Reference](#).

Performance design patterns for Amazon S3

When designing applications to upload and retrieve objects from Amazon S3, use our best practices design patterns for achieving the best performance for your application. We also offer [Performance guidelines for Amazon S3](#) for you to consider when planning your application architecture.

To optimize performance, you can use the following design patterns.

Topics

- [Using caching for frequently accessed content](#)
- [Timeouts and retries for latency-sensitive applications](#)
- [Horizontal scaling and request parallelization for high throughput](#)
- [Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers](#)
- [Optimizing for high-request rate workloads](#)

Using caching for frequently accessed content

Many applications that store data in Amazon S3 serve a "working set" of data that is repeatedly requested by users. If a workload is sending repeated GET requests for a common set of objects, you can use a cache such as [Amazon CloudFront](#), [Amazon ElastiCache](#), or [AWS Elemental MediaStore](#) to optimize performance. Successful cache adoption can result in low latency and high data transfer rates. Applications that use caching also send fewer direct requests to Amazon S3, which can help reduce request costs.

Amazon CloudFront is a fast content delivery network (CDN) that transparently caches data from Amazon S3 in a large set of geographically distributed points of presence (PoPs). When objects might be accessed from multiple Regions, or over the internet, CloudFront allows data to be cached close to the users that are accessing the objects. This can result in high performance delivery of popular Amazon S3 content. For information about CloudFront, see the [Amazon CloudFront Developer Guide](#).

Amazon ElastiCache is a managed, in-memory cache. With ElastiCache, you can provision Amazon EC2 instances that cache objects in memory. This caching results in orders of magnitude reduction in GET latency and substantial increases in download throughput. To use ElastiCache, you modify application logic to both populate the cache with hot objects and check the cache for hot objects before requesting them from Amazon S3. For examples of using ElastiCache to improve Amazon S3 GET performance, see the blog post [Turbocharge Amazon S3 with Amazon ElastiCache for Redis](#).

AWS Elemental MediaStore is a caching and content distribution system specifically built for video workflows and media delivery from Amazon S3. MediaStore provides end-to-end storage APIs specifically for video, and is recommended for performance-sensitive video workloads. For information about MediaStore, see the [AWS Elemental MediaStore User Guide](#).

Timeouts and retries for latency-sensitive applications

There are certain situations where an application receives a response from Amazon S3 indicating that a retry is necessary. Amazon S3 maps bucket and object names to the object data associated with them. If an application generates high request rates (typically sustained rates of over 5,000 requests per second to a small number of objects), it might receive HTTP 503 *slowdown* responses. If these errors occur, each AWS SDK implements automatic retry logic using exponential backoff. If you are not using an AWS SDK, you should implement retry logic when receiving the HTTP 503 error. For information about back-off techniques, see [Retry behavior](#) in the *AWS SDKs and Tools Reference Guide*.

Amazon S3 automatically scales in response to sustained new request rates, dynamically optimizing performance. While Amazon S3 is internally optimizing for a new request rate, you will receive HTTP 503 request responses temporarily until the optimization completes. After Amazon S3 internally optimizes performance for the new request rate, all requests are generally served without retries.

For latency-sensitive applications, Amazon S3 advises tracking and aggressively retrying slower operations. When you retry a request, we recommend using a new connection to Amazon S3 and performing a fresh DNS lookup.

When you make large variably sized requests (for example, more than 128 MB), we advise tracking the throughput being achieved and retrying the slowest 5 percent of the requests. When you make smaller requests (for example, less than 512 KB), where median latencies are often in the tens of milliseconds range, a good guideline is to retry a GET or PUT operation after 2 seconds. If additional retries are needed, the best practice is to back off. For example, we recommend issuing one retry after 2 seconds and a second retry after an additional 4 seconds.

If your application makes fixed-size requests to Amazon S3, you should expect more consistent response times for each of these requests. In this case, a simple strategy is to identify the slowest 1 percent of requests and to retry them. Even a single retry is frequently effective at reducing latency.

If you are using AWS Key Management Service (AWS KMS) for server-side encryption, see [Quotas](#) in the *AWS Key Management Service Developer Guide* for information about the request rates that are supported for your use case.

Horizontal scaling and request parallelization for high throughput

Amazon S3 is a very large distributed system. To help you take advantage of its scale, we encourage you to horizontally scale parallel requests to the Amazon S3 service endpoints. In addition to distributing the requests within Amazon S3, this type of scaling approach helps distribute the load over multiple paths through the network.

For high-throughput transfers, Amazon S3 advises using applications that use multiple connections to GET or PUT data in parallel. For example, this is supported by [Amazon S3 Transfer Manager](#) in the AWS Java SDK, and most of the other AWS SDKs provide similar constructs. For some applications, you can achieve parallel connections by launching multiple requests concurrently in different application threads, or in different application instances. The best approach to take depends on your application and the structure of the objects that you are accessing.

You can use the AWS SDKs to issue GET and PUT requests directly rather than employing the management of transfers in the AWS SDK. This approach lets you tune your workload more directly, while still benefiting from the SDK's support for retries and its handling of any HTTP 503 responses that might occur. As a general rule, when you download large objects from Amazon S3, we suggest making concurrent requests to maximize network throughput and optimize download performance. You can achieve this by either requesting specific byte ranges of the object or downloading individual parts of a multipart object simultaneously. This parallel download approach helps fully utilize your network interface card (NIC) capacity. For objects that were uploaded using multipart upload, we recommend downloading them using the same part sizes or aligning requests to the original part boundaries for best performance. This method of concurrent downloading provides higher aggregate throughput compared to single whole-object requests.

Measuring performance is important when you tune the number of requests to issue concurrently. We recommend starting with a single request at a time. Measure the network bandwidth being achieved and the use of other resources that your application uses in processing the data. You can then identify the bottleneck resource (that is, the resource with the highest usage), and hence the number of requests that are likely to be useful. For example, if processing one request at a time leads to a CPU usage of 25 percent, it suggests that up to four concurrent requests can be accommodated. Measurement is essential, and it is worth confirming resource use as the request rate is increased.

If your application issues requests directly to Amazon S3 using the REST API, we recommend using a pool of HTTP connections and re-using each connection for a series of requests. Avoiding per-request connection setup removes the need to perform TCP slow-start and Secure Sockets Layer

(SSL) handshakes on each request. For information about using the REST API, see the [Amazon Simple Storage Service API Reference](#).

Finally, it's worth paying attention to DNS and double-checking that requests are being spread over a wide pool of Amazon S3 IP addresses. DNS queries for Amazon S3 cycle through a large list of IP endpoints. But caching resolvers or application code that reuses a single IP address do not benefit from address diversity and the load balancing that follows from it. Network utility tools such as the netstat command line tool can show the IP addresses being used for communication with Amazon S3, and we provide guidelines for DNS configurations to use. For more information about these guidelines, see [Making requests](#) in the *Amazon S3 API Reference*.

Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers

[Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#) is effective at minimizing or eliminating the latency caused by geographic distance between globally dispersed clients and a regional application using Amazon S3. Transfer Acceleration uses the globally distributed edge locations in CloudFront for data transport. The AWS edge network has points of presence in more than 50 locations. Today, it is used to distribute content through CloudFront and to provide rapid responses to DNS queries made to [Amazon Route 53](#).

The edge network also helps to accelerate data transfers into and out of Amazon S3. It is ideal for applications that transfer data across or between continents, have a fast internet connection, use large objects, or have a lot of content to upload. As the data arrives at an edge location, data is routed to Amazon S3 over an optimized network path. In general, the farther away you are from an Amazon S3 Region, the higher the speed improvement you can expect from using Transfer Acceleration.

You can set up Transfer Acceleration on new or existing buckets. You can use a separate Amazon S3 Transfer Acceleration endpoint to use the AWS edge locations. The best way to test whether Transfer Acceleration helps client request performance is to use the [Amazon S3 Transfer Acceleration Speed Comparison tool](#). Network configurations and conditions vary from time to time and from location to location. So you are charged only for transfers where Amazon S3 Transfer Acceleration can potentially improve your upload performance. For information about using Transfer Acceleration with different AWS SDKs, see [Enabling and using S3 Transfer Acceleration](#).

Optimizing for high-request rate workloads

Applications that generate high request rates to Amazon S3 require specific design patterns to achieve optimal performance. When your application consistently generates more than 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per prefix, you should implement strategies to distribute requests and handle scaling behavior.

Amazon S3 automatically scales to accommodate higher request rates, but this scaling happens gradually. During the scaling process, you might receive HTTP 503 (Slow Down) responses. These responses are temporary and indicate that Amazon S3 is optimizing its internal systems for your new request pattern. Once scaling is complete, your requests will be served without throttling.

To optimize performance for high-request rate workloads, consider the following strategies:

- **Distribute requests across multiple prefixes** – Use a randomized or sequential prefix pattern to spread requests across multiple partitions. For example, instead of using sequential object names like log-2024-01-01.txt, use randomized prefixes like a1b2/log-2024-01-01.txt. This helps Amazon S3 distribute the load more effectively.
- **Implement exponential backoff for 503 errors** – When you receive HTTP 503 responses, implement retry logic with exponential backoff. Start with a short delay and gradually increase the wait time between retries. The AWS SDKs include built-in retry logic that handles this automatically.
- **Monitor request patterns** – Use Amazon CloudWatch metrics to monitor your request rates and error rates. Pay particular attention to 5xx error metrics, which can indicate when your application is approaching or exceeding current scaling limits.
- **Gradually ramp up request rates** – When launching new applications or significantly increasing request rates, gradually increase your traffic over time rather than immediately jumping to peak rates. This allows Amazon S3 to scale proactively and reduces the likelihood of throttling.
- **Use multiple connections** – Distribute your requests across multiple HTTP connections to maximize throughput and reduce the impact of any single connection issues.

For applications that require consistent high performance, consider using Amazon S3 Express One Zone, which is designed for applications that require single-digit millisecond latencies and can support hundreds of thousands of requests per second. For more information, see [S3 Express One Zone](#).

Hosting a static website using Amazon S3

You can use Amazon S3 to host a static website. On a *static* website, individual webpages include static content. They might also contain client-side scripts.

Note

We recommend that you use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.

With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see [Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket](#) and [Deploying a static website from S3 using the Amplify console in the AWS Amplify Console User Guide](#).

For more information about hosting a static website on Amazon S3, including instructions and step-by-step walkthroughs, see the following topics.

Important

If the bucket that you're using to host your static website has been encrypted using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you must create an Amazon CloudFront distribution to serve your website because SSE-KMS doesn't support anonymous users. When you create your CloudFront distribution, you must use origin access control (OAC) instead of origin access identity (OAI) to secure the origin. OAI doesn't support SSE-KMS, so you must use OAC instead.

For more information about OAC, see [Restrict access to an Amazon S3 origin](#) in the *Amazon CloudFront Developer Guide*. For a tutorial that shows how to host a static website using Amazon CloudFront, see [the section called "Hosting video streaming"](#).

Topics

- [Website endpoints](#)
- [Enabling website hosting](#)
- [Configuring an index document](#)
- [Configuring a custom error document](#)
- [Setting permissions for website access](#)
- [\(Optional\) Logging web traffic](#)
- [\(Optional\) Configuring a webpage redirect](#)
- [Using cross-origin resource sharing \(CORS\)](#)
- [Static website tutorials](#)

Website endpoints

When you configure your bucket as a static website, the website is available at the AWS Region-specific website endpoint of the bucket. Website endpoints are different from the endpoints where you send REST API requests. For more information about the differences between the endpoints, see [Key differences between a website endpoint and a REST API endpoint](#).

Depending on your Region, your Amazon S3 website endpoint follows one of these two formats.

- **s3-website dash (-) Region** - `http://bucket-name.s3-website-Region.amazonaws.com`
- **s3-website dot (.) Region** - `http://bucket-name.s3-website.Region.amazonaws.com`

These URLs return the default index document that you configure for the website. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website Endpoints](#).

Note

To augment the security of your Amazon S3 static websites, the Amazon S3 website endpoint domains (for example, `s3-website-us-east-1.amazonaws.com` or `s3-website.ap-south-1.amazonaws.com`) are registered in the [Public Suffix List \(PSL\)](#). For further security, we recommend that you use cookies with a `_Host-` prefix if you ever need to set sensitive cookies in the domain name for your Amazon S3 static websites. This practice will help to defend your domain against cross-site request forgery attempts (CSRF). For more information see the [Set-Cookie](#) page in the Mozilla Developer Network.

If you want your website to be public, you must make all your content publicly readable for your customers to be able to access it at the website endpoint. For more information, see [Setting permissions for website access](#).

Important

- Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can do one of the following:
 - (Recommended) Use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.

With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see [Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket](#) and [Deploying a static website from S3 using the Amplify console](#) in the [AWS Amplify Console User Guide](#).

- Use Amazon CloudFront to serve a static website hosted on Amazon S3. For more information, see [How do I use CloudFront to serve HTTPS requests for my Amazon S3 bucket?](#) To use HTTPS with a custom domain, see [Configuring a static website using a custom domain registered with Route 53](#).
- Requester Pays buckets do not allow access through a website endpoint. Any request to such a bucket receives a 403 Access Denied response. For more information, see [Using Requester Pays general purpose buckets for storage transfers and usage](#).

Topics

- [Website endpoint examples](#)
- [Adding a DNS CNAME](#)
- [Using a custom domain with Route 53](#)
- [Key differences between a website endpoint and a REST API endpoint](#)

Website endpoint examples

The following examples show how you can access an Amazon S3 bucket that is configured as a static website.

Example — Requesting an object at the root level

To request a specific object that is stored at the root level in the bucket, use the following URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/object-name
```

For example, the following URL requests the photo.jpg object that is stored at the root level in the bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/photo.jpg
```

Example — Requesting an object in a prefix

To request an object that is stored in a folder in your bucket, use this URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/folder-name/object-name
```

The following URL requests the docs/doc1.html object in your bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/docs/doc1.html
```

Adding a DNS CNAME

If you have a registered domain, you can add a DNS CNAME entry to point to the Amazon S3 website endpoint. For example, if you registered the domain www.example-bucket.com, you could create a bucket www.example-bucket.com, and add a DNS CNAME record that points to www.example-bucket.com.s3-website.*Region*.amazonaws.com. All requests to http://www.example-bucket.com are routed to www.example-bucket.com.s3-website.*Region*.amazonaws.com.

For more information, see [Customizing Amazon S3 URLs with CNAME records](#).

Using a custom domain with Route 53

Instead of accessing the website using an Amazon S3 website endpoint, you can use your own domain registered with Amazon Route 53 to serve your content—for example, example.com. You can use Amazon S3 with Route 53 to host a website at the root domain. For example, if you have the root domain example.com and you host your website on Amazon S3, your website visitors can access the site from their browser by entering either `http://www.example.com` or `http://example.com`.

For an example walkthrough, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Key differences between a website endpoint and a REST API endpoint

An Amazon S3 website endpoint is optimized for access from a web browser. The following table summarizes the key differences between a REST API endpoint and a website endpoint.

Key difference	REST API endpoint	Website endpoint
Access control	Supports both public and private content	Supports only publicly readable content
Error message handling	Returns an XML-formatted error response	Returns an HTML document
Redirection support	Not applicable	Supports both object-level and bucket-level redirects
Requests supported	Supports all bucket and object operations	Supports only GET and HEAD requests on objects
Responses to GET and HEAD requests at the root of a bucket	Returns a list of the object keys in the bucket	Returns the index document that is specified in the website configuration

Key difference	REST API endpoint	Website endpoint
Secure Sockets Layer (SSL) support	Supports SSL connections	Does not support SSL connections

For a complete list of Amazon S3 endpoints, see [Amazon S3 endpoints and quotas](#) in the *AWS General Reference*.

Enabling website hosting

When you configure a bucket as a static website, you must enable static website hosting, configure an index document, and set permissions.

You can enable static website hosting using the Amazon S3 console, REST API, the AWS SDKs, the AWS CLI, or CloudFormation.

To configure your website with a custom domain, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Using the S3 console

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for

website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see [Configuring an index document](#).

9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see [Configuring a custom error document](#).

10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see [Configure redirection rules to use advanced conditional redirects](#).

11. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Using the REST API

For more information about sending REST requests directly to enable static website hosting, see the following sections in the Amazon Simple Storage Service API Reference:

- [PUT Bucket website](#)
- [GET Bucket website](#)
- [DELETE Bucket website](#)

Using the AWS SDKs

To host a static website on Amazon S3, you configure an Amazon S3 bucket for website hosting and then upload your website content to the bucket. You can also use the AWS SDKs to create, update, and delete the website configuration programmatically. The SDKs provide wrapper classes around the Amazon S3 REST API. If your application requires it, you can send REST API requests directly from your application.

.NET

The following example shows how to use the AWS SDK for .NET to manage website configuration for a bucket. To add a website configuration to a bucket, you provide a bucket name and a website configuration. The website configuration must include an index document and can contain an optional error document. These documents must be stored in the bucket. For more information, see [PUT Bucket website](#). For more information about the Amazon S3 website feature, see [Hosting a static website using Amazon S3](#).

The following C# code example adds a website configuration to the specified bucket. The configuration specifies both the index document and the error document names. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class WebsiteConfigTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string indexDocumentSuffix = "*** index object key ***"; // For example, index.html.
        private const string errorDocument = "*** error object key ***"; // For example, error.html.
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;
```

```
public static void Main()
{
    client = new AmazonS3Client(bucketRegion);
    AddWebsiteConfigurationAsync(bucketName, indexDocumentSuffix,
errorDocument).Wait();
}

static async Task AddWebsiteConfigurationAsync(string bucketName,
                                              string indexDocumentSuffix,
                                              string errorDocument)
{
    try
    {
        // 1. Put the website configuration.
        PutBucketWebsiteRequest putRequest = new PutBucketWebsiteRequest()
        {
            BucketName = bucketName,
            WebsiteConfiguration = new WebsiteConfiguration()
            {
                IndexDocumentSuffix = indexDocumentSuffix,
                ErrorDocument = errorDocument
            }
        };
        PutBucketWebsiteResponse response = await
client.PutBucketWebsiteAsync(putRequest);

        // 2. Get the website configuration.
        GetBucketWebsiteRequest getRequest = new GetBucketWebsiteRequest()
        {
            BucketName = bucketName
        };
        GetBucketWebsiteResponse getResponse = await
client.GetBucketWebsiteAsync(getRequest);
        Console.WriteLine("Index document: {0}",
getResponse.WebsiteConfiguration.IndexDocumentSuffix);
        Console.WriteLine("Error document: {0}",
getResponse.WebsiteConfiguration.ErrorDocument);
    }
    catch (AmazonS3Exception e)
    {
        Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
    catch (Exception e)
```

```
        {
            Console.WriteLine("Unknown encountered on server. Message:{0}" when
writing an object", e.Message);
        }
    }
}
```

PHP

The following PHP example adds a website configuration to the specified bucket. The `create_website_config` method explicitly provides the index document and error document names. The example also retrieves the website configuration and prints the response. For more information about the Amazon S3 website feature, see [Hosting a static website using Amazon S3](#).

For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Add the website configuration.
$s3->putBucketWebsite([
    'Bucket'           => $bucket,
    'WebsiteConfiguration' => [
        'IndexDocument' => ['Suffix' => 'index.html'],
        'ErrorDocument'  => ['Key' => 'error.html']
    ]
]);

// Retrieve the website configuration.
$result = $s3->getBucketWebsite([
    'Bucket' => $bucket
]);
```

```
echo $result->getPath('IndexDocument/Suffix');

// Delete the website configuration.
$s3->deleteBucketWebsite([
    'Bucket' => $bucket
]);
```

Using the AWS CLI

For more information about using the AWS CLI to configure an S3 bucket as a static website, see [website](#) in the *AWS CLI Command Reference*.

Next, you must configure your index document and set permissions. For information, see [Configuring an index document](#) and [Setting permissions for website access](#).

You can also optionally configure an [error document](#), [web traffic logging](#), or a [redirect](#).

Configuring an index document

When you enable website hosting, you must also configure and upload an index document. An *index document* is a webpage that Amazon S3 returns when a request is made to the root of a website or any subfolder. For example, if a user enters `http://www.example.com` in the browser, the user is not requesting any specific page. In that case, Amazon S3 serves up the index document, which is sometimes referred to as the *default page*.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for your bucket, you upload an HTML file with the index document name to your bucket.

The trailing slash at the root-level URL is optional. For example, if you configure your website with `index.html` as the index document, either of the following URLs returns `index.html`.

```
http://example-bucket.s3-website.Region.amazonaws.com/
http://example-bucket.s3-website.Region.amazonaws.com/
```

For more information about Amazon S3 website endpoints, see [Website endpoints](#).

Index document and folders

In Amazon S3, a bucket is a flat container of objects. It does not provide any hierarchical organization as the file system on your computer does. However, you can create a logical hierarchy by using object key names that imply a folder structure.

For example, consider a bucket with three objects that have the following key names. Although these are stored with no physical hierarchical organization, you can infer the following logical folder structure from the key names:

- sample1.jpg — Object is at the root of the bucket.
- photos/2006/Jan/sample2.jpg — Object is in the photos/2006/Jan subfolder.
- photos/2006/Feb/sample3.jpg — Object is in the photos/2006/Feb subfolder.

In the Amazon S3 console, you can also create a folder in a bucket. For example, you can create a folder named photos. You can upload objects to the bucket or to the photos folder within the bucket. If you add the object sample.jpg to the bucket, the key name is sample.jpg. If you upload the object to the photos folder, the object key name is photos/sample.jpg.

If you create a folder structure in your bucket, you must have an index document at each level. In each folder, the index document must have the same name, for example, index.html. When a user specifies a URL that resembles a folder lookup, the presence or absence of a trailing slash determines the behavior of the website. For example, the following URL, with a trailing slash, returns the photos/index.html index document.

```
http://bucket-name.s3-website.Region.amazonaws.com/photos/
```

However, if you exclude the trailing slash from the preceding URL, Amazon S3 first looks for an object photos in the bucket. If the photos object is not found, it searches for an index document, photos/index.html. If that document is found, Amazon S3 returns a 302 Found message and points to the photos/ key. For subsequent requests to photos/, Amazon S3 returns photos/index.html. If the index document is not found, Amazon S3 returns an error.

Configure an index document

To configure an index document using the S3 console, use the following procedure. You can also configure an index document using the REST API, the AWS SDKs, the AWS CLI, or CloudFormation.

Note

In a versioning-enabled bucket, you may upload multiple copies of the `index.html` but only the newest version will be resolved to. For more information about using S3 Versioning see, [Retaining multiple versions of objects with S3 Versioning](#).

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

If you don't have an `index.html` file, you can use the following HTML to create one:

```
<html xmlns="http://www.w3.org/1999/xhtml" >
<head>
    <title>My Website Home Page</title>
</head>
<body>
    <h1>Welcome to my website</h1>
    <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.

6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see [Enabling website hosting](#).

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

- Drag and drop the index file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

8. (Optional) Upload other website content to your bucket.

Next, you must set permissions for website access. For information, see [Setting permissions for website access](#).

You can also optionally configure an [error document](#), [web traffic logging](#), or a [redirect](#).

Configuring a custom error document

After you configure your bucket as a static website, when an error occurs, Amazon S3 returns an HTML error document. You can optionally configure your bucket with a custom error document so that Amazon S3 returns that document when an error occurs.

Note

Some browsers display their own error message when an error occurs, ignoring the error document that Amazon S3 returns. For example, when an HTTP 404 Not Found error occurs, Google Chrome might ignore the error document that Amazon S3 returns and display its own error.

Topics

- [Amazon S3 HTTP response codes](#)
- [Configuring a custom error document](#)

Amazon S3 HTTP response codes

The following table lists the subset of HTTP response codes that Amazon S3 returns when an error occurs.

HTTP error code	Description
301 Moved Permanently	When a user sends a request directly to the Amazon S3 website endpoint (<code>http://s3-website. <i>Region</i>.amazonaws.com/</code>), Amazon S3 returns a 301 Moved Permanently response and redirects those requests to <code>https://aws.amazon.com/s3/</code> .
302 Found	When Amazon S3 receives a request for a key <code>x</code> , <code>http://<i>bucket-name</i>.s3-website. <i>Region</i>.amazonaws.com/x</code> , without a trailing slash, it first looks for the object with the key name <code>x</code> . If the object is not found, Amazon S3 determines that the request is for subfolder <code>x</code> and redirects the request by adding a slash at the end, and returns 302 Found .
304 Not Modified	Amazon S3 uses request headers <code>If-Modified-Since</code> , <code>If-Unmodified-Since</code> , <code>If-Match</code> and/or <code>If-None-Match</code> to determine whether the requested object is same as the cached copy held by the client. If the object is the same, the website endpoint returns a 304 Not Modified response.
400 Malformed Request	The website endpoint responds with a 400 Malformed Request when a user attempts to access a bucket through the incorrect regional endpoint.
403 Forbidden	The website endpoint responds with a 403 Forbidden when a user request translates to an object that is not publicly readable. The object owner must make the object publicly readable using a bucket policy or an ACL.
404 Not Found	The website endpoint responds with 404 Not Found for the following reasons: <ul style="list-style-type: none">•

HTTP error code	Description
	<p>Amazon S3 determines that the URL of the website refers to an object key that does not exist.</p> <ul style="list-style-type: none">Amazon S3 infers that the request is for an index document that does not exist.A bucket specified in the URL does not exist.A bucket specified in the URL exists, but isn't configured as a website. <p>You can create a custom document that is returned for 404 Not Found. Make sure that the document is uploaded to the bucket configured as a website, and that the website hosting configuration is set to use the document.</p> <p>For information on how Amazon S3 interprets the URL as a request for an object or an index document, see Configuring an index document.</p>
500 Service Error	The website endpoint responds with a 500 Service Error when an internal server error occurs.
503 Service Unavailable	The website endpoint responds with a 503 Service Unavailable when Amazon S3 determines that you need to reduce your request rate.

For each of these errors, Amazon S3 returns a predefined HTML message. The following is an example HTML message that is returned for a **403 Forbidden** response.

403 Forbidden

- Code: AccessDenied
- Message: Access Denied
- RequestId: 873CA367A51F7EC7
- HostId: DdQezl9vkuw5luD5HKsFaTDm9KH4PZzCPRkW3igimILbTu1DiYlvXjgyd7pVxq32

An Error Occurred While Attempting to Retrieve a Custom Error Document

- Code: AccessDenied
- Message: Access Denied

Configuring a custom error document

When you configure your bucket as a static website, you can provide a custom error document that contains a user-friendly error message and additional help. Amazon S3 returns your custom error document for only the HTTP 4XX class of error codes.

To configure a custom error document using the S3 console, follow the steps below. You can also configure an error document using the REST API, the AWS SDKs, the AWS CLI, or CloudFormation. For more information, see the following:

- [PutBucketWebsite](#) in the *Amazon Simple Storage Service API Reference*
- [AWS::S3::Bucket WebsiteConfiguration](#) in the *CloudFormation User Guide*
- [put-bucket-website](#) in the *AWS CLI Command Reference*

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **404.html**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error**

document name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see [Enabling website hosting](#) and [Configuring a custom error document](#).

After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

Setting permissions for website access

When you configure a bucket as a static website, if you want your website to be public, you can grant public read access. To make your bucket publicly readable, you must disable block public access settings for the bucket and write a bucket policy that grants public read access. If your bucket contains objects that are not owned by the bucket owner, you might also need to add an object access control list (ACL) that grants everyone read access.

If you don't want to disable block public access settings for your bucket but you still want your website to be public, you can create a Amazon CloudFront distribution to serve your static website. For more information, see [Speeding up your website with Amazon CloudFront](#) or [Use an Amazon CloudFront distribution to serve a static website in the Amazon Route 53 Developer Guide](#).

Note

On the website endpoint, if a user requests an object that doesn't exist, Amazon S3 returns HTTP response code `404 (Not Found)`. If the object exists but you haven't granted

read permission on it, the website endpoint returns HTTP response code 403 (Access Denied). The user can use the response code to infer whether a specific object exists. If you don't want this behavior, you should not enable website support for your bucket.

Topics

- [Step 1: Edit S3 Block Public Access settings](#)
- [Step 2: Add a bucket policy](#)
- [Object access control lists](#)

Step 1: Edit S3 Block Public Access settings

If you want to configure an existing bucket as a static website that has public access, you must edit Block Public Access settings for that bucket. You might also have to edit your account-level Block Public Access settings. Amazon S3 applies the most restrictive combination of the bucket-level and account-level block public access settings.

For example, if you allow public access for a bucket but block all public access at the account level, Amazon S3 will continue to block public access to the bucket. In this scenario, you would have to edit your bucket-level and account-level Block Public Access settings. For more information, see [Blocking public access to your Amazon S3 storage](#).

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access.

When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.

3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block all public access**, and choose **Save changes**.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#) 

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block all public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through new access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through any access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through new public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through any public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to [edit the Block Public Access settings](#) for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 2: Add a bucket policy

To make the objects in your bucket publicly readable, you must write a bucket policy that grants everyone `s3:GetObject` permission.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review [How can I secure the files in my Amazon S3 bucket?](#) to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::Bucket-Name/*"  
            ]  
        }  
    ]  
}
```

5. Update the Resource to your bucket name.

In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see [How do I add an S3 bucket policy?](#)

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Object access control lists

You can use a bucket policy to grant public read permission to your objects. However, the bucket policy applies only to objects that are owned by the bucket owner. If your bucket contains objects that aren't owned by the bucket owner, the bucket owner should use the object access control list (ACL) to grant public READ permission on those objects.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To make an object publicly readable using an ACL, grant READ permission to the AllUsers group, as shown in the following grant element. Add this grant element to the object ACL. For information about managing ACLs, see [Access control list \(ACL\) overview](#).

```
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
  </Grantee>
  <Permission>READ</Permission>
</Grant>
```

(Optional) Logging web traffic

You can optionally enable Amazon S3 server access logging for a bucket that is configured as a static website. Server access logging provides detailed records for the requests that are made to your bucket. For more information, see [Logging requests with server access logging](#). If you plan to use Amazon CloudFront to [speed up your website](#), you can also use CloudFront logging. For more information, see [Configuring and Using Access Logs](#) in the *Amazon CloudFront Developer Guide*.

To enable server access logging for your static website bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the same Region where you created the bucket that is configured as a static website, create a general purpose bucket for logging, for example logs.example.com.
3. Create a folder for the server access logging log files (for example, logs).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, cdn).

For more information, see [Speeding up your website with Amazon CloudFront](#).

5. In the **Buckets** list, choose your bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:
 - Browse to the folder and bucket location:

1. Choose **Browse S3**.
 2. Choose the bucket name, and then choose the logs folder.
 3. Choose **Choose path**.
- Enter the S3 bucket path, for example, `s3://logs.example.com/logs/`.
10. Choose **Save changes**.

In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

(Optional) Configuring a webpage redirect

If your Amazon S3 bucket is configured for static website hosting, you can configure redirects for your bucket or the objects in it. You have the following options for configuring redirects.

Topics

- [Redirect requests for your bucket's website endpoint to another bucket or domain](#)
- [Configure redirection rules to use advanced conditional redirects](#)
- [Redirect requests for an object](#)

Redirect requests for your bucket's website endpoint to another bucket or domain

You can redirect all requests to a website endpoint for a bucket to another bucket or domain. If you redirect all requests, any request made to the website endpoint is redirected to the specified bucket or domain.

For example, if your root domain is `example.com`, and you want to serve requests for both `http://example.com` and `http://www.example.com`, you must create two buckets named `example.com` and `www.example.com`. Then, maintain the content in the `example.com` bucket, and configure the other `www.example.com` bucket to redirect all requests to the `example.com` bucket. For more information, see [Configuring a Static Website Using a Custom Domain Name](#).

To redirect requests for a bucket website endpoint

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. Under **Buckets**, choose the name of the bucket that you want to redirect requests from (for example, `www.example.com`).
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. Choose **Redirect requests for an object**.
6. In the **Host name** box, enter the website endpoint for your bucket or your custom domain.

For example, if you are redirecting to a root domain address, you would enter `example.com`.

7. For **Protocol**, choose the protocol for the redirected requests (`none`, `http`, or `https`).
If you do not specify a protocol, the default option is `none`.
8. Choose **Save changes**.

Configure redirection rules to use advanced conditional redirects

Using advanced redirection rules, you can route requests conditionally according to specific object key names, prefixes in the request, or response codes. For example, suppose that you delete or rename an object in your bucket. You can add a routing rule that redirects the request to another object. If you want to make a folder unavailable, you can add a routing rule to redirect the request to another webpage. You can also add a routing rule to handle error conditions by routing requests that return the error to another domain when the error is processed.

When enabling static website hosting for your bucket, you can optionally specify advanced redirection rules. Amazon S3 has a limitation of 50 routing rules per website configuration. If you require more than 50 routing rules, you can use object redirect. For more information, see [Using the S3 console](#).

For more information about configuring routing rules using the REST API, see [PutBucketWebsite](#) in the *Amazon Simple Storage Service API Reference*.

Important

To create redirection rules in the new Amazon S3 console, you must use JSON. For JSON examples, see [Redirection rules examples](#).

To configure redirection rules for a static website

To add redirection rules for a bucket that already has static website hosting enabled, follow these steps.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of a bucket that you have configured as a static website.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. In **Redirection rules** box, enter your redirection rules in JSON.

In the S3 console you describe the rules using JSON. For JSON examples, see [Redirection rules examples](#). Amazon S3 has a limitation of 50 routing rules per website configuration.

7. Choose **Save changes**.

Routing rule elements

The following is general syntax for defining the routing rules in a website configuration in JSON and XML. To configure redirection rules in the new S3 console, you must use JSON. For JSON examples, see [Redirection rules examples](#).

JSON

```
[  
 {  
   "Condition": {  
     "HttpErrorCodeReturnedEquals": "string",  
     "KeyPrefixEquals": "string"  
   },  
   "Redirect": {  
     "HostName": "string",  
     "HttpRedirectCode": "string",  
     "Protocol": "http"|"https",  
     "ReplaceKeyPrefixWith": "string",  
     "ReplaceKeyWith": "string"  
   }  
 }  
 ]
```

Note: Redirect must each have at least one child element. You can have either ReplaceKeyPrefix with or ReplaceKeyWith but not both.

XML

```
<RoutingRules> =
<RoutingRules>
    <RoutingRule>...</RoutingRule>
    [<RoutingRule>...</RoutingRule>
     ...
    ]
</RoutingRules>

<RoutingRule> =
<RoutingRule>
    [ <Condition>...</Condition> ]
    <Redirect>...</Redirect>
</RoutingRule>

<Condition> =
<Condition>
    [ <KeyPrefixEquals>...</KeyPrefixEquals> ]
    [ <HttpErrorCodeReturnedEquals>...</HttpErrorCodeReturnedEquals> ]
</Condition>
Note: <Condition> must have at least one child element.

<Redirect> =
<Redirect>
    [ <HostName>...</HostName> ]
    [ <Protocol>...</Protocol> ]
    [ <ReplaceKeyPrefixWith>...</ReplaceKeyPrefixWith> ]
    [ <ReplaceKeyWith>...</ReplaceKeyWith> ]
    [ <HttpRedirectCode>...</HttpRedirectCode> ]
</Redirect>

Note: <Redirect> must have at least one child element. You can have either ReplaceKeyPrefix with or ReplaceKeyWith but not both.
```

The following table describes the elements in the routing rule.

Name	Description
RoutingRules	Container for a collection of <code>RoutingRule</code> elements.
RoutingRule	<p>A rule that identifies a condition and the redirect that is applied when the condition is met.</p> <p>Condition:</p> <ul style="list-style-type: none">• A <code>RoutingRules</code> container must contain at least one routing rule.
Condition	Container for describing a condition that must be met for the specified redirect to be applied. If the routing rule does not include a condition, the rule is applied to all requests.
KeyPrefixEquals	<p>The prefix of the object key name from which requests are redirected.</p> <p><code>KeyPrefixEquals</code> is required if <code>HttpErrorCodeReturnedEquals</code> is not specified. If both <code>KeyPrefixEquals</code> and <code>HttpErrorCodeReturnedEquals</code> are specified, both must be true for the condition to be met.</p>
HttpErrorCodeReturnedEquals	<p>The HTTP error code that must match for the redirect to apply. If an error occurs, and if the error code meets this value, then the specified redirect applies.</p> <p><code>HttpErrorCodeReturnedEquals</code> is required if <code>KeyPrefixEquals</code> is not specified. If both <code>KeyPrefixEquals</code> and <code>HttpErrorCodeReturnedEquals</code> are specified, both must be true for the condition to be met.</p>
Redirect	

Name	Description
	Container element that provides instructions for redirecting the request. You can redirect requests to another host or another page, or you can specify another protocol to use. A <code>RoutingRule</code> must have a <code>Redirect</code> element. A <code>Redirect</code> element must contain at least one of the following sibling elements: <code>Protocol</code> , <code>HostName</code> , <code>ReplaceKeyPrefixWith</code> , <code>ReplaceKeyWith</code> , or <code>HttpRedirectCode</code> .
<code>Protocol</code>	The protocol, <code>http</code> or <code>https</code> , to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>Protocol</code> is not required.
<code>HostName</code>	The hostname to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>HostName</code> is not required.
<code>ReplaceKeyPrefixWith</code>	The prefix of the object key name that replaces the value of <code>KeyPrefixEquals</code> in the redirect request. If one of its siblings is supplied, <code>ReplaceKeyPrefixWith</code> is not required. It can be supplied only if <code>ReplaceKeyWith</code> is not supplied.
<code>ReplaceKeyWith</code>	The object key to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>ReplaceKeyWith</code> is not required. It can be supplied only if <code>ReplaceKeyPrefixWith</code> is not supplied.

Name	Description
HttpRedirectCode	The HTTP redirect code to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>HttpRedirectCode</code> is not required.

Redirection rules examples

The following examples explain common redirection tasks:

Important

To create redirection rules in the new Amazon S3 console, you must use JSON.

Example 1: Redirect after renaming a key prefix

Suppose that your bucket contains the following objects:

- index.html
- docs/article1.html
- docs/article2.html

You decide to rename the folder from `docs/` to `documents/`. After you make this change, you need to redirect requests for prefix `docs/` to `documents/`. For example, request for `docs/article1.html` will be redirected to `documents/article1.html`.

In this case, you add the following routing rule to the website configuration.

JSON

```
[  
  {  
    "Condition": {  
      "KeyPrefixEquals": "docs/"  
    },
```

```
        "Redirect": {  
            "ReplaceKeyPrefixWith": "documents/"  
        }  
    }  
]
```

XML

```
<RoutingRules>  
  <RoutingRule>  
    <Condition>  
      <KeyPrefixEquals>docs/</KeyPrefixEquals>  
    </Condition>  
    <Redirect>  
      <ReplaceKeyPrefixWith>documents/</ReplaceKeyPrefixWith>  
    </Redirect>  
  </RoutingRule>  
</RoutingRules>
```

Example 2: Redirect requests for a deleted folder to a page

Suppose that you delete the `images/` folder (that is, you delete all objects with the key prefix `images/`). You can add a routing rule that redirects requests for any object with the key prefix `images/` to a page named `folderdeleted.html`.

JSON

```
[  
  {  
    "Condition": {  
      "KeyPrefixEquals": "images/"  
    },  
    "Redirect": {  
      "ReplaceKeyWith": "folderdeleted.html"  
    }  
  }  
]
```

XML

```
<RoutingRules>
```

```
<RoutingRule>
<Condition>
    <KeyPrefixEquals>images/</KeyPrefixEquals>
</Condition>
<Redirect>
    <ReplaceKeyWith>folderdeleted.html</ReplaceKeyWith>
</Redirect>
</RoutingRule>
</RoutingRules>
```

Example 3: Redirect to another domain with a specific path

Suppose you want to redirect requests for a specific path to another domain. For example, you want to redirect requests for /redirect/me to https://example.com/new/path.

When using both HostName and ReplaceKeyWith together, Amazon S3 constructs the redirect URL by concatenating the hostname and the replacement key with a forward slash between them. Therefore, you should not include a leading slash in the ReplaceKeyWith value. Amazon S3 automatically adds the forward slash between the hostname and the replacement key.

JSON

```
[{
    "Condition": {
        "KeyPrefixEquals": "redirect/me"
    },
    "Redirect": {
        "HostName": "example.com",
        "ReplaceKeyWith": "new/path"
    }
}]
```

XML

```
<RoutingRules>
    <RoutingRule>
        <Condition>
            <KeyPrefixEquals>redirect/me</KeyPrefixEquals>
        </Condition>
```

```
<Redirect>
  <HostName>example.com</HostName>
  <ReplaceKeyWith>new/path</ReplaceKeyWith>
</Redirect>
</RoutingRule>
</RoutingRules>
```

This configuration redirects a request for `https://yourbucket.s3-website-region.amazonaws.com/redirect/me` to `https://example.com/new/path`. Note that `ReplaceKeyWith` is set to `new/path` without a leading slash.

Example 4: Redirect for an HTTP error

Suppose that when a requested object is not found, you want to redirect requests to an Amazon Elastic Compute Cloud (Amazon EC2) instance. Add a redirection rule so that when an HTTP status code 404 (Not Found) is returned, the site visitor is redirected to an Amazon EC2 instance that handles the request.

The following example also inserts the object key prefix `report-404/` in the redirect. For example, if you request a page `ExamplePage.html` and it results in an HTTP 404 error, the request is redirected to a page `report-404/ExamplePage.html` on the specified Amazon EC2 instance. If there is no routing rule and the HTTP error 404 occurs, the error document that is specified in the configuration is returned.

JSON

```
[{
  {
    "Condition": {
      "HttpErrorCodeReturnedEquals": "404"
    },
    "Redirect": {
      "HostName": "ec2-11-22-333-44.compute-1.amazonaws.com",
      "ReplaceKeyPrefixWith": "report-404/"
    }
  }
}]
```

XML

```
<RoutingRules>
```

```
<RoutingRule>
<Condition>
  <HttpErrorCodeReturnedEquals>404</HttpErrorCodeReturnedEquals >
</Condition>
<Redirect>
  <HostName>ec2-11-22-333-44.compute-1.amazonaws.com</HostName>
  <ReplaceKeyPrefixWith>report-404/<ReplaceKeyPrefixWith>
</Redirect>
</RoutingRule>
</RoutingRules>
```

Redirect requests for an object

You can redirect requests for an object to another object or URL by setting the website redirect location in the metadata of the object. You set the redirect by adding the `x-amz-website-redirect-location` property to the object metadata. On the Amazon S3 console, you set the **Website Redirect Location** in the metadata of the object. If you use the [Amazon S3 API](#), you set `x-amz-website-redirect-location`. The website then interprets the object as a 301 redirect.

To redirect a request to another object, you set the redirect location to the key of the target object. To redirect a request to an external URL, you set the redirect location to the URL that you want. For more information about object metadata, see [System-defined object metadata](#).

When you set a page redirect, you can either keep or delete the source object content. For example, if you have a `page1.html` object in your bucket, you can redirect any requests for this page to another object, `page2.html`. You have two options:

- Keep the content of the `page1.html` object and redirect page requests.
- Delete the content of `page1.html` and upload a zero-byte object named `page1.html` to replace the existing object and redirect page requests.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you have configured as a static website (for example, `example.com`).
3. Under **Objects**, select your object.
4. Choose **Actions**, and choose **Edit metadata**.

5. Choose **Metadata**.
6. Choose **Add Metadata**.
7. Under **Type**, choose **System Defined**.
8. In **Key**, choose **x-amz-website-redirect-location**.
9. In **Value**, enter the key name of the object that you want to redirect to, for example, /page2.html.

For another object in the same bucket, the / prefix in the value is required. You can also set the value to an external URL, for example, http://www.example.com.

10. Choose **Edit metadata**.

Using the REST API

The following Amazon S3 API actions support the x-amz-website-redirect-location header in the request. Amazon S3 stores the header value in the object metadata as x-amz-website-redirect-location.

- [PUT Object](#)
- [Initiate Multipart Upload](#)
- [POST Object](#)
- [PUT Object - Copy](#)

A bucket configured for website hosting has both the website endpoint and the REST endpoint. A request for a page that is configured as a 301 redirect has the following possible outcomes, depending on the endpoint of the request:

- **Region-specific website endpoint** – Amazon S3 redirects the page request according to the value of the x-amz-website-redirect-location property.
- **REST endpoint** – Amazon S3 doesn't redirect the page request. It returns the requested object.

For more information about the endpoints, see [Key differences between a website endpoint and a REST API endpoint](#).

When setting a page redirect, you can either keep or delete the object content. For example, suppose that you have a page1.html object in your bucket.

- To keep the content of page1.html and only redirect page requests, you can submit a [PUT Object - Copy](#) request to create a new page1.html object that uses the existing page1.html object as the source. In your request, you set the x-amz-website-redirect-location header. When the request is complete, you have the original page with its content unchanged, but Amazon S3 redirects any requests for the page to the redirect location that you specify.
- To delete the content of the page1.html object and redirect requests for the page, you can send a PUT Object request to upload a zero-byte object that has the same object key: page1.html. In the PUT request, you set x-amz-website-redirect-location for page1.html to the new object. When the request is complete, page1.html has no content, and requests are redirected to the location that is specified by x-amz-website-redirect-location.

When you retrieve the object using the [GET Object](#) action, along with other object metadata, Amazon S3 returns the x-amz-website-redirect-location header in the response.

Using cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section provides an overview of CORS. The subtopics describe how you can enable CORS using the Amazon S3 console, or programmatically by using the Amazon S3 REST API and the AWS SDKs.

Cross-origin resource sharing: Use-case scenarios

The following are example scenarios for using CORS.

Scenario 1

Suppose that you are hosting a website in an Amazon S3 bucket named website as described in [Hosting a static website using Amazon S3](#). Your users load the website endpoint:

`http://website.s3-website.us-east-1.amazonaws.com`

Now you want to use JavaScript on the webpages that are stored in this bucket to be able to make authenticated GET and PUT requests against the same bucket by using the Amazon S3

API endpoint for the bucket, `website.s3.us-east-1.amazonaws.com`. A browser would normally block JavaScript from allowing those requests, but with CORS you can configure your bucket to explicitly enable cross-origin requests from `website.s3-website.us-east-1.amazonaws.com`.

Scenario 2

Suppose that you want to host a web font from your S3 bucket. Again, browsers require a CORS check (also called a preflight check) for loading web fonts. You would configure the bucket that is hosting the web font to allow any origin to make these requests.

How does Amazon S3 evaluate the CORS configuration on a bucket?

When Amazon S3 receives a preflight request from a browser, it evaluates the CORS configuration for the bucket and uses the first CORSRule rule that matches the incoming browser request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration.
- The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration.
- The headers listed in the `Access-Control-Request-Headers` header in a pre-flight request must match the headers in the `AllowedHeaders` element in your CORS configuration.

 **Note**

The ACLs and policies continue to apply when you enable CORS on your bucket.

How Object Lambda Access Point supports CORS

When S3 Object Lambda receives a request from a browser or the request includes an `Origin` header, S3 Object Lambda always adds an `"AllowedOrigins": "*"` header field.

For more information about using CORS, see the following topics.

Topics

- [Elements of a CORS configuration](#)
- [Configuring cross-origin resource sharing \(CORS\)](#)
- [Testing CORS](#)
- [Troubleshooting CORS](#)

Elements of a CORS configuration

To configure your bucket to allow cross-origin requests, you create a CORS configuration. The CORS configuration is a document with elements that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. You can add up to 100 rules to the configuration. You can add the CORS configuration as the `cors` subresource to the bucket.

If you are configuring CORS in the S3 console, you must use JSON to create a CORS configuration. The new S3 console only supports JSON CORS configurations.

For more information about the CORS configuration and the elements in it, see the topics below. For instructions on how to add a CORS configuration, see [Configuring cross-origin resource sharing \(CORS\)](#).

Important

In the S3 console, the CORS configuration must be JSON.

Topics

- [AllowedMethods element](#)
- [AllowedOrigins element](#)
- [AllowedHeaders element](#)
- [ExposeHeaders element](#)
- [MaxAgeSeconds element](#)
- [Examples of CORS configurations](#)

AllowedMethods element

In the CORS configuration, you can specify the following values for the AllowedMethods element.

- GET
- PUT
- POST
- DELETE
- HEAD

AllowedOrigins element

In the AllowedOrigins element, you specify the origins that you want to allow cross-domain requests from, for example, `http://www.example.com`. The origin string can contain only one * wildcard character, such as `http://*.example.com`. You can optionally specify * as the origin to enable all the origins to send cross-origin requests. You can also specify `https` to enable only secure origins.

AllowedHeaders element

The AllowedHeaders element specifies which headers are allowed in a preflight request through the Access-Control-Request-Headers header. Each header name in the Access-Control-Request-Headers header must match a corresponding entry in the element. Amazon S3 will send only the allowed headers in a response that were requested. For a sample list of headers that can be used in requests to Amazon S3, go to [Common Request Headers](#) in the *Amazon Simple Storage Service API Reference* guide.

Each AllowedHeaders string in your configuration can contain at most one * wildcard character. For example, `<AllowedHeader>x-amz-*</AllowedHeader>` will enable all Amazon-specific headers.

ExposeHeaders element

Each ExposeHeader element identifies a header in the response that you want customers to be able to access from their applications (for example, from a JavaScript XMLHttpRequest object). For a list of common Amazon S3 response headers, go to [Common Response Headers](#) in the *Amazon Simple Storage Service API Reference* guide.

MaxAgeSeconds element

The MaxAgeSeconds element specifies the time in seconds that your browser can cache the response for a preflight request as identified by the resource, the HTTP method, and the origin.

Examples of CORS configurations

Instead of accessing a website by using an Amazon S3 website endpoint, you can use your own domain, such as example1.com to serve your content. For information about using your own domain, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

The following example CORS configuration has three rules, which are specified as `CORSRule` elements:

- The first rule allows cross-origin PUT, POST, and DELETE requests from the `http://www.example1.com` origin. The rule also allows all headers in a preflight OPTIONS request through the `Access-Control-Request-Headers` header. In response to preflight OPTIONS requests, Amazon S3 returns requested headers.
- The second rule allows the same cross-origin requests as the first rule, but the rule applies to another origin, `http://www.example2.com`.
- The third rule allows cross-origin GET requests from all origins. The `*` wildcard character refers to all origins.

JSON

```
[  
  {  
    "AllowedHeaders": [  
      "*"  
    ],  
    "AllowedMethods": [  
      "PUT",  
      "POST",  
      "DELETE"  
    ],  
    "AllowedOrigins": [  
      "http://www.example1.com"  
    ],  
    "ExposeHeaders": []  
  },  
  {  
    "AllowedHeaders": [  
      "*"  
    ],  
    "AllowedMethods": [  
      "GET"  
    ]  
  }]
```

```
        "PUT",
        "POST",
        "DELETE"
    ],
    "AllowedOrigins": [
        "http://www.example2.com"
    ],
    "ExposeHeaders": []
},
{
    "AllowedHeaders": [],
    "AllowedMethods": [
        "GET"
    ],
    "AllowedOrigins": [
        "*"
    ],
    "ExposeHeaders": []
}
]
```

XML

```
<CORSConfiguration>
<CORSRule>
    <AllowedOrigin>http://www.example1.com</AllowedOrigin>

    <AllowedMethod>PUT</AllowedMethod>
    <AllowedMethod>POST</AllowedMethod>
    <AllowedMethod>DELETE</AllowedMethod>

    <AllowedHeader>*</AllowedHeader>
</CORSRule>
<CORSRule>
    <AllowedOrigin>http://www.example2.com</AllowedOrigin>

    <AllowedMethod>PUT</AllowedMethod>
    <AllowedMethod>POST</AllowedMethod>
    <AllowedMethod>DELETE</AllowedMethod>

    <AllowedHeader>*</AllowedHeader>
</CORSRule>
<CORSRule>
```

```
<AllowedOrigin>*</AllowedOrigin>
<AllowedMethod>GET</AllowedMethod>
</CORSRule>
</CORSConfiguration>
```

The CORS configuration also allows optional configuration parameters, as shown in the following CORS configuration. In this example, the CORS configuration allows cross-origin PUT, POST, and DELETE requests from the `http://www.example.com` origin.

JSON

```
[  
  {  
    "AllowedHeaders": [  
      "*"  
    ],  
    "AllowedMethods": [  
      "PUT",  
      "POST",  
      "DELETE"  
    ],  
    "AllowedOrigins": [  
      "http://www.example.com"  
    ],  
    "ExposeHeaders": [  
      "x-amz-server-side-encryption",  
      "x-amz-request-id",  
      "x-amz-id-2"  
    ],  
    "MaxAgeSeconds": 3000  
  }  
]
```

XML

```
<CORSConfiguration>
  <CORSRule>
    <AllowedOrigin>http://www.example.com</AllowedOrigin>
    <AllowedMethod>PUT</AllowedMethod>
    <AllowedMethod>POST</AllowedMethod>
    <AllowedMethod>DELETE</AllowedMethod>
    <AllowedHeader>*</AllowedHeader>
```

```
<MaxAgeSeconds>3000</MaxAgeSeconds>
<ExposeHeader>x-amz-server-side-encryption</
ExposeHeader>
<ExposeHeader>x-amz-request-id</
ExposeHeader>
<ExposeHeader>x-amz-id-2</ExposeHeader>
</CORSRule>
</CORSConfiguration>
```

The CORSRule element in the preceding configuration includes the following optional elements:

- **MaxAgeSeconds**—Specifies the amount of time in seconds (in this example, 3000) that the browser caches an Amazon S3 response to a preflight OPTIONS request for the specified resource. By caching the response, the browser does not have to send preflight requests to Amazon S3 if the original request will be repeated.
- **ExposeHeaders**—Identifies the response headers (in this example, `x-amz-server-side-encryption`, `x-amz-request-id`, and `x-amz-id-2`) that customers are able to access from their applications (for example, from a JavaScript XMLHttpRequest object).

Configuring cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section shows you how to enable CORS using the Amazon S3 console, the Amazon S3 REST API, and the AWS SDKs. To configure your bucket to allow cross-origin requests, you add a CORS configuration to the bucket. A CORS configuration is a document that defines rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) supported for each origin, and other operation-specific information. In the S3 console, the CORS configuration must be a JSON document.

For example CORS configurations in JSON and XML, see [Elements of a CORS configuration](#).

Using the S3 console

This section explains how to use the Amazon S3 console to add a cross-origin resource sharing (CORS) configuration to an S3 bucket.

When you enable CORS on the bucket, the access control lists (ACLs) and other access permission policies continue to apply.

Important

In the S3 console, the CORS configuration must be JSON. For examples CORS configurations in JSON and XML, see [Elements of a CORS configuration](#).

To add a CORS configuration to an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a bucket policy for.
4. Choose **Permissions**.
5. In the **Cross-origin resource sharing (CORS)** section, choose **Edit**.
6. In the **CORS configuration editor** text box, type or copy and paste a new CORS configuration, or edit an existing configuration.

The CORS configuration is a JSON file. The text that you type in the editor must be valid JSON. For more information, see [Elements of a CORS configuration](#).

7. Choose **Save changes**.

Note

Amazon S3 displays the Amazon Resource Name (ARN) for the bucket next to the **CORS configuration editor** title. For more information about ARNs, see [Amazon Resource Names \(ARNs\) and AWS Service Namespaces](#) in the *Amazon Web Services General Reference*.

Using the AWS SDKs

You can use the AWS SDK to manage cross-origin resource sharing (CORS) for a bucket. For more information about CORS, see [Using cross-origin resource sharing \(CORS\)](#).

The following examples:

- Creates a CORS configuration and sets the configuration on a bucket
- Retrieves the configuration and modifies it by adding a rule
- Adds the modified configuration to the bucket
- Deletes the configuration

Java

Example

Example

For instructions on how to create and test a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

```

ArrayList<CORSRule.AllowedMethods>();
    rule2AM.add(CORSRule.AllowedMethods.GET);
    CORSRule rule2 = new
CORSRule().withId("CORSRule2").withAllowedMethods(rule2AM)
    .withAllowedOrigins(Arrays.asList("*")).withMaxAgeSeconds(3000)
    .withExposedHeaders(Arrays.asList("x-amz-server-side-encryption"));

    List<CORSRule> rules = new ArrayList<CORSRule>();
    rules.add(rule1);
    rules.add(rule2);

    // Add the rules to a new CORS configuration.
    BucketCrossOriginConfiguration configuration = new
BucketCrossOriginConfiguration();
    configuration.setRules(rules);

    try {
        AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
            .withCredentials(new ProfileCredentialsProvider())
            .withRegion(clientRegion)
            .build();

        // Add the configuration to the bucket.
        s3Client.setBucketCrossOriginConfiguration(bucketName, configuration);

        // Retrieve and display the configuration.
        configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
        printCORSConfiguration(configuration);

        // Add another new rule.
        List<CORSRule.AllowedMethods> rule3AM = new
ArrayList<CORSRule.AllowedMethods>();
        rule3AM.add(CORSRule.AllowedMethods.HEAD);
        CORSRule rule3 = new
CORSRule().withId("CORSRule3").withAllowedMethods(rule3AM)
    .withAllowedOrigins(Arrays.asList("http://www.example.com"));

        rules = configuration.getRules();
        rules.add(rule3);
```

```
        configuration.setRules(rules);
        s3Client.setBucketCrossOriginConfiguration(bucketName, configuration);

        // Verify that the new rule was added by checking the number of rules in
the
        // configuration.
        configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
        System.out.println("Expected # of rules = 3, found " +
configuration.getRules().size());

        // Delete the configuration.
        s3Client.deleteBucketCrossOriginConfiguration(bucketName);
        System.out.println("Removed CORS configuration.");

        // Retrieve and display the configuration to verify that it was
        // successfully deleted.
        configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
        printCORSConfiguration(configuration);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}

private static void printCORSConfiguration(BucketCrossOriginConfiguration
configuration) {
    if (configuration == null) {
        System.out.println("Configuration is null.");
    } else {
        System.out.println("Configuration has " +
configuration.getRules().size() + " rules\n");

        for (CORSRule rule : configuration.getRules()) {
            System.out.println("Rule ID: " + rule.getId());
            System.out.println("MaxAgeSeconds: " + rule.getMaxAgeSeconds());
            System.out.println("AllowedMethod: " + rule.getAllowedMethods());
            System.out.println("AllowedOrigins: " + rule.getAllowedOrigins());
            System.out.println("AllowedHeaders: " + rule.getAllowedHeaders());
            System.out.println("ExposeHeader: " + rule.getExposedHeaders());
        }
    }
}
```

```
        System.out.println();
    }
}
}
}
```

.NET

Example

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CORSTest
    {
        private const string bucketName = "**** bucket name ****";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            CORSConfigTestAsync().Wait();
        }
        private static async Task CORSConfigTestAsync()
        {
            try
            {
                // Create a new configuration request and add two rules
                CORSConfiguration configuration = new CORSConfiguration
                {
                    Rules = new System.Collections.Generic.List<CORSRule>
```

```
{  
    new CORSRule

            return;
        }

        Console.WriteLine("Configuration has {0} rules:",
configuration.Rules.Count);
        foreach (CORSRule rule in configuration.Rules)
        {
            Console.WriteLine("Rule ID: {0}", rule.Id);
            Console.WriteLine("MaxAgeSeconds: {0}", rule.MaxAgeSeconds);
            Console.WriteLine("AllowedMethod: {0}", string.Join(", ",
rule.AllowedMethods.ToArray()));
            Console.WriteLine("AllowedOrigins: {0}", string.Join(", ",
rule.AllowedOrigins.ToArray()));
            Console.WriteLine("AllowedHeaders: {0}", string.Join(", ",
rule.AllowedHeaders.ToArray()));
            Console.WriteLine("ExposeHeader: {0}", string.Join(", ",
rule.ExposeHeaders.ToArray()));
        }
    }
}
```

Using the REST API

To set a CORS configuration on your bucket, you can use the AWS Management Console. If your application requires it, you can also send REST requests directly. The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API actions related to the CORS configuration:

- [PutBucketCors](#)
- [GetBucketCors](#)
- [DeleteBucketCors](#)
- [OPTIONS object](#)

Testing CORS

To test your CORS configuration, a CORS preflight request can be sent with the OPTIONS method so that the server can respond if it is acceptable to send the request. When Amazon S3 receives a preflight request, S3 evaluates the CORS configuration for the bucket and uses the first CORSRule rule that matches the incoming request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The Origin header in a CORS request to your bucket must match the origins in the AllowedOrigins element in your CORS configuration.
- The HTTP methods that are specified in the Access-Control-Request-Method in a CORS request to your bucket must match the method or methods listed in the AllowedMethods element in your CORS configuration.
- The headers listed in the Access-Control-Request-Headers header in a preflight request must match the headers in the AllowedHeaders element in your CORS configuration.

The following is an example of a CORS configuration. To create a CORS Configuration, see [Configuring CORS](#). For more examples of a CORS configuration, see [Elements of a CORS configuration](#).

For guidance on configuring and troubleshooting CORS rules, see [How do I configure CORS in Amazon S3 and confirm the CORS rules using cURL?](#) in the AWS re:Post Knowledge Center.

JSON

```
[  
  {  
    "AllowedHeaders": [  
      "Authorization"  
    ],  
    "AllowedMethods": [  
      "GET",  
      "PUT",  
      "POST",  
      "DELETE"  
    ],  
    "AllowedOrigins": [  
      "http://www.example1.com"  
    ],  
    "ExposeHeaders": [  
      "x-amz-meta-custom-header"  
    ]  
  }  
]
```

To test the CORS configuration, you can send a preflight OPTIONS check by using the following CURL command. CURL is a command-line tool that can be used to interact with S3. For more information, see [CURL](#).

```
curl -v -X OPTIONS \  
-H "Origin: http://www.example1.com" \  
-H "Access-Control-Request-Method: PUT" \  
-H "Access-Control-Request-Headers: Authorization" \  
-H "Access-Control-Expose-Headers: x-amz-meta-custom-header"\  
  "http://bucket_name.s3.amazonaws.com/object_prefix_name"
```

In the above example, the curl -v -x OPTIONS command is used to send a preflight request to S3 to inquire if it is allowed by S3 to send a PUT request on an object from the cross origin http://www.example1.com. The headers Access-Control-Request-Headers and Access-Control-Expose-Headers are optional.

- In response to the Access-Control-Request-Method header in the preflight OPTIONS request, Amazon S3 returns the list of allowed methods if the requested methods match.
- In response to the Access-Control-Request-Headers header in the preflight OPTIONS request, Amazon S3 returns the list of allowed headers if the requested headers match.
- In response to the Access-Control-Expose-Headers header in the preflight OPTIONS request, Amazon S3 returns a list of allowed headers if the requested headers match the allowed headers that can be accessed by scripts running in the browser.

 **Note**

When sending a preflight request, if any of the CORS request headers are not allowed, none of the response CORS headers are returned.

In response to this preflight OPTIONS request, you will receive a 200 OK response. For common error codes received when testing CORS and more information to solve CORS related issues, see [Troubleshooting CORS](#).

```
< HTTP/1.1 200 OK
< Date: Fri, 12 Jul 2024 00:23:51 GMT
< Access-Control-Allow-Origin: http://www.example1.com
< Access-Control-Allow-Methods: GET, PUT, POST, DELETE
< Access-Control-Allow-Headers: Authorization
< Access-Control-Expose-Headers: x-amz-meta-custom-header
< Access-Control-Allow-Credentials: true
< Vary: Origin, Access-Control-Request-Headers, Access-Control-Request-Method
< Server: AmazonS3
< Content-Length: 0
```

Troubleshooting CORS

The following topics can help you troubleshoot some common CORS issues related to S3.

Topics

- [403 Forbidden error: CORS is not enabled for this bucket](#)
- [403 Forbidden error: This CORS request is not allowed](#)
- [Headers not found in CORS response](#)

- [Considerations of CORS on S3 proxy integrations](#)

403 Forbidden error: CORS is not enabled for this bucket

The following 403 Forbidden error occurs when a cross-origin request is sent to Amazon S3 but CORS is not configured on your S3 bucket.

Error: HTTP/1.1 403 Forbidden CORS Response: CORS is not enabled for this bucket.

The CORS configuration is a document or policy with rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. See how to [configure CORS](#) on S3 by using the Amazon S3 console, AWS SDKs, and REST API. For more information on CORS and examples of a CORS configuration, see [Elements of CORS](#).

403 Forbidden error: This CORS request is not allowed

The following 403 Forbidden error is received when a CORS rule in your CORS configuration doesn't match the data in your request.

Error: HTTP/1.1 403 Forbidden CORS Response: This CORS request is not allowed.

As a result, this 403 Forbidden error can occur for multiple reasons:

- Origin is not allowed.
- Methods are not allowed.
- Requested headers are not allowed.

For each request that Amazon S3 receives, you must have a CORS rule in your CORS configuration that matches the data in your request.

Origin is not allowed

The Origin header in a CORS request to your bucket must match the origins in the AllowedOrigins element in your CORS configuration. A wildcard character ("*") in the AllowedOrigins element would match all HTTP methods. For more information on how to update the AllowedOrigins element, see [Configuring cross-origin resource sharing \(CORS\)](#).

For example, if only the `http://www.example1.com` domain is included in the `AllowedOrigins` element, then a CORS request sent from the `http://www.example2.com` domain would receive the `403 Forbidden` error.

The following example shows part of a CORS configuration that includes the `http://www.example1.com` domain in the `AllowedOrigins` element.

```
"AllowedOrigins": [  
    "http://www.example1.com"  
]
```

For a CORS request sent from the `http://www.example2.com` domain to be successful, the `http://www.example2.com` domain should be included in the `AllowedOrigins` element of CORS configuration.

```
"AllowedOrigins": [  
    "http://www.example1.com"  
    "http://www.example2.com"  
]
```

Methods are not allowed

The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration. A wildcard character ("`*`") in `AllowedMethods` would match all HTTP methods. For more information on how to update the `AllowedOrigins` element, see [Configuring cross-origin resource sharing \(CORS\)](#).

In a CORS configuration, you can specify the following methods in the `AllowedMethods` element:

- GET
- PUT
- POST
- DELETE
- HEAD

The following example shows part of a CORS configuration that includes the `GET` method in the `AllowedMethods` element. Only requests including the `GET` method would succeed.

```
"AllowedMethods": [  
    "GET"  
]
```

If an HTTP method (for example, PUT) was used in a CORS request or included in a pre-flight CORS request to your bucket but the method isn't present in your CORS configuration, the request would result in a 403 Forbidden error. To allow this CORS request or CORS pre-flight request, the PUT method must be added to your CORS configuration.

```
"AllowedMethods": [  
    "GET"  
    "PUT"  
]
```

Requested headers are not allowed

The headers listed in the Access-Control-Request-Headers header in a pre-flight request must match the headers in the AllowedHeaders element in your CORS configuration. For a list of common headers that can be used in requests to Amazon S3, see [Common Request Headers](#). For more information on how to update the AllowedHeaders element, see [Configuring cross-origin resource sharing \(CORS\)](#).

The following example shows part of a CORS configuration that includes the Authorization header in the AllowedHeaders element. Only requests for the Authorization header would succeed.

```
"AllowedHeaders": [  
    "Authorization"  
]
```

If a header (for example Content-MD5 was included in a CORS request but the header isn't present in your CORS configuration, the request would result in a 403 Forbidden error. To allow this CORS request , the Content-MD5 header must be added to your CORS configuration. If you want to pass both Authorization and Content-MD5 headers in a CORS request to your bucket, confirm that both headers are included in the AllowedHeaders element in your CORS configuration.

```
"AllowedHeaders": [  
    "Authorization"
```

```
"Content-MD5"
```

```
]
```

Headers not found in CORS response

The `ExposeHeaders` element in your CORS configuration identifies which response headers that you would like to make accessible to scripts and applications running in browsers, in response to a CORS request.

If your objects stored in your S3 bucket have user-defined metadata (for example, `x-amz-meta-custom-header`) along with the response data, this custom header could contain additional metadata or information that you want to access from your client-side JavaScript code. However, by default, browsers block access to custom headers for security reasons. To allow your client-side JavaScript to access custom headers, you need to include the header in your CORS configuration.

In the example below, the `x-amz-meta-custom-header1` header is included in the `ExposeHeaders` element. The `x-amz-meta-custom-header2` isn't included in the `ExposeHeaders` element and is missing from the CORS configuration. In the response, only the values included in the `ExposeHeaders` element would be returned. If the request included the `x-amz-meta-custom-header2` header in the `Access-Control-Expose-Headers` header, the response would still return a `200 OK`. However, only the permitted header, For example `x-amz-meta-custom-header` would be returned and show in the response.

```
"ExposeHeaders": [  
    "x-amz-meta-custom-header1"  
]
```

To ensure all headers appear in the response, add all permitted headers to the `ExposeHeaders` element in your CORS configuration as shown below.

```
"ExposeHeaders": [  
    "x-amz-meta-custom-header1",  
    "x-amz-meta-custom-header2"  
]
```

Considerations of CORS on S3 proxy integrations

If you are experiencing errors and have already checked the CORS configuration on your S3 bucket, and the cross-origin request is sent to proxies such as AWS CloudFront, try the following:

- Configure the settings to allow the OPTIONS method for HTTP requests.
- Configure the proxy to forward the following headers: Origin, Access-Control-Request-Headers, and Access-Control-Request-Method.
- Configure the proxy settings to include the origin header in its cache key. This is important because caching proxies that don't include the origin header in their cache key may serve cached responses that don't include the appropriate CORS headers for different origins.

Some proxies provide pre-defined features for CORS requests. For example, in CloudFront, you can configure a policy that includes the headers

that enable cross-origin resource sharing (CORS) requests when the origin is an Amazon S3 bucket.

This policy has the following settings:

- Headers included in origin requests:

Origin

Access-Control-Request-Headers

Access-Control-Request-Method

- Cookies included in origin requests: None
- Query strings included in origin requests: None

For more information, see [Control origin requests with a policy](#) and [Use managed origin request policies](#) in the *CloudFront Developer Guide*.

Static website tutorials

The following tutorials or walkthroughs present complete procedures for how to create and configure an Amazon S3 general purpose bucket for static website hosting and hosting on-demand video streaming. The purpose of these tutorials is to provide general guidance. These tutorials are intended for a lab-type environment, and they use example bucket names, user names, and so on. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

- [Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53](#) – You can use Amazon S3 with Amazon CloudFront to host videos for on-demand

viewing in a secure and scalable way. After your video is packaged into the right formats, you can store it on a server or in an S3 general purpose bucket, and then deliver it with CloudFront as viewers request it. In this tutorial, you will learn how to configure your general purpose bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management. CloudFront serves the video from its cache, retrieving it from your general purpose bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see [Optimizing caching and availability](#) in the *Amazon CloudFront Developer Guide*.

- [**Configuring a static website**](#) – You can configure a general purpose bucket to function like a website. This tutorial walks you through the steps of hosting a website on Amazon S3 including creating a bucket, enabling static website hosting in the S3 console, creating an index document and creating an error document. For more information, see [Hosting a static website using Amazon S3](#).
- [**Configuring a static website using a custom domain registered with Route 53**](#) – You can create and configure a general purpose bucket to host a static website and create redirects on S3 for a website with a custom domain name that is registered with Amazon Route 53. You use Route 53 to register domains and to define where you want to route internet traffic for your domain. This tutorial shows how to create Route 53 alias records that routes traffic for your domain and subdomain to your general purpose bucket that contains an HTML file. For more information, see [Use your domain for a static website in an Amazon S3 bucket](#) in the *Amazon Route 53 Developer Guide*. After you complete this tutorial, you can optionally use CloudFront to improve the performance of your website. For more information, see [Speeding up your website with Amazon CloudFront](#).
- [**Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket**](#) – We recommend that you use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information, see [Deploying a static website from S3 using the Amplify console](#) in the *AWS Amplify Hosting User Guide*.

Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53

You can use Amazon S3 with Amazon CloudFront to host videos for on-demand viewing in a secure and scalable way. Video on demand (VOD) streaming means that your video content is stored on a server and viewers can watch it at any time.

CloudFront is a fast, highly secure, and programmable content delivery network (CDN) service. CloudFront can deliver your content securely over HTTPS from all of the CloudFront edge locations around the globe. For more information about CloudFront, see [What is Amazon CloudFront?](#) in the *Amazon CloudFront Developer Guide*.

CloudFront caching reduces the number of requests that your origin server must respond to directly. When a viewer (end user) requests a video that you serve with CloudFront, the request is routed to a nearby edge location closer to where the viewer is located. CloudFront serves the video from its cache, retrieving it from the S3 bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see [Optimizing caching and availability](#) in the *Amazon CloudFront Developer Guide*.

Objective

In this tutorial, you configure an S3 bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management.

Topics

- [Prerequisites: Register and configure a custom domain with Route 53](#)
- [Step 1: Create an S3 bucket](#)
- [Step 2: Upload a video to the S3 bucket](#)
- [Step 3: Create a CloudFront origin access identity](#)
- [Step 4: Create a CloudFront distribution](#)
- [Step 5: Access the video through the CloudFront distribution](#)
- [Step 6: Configure your CloudFront distribution to use your custom domain name](#)
- [Step 7: Access the S3 video through the CloudFront distribution with the custom domain name](#)
- [\(Optional\) Step 8: View data about requests received by your CloudFront distribution](#)
- [Step 9: Clean up](#)
- [Next steps](#)

Prerequisites: Register and configure a custom domain with Route 53

Before you start this tutorial, you must register and configure a custom domain (for example, **example.com**) with Route 53 so that you can configure your CloudFront distribution to use a custom domain name later.

Without a custom domain name, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

`https://CloudFront distribution domain name/Path to an S3 video`

For example, `https://d111111abcdef8.cloudfront.net/sample.mp4`.

After you configure your CloudFront distribution to use a custom domain name configured with Route 53, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

<https://CloudFront distribution alternate domain name/Path to an S3 video>

For example, <https://www.example.com/sample.mp4>. A custom domain name is simpler and more intuitive for your viewers to use.

To register a custom domain, see [Registering a new domain using Route 53](#) in the *Amazon Route 53 Developer Guide*.

When you register a domain name with Route 53, Route 53 creates the hosted zone for you, which you will use later in this tutorial. This hosted zone is where you store information about how to route traffic for your domain, for example, to an Amazon EC2 instance or a CloudFront distribution.

There are fees associated with domain registration, your hosted zone, and DNS queries received by your domain. For more information, see [Amazon Route 53 Pricing](#).

 **Note**

When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see [Registering a new domain](#) in the *Amazon Route 53 Developer Guide*.

Step 1: Create an S3 bucket

Create a bucket to store the original video that you plan to stream.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

 **Note**

To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket (for example, **tutorial-bucket**).

For more information about naming buckets in Amazon S3, see [General purpose bucket naming rules](#).

6. For **Region**, choose the AWS Region where you want the bucket to reside.

If possible, you should pick the Region that is closest to the majority of your viewers. For more information about the bucket Region, see [General purpose buckets overview](#).

7. For **Block Public Access settings for this bucket**, keep the default settings (**Block all public access** is enabled).

Even with **Block all public access** enabled, viewers can still access the uploaded video through CloudFront. This feature is a major advantage of using CloudFront to host a video stored in S3.

We recommend that you keep all settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

8. For the remaining settings, keep the defaults.

(Optional) If you want to configure additional bucket settings for your specific use case, see [Creating a general purpose bucket](#).

9. Choose **Create bucket**.

Step 2: Upload a video to the S3 bucket

The following procedure describes how to upload a video file to an S3 bucket by using the console. If you're uploading many large video files to S3, you might want to use [Amazon S3 Transfer Acceleration](#) to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. For more information, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

To upload a file to the bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**.

For example, you can upload a video file named sample.mp4.
7. Choose **Upload**.

Step 3: Create a CloudFront origin access identity

To restrict direct access to the video from your S3 bucket, create a special CloudFront user called an origin access identity (OAI). You will associate the OAI with your distribution later in this tutorial. By using an OAI, you make sure that viewers can't bypass CloudFront and get the video directly from the S3 bucket. Only the CloudFront OAI can access the file in the S3 bucket. For more information, see [Restrict access to an Amazon S3 origin](#) in the *Amazon CloudFront Developer Guide*.

Important

If the bucket that you're using to host your static website has been encrypted using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you must use origin access control (OAC) instead of origin access identity (OAI) to secure the origin. OAI doesn't support SSE-KMS, so you must use OAC instead. For more information about OAC, see [Restrict access to an Amazon S3 origin](#) in the *Amazon CloudFront Developer Guide*.

To create a CloudFront OAI

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, under the **Security** section, choose **Origin access**.
3. Under the **Identities** tab, choose **Create origin access identity**.
4. Enter a name (for example, **S3-OAI**) for the new origin access identity.
5. Choose **Create**.

Step 4: Create a CloudFront distribution

To use CloudFront to serve and distribute the video in your S3 bucket, you must create a CloudFront distribution.

Substeps

- [Create a CloudFront distribution](#)
- [Review the bucket policy](#)

Create a CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. Choose **Create distribution**.
4. In the **Origin** section, for **Origin domain**, choose the domain name of your S3 origin, which starts with the name of the S3 bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
5. For **Origin access**, choose **Legacy access identities**.
6. Under **Origin access identity**, choose the origin access identity that you created in [Step 3](#) (for example, **S3-OAI**).
7. Under **Bucket policy**, choose **Yes, update the bucket policy**.
8. In the **Default cache behavior** section, under **Viewer protocol policy**, choose **Redirect HTTP to HTTPS**.

When you choose this feature, HTTP requests are automatically redirected to HTTPS to secure your website and protect your viewers' data.

9. For the other settings in the **Default cache behaviors** section, keep the default values.

(Optional) You can control how long your file stays in a CloudFront cache before CloudFront forwards another request to your origin. Reducing the duration allows you to serve dynamic content. Increasing the duration means that your viewers get better performance because your files are more likely to be served directly from the edge cache. A longer duration also reduces the load on your origin. For more information, see [Managing how long content stays in the cache \(expiration\)](#) in the *Amazon CloudFront Developer Guide*.

10. For the other sections, keep the remaining settings set to the defaults.

For more information about the different settings options, see [Values That You Specify When You Create or Update a Distribution](#) in the *Amazon CloudFront Developer Guide*.

11. At the bottom of the page, choose **Create distribution**.
12. On the **General** tab for your CloudFront distribution, under **Details**, the value of the **Last modified** column for your distribution changes from **Deploying** to the timestamp when the distribution was last modified. This process typically takes a few minutes.

Review the bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you used earlier as the origin of your CloudFront distribution (for example, **tutorial-bucket**).
4. Choose the **Permissions** tab.
5. In the **Bucket policy** section, confirm that you see a statement similar to the following in the bucket policy text:

```
{  
    "Version": "2008-10-17",  
    "Id": "PolicyForCloudFrontPrivateContent",  
    "Statement": [  
        {  
            "Sid": "1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access  
Identity EH1HDMB1FH2TC"  
            },  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::tutorial-bucket/*"  
        }  
    ]  
}
```

This is the statement that your CloudFront distribution added to your bucket policy when you chose **Yes, update the bucket policy** earlier.

This bucket policy update indicates that you successfully configured the CloudFront distribution to restrict access to the S3 bucket. Because of this restriction, objects in the bucket can be accessed only through your CloudFront distribution.

Step 5: Access the video through the CloudFront distribution

Now, CloudFront can serve the video stored in your S3 bucket. To access your video through CloudFront, you must combine your CloudFront distribution domain name with the path to the video in the S3 bucket.

To create a URL to the S3 video using the CloudFront distribution domain name

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. To get the distribution domain name, do the following:
 - a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
 - b. After finding the distribution in the list, widen the **Domain name** column to copy the domain name value for your CloudFront distribution.
4. In a new browser tab, paste the distribution domain name that you copied.
5. Return to the previous browser tab, and open the S3 console at <https://console.aws.amazon.com/s3/>.
6. In the left navigation pane, choose **Buckets**.
7. In the **Buckets** list, choose the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
8. In the **Objects** list, choose the name of the video that you uploaded in [Step 2](#) (for example, **sample.mp4**).
9. On the object detail page, in the **Object overview** section, copy the value of the **Key**. This value is the path to the uploaded video object in the S3 bucket.
10. Return to the browser tab where you previously pasted the distribution domain name, enter a forward slash (/) after the distribution domain name, and then paste the path to the video that you copied earlier (for example, **sample.mp4**).

Now, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

`https://CloudFront distribution domain name/Path to the S3 video`

Replace *CloudFront distribution domain name* and *Path to the S3 video* with the appropriate values. An example URL is `https://d111111abcdef8.cloudfront.net/sample.mp4`.

Step 6: Configure your CloudFront distribution to use your custom domain name

To use your own domain name instead of the CloudFront domain name in the URL to access the S3 video, add an alternate domain name to your CloudFront distribution.

Substeps

- [Request an SSL certificate](#)
- [Add the alternate domain name to your CloudFront distribution](#)
- [Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name](#)
- [Check whether IPv6 is enabled for your distribution and create another DNS record if needed](#)

Request an SSL certificate

To allow your viewers to use HTTPS and your custom domain name in the URL for your video streaming, use AWS Certificate Manager (ACM) to request a Secure Sockets Layer (SSL) certificate. The SSL certificate establishes an encrypted network connection to the website.

1. Sign in to the AWS Management Console and open the ACM console at <https://console.aws.amazon.com/acm/>.
2. If the introductory page appears, under **Provision certificates**, choose **Get Started**.
3. On the **Request a certificate** page, choose **Request a public certificate**, and then choose **Request a certificate**.
4. On the **Add domain names** page, enter the fully qualified domain name (FQDN) of the site that you want to secure with an SSL/TLS certificate. You can use an asterisk (*) to request a wildcard certificate to protect several site names in the same domain. For this tutorial, enter

- * and the custom domain name that you configured in [Prerequisites](#). For example, enter *.example.com, and then choose **Next**.

For more information, see [To request an ACM public certificate \(console\)](#) in the *AWS Certificate Manager User Guide*.

5. On the **Select validation method** page, choose **DNS validation**. Then, choose **Next**.

If you are able to edit your DNS configuration, we recommend that you use DNS domain validation rather than email validation. DNS validation has multiple benefits over email validation. For more information, see [Option 1: DNS validation](#) in the *AWS Certificate Manager User Guide*.

6. (Optional) On the **Add tags** page, tag your certificate with metadata.
7. Choose **Review**.
8. On the **Review** page, verify that the information under **Domain name** and **Validation method** are correct. Then, choose **Confirm and request**.

The **Validation** page shows that your request is being processed and that the certificate domain is being validated. The certificate awaiting validation is in the **Pending validation** status.

9. On the **Validation** page, choose the down arrow to the left of your custom domain name, and then choose **Create record in Route 53** to validate your domain ownership through DNS.

Doing this adds a CNAME record provided by AWS Certificate Manager to your DNS configuration.

10. In the **Create record in Route 53** dialog box, choose **Create**.

The **Validation** page should display a status notification of **Success** at the bottom.

11. Choose **Continue** to view the **Certificates** list page.

The **Status** for your new certificate changes from **Pending validation** to **Issued** within 30 minutes.

Add the alternate domain name to your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.

3. Choose the ID for the distribution that you created in [Step 4](#).
4. On the **General** tab, go to the **Settings** section, and choose **Edit**.
5. On the **Edit settings** page, for **Alternate domain name (CNAME) - optional**, choose **Add item** to add the custom domain names that you want to use in the URL for the S3 video served by this CloudFront distribution.

In this tutorial, for example, if you want to route traffic for a subdomain, such as `www.example.com`, enter the subdomain name (`www`) with the domain name (`example.com`). Specifically, enter `www.example.com`.

 **Note**

The alternate domain name (CNAME) that you add must be covered by the SSL certificate that you previously attached to your CloudFront distribution.

6. For **Custom SSL certificate - optional**, choose the SSL certificate that you requested earlier (for example, `*.example.com`).

 **Note**

If you don't see the SSL certificate immediately after you request it, wait 30 minutes, and then refresh the list until the SSL certificate is available for you to select.

7. Keep the remaining settings set to the defaults. Choose **Save changes**.
8. On the **General** tab for the distribution, wait for the value of **Last modified** to change from **Deploying** to the timestamp when the distribution was last modified.

Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name

1. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in [Prerequisites](#) (for example, `example.com`).
4. Choose **Create record**, and then use the **Quick create record** method.

5. For **Record name**, keep the value for the record name the same as the alternate domain name of the CloudFront distribution that you added earlier.

In this tutorial, to route traffic to a subdomain, such as `www.example.com`, enter the subdomain name without the domain name. For example, enter only `www` in the text field before your custom domain name.

6. For **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Value**, choose the **Alias** toggle to enable the alias resource.
8. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.
9. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in [Step 4](#).

To find the domain name of your CloudFront distribution, do the following:

- a. In a new browser tab, sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v3/home>.
 - b. In the left navigation pane, choose **Distributions**.
 - c. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
 - d. After finding the distribution in the list, widen the **Domain name** column to see the domain name value for your CloudFront distribution.
10. On the **Create record** page in the Route 53 console, for the remaining settings, keep the defaults.
 11. Choose **Create records**.

Check whether IPv6 is enabled for your distribution and create another DNS record if needed

If IPv6 is enabled for your distribution, you must create another DNS record.

1. To check whether IPv6 is enabled for your distribution, do the following:
 - a. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
 - b. In the left navigation pane, choose **Distributions**.
 - c. Choose the ID of the CloudFront distribution that you created in [Step 4](#).

- d. On the **General** tab, under **Settings**, check whether **IPv6** is set to **Enabled**.
If IPv6 is enabled for your distribution, you must create another DNS record.
2. If IPv6 is enabled for your distribution, do the following to create a DNS record:
- a. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
 - b. In the left navigation pane, choose **Hosted zones**.
 - c. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in [Prerequisites](#) (for example, `example.com`).
 - d. Choose **Create record**, and then use the **Quick create record** method.
 - e. For **Record name**, in the text field before your custom domain name, type the same value that you typed when you created the IPv4 DNS record earlier. For example, in this tutorial, to route traffic for the subdomain `www.example.com`, enter only `www`.
 - f. For **Record type**, choose **AAAA - Routes traffic to an IPv6 address and some AWS resources**.
 - g. For **Value**, choose the **Alias** toggle to enable the alias resource.
 - h. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.
 - i. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in [Step 4](#).
 - j. For the remaining settings, keep the defaults.
 - k. Choose **Create records**.

Step 7: Access the S3 video through the CloudFront distribution with the custom domain name

To access the S3 video using the custom URL, you must combine your alternate domain name with the path to the video in the S3 bucket.

To create a custom URL to access the S3 video through the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. To get the alternate domain name of your CloudFront distribution, do the following:

- a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
 - b. After finding the distribution in the list, widen the **Alternate domain names** column to copy the value of the alternate domain name of your CloudFront distribution.
4. In a new browser tab, paste the alternate domain name of the CloudFront distribution.
 5. Return to the previous browser tab, and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 6. Find the path to your S3 video, as explained in [Step 5](#).
 7. Return to the browser tab where you previously pasted the alternate domain name, enter a forward slash (/), and then paste the path to your S3 video (for example, sample.mp4).

Now, your S3 video is publicly accessible and hosted through CloudFront at a custom URL that looks similar to the following:

`https://CloudFront distribution alternate domain name/Path to the S3 video`

Replace *CloudFront distribution alternate domain name* and *Path to the S3 video* with the appropriate values. An example URL is <https://www.example.com/sample.mp4>.

(Optional) Step 8: View data about requests received by your CloudFront distribution

To view data about requests received by your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, under **Reports & analytics**, choose the reports from the console, ranging from **Cache statistics**, **Popular Objects**, **Top Referrers**, **Usage**, and **Viewers**.

You can filter each report dashboard. For more information, see [CloudFront Reports in the Console](#) in the *Amazon CloudFront Developer Guide*.

3. To filter data, choose the ID of the CloudFront distribution that you created in [Step 4](#).

Step 9: Clean up

If you hosted an S3 streaming video using CloudFront and Route 53 only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

Note

When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see [Registering a new domain](#) in the *Amazon Route 53 Developer Guide*.

Substeps

- [Delete the CloudFront distribution](#)
- [Delete the DNS record](#)
- [Delete the public hosted zone for your custom domain](#)
- [Delete the custom domain name from Route 53](#)
- [Delete the original video in the S3 source bucket](#)
- [Delete the S3 source bucket](#)

Delete the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
4. To delete the CloudFront distribution, you must disable it first.
 - If the value of the **Status** column is **Enabled** and the value of **Last modified** is the timestamp when the distribution was last modified, continue to disable the distribution before deleting it.
 - If the value of **Status** is **Enabled** and the value of **Last modified** is **Deploying**, wait until the value of **Status** changes to the timestamp when the distribution was last modified. Then continue to disable the distribution before deleting it.

5. To disable the CloudFront distribution, do the following:

- a. In the **Distributions** list, select the check box next to the ID for the distribution that you want to delete.
- b. To disable the distribution, choose **Disable**, and then choose **Disable** to confirm.

If you disable a distribution that has an alternate domain name associated with it, CloudFront stops accepting traffic for that domain name (such as `www.example.com`), even if another distribution has an alternate domain name with a wildcard (*) that matches the same domain (such as `*.example.com`).

- c. The value of **Status** immediately changes to **Disabled**. Wait until the value of **Last modified** changes from **Deploying** to the timestamp when the distribution was last modified.

Because CloudFront must propagate this change to all edge locations, it might take a few minutes before the update is complete and the **Delete** option is available for you to delete the distribution.

6. To delete the disabled distribution, do the following:

- a. Choose the check box next to the ID for the distribution that you want to delete.
- b. Choose **Delete**, and then choose **Delete** to confirm.

Delete the DNS record

If you want to delete the public hosted zone for the domain (including the DNS record), see [Delete the public hosted zone for your custom domain](#) in the *Amazon Route 53 Developer Guide*. If you only want to delete the DNS record created in [Step 6](#), do the following:

1. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in [Prerequisites](#) (for example, `example.com`).
4. In the list of records, select the check box next to the records that you want to delete (the records that you created in [Step 6](#)).

Note

You can't delete records that have a **Type** value of **NS** or **SOA**.

5. Choose **Delete records**.
6. To confirm the deletion, choose **Delete**.

Changes to records take time to propagate to the Route 53 DNS servers. Currently, the only way to verify that your changes have propagated is to use the [GetChange API action](#). Changes usually propagate to all Route 53 name servers within 60 seconds.

Delete the public hosted zone for your custom domain

Warning

If you want to keep your domain registration but stop routing internet traffic to your website or web application, we recommend that you delete records in the hosted zone (as described in the prior section) instead of deleting the hosted zone.

If you delete a hosted zone, someone else can use the domain and route traffic to their own resources using your domain name.

In addition, if you delete a hosted zone, you can't undelete it. You must create a new hosted zone and update the name servers for your domain registration, which can take up to 48 hours to take effect.

If you want to make the domain unavailable on the internet, you can first transfer your DNS service to a free DNS service and then delete the Route 53 hosted zone. This prevents future DNS queries from possibly being misrouted.

1. If the domain is registered with Route 53, see [Adding or changing name servers and glue records for a domain](#) in the *Amazon Route 53 Developer Guide* for information about how to replace Route 53 name servers with name servers for the new DNS service.
2. If the domain is registered with another registrar, use the method provided by the registrar to change name servers for the domain.

Note

If you're deleting a hosted zone for a subdomain (`www.example.com`), you don't need to change name servers for the domain (`example.com`).

1. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that you want to delete.
4. On the **Records** tab for your hosted zone, confirm that the hosted zone that you want to delete contains only an **NS** and an **SOA** record.

If it contains additional records, delete them first.

If you created any NS records for subdomains in the hosted zone, delete those records too.

5. On the **DNSSEC signing** tab for your hosted zone, disable DNSSEC signing if it was enabled. For more information, see [Disabling DNSSEC signing](#) in the *Amazon Route 53 Developer Guide*.
6. At the top of the details page of the hosted zone, choose **Delete zone**.
7. To confirm the deletion, enter **delete**, and then choose **Delete**.

Delete the custom domain name from Route 53

For most top-level domains (TLDs), you can delete the registration if you no longer want it. If you delete a domain name registration from Route 53 before the registration is scheduled to expire, AWS does not refund the registration fee. For more information, see [Deleting a domain name registration](#) in the *Amazon Route 53 Developer Guide*.

⚠ Important

If you want to transfer the domain between AWS accounts or transfer the domain to another registrar, don't delete the domain and expect to immediately reregister it. Instead, see the applicable documentation in the *Amazon Route 53 Developer Guide*:

- [Transferring a domain to a different AWS account](#)

- [Transferring a domain from Amazon Route 53 to another registrar](#)

Delete the original video in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the video to in [Step 2](#) (for example, **tutorial-bucket**).
4. On the **Objects** tab, select the check box next to the name of the object that you want to delete (for example, `sample.mp4`).
5. Choose **Delete**.
6. Under **Permanently delete objects?**, enter **permanently delete** to confirm that you want to delete this object.
7. Choose **Delete objects**.

Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, select the option button next to the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

Next steps

After you complete this tutorial, you can further explore the following related use cases:

- Transcode S3 videos into streaming formats needed by a particular television or connected device before hosting these videos with a CloudFront distribution.

To use Amazon S3 Batch Operations, AWS Lambda and AWS Elemental MediaConvert to batch-transcode a collection of videos to a variety of output media formats, see [Tutorial: Batch-transcoding videos with S3 Batch Operations](#).

- Host other objects stored in S3, such as images, audio, motion graphics, style sheets, HTML, JavaScript, React apps, and so on, using CloudFront and Route 53.

For example, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#) and [Speeding up your website with Amazon CloudFront](#).

- Use [Amazon S3 Transfer Acceleration](#) to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. Transfer Acceleration improves transfer performance by routing traffic through the CloudFront globally distributed edge locations and over the AWS backbone networks. It also uses network protocol optimizations. For more information, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

Tutorial: Configuring a static website on Amazon S3

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see [Default encryption FAQ](#).

You can configure an Amazon S3 bucket to function like a website. This example walks you through the steps of hosting a website on Amazon S3.

Important

The following tutorial requires disabling Block Public Access. We recommend keeping Block Public Access enabled. If you want to keep all four Block Public Access settings enabled

and host a static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Amazon S3 static websites support only HTTP endpoints. Amazon CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks. For more information, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

Topics

- [Step 1: Create a bucket](#)
- [Step 2: Enable static website hosting](#)
- [Step 3: Edit Block Public Access settings](#)
- [Step 4: Add a bucket policy that makes your bucket content publicly available](#)
- [Step 5: Configure an index document](#)
- [Step 6: Configure an error document](#)
- [Step 7: Test your website endpoint](#)
- [Step 8: Clean up](#)

Step 1: Create a bucket

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see [Creating a general purpose bucket](#).

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose **Create bucket**.
3. Enter the **Bucket name** (for example, **example.com**).
4. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see [Website endpoints](#).

5. To accept the default settings and create the bucket, choose **Create**.

Step 2: Enable static website hosting

After you create a bucket, you can enable static website hosting for your bucket. You can create a new bucket or use an existing bucket.

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see [Configuring an index document](#).

9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see [Configuring a custom error document](#).

10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see [Configure redirection rules to use advanced conditional redirects](#).

11. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Step 3: Edit Block Public Access settings

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access.

When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block all public access**, and choose **Save changes**.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#)

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block all public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through new access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through any access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through new public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through any public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to [edit the Block Public Access settings](#) for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 4: Add a bucket policy that makes your bucket content publicly available

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

⚠ Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review [How can I secure the files in my Amazon S3 bucket?](#) to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::Bucket-Name/*"  
            ]  
        }  
    ]  
}
```

5. Update the Resource to your bucket name.

In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see [How do I add an S3 bucket policy?](#)

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Step 5: Configure an index document

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

If you don't have an `index.html` file, you can use the following HTML to create one:

```
<html xmlns="http://www.w3.org/1999/xhtml" >
<head>
    <title>My Website Home Page</title>
</head>
<body>
    <h1>Welcome to my website</h1>
    <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.

5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see [Enabling website hosting](#).

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:
 - Drag and drop the index file into the console bucket listing.
 - Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

8. (Optional) Upload other website content to your bucket.

Step 6: Configure an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, `404.html`). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.

6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, 404.html). For more information, see [Enabling website hosting](#) and [Configuring a custom error document](#).

After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

Step 7: Test your website endpoint

After you configure static website hosting for your bucket, you can test your website endpoint.

Note

Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.

For more information, see [How do I use CloudFront to serve a static website hosted on Amazon S3?](#) and [Requiring HTTPS for communication between viewers and CloudFront](#).

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

Your index document opens in a separate browser window.

You now have a website hosted on Amazon S3. This website is available at the Amazon S3 website endpoint. However, you might have a domain, such as example.com, that you want to use to serve the content from the website you created. You might also want to use Amazon S3 root domain support to serve requests for both http://www.example.com and http://example.com. This requires additional steps. For an example, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Step 8: Clean up

If you created your static website only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available. For more information, see [Deleting a general purpose bucket](#).

Tutorial: Configuring a static website using a custom domain registered with Route 53

Suppose that you want to host a static website on Amazon S3. You've registered a domain with Amazon Route 53 (for example, example.com), and you want requests for `http://www.example.com` and `http://example.com` to be served from your Amazon S3 content. You can use this walkthrough to learn how to host a static website and create redirects on Amazon S3 for a website with a custom domain name that is registered with Route 53. You can work with an existing website that you want to host on Amazon S3, or use this walkthrough to start from scratch.

After you complete this walkthrough, you can optionally use Amazon CloudFront to improve the performance of your website. For more information, see [Speeding up your website with Amazon CloudFront](#).

Note

Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For a tutorial about how to host your content securely with CloudFront and Amazon S3, see [Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53](#). For more information, see [How do I use CloudFront to serve a static website hosted on Amazon S3?](#) and [Requiring HTTPS for communication between viewers and CloudFront](#).

Automating static website setup with an CloudFormation template

You can use an CloudFormation template to automate your static website setup. The CloudFormation template sets up the components that you need to host a secure static website so that you can focus more on your website's content and less on configuring components.

The CloudFormation template includes the following components:

- Amazon S3 – Creates an Amazon S3 bucket to host your static website.
- CloudFront – Creates a CloudFront distribution to speed up your static website.
- Lambda@Edge – Uses [Lambda@Edge](#) to add security headers to every server response. Security headers are a group of headers in the web server response that tell web browsers to take extra security precautions. For more information, see the blog post [Adding HTTP security headers using Lambda@Edge and Amazon CloudFront](#).

This CloudFormation template is available for you to download and use. For information and instructions, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

Topics

- [Before you begin](#)
- [Step 1: Register a custom domain with Route 53](#)
- [Step 2: Create two buckets](#)
- [Step 3: Configure your root domain bucket for website hosting](#)
- [Step 4: Configure your subdomain bucket for website redirect](#)
- [Step 5: Configure logging for website traffic](#)
- [Step 6: Upload index and website content](#)
- [Step 7: Upload an error document](#)
- [Step 8: Edit S3 Block Public Access settings](#)
- [Step 9: Attach a bucket policy](#)
- [Step 10: Test your domain endpoint](#)
- [Step 11: Add alias records for your domain and subdomain](#)
- [Step 12: Test the website](#)
- [Speeding up your website with Amazon CloudFront](#)
- [Cleaning up your example resources](#)

Before you begin

As you follow the steps in this example, you work with the following services:

Amazon Route 53 – You use Route 53 to register domains and to define where you want to route internet traffic for your domain. The example shows how to create Route 53 alias records that

route traffic for your domain (`example.com`) and subdomain (`www.example.com`) to an Amazon S3 bucket that contains an HTML file.

Amazon S3 – You use Amazon S3 to create buckets, upload a sample website page, configure permissions so that everyone can see the content, and then configure the buckets for website hosting.

Step 1: Register a custom domain with Route 53

If you don't already have a registered domain name, such as `example.com`, register one with Route 53. For more information, see [Registering a new domain](#) in the *Amazon Route 53 Developer Guide*. After you register your domain name, you can create and configure your Amazon S3 buckets for website hosting.

Step 2: Create two buckets

To support requests from both the root domain and subdomain, you create two buckets.

- **Domain bucket** – `example.com`
- **Subdomain bucket** – `www.example.com`

These bucket names must match your domain name exactly. In this example, the domain name is `example.com`. You host your content out of the root domain bucket (`example.com`). You create a redirect request for the subdomain bucket (`www.example.com`). If someone enters `www.example.com` in their browser, they are redirected to `example.com` and see the content that is hosted in the Amazon S3 bucket with that name.

To create your buckets for website hosting

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see [Creating a general purpose bucket](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Create your root domain bucket:
 - a. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

- b. In the left navigation pane, choose **General purpose buckets**.
- c. Choose **Create bucket**. The **Create bucket** page opens.
- d. Enter the **Bucket name** (for example, `example.com`).
- e. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see [Website endpoints](#).

- f. To accept the default settings and create the bucket, choose **Create**.
3. Create your subdomain bucket:
 - a. Choose **Create bucket**.
 - b. Enter the **Bucket name** (for example, `www.example.com`).
 - c. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see [Website endpoints](#).

- d. To accept the default settings and create the bucket, choose **Create**.

In the next step, you configure `example.com` for website hosting.

Step 3: Configure your root domain bucket for website hosting

In this step, you configure your root domain bucket (`example.com`) as a website. This bucket will contain your website content. When you configure a bucket for website hosting, you can access the website using the [Website endpoints](#).

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see [Configuring an index document](#).

9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see [Configuring a custom error document](#).

10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see [Configure redirection rules to use advanced conditional redirects](#).

11. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

After you [edit block public access settings](#) and [add a bucket policy](#) that allows public read access, you can use the website endpoint to access your website.

In the next step, you configure your subdomain (`www.example.com`) to redirect requests to your domain (`example.com`).

Step 4: Configure your subdomain bucket for website redirect

After you configure your root domain bucket for website hosting, you can configure your subdomain bucket to redirect all requests to the domain. In this example, all requests for `www.example.com` are redirected to `example.com`.

To configure a redirect request

1. On the Amazon S3 console, in the **General purpose buckets** list, choose your subdomain bucket name (`www.example.com` in this example).
2. Choose **Properties**.
3. Under **Static website hosting**, choose **Edit**.
4. Choose **Redirect requests for an object**.
5. In the **Target bucket** box, enter your root domain, for example, `example.com`.
6. For **Protocol**, choose `http`.
7. Choose **Save changes**.

Step 5: Configure logging for website traffic

If you want to track the number of visitors accessing your website, you can optionally enable logging for your root domain bucket. For more information, see [Logging requests with server access logging](#). If you plan to use Amazon CloudFront to speed up your website, you can also use CloudFront logging.

To enable server access logging for your root domain bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the same Region where you created the bucket that is configured as a static website, create a bucket for logging, for example logs.example.com.
3. Create a folder for the server access logging log files (for example, logs).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, cdn).

⚠ Important

When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the awslogsdelivery account FULL_CONTROL permissions to write logs to your bucket. For more information, see [Permissions required to configure standard logging and to access your log files](#) in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

5. In the **Buckets** list, choose your root domain bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:
 - Browse to the folder and bucket location:
 1. Choose **Browse S3**.
 2. Choose the bucket name, and then choose the logs folder.
 3. Choose **Choose path**.
 - Enter the S3 bucket path, for example, s3://logs.example.com/logs/.
10. Choose **Save changes**.

In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

Step 6: Upload index and website content

In this step, you upload your index document and optional website content to your root domain bucket.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

If you don't have an `index.html` file, you can use the following HTML to create one:

```
<html xmlns="http://www.w3.org/1999/xhtml" >
<head>
    <title>My Website Home Page</title>
</head>
<body>
    <h1>Welcome to my website</h1>
    <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see [Enabling website hosting](#).

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

- Drag and drop the index file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

8. (Optional) Upload other website content to your bucket.

Step 7: Upload an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **404.html**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see [Enabling website hosting](#) and [Configuring a custom error document](#).

After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

Step 8: Edit S3 Block Public Access settings

In this example, you edit block public access settings for the domain bucket (example.com) to allow public access.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access.

When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block all public access**, and choose **Save changes**.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#)

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block all public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through new access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through any access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through new public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through any public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to [edit the Block Public Access settings](#) for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 9: Attach a bucket policy

In this example, you attach a bucket policy to the domain bucket (example.com) to allow public read access. You replace the **Bucket-Name** in the example bucket policy with the name of your domain bucket, for example example.com.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

⚠ Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review [How can I secure the files in my Amazon S3 bucket?](#) to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::Bucket-Name/*"  
            ]  
        }  
    ]  
}
```

5. Update the Resource to your bucket name.

In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see [How do I add an S3 bucket policy?](#)

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

In the next step, you can figure out your website endpoints and test your domain endpoint.

Step 10: Test your domain endpoint

After you configure your domain bucket to host a public website, you can test your endpoint. For more information, see [Website endpoints](#). You can only test the endpoint for your domain bucket because your subdomain bucket is set up for website redirect and not static website hosting.

Note

Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.

For more information, see [How do I use CloudFront to serve a static website hosted on Amazon S3?](#) and [Requiring HTTPS for communication between viewers and CloudFront](#).

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

Your index document opens in a separate browser window.

In the next step, you use Amazon Route 53 to enable customers to use both of your custom URLs to navigate to your site.

Step 11: Add alias records for your domain and subdomain

In this step, you create the alias records that you add to the hosted zone for your domain maps `example.com` and `www.example.com`. Instead of using IP addresses, the alias records use the

Amazon S3 website endpoints. Amazon Route 53 maintains a mapping between the alias records and the IP addresses where the Amazon S3 buckets reside. You create two alias records, one for your root domain and one for your subdomain.

Add an alias record for your root domain and subdomain

To add an alias record for your root domain (`example.com`)

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.

 **Note**

If you don't already use Route 53, see [Step 1: Register a domain](#) in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create record**.
5. Choose **Switch to wizard**.

 **Note**

If you want to use quick create to create your alias records, see [Configuring Route 53 to route traffic to an S3 Bucket](#).

6. Choose **Simple routing**, and choose **Next**.
7. Choose **Define simple record**.
8. In **Record name**, accept the default value, which is the name of your hosted zone and your domain.
9. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
10. Choose the Region.
11. Choose the S3 bucket.

The bucket name should match the name that appears in the **Name** box. In the **Choose S3 bucket** list, the bucket name appears with the Amazon S3 website endpoint for the Region

where the bucket was created, for example, `s3-website-us-west-1.amazonaws.com` (`example.com`).

Choose S3 bucket lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, `s3-website-us-west-2.amazonaws.com`. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website endpoints](#). For more information about the alias target, see [Value/route traffic to](#) in the *Amazon Route 53 Developer Guide*.

12. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
13. For **Evaluate target health**, choose **No**.
14. Choose **Define simple record**.

To add an alias record for your subdomain (`www.example.com`)

1. Under **Configure records**, choose **Define simple record**.
2. In **Record name** for your subdomain, type `www`.
3. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
4. Choose the Region.
5. Choose the S3 bucket, for example, `s3-website-us-west-2.amazonaws.com` (`www.example.com`).

If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, `s3-website-us-west-2.amazonaws.com`. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website endpoints](#). For more information about the alias target, see [Value/route traffic to](#) in the *Amazon Route 53 Developer Guide*.

6. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Evaluate target health**, choose **No**.
8. Choose **Define simple record**.

9. On the **Configure records** page, choose **Create records**.

Note

Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Add an alias record for your root domain and subdomain (old Route 53 console)

To add an alias record for your root domain (`example.com`)

The Route 53 console has been redesigned. In the Route 53 console you can temporarily use the old console. If you choose to work with the old Route 53 console, use the procedure below.

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.

Note

If you don't already use Route 53, see [Step 1: Register a domain](#) in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted Zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create Record Set**.
5. Specify the following values:

Name

Accept the default value, which is the name of your hosted zone and your domain.

For the root domain, you don't need to enter any additional information in the **Name** field.

Type

Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose your bucket name.

The bucket name should match the name that appears in the **Name** box. In the **Alias Target** listing, the bucket name is followed by the Amazon S3 website endpoint for the Region where the bucket was created, for example example.com (s3-website-us-west-2.amazonaws.com). **Alias Target** lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Alias Target** listing, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, s3-website-us-west-2. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website endpoints](#). For more information about the alias target, see [Value/route traffic to](#) in the [Amazon Route 53 Developer Guide](#).

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

6. Choose **Create**.

To add an alias record for your subdomain (www.example.com)

1. In the hosted zone for your root domain (example.com), choose **Create Record Set**.
2. Specify the following values:

Name

For the subdomain, enter www in the box.

Type

Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose the same bucket name that appears in the **Name** field—for example, `www.example.com` (`s3-website-us-west-2.amazonaws.com`).

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

3. Choose **Create**.

Note

Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Step 12: Test the website

Verify that the website and the redirect work correctly. In your browser, enter your URLs. In this example, you can try the following URLs:

- **Domain** (`http://example.com`) – Displays the index document in the `example.com` bucket.
- **Subdomain** (`http://www.example.com`) – Redirects your request to `http://example.com`. You see the index document in the `example.com` bucket.

If your website or redirect links don't work, you can try the following:

- **Clear cache** – Clear the cache of your web browser.
- **Check name servers** – If your web page and redirect links don't work after you've cleared your cache, you can compare the name servers for your domain and the name servers for your hosted zone. If the name servers don't match, you might need to update your domain name servers to match those listed under your hosted zone. For more information, see [Adding or changing name servers and glue records for a domain](#).

After you've successfully tested your root domain and subdomain, you can set up an [Amazon CloudFront](#) distribution to improve the performance of your website and provide logs that you can use to review website traffic. For more information, see [Speeding up your website with Amazon CloudFront](#).

Speeding up your website with Amazon CloudFront

You can use [Amazon CloudFront](#) to improve the performance of your Amazon S3 website. CloudFront makes your website files (such as HTML, images, and video) available from data centers around the world (known as *edge locations*). When a visitor requests a file from your website, CloudFront automatically redirects the request to a copy of the file at the nearest edge location. This results in faster download times than if the visitor had requested the content from a data center that is located farther away.

CloudFront caches content at edge locations for a period of time that you specify. If a visitor requests content that has been cached for longer than the expiration date, CloudFront checks the origin server to see if a newer version of the content is available. If a newer version is available, CloudFront copies the new version to the edge location. Changes that you make to the original content are replicated to edge locations as visitors request the content.

Using CloudFront without Route 53

The tutorial on this page uses Route 53 to point to your CloudFront distribution. However, if you want to serve content hosted in an Amazon S3 bucket using CloudFront without using Route 53, see [Amazon CloudFront Tutorials: Setting up a Dynamic Content Distribution for Amazon S3](#). When you serve content hosted in an Amazon S3 bucket using CloudFront, you can use any bucket name, and both HTTP and HTTPS are supported.

Automating set up with an CloudFormation template

For more information about using an CloudFormation template to configure a secure static website that creates a CloudFront distribution to serve your website, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

Topics

- [Step 1: Create a CloudFront distribution](#)
- [Step 2: Update the record sets for your domain and subdomain](#)
- [\(Optional\) Step 3: Check the log files](#)

Step 1: Create a CloudFront distribution

First, you create a CloudFront distribution. This makes your website available from data centers around the world.

To create a distribution with an Amazon S3 origin

1. Open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. Choose **Create Distribution**.
3. On the **Create Distribution** page, in the **Origin Settings** section, for **Origin Domain Name**, enter the Amazon S3 website endpoint for your bucket—for example, **example.com.s3-website.us-west-1.amazonaws.com**.

CloudFront fills in the **Origin ID** for you.

4. For **Default Cache Behavior Settings**, keep the values set to the defaults.

With the default settings for **Viewer Protocol Policy**, you can use HTTPS for your static website. For more information these configuration options, see [Values that You Specify When You Create or Update a Web Distribution](#) in the *Amazon CloudFront Developer Guide*.

5. For **Distribution Settings**, do the following:
 - a. Leave **Price Class** set to **Use All Edge Locations (Best Performance)**.
 - b. Set **Alternate Domain Names (CNAMEs)** to the root domain and www subdomain. In this tutorial, these are example.com and www.example.com.

⚠ Important

Before you perform this step, note the [requirements for using alternate domain names](#), in particular the need for a valid SSL/TLS certificate.

- c. For **SSL Certificate**, choose **Custom SSL Certificate (example.com)**, and choose the custom certificate that covers the domain and subdomain names.

For more information, see [SSL Certificate](#) in the *Amazon CloudFront Developer Guide*.

- d. In **Default Root Object**, enter the name of your index document, for example, `index.html`.

If the URL used to access the distribution doesn't contain a file name, the CloudFront distribution returns the index document. The **Default Root Object** should exactly match the name of the index document for your static website. For more information, see [Configuring an index document](#).

- e. Set **Logging** to **On**.

⚠ Important

When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see [Permissions required to configure standard logging and to access your log files](#) in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

- f. For **Bucket for Logs**, choose the logging bucket that you created.

For more information about configuring a logging bucket, see [\(Optional\) Logging web traffic](#).

- g. If you want to store the logs that are generated by traffic to the CloudFront distribution in a folder, in **Log Prefix**, enter the folder name.
- h. Keep all other settings at their default values.

6. Choose **Create Distribution**.
7. To see the status of the distribution, find the distribution in the console and check the **Status** column.

A status of **InProgress** indicates that the distribution is not yet fully deployed.

After your distribution is deployed, you can reference your content with the new CloudFront domain name.

8. Record the value of **Domain Name** shown in the CloudFront console, for example, `dj4p1rv6mvubz.cloudfront.net`.
9. To verify that your CloudFront distribution is working, enter the domain name of the distribution in a web browser.

If your website is visible, the CloudFront distribution works. If your website has a custom domain registered with Amazon Route 53, you will need the CloudFront domain name to update the record set in the next step.

Step 2: Update the record sets for your domain and subdomain

Now that you have successfully created a CloudFront distribution, update the alias record in Route 53 to point to the new CloudFront distribution.

To update the alias record to point to a CloudFront distribution

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation, choose **Hosted zones**.
3. On the **Hosted Zones** page, choose the hosted zone that you created for your subdomain, for example, `www.example.com`.
4. Under **Records**, select the A record that you created for your subdomain.
5. Under **Record details**, choose **Edit record**.
6. Under **Route traffic to**, choose **Alias to CloudFront distribution**.
7. Under **Choose distribution**, choose the CloudFront distribution.
8. Choose **Save**.
9. To redirect the A record for the root domain to the CloudFront distribution, repeat this procedure for the root domain, for example, `example.com`.

The update to the record sets takes effect within 2–48 hours.

10. To see whether the new A records have taken effect, in a web browser, enter your subdomain URL, for example, `http://www.example.com`.

If the browser no longer redirects you to the root domain (for example, `http://example.com`), the new A records are in place. When the new A record has taken effect, traffic routed by the new A record to the CloudFront distribution is not redirected to the root domain. Any visitors who reference the site by using `http://example.com` or `http://www.example.com` are redirected to the nearest CloudFront edge location, where they benefit from faster download times.

 **Tip**

Browsers can cache redirect settings. If you think the new A record settings should have taken effect, but your browser still redirects `http://www.example.com` to `http://example.com`, try clearing your browser history and cache, closing and reopening your browser application, or using a different web browser.

(Optional) Step 3: Check the log files

The access logs tell you how many people are visiting the website. They also contain valuable business data that you can analyze with other services, such as [Amazon EMR](#).

CloudFront logs are stored in the bucket and folder that you choose when you create a CloudFront distribution and enable logging. CloudFront writes logs to your log bucket within 24 hours from when the corresponding requests are made.

To see the log files for your website

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the logging bucket for your website.
3. Choose the CloudFront logs folder.
4. Download the .gzip files written by CloudFront before opening them.

If you created your website only as a learning exercise, you can delete the resources that you allocated so that you no longer accrue charges. To do so, see [Cleaning up your example resources](#). After you delete your AWS resources, your website is no longer available.

Cleaning up your example resources

If you created your static website as a learning exercise, you should delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available.

Tasks

- [Step 1: Delete the Amazon CloudFront distribution](#)
- [Step 2: Delete the Route 53 hosted zone](#)
- [Step 3: Disable logging and delete your S3 bucket](#)

Step 1: Delete the Amazon CloudFront distribution

Before you delete an Amazon CloudFront distribution, you must disable it. A disabled distribution is no longer functional and does not accrue charges. You can enable a disabled distribution at any time. After you delete a disabled distribution, it is no longer available.

To disable and delete a CloudFront distribution

1. Open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. Select the distribution that you want to disable, and then choose **Disable**.
3. When prompted for confirmation, choose **Yes, Disable**.
4. Select the disabled distribution, and then choose **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Step 2: Delete the Route 53 hosted zone

Before you delete the hosted zone, you must delete the record sets that you created. You don't need to delete the NS and SOA records; these are automatically deleted when you delete the hosted zone.

To delete the record sets

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the list of domain names, select your domain name, and then choose **Go to Record Sets**.
3. In the list of record sets, select the A records that you created.

The type of each record set is listed in the **Type** column.

4. Choose **Delete Record Set**.
5. When prompted for confirmation, choose **Confirm**.

To delete a Route 53 hosted zone

1. Continuing from the previous procedure, choose **Back to Hosted Zones**.
2. Select your domain name, and then choose **Delete Hosted Zone**.
3. When prompted for confirmation, choose **Confirm**.

Step 3: Disable logging and delete your S3 bucket

Before you delete your S3 bucket, make sure that logging is disabled for the bucket. Otherwise, AWS continues to write logs to your bucket as you delete it.

To disable logging for a bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Under **Buckets**, choose your bucket name, and then choose **Properties**.
3. From **Properties**, choose **Logging**.
4. Clear the **Enabled** check box.
5. Choose **Save**.

Now, you can delete your bucket. For more information, see [Deleting a general purpose bucket](#).

Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket

We recommend that you use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. Deploying a static website using Amplify Hosting provides you with the following benefits and features:

- **Deployment to the AWS content delivery network (CDN) powered by Amazon CloudFront -** CloudFront is a web service that speeds up distribution of your static and dynamic web content to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations. When a user requests content that you're serving with CloudFront, the request is routed to the edge location that provides the lowest latency (time delay), so that content is delivered with the best possible performance, increased reliability and availability. For more information, see [How CloudFront delivers content](#) in the *Amazon CloudFront Developer Guide*.
- **HTTPS support** - Provides secure communication and data transfer between your website and a user's web browser.
- **Custom domains** - Easily connect your website to a custom URL purchased from a domain registrar such as Amazon Route 53.
- **Custom SSL certificates** - When you set up your custom domain, you can use the default managed certificate that Amplify provisions for you or you can use your own custom certificate purchased from the third-party certificate authority of your choice.
- **Built in metrics and CloudWatch monitoring** - Monitor traffic, errors, data transfer, and latency for your website.
- **Password protection** - Restrict access to your website, by setting up a username and password requirement in the Amplify console.
- **Redirects and rewrites** - Create redirect and rewrite rules in the Amplify console to enable a web server to reroute navigation from one URL to another.

When you deploy your application from an Amazon S3 general purpose bucket to Amplify Hosting, AWS charges are based on Amplify's pricing model. For more information, see [AWS Amplify Pricing](#).

 **Important**

Amplify Hosting is not available in all of the AWS Regions where Amazon S3 is available. To deploy a static website to Amplify Hosting, the Amazon S3 general purpose bucket containing your website must be located in a region where Amplify is available. For the list of regions where Amplify is available, see [Amplify endpoints](#) in the *Amazon Web Services General Reference*.

You can start the deployment process from the Amazon S3 console, the Amplify console, the AWS CLI, or the AWS SDKs. You can only deploy to Amplify from a general purpose bucket located in your own account. Amplify doesn't support cross-account bucket access.

Use the following instructions to deploy a static website from an Amazon S3 general purpose bucket to Amplify Hosting starting from the Amazon S3 console.

Deploying a static website to Amplify from the S3 console

To deploy a static website from the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the general purpose bucket that contains the website you want to deploy to Amplify Hosting.
4. Choose the **Properties** tab.
5. Under **Static website hosting**, choose **Create Amplify app**. At this step, the deployment process will move to the Amplify console.
6. On the **Deploy with S3** page, do the following steps.
 - a. For **App name**, enter the name of your app or website.
 - b. For **Branch name**, enter the name of your app's backend.
 - c. For **S3 location of objects to host**, either enter the directory path to your general purpose bucket or choose **Browse S3** to locate and select it.
7. Choose **Save and deploy**.

Note

If you update any of the objects for a static website in your general purpose bucket hosted on Amplify, you must redeploy the application to Amplify Hosting to cause the changes to take effect. Amplify Hosting doesn't automatically detect changes to your bucket. For more information, see [Updating a static website deployed to Amplify from an S3 bucket](#) in the [AWS Amplify Hosting User Guide](#).

To start directly from the Amplify console, see [Deploying a static website from S3 using the Amplify console](#) in the *AWS Amplify Hosting User Guide*.

To get started using the AWS SDKs, see [Creating a bucket policy to deploy a static website from S3 using the AWS SDKs](#) in the *AWS Amplify Hosting User Guide*.

Tagging for cost allocation or attribute-based access control (ABAC)

An AWS tag is a key-value pair that holds metadata. You attach the tags to your Amazon S3 resources, such as buckets. You can tag resources when you create them or manage tags on existing resources. There is no additional charge for using tags beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

How tags work

Amazon S3 support two types of tags:

- **AWS-generated tags:** AWS automatically applies these tags, and you cannot modify them or remove them. To learn more about AWS-generated tags, see [Using AWS-generated tags](#).
- **User-defined tags:** You apply these tags to your S3 resources and manage them.

User-defined tags

A user-defined tag is a tag key-value pair that you use to label your resources. User-defined tags consist of a required key and an optional value. These are the main components of a user-defined tag:

The tag key

The tag key is the required name of the tag. For example, project is the tag key in the following tag key-value pair:

Key	Value
project	Trinity

The tag key is a case-sensitive string that must contain between 1 and 128 Unicode characters. Keys can only contain Unicode letters or numbers, white space, and the following symbols:

- _ - underscore

- . - period
- : - colon
- / - forward slash
- = - equal sign
- + - plus sign
- @ - at sign
- - - dash

The tag value

The tag value is an optional string. For example, `Trinity` is the tag value in this tag key-value pair:

Key	Value
<code>project</code>	<code>Trinity</code>

The tag value is a case-sensitive string that can contain between 0 and 256 Unicode characters. Values can only contain Unicode letters or numbers, white space, and the following symbols:

- _ - underscore
- . - period
- : - colon
- / - forward slash
- = - equal sign
- + - plus sign
- @ - at sign
- - - dash

For details on the characters allowed in user-defined tags and other restrictions, see [User-Defined Tag Restrictions](#) in the *AWS Billing and Cost Management User Guide*.

The tag set

Each S3 resource has one *tag set* that contains all of the tag key and value pairs that are assigned to that bucket. A tag set can be empty, or it can contain as many as 50 user-defined tags, except in the case of tagging objects. Objects can have up to 10 tags only.

While each key must be unique in a tag set, you can use the same value multiple times. For example, you can have the same value, `Trinity`, for following two tag keys:

Key	Value
project	Trinity
cost-center	Trinity

When you add a tag that has the same key as an existing tag, the new value overwrites the old value.

AWS does not apply any semantic meaning to your tags. We interpret tags strictly as character strings.

To add, list, modify, or delete tags, you can use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API.

Common ways to use tags

Use tags on your S3 resources for:

- 1. Cost allocation** – Track storage costs by bucket tag in AWS Billing and Cost Management.
- 2. Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 resources based on their tags.

 **Note**

You can use the same tags for both cost allocation and access control.

Using tags for cost allocation

Track your Amazon S3 storage costs by applying tags to S3 resources and activating these tags for cost allocation.

To start tracking costs:

1. Add tags to your S3 resources or use existing tags. For example, you can label buckets with a tag that identifies a project or a group of projects.
2. Activate the tags for cost allocation in the AWS Billing and Cost Management console. See [Activating user-defined cost allocation tags](#) in the *AWS Billing and Cost Management User Guide*. You can activate user-defined or AWS-generated tags. For more information, see [Organizing and tracking costs using AWS cost allocation tags](#).

AWS uses the activated tags to organize your resource costs in various billing and cost management tools, such as:

- **Cost allocation report**

Provides a high-level view of costs organized by your activated tags. For more information, see [Using the monthly cost allocation report](#) in the *AWS Billing User Guide*.

- **Cost and Usage Report (CUR)**

Provides the most detailed set of AWS cost and usage data, including tag-based cost breakdowns. For more information, see [What are AWS Cost and Usage Reports?](#) in the *AWS Data Export User Guide*.

Amazon S3 resources that support tracking costs with tags

The following Amazon S3 resources support storage cost tracking using tags.

- **S3 general purpose buckets**

For more information, see [Using tags with S3 general purpose buckets](#).

- **S3 Directory buckets**

For more information, see [Using tags with S3 directory buckets](#).

- **S3 tables**

For more information, see [Using tags with S3 tables](#).

- **S3 vector index**

For more information, see [Using tags with S3 vector indexes](#)

Using tags for attribute-based access control (ABAC)

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes, i.e., tags. You can attach tags to AWS Identity and Access Management (IAM) entities (users or roles) and to AWS resources, such as Amazon S3 Access Points and directory buckets. Then, you control permissions to these resources using tag-based conditions in access control policies to allow or deny operations when these conditions are met.

With ABAC, you use tag-based condition keys in your AWS organizations, IAM, and S3 resource policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 resources based on the bucket's tags by using [condition keys](#).

Supported condition keys

You can use the following AWS condition keys for all Amazon S3 resources that support ABAC.

- `aws:ResourceTag/key-name`
- `aws:RequestTag/key-name`
- `aws:TagKeys`

Some resources support additional Amazon S3 condition keys. For a complete list of condition keys that can be used for ABAC and example policies, see the following tagging topics for the resource.

Amazon S3 resources that support ABAC

The following Amazon S3 resources support attribute-based access control (ABAC) using tags.

- **S3 general purpose buckets**

For more information, see [Using tags with S3 general purpose buckets](#).

- **Access points**

For more information, see [Using tags with S3 Access Points for general purpose buckets](#) and [Using tags with S3 Access Points for directory buckets](#).

- **Batch operation jobs**

For more information, see [Controlling access and labeling jobs using tags](#).

- **S3 Directory buckets**

For more information, see [Using tags with S3 directory buckets](#).

- **Objects**

For more information, see [Categorizing your objects using tags](#).

- **S3 Access Grants**

For more information, see [Managing tags for S3 Access Grants](#).

- **S3 Storage Lens Groups**

For more information, see [Managing AWS resource tags with Storage Lens groups](#).

- **S3 table buckets and tables**

For more information, see [Using tags with S3 table buckets](#) and [Using tags with S3 tables](#).

- **S3 Vector buckets and indexes**

For more information, see [Using tags with S3 vector buckets](#) and [Using tags with S3 vector indexes](#).

Planning your tagging strategy

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the [Tagging Best Practices AWS Whitepaper](#).

Best practices for tagging Amazon S3 resources

When you use tags, we recommend that you adhere to the following best practices:

- Document conventions for tag use that are followed by all teams in your organization. In particular, ensure the names are both descriptive and consistent. For example, standardize on the format environment:prod rather than tagging some resources with env:production.

 **Important**

Do not store personally identifiable information (PII) or other confidential or sensitive information in tags.

- Automate tagging to ensure consistency. For example, you can include tags in an CloudFormation template. When you create resources with the template, the resources are tagged automatically.
- Use tags only when necessary. Avoid unnecessary tag proliferation and complexity.
- Review tags periodically for relevance and accuracy. Remove or modify outdated tags as needed.
- Consider creating tags with the AWS Tag Editor in the AWS Management Console. You can use the Tag Editor to add tags to multiple supported AWS resources, including Amazon S3 resources, at the same time. For more information, see [Tag Editor](#) in the *AWS Resource Groups User Guide*.

Managing tags for Amazon S3 resources

For more information on how to manage tags for Amazon S3 resources, see the following:

- [Using tags with S3 Access Points for general purpose buckets](#)
- [Using tags with S3 Access Points for directory buckets](#)
- [Controlling access and labeling jobs using tags](#)
- [Using tags with S3 directory buckets](#)
- [Using cost allocation S3 bucket tags](#)
- [Categorizing your objects using tags](#)
- [Managing tags for S3 Access Grants](#)
- [Managing AWS resource tags with Storage Lens groups](#)
- [Using tags with S3 general purpose buckets](#)
- [Using tags with S3 vector buckets](#)
- [Using tags with S3 vector indexes](#)

Using tags with S3 general purpose buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 general purpose buckets. You can tag S3 buckets when you create them or manage tags on existing buckets. For general information about tags, see [Tagging for cost allocation or attribute-based access control \(ABAC\)](#).

 **Note**

There is no additional charge for using tags on buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#).

Common ways to use tags with buckets

Use tags on your S3 buckets for:

1. **Cost allocation** – Track storage costs by bucket tag in AWS Billing and Cost Management. For more information, see [Using tags for cost allocation](#).
2. **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 buckets based on their tags. For more information, see [Using tags for ABAC](#).

 **Note**

For general purpose buckets, ABAC is not enabled by default. To enable ABAC for general purpose buckets, see [Enabling ABAC in general purpose buckets](#). For Amazon S3 resources such as access points and directory buckets, ABAC is enabled by default. You can use the same tags for both cost allocation and access control.

ABAC for S3 general purpose buckets

Amazon S3 general purpose buckets support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and S3 bucket policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 buckets based on the bucket's tags by using the following [global condition keys](#):

- `aws:ResourceTag/key-name`
 - Use this condition key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. S3 evaluates this condition key only after you enable ABAC on your bucket. For example, you could require that access to a resource is allowed only if the resource has the attached tag key `Dept` with the value `Marketing`. For more information, see [Controlling access to AWS resources](#).
- `aws:RequestTag/key-name`
 - Use this condition key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key `Dept` and that it has the value `Accounting`. For more information, see [Controlling access during AWS requests](#). You can use this condition key to restrict which tag key-value pairs can be passed during the `TagResource` and `CreateBucket` API operations.
- `aws:TagKeys`
 - Use this condition key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see [Controlling access based on tag keys](#).
- `s3:BucketTag/tag-key`
 - Use this condition key to grant permissions to specific data in buckets using tags. This condition key is applicable only after ABAC is enabled on your bucket. When accessing a bucket by using an access point, the `aws:ResourceTag/tag-key` condition key references the tags on the bucket both when authorizing against the access point and the bucket. The `s3:BucketTag/tag-key` will reference the tags only of the bucket it is being authorized against.

 **Note**

When creating buckets with tags, note that tag-based conditions to access your bucket using `aws:ResourceTag` and `s3:BucketTag` condition keys are applicable only after you enable ABAC on the bucket. To learn more, see [Enabling ABAC in general purpose buckets](#).

Example ABAC policies for buckets

See the following example ABAC policies for Amazon S3 buckets.

1.1 - IAM policy to create or modify buckets with specific tags

In this IAM policy, users or roles with this policy can only create S3 buckets if they tag the bucket with the tag key `project` and tag value `Trinity` in the bucket creation request. They can also add or modify tags on existing S3 buckets as long as the `TagResource` request includes the tag key-value pair `project:Trinity`. This policy does not grant read, write, or delete permissions on the buckets or its objects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateBucketWithTags",
      "Effect": "Allow",
      "Action": [
        "s3:CreateBucket",
        "s3:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/project": [
            "Trinity"
          ]
        }
      }
    }
  ]
}
```

1.2 - Bucket policy to restrict operations

In this bucket policy, IAM principals (users and roles) are denied `s3>ListBucket`, `s3GetObject`, and `s3PutObject` actions on the bucket only if value of the `project` tag on the bucket matches the value of the `project` tag on the principal.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Sid": "DenyObjectOperations",
        "Effect": "Deny",
        "Principal": "*",
        "Action": ["s3>ListBucket",
                   "s3>GetObject",
                   "s3>PutObject"],
        "Resource": "arn:aws:s3:::aws-s3-demo/*",
        "Condition": {
            "StringEquals": {
                "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
            }
        }
    }
]
```

1.3 - IAM policy to modify tags on existing resources

In this IAM policy, IAM principals (users or roles) can modify tags on a bucket only if the value of the bucket's project tag matches the value of the principal's project tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these buckets. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your buckets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceTaggingRulesOnModification",
            "Effect": "Allow",
            "Action": [
                "s3>TagResource",
                "s3>CreateBucket"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": [
                        "project",
                        "environment",
                        "owner",
                        "cost-center"
                    ]
                }
            }
        }
]
```

```
        "owner",
        "cost-center"
    ]
}
}
]
}
```

1.4 - Using the s3:BucketTag condition key

In this IAM policy, the condition statement allows access to the aws-s3-demo bucket's data only if the bucket has the tag key Environment and tag value Production.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessViaSpecificBucket",
      "Effect": "Allow",
      "Action": "*",
      "Resource": ["arn:aws:s3:::aws-s3-demo", "arn:aws:s3:::aws-s3-demo/*"],
      "Condition": {
        "StringEquals": {
          "s3:BucketTag/Environment": "Production"
        }
      }
    }
  ]
}
```

You can add or manage tags for S3 buckets using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: [TagResource](#), [UntagResource](#), and [ListTagsForResource](#). For more information, see:

Topics

- [Enabling ABAC in general purpose buckets](#)
- [Creating general purpose buckets with tags](#)
- [Adding a tag to a bucket](#)
- [Viewing bucket tags](#)

- [Deleting a tag from a bucket](#)

Enabling ABAC in general purpose buckets

Attribute-based access control (ABAC) is an authorization strategy that you use to define permissions based on attributes, i.e., tags. By default, ABAC is disabled for all Amazon S3 general purpose buckets. To use ABAC for general purpose buckets, you must enable it.

Before enabling ABAC for your general purpose bucket, we recommend that you first complete the tasks described in the following topics:

Topics

- [Auditing your policies before enabling ABAC](#)

Auditing your policies before enabling ABAC

Before you enable ABAC for your bucket, if your bucket has tags, audit your access control policies to review if tag-based conditions reference any of the existing tags on your buckets. If they do, confirm that these policies are set up as intended and that enabling tag-based access control does not create unintentional authorization changes to your Amazon S3 workflows. Doing so will help you ensure that your policies function as intended after ABAC is enabled on your buckets. For examples of using attribute-based conditions with tags, see [Using tags with S3 general purpose buckets](#).

Including the required permissions in your IAM policies

You need the following Amazon S3 permissions to enable ABAC for your bucket:

- `s3:PutBucketAbac` – Update the ABAC status for your general purpose bucket.
- `s3:GetBucketAbac` – View the ABAC status for your general purpose bucket

After you enable ABAC, the permissions you previously used to add tags to a bucket or delete tags from a bucket, `PutBucketTagging` or `DeleteBucketTagging`, will no longer work. Instead, use the `TagResource` and `UntagResource` APIs to perform these tasks.

We recommend you use `TagResource` and `UntagResource` APIs to manage tagging before enabling ABAC on your buckets. The Amazon S3 Console and CloudFormation now use the

TagResource and UntagResource APIs by default. You can also disable ABAC on your bucket by using the PutBucketAbac API. You can use GetBucketTagging to list tags on your buckets. This API will continue to work after you enable ABAC for your buckets. Alternatively you can also use ListTagsForResource to list all tags on your buckets.

You will need the following permissions to apply tags to and remove them from general purpose buckets.

- s3:TagResource - Add tags to an AWS resource, such as an Amazon S3 general purpose bucket.
- s3:UntagResource - Remove tags from an AWS resource, such as an Amazon S3 general purpose bucket.
- s3>ListTagsForResource - View the tags applied to an AWS resource, such as an Amazon S3 general purpose bucket.

The following IAM policy grants the permission to enable ABAC and view its status for your bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutBucketAbac",  
                "s3:GetBucketAbac"  
            ],  
            "Resource": "arn:aws:s3:::my-s3-bucket/*"  
        }  
    ]  
}
```

For more information on tagging general purpose buckets and example ABAC policies for general purpose buckets, see [Using tags with S3 general purpose buckets](#).

Steps

If you have s3:PutBucketAbac permission for a general purpose bucket, you can enable ABAC for the bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To enable ABAC for a general purpose bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. In the **Bucket ABAC** panel, and choose **Edit**.
6. Choose the **Enable** toggle.
7. Review and acknowledge the permissions you will need to manage tags after you enable ABAC: `TagResource`, `UntagResource`, and `ListTagsForResource`.
8. Choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to add enable ABAC for a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.AbacStatus;
import software.amazon.awssdk.services.s3.model.GetBucketAbacRequest;
import software.amazon.awssdk.services.s3.model.GetBucketAbacResponse;
import software.amazon.awssdk.services.s3.model.PutBucketAbacRequest;
import software.amazon.awssdk.services.s3.model.PutBucketAbacResponse;
import software.amazon.awssdk.regions.Region;

public class BucketAbac {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        S3Client s3 = S3Client.builder()
            .region(region)
            .build();

        putBucketAbac(s3, "amzn-s3-demo-bucket", "Enabled");
        getBucketAbac(s3, "amzn-s3-demo-bucket");
    }
}
```

```
        putBucketAbac(s3, "amzn-s3-demo-bucket", "Disabled");
        getBucketAbac(s3, "amzn-s3-demo-bucket");
    }

    /**
     * Sets the ABAC (Attribute-Based Access Control) status for a specified S3
     * bucket.
     *
     * @param s3 The S3Client instance to use for the API call
     * @param bucketName The name of the S3 bucket to update
     * @param status The desired ABAC status ("Enabled" or "Disabled")
     */
    public static void putBucketAbac(S3Client s3, String bucketName, String status)
{
    try {
        AbacStatus abacStatus = AbacStatus.builder()
            .abacStatus(status)
            .build();
        PutBucketAbacRequest request = PutBucketAbacRequest.builder()
            .bucket(bucketName)
            .abacStatus(abacStatus)
            .build();
        s3.putBucketAbac(request);
    } catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

/**
 * Retrieves the current ABAC (Attribute-Based Access Control) status for a
 * specified S3 bucket.
 *
 * @param s3 The S3Client instance to use for the API call
 * @param bucketName The name of the S3 bucket to query
 */
public static void getBucketAbac(S3Client s3, String bucketName) {
    try {
        GetBucketAbacRequest request = GetBucketAbacRequest.builder()
            .bucket(bucketName)
            .build();
        GetBucketAbacResponse response = s3.getBucketAbac(request);
    } catch (S3Exception e) {
```

```
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

This example shows you how to add enable ABAC for a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [PutBucketAbac](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to enable ABAC for a general purpose bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
# Enable ABAC on a general purpose bucket

aws s3api put-bucket-abac --bucket amzn-s3-demo-bucket --abac-status Status=Enabled --
region us-east-2

# Disable ABAC on a general purpose bucket

aws s3api put-bucket-abac --bucket amzn-s3-demo-bucket --abac-status Status=Disabled --
region us-east-2

# Get ABAC status on a general purpose bucket

aws s3api get-bucket-abac --bucket amzn-s3-demo-bucket --region us-east-2
```

Creating general purpose buckets with tags

You can tag Amazon S3 general purpose buckets when you create them. There is no additional charge for using tags on buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging buckets, see [Using tags with S3 general purpose buckets](#).

Permissions

To create a bucket with tags, you must have the following permissions:

- `s3:CreateBucket`
- `s3:TagResource`

Amazon S3 Console and CloudFormation now use this capability to create buckets with tags.

Troubleshooting errors

If you encounter an error when attempting to create a bucket with tags, you can do the following:

- Verify that you have the required [Permissions](#) to create the bucket and add a tag to it.
- Check your IAM policy for `aws:TagKeys` or `aws:RequestTag/key-name` condition keys. You might be required to label your buckets only with specific tag keys and values. For more information, see [Using tags for attribute-based access control \(ABAC\)](#).

Note

Amazon S3 and CloudFormation now use this capability to create buckets with tags. When creating buckets with tags, note that tag-based conditions to access your bucket using `aws:ResourceTag` and `s3:BucketTag` condition keys are applicable only after you enable ABAC on the bucket. To learn more, see [Enabling ABAC in general purpose buckets](#).

Steps

You can create a bucket with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create a bucket with tags using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **buckets**.
3. Choose **create bucket** to create a new bucket.
4. Create a bucket a general purpose bucket as you normally would; see [Creating a general purpose bucket](#).
5. On the **Create bucket** page, **Tags** is an option when creating a new bucket.
6. Enter a name for the bucket. For more information, see [General purpose bucket naming rules](#).
7. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
8. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
9. After you complete specifying the options for your new bucket, choose **Create bucket**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to create a general purpose bucket with tags by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.BucketLocationConstraint;
import software.amazon.awssdk.services.s3.model.CreateBucketConfiguration;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateBucketResponse;
import software.amazon.awssdk.services.s3.model.Tag;

public class CreateBucketWithTagsExample {
    public static void createBucketWithTagsExample() {
        S3Client s3 = S3Client.builder().region(Region.US_WEST_2).build();

        CreateBucketConfiguration bucketConfiguration =
        CreateBucketConfiguration.builder()
```

```
.locationConstraint(BucketLocationConstraint.US_WEST_2)
.tags(Tag.builder().key("MyTagKey").value("MyTagValue").build())
.build();

CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
.bucket("mybucket")
.createBucketConfiguration(bucketConfiguration)
.build();

CreateBucketResponse response = s3.createBucket(createBucketRequest);
System.out.println("Status code (should be 200):");
System.out.println(response.sdkHttpResponse().statusCode());
}

}
```

Using the REST API

For information about the Amazon S3 REST API support for creating a general purpose bucket with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- [CreateBucket](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a bucket with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

When you create a bucket, you must provide configuration details and use the following naming convention: *amzn-s3-demo-bucket*

Request:

```
aws s3api create-bucket \
--bucket mybucket \
--create-bucket-configuration 'LocationConstraint=us-
west-2,Tags=[{Key=MyTagKey,Value=MyTagValue}]' --region us-west-2"
```

Response:

```
{  
  "Location": "http://mybuckets3.amazonaws.com/"  
}
```

Adding a tag to a bucket

You can add tags to Amazon S3 buckets and modify these tags. There is no additional charge for using tags on buckets beyond the standard S3 API request rates. For more information, see [Amazon S3 pricing](#). For more information about tagging buckets, see [Using tags with S3 general purpose buckets](#).

Permissions

To add a tag to a bucket, you must have the following permission:

- s3:TagResource

Troubleshooting errors

If you encounter an error when attempting to add a tag to a bucket, you can do the following:

- Verify that you have the required [Permissions](#) to add a tag to a bucket.
- If you attempted to add a tag key that starts with the AWS reserved prefix aws :, change the tag key and try again.

Steps

You can add tags to buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To add tags to a bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **buckets**.

3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to add tags to a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;
import software.amazon.awssdk.services.s3control.model.TagResourceResponse;

public class TagResourceExample {
    public static void tagResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
            .resourceArn("arn:aws::s3:::bucket/my-bucket")
            .accountId("111122223333")
            .tags(Tag.builder().key("MyTagKey").value("MyTagName").build())
            .build();

        TagResourceResponse response = s3Control.tagResource(tagResourceRequest);
        System.out.println("Status code (should be 204):");
        System.out.println(response.sdkHttpResponse().statusCode());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a general purpose bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control tag-resource --resource-arn arn:aws:s3:::amzn-s3-demo-bucket --region us-east-2 --account-id 444455556666 --tags '[{"Key": "mykey", "Value": "myvalue"}]'
```

Viewing bucket tags

You can view or list tags applied to S3 buckets. For more information about tags, see [Using tags with S3 general purpose buckets](#).

Permissions

To view tags applied to a bucket, you must have the following permission:

- `s3>ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a bucket, you can do the following:

- Verify that you have the required [Permissions](#) to view or list the tags of the bucket.

Steps

You can view tags applied to buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the general purpose bucket.
6. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your bucket by AWS services.

Using the AWS SDKs

This section provides an example of how to view tags applied to a general purpose bucket by using the AWS SDKs.

SDK for Java 2.x

This example shows you how to view tags applied to a general purpose bucket by using the AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResourceExample {
    public static void listTagsForResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();

        ListTagsForResourceRequest listTagsForResourceRequest =
            ListTagsForResourceRequest.builder()
```

```
        .resourceArn("arn:aws::s3:::bucket/my-bucket")
        .accountId("111122223333")
        .build();

    ListTagsForResourceResponse response =
s3Control.listTagsForResource(listTagsForResourceRequest);
    System.out.println("Tags on my resource:");
    System.out.println(response.toString());
}
}
```

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [ListTagsforResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a bucket. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:us-east-1:444455556666:bucket/prefix--use1-az4--x-s3 \
```

Response - tags present:

```
{
  "Tags": [
    {
      "Key": "MyKey1",
      "Value": "MyValue1"
    },
    {
```

```
        "Key": "MyKey2",
        "Value": "MyValue2"
    },
    {
        "Key": "MyKey3",
        "Value": "MyValue3"
    }
]
```

Response - no tags present:

```
{
    "Tags": []
}
```

Deleting a tag from a bucket

You can remove tags from S3 buckets. An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 buckets. For more information about tags, see [Using tags with S3 general purpose buckets](#).

Note

If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the bucket.

Permissions

To delete a tag from a bucket, you must have the following permission:

- s3:UntagResource

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a bucket, you can do the following:

- Verify that you have the required [Permissions](#) to delete a tag from a bucket.

Steps

You can delete tags from buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from a bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to delete tags from a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;
import software.amazon.awssdk.services.s3control.model.UntagResourceResponse;

public class UntagResourceExample {
    public static void untagResourceExample() {
        S3ControlClient s3Control =
            S3ControlClient.builder().region(Region.US_WEST_2).build();
```

```
UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
    .resourceArn("arn:aws::s3:::bucket/my-bucket")
    .accountId("111122223333")
    .tagKeys("myTagKey")
    .build();

UntagResourceResponse response =
s3Control.untagResource(untagResourceRequest);
System.out.println("Status code (should be 204):");
System.out.println(response.sdkHttpResponse().statusCode());
}
```

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- [UnTagResource](#)

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a general purpose bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control untag-resource \
--resource-arn arn:aws::s3:::amzn-s3-demo-bucket --region us-east-2 --account-
id 111122223333 \
--tag-keys "tagkey1" "tagkey2"
```

Quotas

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Amazon S3 quotas include number of general purpose buckets, directory buckets, access points and more. You can request an increase for some quotas, but not all quotas can be increased. These increases are not granted immediately, so it may take a couple of days for your increase to become effective.

For a list of Amazon S3 quotas and their default values see, [Amazon S3 quotas](#) in the *AWS General Reference*.

Quota increases

To request a quota increase

You can request a quota increase by using one of following options:

- From the AWS Management Console: Open the [Service Quotas console](#). In the navigation pane, choose **AWS services**. Select **Amazon S3**, select a quota, and follow the directions to request a quota increase. For instructions, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.
- From the AWS CLI: Use the [`request-service-quota-increase`](#) AWS CLI command. For instructions, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

Reference

In addition to the Amazon S3 console, you can work with Amazon S3 programmatically using the Amazon S3 REST APIs, AWS SDKs, or AWS Command Line Interface (AWS CLI).

- [Amazon Simple Storage Service API Reference](#)
- [Code examples](#) in the *Amazon Simple Storage Service API Reference*
- [AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.
- [AWS SDKs](#)

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS CLI	AWS CLI code examples.
AWS SDK for Go	AWS SDK for Go code examples

Document history

- **Current API version:** 2006-03-01

The following table describes the important changes in each release of the *Amazon Simple Storage Service API Reference* and the *Amazon S3 User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
<u>S3 Tables updated the AmazonS3TablesFull Access AWS managed policy for S3 Tables</u>	S3 Tables updated the AWS-managed policy called AmazonS3TablesFull Access . This policy now grants permissions to pass a role to the S3 Tables Replication service. For more information, see <u>AWS managed policies for S3 Tables</u> .	December 2, 2025
<u>S3 Tables now supports automatic replication</u>	S3 Tables now supports automatic replication of Apache Iceberg tables stored in Amazon S3 table buckets. For more information, see <u>Replicating S3 tables</u> .	December 2, 2025
<u>S3 Tables now supports Intelligent-Tiering access tiers</u>	S3 Tables now supports Intelligent-Tiering access tiers which continuously monitors access patterns and automatically moves table data between access tiers. For more information, see <u>Cost optimization for tables with Intelligent-Tiering</u> .	December 2, 2025

[Large object support](#)

Amazon S3 has increased the maximum size of an object you can store in an S3 bucket from 5 TB to 50 TB. For uploading these larger objects, you must implement the Multipart Upload REST API to upload objects in parts, and when downloading these objects, use concurrent GetObject requests, as single GET requests are limited to 5 TB. For more information, see [Uploading objects](#) and [Downloading objects](#).

[Amazon S3 Metadata is now available in 22 additional AWS Regions](#)

For more information, see [Amazon S3 Metadata AWS Regions](#).

December 2, 2025

November 26, 2025

[Amazon S3 console adds integration with Amazon SageMaker Unified Studio for Amazon S3 Tables](#)

You can now query your data in S3 Tables by using a rich SQL editor provided by Amazon SageMaker Unified Studio, accessible directly from the S3 console with a few clicks. Within SageMaker Unified Studio, you can write SQL queries or ask questions using natural language, and a SQL query is automatically generated based on the context of your data. Then, you can schedule queries to automate data processing. For more information, see [Using S3 Tables with SageMaker Unified Studio.](#)

November 21, 2025

<u>Amazon S3 now supports tags on S3 Tables for attribute-based access control (ABAC) and cost allocation</u>	<p>Amazon S3 now supports tagging S3 Tables for attribute-based access control (ABAC) and cost allocation. You can use tags for ABAC to automatically manage permissions for users and roles accessing table buckets and tables, eliminating frequent IAM or S3 Tables resource-based policy updates and simplifying how you govern access at scale. You can also add tags to individual tables to track and organize AWS costs using AWS Billing and Cost Management.</p> <p>Amazon S3 supports tags on S3 Tables in all AWS Regions where S3 Tables is available. You can get started with tagging by using the AWS Management Console, SDK, API, or CLI. For more information, see <u>Tagging for cost allocation or attribute-based access control (ABAC)</u>.</p>	November 6, 2025
<u>Amazon S3 Metadata is now available in three additional AWS Regions</u>	<p>Amazon S3 Metadata is now available in three additional AWS Regions: Europe (Frankfurt), Europe (Ireland), and Asia Pacific (Tokyo). For more information, see <u>Amazon S3 Metadata AWS Regions</u>.</p>	October 22, 2025

S3 Object Lambda will no longer be open to new customers starting on November 7th, 2025

S3 Object Lambda will no longer be open to new customers starting November 7, 2025. If you would like to use S3 Object Lambda, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see [Amazon S3 Object Lambda availability change](#).

October 7, 2025

[Amazon S3 now supports conditional deletes in general purpose buckets](#)

Amazon S3 now supports conditional deletes in general purpose buckets. Conditional deletes verify that an object is unchanged before deleting it. Using conditional deletes helps you to prevent accidental deletions in high-concurrency, multiple-writer scenarios. You can now perform conditional deletes using the HTTP `if-match` header with an ETag value. Amazon S3 only allows your delete request to succeed if the Etag provided matches that of the object. Additionally, you can use the `s3:if-match` condition key in your S3 bucket policies to enforce conditional delete operations. For example, you can require clients to use the HTTP `if-match` header in both `DeleteObject` and `DeleteObjects` API operation requests, helping you to minimize the risk of accidentally deleting objects in your bucket. For more information, see [How to perform conditional deletes](#).

September 16, 2025

[Amazon S3 Batch Operation
s now supports managing
objects within an S3 bucket,
prefix, suffix, or more, in a
single step in the Amazon S3
console](#)

When creating an S3 Batch Operations job, you can specify the objects on which to perform the operation. With this feature, you can instead specify an entire bucket, prefix, suffix, creation date, or storage class. Batch Operations will then apply the operation to all the matching objects and notify you when the job is finished. For more information, see [Performing object operations in bulk with Batch Operations.](#)

September 15, 2025

[Amazon S3 now supports
Access Points tags for
attribute-based access control
\(ABAC\)](#)

Amazon S3 now supports tagging Access Points for both general purpose and directory buckets. Add tags to access points and use attribute-based access control (ABAC) to scale access. You can get started with tagging access points using the AWS Management Console, S3 REST API, AWS CLI, or the AWS SDK. To learn more about using tags for ABAC, see [Using tags for attribute-based access control \(ABAC\).](#)

July 31, 2025

[Amazon S3 Vectors \(Preview\)](#)

Amazon S3 Vectors delivers purpose-built, cost-optimized vector storage for your semantic search and AI applications. S3 Vectors introduces a new bucket type, the vector bucket, which is optimized for durable, low-cost vector storage. For more information, see [Working with S3 Vectors and vector buckets.](#)

July 15, 2025

[Amazon S3 Metadata now supports existing objects](#)

Amazon S3 Metadata creates and manages metadata that provides information about datasets stored in S3, so you can more easily discover and use your S3 data. Previously, S3 Metadata supported new and updated objects. Now, S3 Metadata also creates and manages metadata for all your existing S3 data. S3 Metadata now creates and maintains two Apache Iceberg tables that give you a queryable and continuously updated view of the metadata associated with the objects in a general purpose bucket. A journal table records changes made to your data in near real time, helping you to identify new data uploaded to your bucket, track recently deleted objects, monitor S3 Lifecycle transitions, and more. A new live inventory table provides and maintains an up-to-date view of all objects in your bucket. Both S3 Metadata tables are stored in an AWS managed Iceberg table bucket in your account, and can be queried using standard SQL through AWS analytics services, such as Amazon Athena or Amazon EMR, and

July 15, 2025

open source tooling, such as DuckDB and Pylceberg. For more information, see [Accelerating data discovery with S3 Metadata](#).

[Amazon S3 Express One Zone now supports tags for cost allocation and attribute-based access control](#)

Amazon S3 Express One Zone, a high performance S3 storage class, now supports tags for cost allocation and attribute-based access control (ABAC). You can add tags to S3 directory buckets to track and organize AWS costs using AWS Billing and Cost Management. Additionally, with ABAC support, you can scale access control to your directory buckets by using tags. S3 Express One Zone supports tags on directory buckets in all AWS Regions where the storage class is available. You can get started with tagging using the AWS Management Console, S3 REST API, AWS CLI, or the AWS SDK. To learn more about using tags to simplify cost allocation or ABAC, see [Using tags with S3 directory buckets](#).

<u>S3 Tables now supports CloudTrail events for maintenance operations</u>	<p>S3 Tables now supports AWS CloudTrail events for maintenance operation s. You can now track and audit maintenance activities performed on your S3 Tables resources through CloudTrai l logs. For more information, see S3 Tables maintenance.</p>	June 30, 2025
<u>Access points now supports attaching to an FSx for OpenZFS volume</u>	<p>You can create and attach an access point to an FSx for OpenZFS volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data. Your data continues to reside on the Amazon FSx file system and continues to be directly accessible for your existing workloads. For more information, see Managing access to shared datasets with access points.</p>	June 25, 2025
<u>S3 Tables now supports new compaction strategies for tables</u>	<p>S3 Tables now supports multiple compaction strategie s to optimize query perform ance based on different data access patterns. The new strategies include Sort and Z- order. For more information, see Compaction Strategies for tables.</p>	June 18, 2025

[Enhanced access denied error messages for same-organization requests](#)

Amazon S3 now includes additional context in access denied (HTTP 403 Forbidden) errors for requests made to resources within the same organization in AWS Organizations. This new context includes the type of policy that denied access, the reason for denial, and information about the AWS Identity and Access Management (IAM) user or role that requested access to the resource. This context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-organization requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions. For more information, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3..](#)

June 16, 2025

[S3 Tables adds new AWS managed policy for S3 Tables](#)

S3 Tables added a new AWS-managed policy called AmazonS3TablesLakeFormationServiceRole. This policy grants permissions that allow the Lake Formation service role access to Amazon S3 tables and table buckets. For more information, see [AWS managed policies for S3 Tables](#).

May 19, 2025

[S3 Tables now supports SSE-KMS using customer managed keys](#)

S3 Tables now supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) using customer managed keys. You can apply SSE-KMS encryption at the table bucket and table level. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\) in table buckets](#).

April 16, 2025

[Access points for directory buckets are available in AWS Local Zones](#)

Directory buckets now support access points to simplify managing data access at scale for shared datasets in Amazon S3. With this new feature, you can create hundreds of access points per bucket, each with a distinct name and permissions customized for each application. For more information, see [Managing access to shared datasets in directory buckets with access points.](#)

March 31, 2025

[S3 table bucket integration with Amazon SageMaker Lakehouse is now generally available](#)

You can integrate S3 table buckets with Amazon SageMaker Lakehouse to access tables from AWS analytics services, such as Amazon Athena, Amazon Redshift, and Quick Suite. Amazon SageMaker Lakehouse unifies your data across Amazon S3 data lakes and Amazon Redshift data warehouses, so you can build analytics, machine learning (ML), and generative AI applications on a single copy of data. The integration populates the AWS Glue Data Catalog with your table resources, and federates access to these resources with AWS Lake Formation. The integration enables fine-grained access control through Lake Formation to provide additional security. For more information about integrating, see [Using Amazon S3 Tables with AWS analytics services](#). If you set up the integration with the preview release, you can continue to use your current integration. However, the updated integration process provides performance improvements,

March 13, 2025

so we recommend migrating . To migrate to the updated integration, see [Migrating to the updated integration process.](#)

[S3 Tables create table and query table support added to the Amazon S3 console](#)

S3 Tables now support create table and query table operations directly from the Amazon S3 console by using Amazon Athena. With this new feature, you can now create a table, populate it with data, and query it with just a few steps in the Amazon S3 console. For more information, see [Creating an Amazon S3 table](#) and [Querying Amazon S3 tables with Athena](#).

[S3 Tables adds support for adding schemas when creating tables](#)

You can now use the S3 Tables CreateTable API operation to create tables with schemas by adding an optional metadata flag. For more information, see [Creating an Amazon S3 table](#).

March 13, 2025

January 30, 2025

S3 Metadata is now generally available

Amazon S3 Metadata is now generally available. S3 Metadata helps you easily discover and understand your S3 data with automated, queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics, artificial intelligence and machine learning (AI/ML) model training, and more. S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see [Accelerating data discovery with S3 Metadata](#).

AWS managed policies – New policies

S3 Tables added two new AWS managed policies.

January 27, 2025

December 6, 2024

S3 Metadata preview

Amazon S3 Metadata helps you easily discover and understand your S3 data with automated, queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics, artificial intelligence and machine learning (AI/ML) model training, and more.

S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see [Accelerating data discovery with S3 Metadata](#).

December 3, 2024

S3 Tables

Amazon S3 Tables provide S3 storage that's optimized for analytics workloads, with features that improve query performance, reduce storage costs for tables, and simplify the operation of data lakes at scale. S3 Tables introduce a new bucket type: table buckets, which are purpose-built for storing Apache Iceberg tables as subresources. Table buckets provide higher transactions per second (TPS) and better query throughput compared to self-managed tables in S3 general purpose buckets. You can automatically integrate your table buckets with AWS analytics services, such as Athena, Amazon Redshift Quick Suite, and more. For more information, see [Working with Amazon S3 Tables and table buckets](#).

December 3, 2024

Storage Browser for S3

Storage Browser for S3 is an open source component that you can add to your web applications to provide your end users with a simple interface for data stored in S3. For more information, see [Storage Browser for S3](#).

December 1, 2024

<u>New Amazon S3 checksum algorithm and improved checksum integrity features</u>	Amazon S3 adds the CRC-64NVME checksum algorithm and improved checksum integrity features. For more information, see <u>Checking object integrity in Amazon S3</u> .	December 1, 2024
<u>Data residency workloads</u>	In Dedicated Local Zones, you can create S3 directory buckets to store data for your data residency and isolation use cases. For more information, see <u>Data residency workloads</u> .	December 1, 2024
<u>New condition keys to enforce conditional writes</u>	Amazon S3 adds new condition keys <code>s3:if-match</code> and <code>s3:if-none-match</code> to use in bucket policies to force clients to use the <code>If-None-Match</code> or <code>If-Match</code> HTTP header. For more information, see <u>Enforce conditional writes on Amazon S3 buckets</u> .	November 25, 2024

[New HTTP header for conditional writes to check if the object has changed](#)

Amazon S3 adds the If-Match HTTP header to check an object's entity tag (ETag) before writing an object for some API operations. With this header, Amazon S3 compares the provided ETag value with the ETag value of the object in S3. If the ETag values don't match, the operation fails. For more information, see [How to prevent object overwrites with conditional writes.](#)

[Amazon Redshift now integrates with S3 Access Grants](#)

Amazon Redshift customers can now use S3 Access Grants to scale and manage permissions for their S3 data. This allows Amazon Redshift customers to scale S3 permissions for corporate identities by using AWS IAM Identity Center as well as for IAM users and groups. For more information, see [Amazon Redshift integration with Amazon S3 Access Grants.](#)

November 25, 2024

November 15, 2024

<u>AWS Organizations member accounts can now regain access to accidentally locked Amazon S3 buckets</u>	<p>AWS Organizations member accounts can now use a simple process through AWS Identity and Access Management (IAM) to regain access to accidentally locked Amazon S3 buckets. For more information, see <u>Perform a privileged task on an AWS Organizations member account in the AWS Identity and Access Management User Guide</u>.</p>	November 14, 2024
<u>Resource control policies (RCPs), a new type of authorization policy in AWS Organizations is also available for Amazon S3 buckets</u>	<p>Resource control policies (RCPs), a new authorization policy managed in AWS Organizations can be used to set the maximum available permissions on Amazon S3 buckets within your entire organization. For more information, see <u>Resource control policies (RCPs) in the AWS Organizations User Guide</u>.</p>	November 13, 2024
<u>Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets</u>	<p>Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets. To view your bucket utilization or request an increase, visit the <u>Service Quotas console</u>.</p>	September 30, 2024

<u>New default minimum object size transition behavior for Amazon S3 Lifecycle configurations</u>	Amazon S3 now applies a default behavior to S3 Lifecycle configurations that prevents objects smaller than 128 KB from being transitioned to any storage class. To learn how to override this behavior, see <u>Allowing objects smaller than 128 KB to be transitioned</u> .	September 24, 2024
<u>Directory buckets now support SSE-KMS using customer managed keys.</u>	Directory buckets now supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) using customer managed keys. You have more options to encrypt and manage the security of your data in directory buckets. For more information, see <u>Data protection and encryption in directory buckets</u> .	September 17, 2024

[S3 Access Grants supports an API action that lists the caller's access grants](#)

IAM identities and IAM Identity Center corporate directory identities can now use the `ListCallerAccessGrants` API to list all of the Amazon S3 buckets, prefixes, and objects they can access, as defined by their S3 Access Grants. Use this API to discover all of the S3 data an IAM or corporate directory identity can access through S3 Access Grants, within a particular AWS account. For more information, see [List the caller's access grants.](#)

September 5, 2024

[Enhanced access denied error messages for same-account requests](#)

Amazon S3 now includes additional context in access denied (HTTP 403) `Forbidden` errors for requests made to resources within the same AWS account. This new context includes the type of policy that denied access, the reason for denial, and information about the AWS Identity and Access Management (IAM) user or role that requested access to the resource. This context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-account requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions. For more information, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3..](#)

August 21, 2024

[Amazon S3 supports using conditional writes for PutObject and CompleteMultipartUpload](#)

You can check for the existence of an object in your bucket before creating it using a conditional write on upload operations. This can prevent overwrites of existing data. Conditional writes will validate there is no existing object with the same key name already in your bucket. For more information, see [Conditional requests](#).

[Amazon S3 no longer charges for several HTTP error codes](#)

Amazon S3 has completed a change so unauthorized requests that customers did not initiate are free of charge. For more information, see [Billing for Amazon S3 error responses](#).

[Amazon S3 Select is no longer available to new customers](#)

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#).

August 20, 2024

August 19, 2024

July 25, 2024

<u>Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key</u>	Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key to control whether users can include optional metadata fields in their reports. For more information, see Control S3 Inventory report configuration creation .	February 20, 2024
<u>IPv6 support for S3 on Outposts</u>	You can now access S3 on Outposts buckets using IPv6 via S3 on Outposts dual-stack endpoints. IPv6 support for S3 on Outposts allows you to manage your S3 on Outposts buckets and control plane resources over IPv6 networks.	January 16, 2024
<u>New high-performance, single-zone Amazon S3 storage class – S3 Express One Zone</u>	Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. For more information, see S3 Express One Zone .	November 28, 2023
<u>Mountpoint for Amazon S3 adds support for S3 Express One Zone</u>	You can now mount S3 Express One Zone directory buckets with Mountpoint .	November 28, 2023

<u>Lambda invocation schema version</u>	Amazon S3 Batch Operation s introduces a new Lambda invocation schema version for use with Batch Operations jobs that act on directory buckets. For more information, see <u>Using Lambda and Amazon S3 batch operations with directory buckets.</u>	November 28, 2023
<u>Import action for directory buckets</u>	Amazon S3 introduces the import action. Import is a streamlined method for creating Amazon S3 Batch Operations jobs to copy objects from general purpose buckets to directory buckets. For more information, see <u>Importing objects into a directory bucket.</u>	November 28, 2023
<u>Manage S3 access with S3 Access Grants</u>	Amazon S3 Access Grants enables you to manage data permissions at scale for AWS Identity and Access Management (IAM) principals in addition to directory identities from corporate directories such as Azure AD. You can now enforce least-privilege S3 permissions and easily scale those permissions based on your business needs. For more information, see <u>Managing access with S3 Access Grants.</u>	November 26, 2023

<u>Mountpoint for Amazon S3 adds caching feature</u>	With Mountpoint , you can now configure caching for repeatedly accessed data.	November 22, 2023
<u>Enhanced Amazon S3 Batch Operations manifest generation</u>	You can now direct Amazon S3 Batch Operations to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see Creating an Amazon S3 Batch Operations job .	November 22, 2023
<u>Existing Amazon S3 buckets can now add Object Lock configurations</u>	You can now enable Object Lock on existing Amazon S3 bucket. You may set legal holds and retention periods for new or existing buckets. For more information, see Using Object Lock .	November 20, 2023
<u>S3 Storage Lens request metrics for prefixes</u>	S3 Storage Lens introduces request metrics for prefixes within an Amazon S3 bucket. For more information, see Metrics categories .	November 17, 2023

<u>Amazon S3 Storage Lens groups</u>	S3 Storage Lens introduce s Storage Lens groups, a custom defined filter for objects based on object metadata. For more information, see <u>Working with Amazon S3 Storage Lens groups</u> .	November 15, 2023
<u>New IAM policy</u>	S3 on Outposts introduce s AWSServiceRoleForS3OnOutposts , a service-linked role to help manage network resources for you. For more information, see <u>Using service-linked roles for S3 on Outposts</u> .	October 3, 2023
<u>Amazon S3 provides the Last-Modified time for delete markers</u>	Amazon S3 provides the Last-Modified time of delete markers in the response headers of S3 Head and Get API operations. For more information, see <u>Working with delete markers</u> .	September 27, 2023
<u>Amazon S3 update to AWS managed policy</u>	Amazon S3 added s3:Describe* permissions to AmazonS3ReadOnlyAccess . For more information, see <u>AWS managed policies for Amazon S3</u> .	August 11, 2023

<u>Improved start times for Standard restore requests made through S3 Batch Operations</u>	Standard retrievals for restore requests that are made through S3 Batch Operations now can start within minutes. For more information, see <u>Archive Retrieval Options</u> .	August 9, 2023
<u>Added Mountpoint, a high-throughput client for mounting an Amazon S3 bucket as a local file system.</u>	With <u>Mountpoint</u> , your applications can access objects stored in Amazon S3 through file operations, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface.	August 9, 2023
<u>Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)</u>	Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. For more information, see <u>Using dual-layer server-side encryption with AWS KMS keys</u> .	June 13, 2023

<u>Amazon S3 enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new buckets.</u>	Amazon S3 now automatically enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new S3 buckets in all AWS Regions. For more information, see Blocking public access to your Amazon S3 storage and Controlling ownership of objects and disabling ACLs for your bucket.	April 27, 2023
<u>S3 Replication Operations Failed metric</u>	Amazon S3 adds new Amazon CloudWatch metric to monitor S3 Replication failures. For more information, see Monitoring progress with replication metrics.	April 5, 2023
<u>Private DNS</u>	AWS PrivateLink for Amazon S3 now supports Private DNS. For more information, see Private DNS.	March 14, 2023
<u>Cross-account access points support in the Amazon S3 console</u>	Amazon S3 now supports creating cross-account access points with the Amazon S3 console. For more information, see Creating access points.	March 14, 2023

<u>Amazon S3 on Outposts supports S3 Replication on Outposts</u>	With local S3 Replicati on, you can automatically replicate objects to a single Outposts destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Outposts or within the same Outposts as the source bucket. For more information, see <u>Replicating objects for S3 on Outposts</u> .	March 14, 2023
<u>Amazon S3 Object Lambda Access Point alias</u>	When you create an Object Lambda Access Point, Amazon S3 automatically generates a unique alias for your Object Lambda Access Point. You can use this alias instead of an Amazon S3 bucket name or the Object Lambda Access Point Amazon Resource Name (ARN) in a request for access point data plane operations. For more information, see <u>How to use a bucket-style alias for your Object Lambda Access Point</u> .	March 14, 2023
<u>Amazon S3 Multi-Region Access Points cross-account support</u>	Amazon S3 now supports creating cross-account Multi-Region Access Points with the Amazon S3 console. For more information, see <u>Creating Multi-Region Access Points</u> .	March 14, 2023

<u>Cross-account access points</u>	Amazon S3 supports creating cross-account access points. You can create a cross-account access point by using the AWS Command Line Interface (AWS CLI) or the REST API <code>CreateAccessPoint</code> operation. For more information, see <u>Creating access points</u> .	November 30, 2022
<u>Amazon S3 supports failover controls for Amazon S3 Multi-Region Access Points</u>	Amazon S3 introduces failover control for Multi-Region Access Points. These controls let you shift S3 data access request traffic routed through an Amazon S3 Multi-Region Access Point to an alternate AWS Region within minutes to test and build highly available applications. For more information, see <u>Amazon S3 Multi-Region Access Point failover controls</u> .	November 28, 2022
<u>Amazon S3 Storage Lens increases organization-wide visibility with 34 new metrics</u>	S3 Storage Lens introduces 34 additional metrics to uncover deeper cost-optimization opportunities, identify data-protection best practices, and improve the performance of application workflows. For more information, see <u>S3 Storage Lens metrics</u> .	November 17, 2022

<u>Amazon S3 supports higher restore request rates for S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive</u>	Amazon S3 supports restore requests at a rate of up to 1,000 transactions per second, per AWS account for the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.	November 15, 2022
<u>Amazon S3 on Outposts supports additional S3 Lifecycle actions and filters</u>	S3 on Outposts supports additional S3 Lifecycle rules to optimize capacity management. You can expire objects as they age or are replaced with newer versions. You can create a lifecycle rule for a whole bucket or a subset of objects in a bucket by filtering with prefixes, object tags, or object size. For more information, see <u>Creating and managing a lifecycle configuration</u> .	November 2, 2022
<u>S3 Replication support for SSE-C objects</u>	You can replicate objects that are created using server-side encryption with customer-provided keys. For more information about replicating encrypted objects, see <u>Replicating objects created with server-side encryption (SSE-C, SSE-S3, SSE-KMS)</u> .	October 24, 2022

[Amazon S3 on Outposts supports access point aliases](#)

With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Every time you create an access point for a bucket, S3 on Outposts automatically generates an access point alias. You can use this access point alias instead of an access point ARN for any data plane operation. For more information, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

October 21, 2022

[S3 Object Lambda supports the HeadObject , ListObjects , and ListObjectsV2 operations](#)

You can use custom code to modify the data returned by standard S3 GET, LIST, or HEAD requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see [Transforming objects with S3 Object Lambda](#).

October 4, 2022

[Amazon S3 on Outposts supports S3 Versioning](#)

When enabled, S3 Versioning saves multiple distinct copies of an object in the same bucket. You can use S3 Versioning to preserve, retrieve, and restore every version of every object stored in your Outposts buckets. S3 Versioning helps you recover from unintended user actions and application failures. For more information, see [Managing S3 Versioning for your S3 on Outposts bucket](#).

September 21, 2022

[AWS Backup for Amazon S3](#)

AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information, see [Using AWS Backup for Amazon S3](#).

February 18, 2022

[Use S3 Batch Replication to replicate existing objects](#)

With S3 Batch Replication, you can replicate objects that existed before a replication configuration was in place. Replicating existing objects is done through the use of a Batch Operations job. S3 Batch Replication differs from live replication, which continuously and automatically copies new objects across Amazon S3 buckets. For more information, see [Replicating existing objects with S3 Batch Replication](#).

[Rename of S3 Glacier Flexible Retrieval](#)

The Glacier storage class has been renamed to S3 Glacier Flexible Retrieval. This change does not impact the API.

February 8, 2022

November 30, 2021

<u>New S3 Object Ownership setting to disable ACLs</u>	You can apply the bucket owner enforced setting for Object Ownership to disable ACLs for your bucket and the objects in it and take ownership of every object in your bucket. The bucket owner enforced setting simplifies access management for data stored in Amazon S3. For more information, see <u>Controlling ownership of objects and disabling ACLs for your bucket.</u>	November 30, 2021
<u>New S3 Intelligent-Tiering storage class</u>	S3 Intelligent-Tiering Archive Instant Access is an additional storage class under S3 Intelligent-Tiering. For more information, see <u>How S3 Intelligent-Tiering works.</u>	November 30, 2021
<u>New S3 Glacier Instant Retrieval storage class</u>	You can now place objects in the S3 Glacier Instant Retrieval storage class. For more information about this storage class, see <u>Using Amazon S3 storage classes.</u>	November 30, 2021

<u>AWS Backup for Amazon S3 Preview</u>	AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information, see <u>Using AWS Backup for Amazon S3</u> .	November 30, 2021
<u>AWS Identity and Access Management Access Analyzer for Amazon S3</u>	IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. To learn more about validating policies using IAM Access Analyzer, see <u>IAM Access Analyzer policy validation</u> in the <i>IAM User Guide</i> .	November 30, 2021
<u>New event types</u>	New event types added to Amazon S3 Event Notifications, see <u>Amazon S3 Event Notifications</u> .	November 29, 2021
<u>Enable Amazon EventBridge on buckets</u>	You can enable EventBridge on Amazon S3 buckets to send events to Amazon EventBridge, see <u>Using EventBridge</u> .	November 29, 2021
<u>New S3 Lifecycle filters</u>	You can create lifecycle rules based on object size or specify how many noncurrent object versions to keep. For more information, see <u>Examples of S3 Lifecycle configuration</u> .	November 23, 2021

[Publish Amazon S3 Storage](#)

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, like alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, the CloudWatch APIs enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information, see the [Monitor S3 Storage Lens metrics in CloudWatch](#).

November 22, 2021

[Lens metrics to Amazon CloudWatch](#)[Multi-Region Access Points](#)

You can use Multi-Region Access Points to create a global endpoint that applications can use to fulfill requests from Amazon S3 buckets located in multiple AWS Regions. You can use this Multi-Region Access Point to route data to a bucket with the lowest latency. For more information about Multi-Region Access Points and how to use them, see [Multi-Region Access Point in Amazon S3](#).

September 2, 2021

[Amazon S3 on Outposts adds direct local access for applications](#)

Run your applications outside the AWS Outposts virtual private cloud (VPC) and access your S3 on Outposts data. You can also access S3 on Outposts objects directly from your on-premises network. For more information about configuring S3 on Outposts endpoints using [customer-owned IP \(CoIP\) addresses](#) and accessing your objects by creating a [local gateway](#) from your on-premises network, see [Accessing Amazon S3 on Outposts using VPC-only access points](#).

July 29, 2021

[Amazon S3 access point alias](#)

When you create an access point, Amazon S3 automatically generates an alias that you can use instead of a bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for any access point data plane operation. For more information, see [Using a bucket-style alias for your access point](#).

July 26, 2021

<u>Amazon S3 Inventory and S3 Batch Operations support S3</u>	Amazon S3 Inventory and Batch Operations support identifying and copying existing objects with S3 Bucket Keys. S3 Bucket Keys accelerate the reduction of server-side encryption costs for existing objects. For more information, see <u>Amazon S3 Inventory and Batch Operations Copy object</u> .	June 3, 2021
<u>Amazon S3 Storage Lens metrics account snapshot</u>	The S3 Storage Lens account snapshot displays your total storage, object count, and average object size on the S3 console home (Buckets) page by summarizing metrics from your default dashboard. For more information, see <u>S3 Storage Lens metrics account snapshot</u> .	May 5, 2021
<u>Increased Amazon S3 on Outposts endpoint support</u>	S3 on Outposts now supports up to 100 endpoints per Outpost. For more information, see <u>S3 on Outposts network restrictions</u> .	April 29, 2021

<u>Amazon S3 on Outposts event notifications in Amazon CloudWatch Events</u>	You can use CloudWatch Events to create a rule to capture any S3 on Outposts API event and get notified through all supported CloudWatch targets. For more information, see <u>Receiving S3 on Outposts event notifications using CloudWatch Events.</u>	April 19, 2021
<u>S3 Object Lambda</u>	With S3 Object Lambda, you can add your own code to Amazon S3 GET requests to modify and process data as it is returned to an application. You can use custom code to modify the data returned by standard S3 GET requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see <u>Transforming objects.</u>	March 18, 2021

<u>AWS PrivateLink</u>	With AWS PrivateLink for Amazon S3, you can connect directly to S3 by using an interface endpoint in your virtual private cloud (VPC) instead of connecting over the internet. Interface endpoints are directly accessible from applications that are on premises or in a different AWS Region. For more information, see <u>AWS PrivateLink for Amazon S3</u> .	February 2, 2021
<u>Managing Amazon S3 on Outposts capacity with AWS CloudTrail</u>	S3 on Outposts management events are available through CloudTrail logs. For more information, see <u>Managing S3 on Outposts capacity with CloudTrail</u> .	December 21, 2020
<u>Strong consistency</u>	Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your S3 bucket in all AWS Regions. In addition, read operations on Amazon S3 Select, Amazon S3 access control lists, Amazon S3 Object Tags, and object metadata (for example, HEAD object) are strongly consistent. For more information, see <u>Amazon S3 data consistency model</u> .	December 1, 2020

<u>Amazon S3 replica modification sync</u>	Amazon S3 replica modification sync keeps object metadata, such as tags, ACLs, and Object Lock settings, in sync between source objects and replicas. When this feature is enabled, Amazon S3 replicates metadata changes made to either the source object or the replica copies. For more information, see <u>Replicating metadata changes with replica modification sync.</u>	December 1, 2020
<u>Amazon S3 Bucket Keys</u>	Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (SSE-KMS). This new bucket-level key for server-side encryption can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see <u>Reducing the cost of SSE-KMS by using S3 Bucket Keys.</u>	December 1, 2020

[Amazon S3 Storage Lens](#)

S3 Storage Lens aggregate your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket. For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#).

November 18, 2020

<u>Tracing S3 requests using AWS X-Ray</u>	Amazon S3 integrates with X-Ray to propagate the trace context and give you one request chain with upstream and downstream nodes. For more information, see Tracing requests using X-Ray .	November 16, 2020
<u>S3 Replication metrics</u>	S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. For more information, see Replication metrics and Amazon S3 event notifications .	November 9, 2020
<u>S3 Intelligent-Tiering Archive Access and Deep Archive Access</u>	S3 Intelligent-Tiering Archive Access and Deep Archive Access are additional storage tiers under S3 Intelligent-Tiering. For more information, see Storage class for automatically optimizing frequently and infrequently accessed objects .	November 9, 2020
<u>Delete marker replication</u>	With delete marker replication, you can ensure that delete markers are copied to your destination buckets for your replication rules. For more information, see Using delete marker replication .	November 9, 2020

<u>S3 Object Ownership</u>	Object Ownership is an S3 bucket setting that you can use to control ownership of new objects that are uploaded to your buckets. For more information, see <u>Using S3 Object Ownership</u> .	October 2, 2020
<u>Amazon S3 on Outposts</u>	With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and easily store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API. For more information, see <u>Using Amazon S3 on Outposts</u> .	September 30, 2020
<u>Bucket owner condition</u>	You can use the Amazon S3 bucket owner condition to ensure that the buckets you use in your S3 operations belong to the AWS accounts that you expect. For more information, see <u>Bucket owner condition</u> .	September 11, 2020

<u>S3 Batch Operations support for Object Lock Retention</u>	You can now use Batch Operations with S3 Object Lock to apply retention settings to many Amazon S3 objects at once. For more information, see <u>Setting S3 Object Lock Retention dates with S3 Batch Operations</u> .	May 4, 2020
<u>S3 Batch Operations support for Object Lock Legal Hold</u>	You can now use Batch Operations with S3 Object Lock to add a legal hold to many Amazon S3 objects at once. For more information, see <u>Using S3 Batch Operations for setting S3 Object Lock Legal Hold</u> .	May 4, 2020
<u>Job tags for S3 Batch Operations</u>	You can add tags to your S3 Batch Operations jobs to control and label those jobs. For more information, see <u>Tags for S3 Batch Operations jobs</u> .	March 16, 2020
<u>Amazon S3 access points</u>	Amazon S3 access points simplify managing data access at scale for shared datasets in S3. Access points are named network endpoints that are attached to buckets that you can use to perform S3 object operations. For more information, see <u>Managing data access with Amazon S3 access points</u> .	December 2, 2019

<u>Access Analyzer for Amazon S3</u>	Access Analyzer for Amazon S3 alerts you to S3 buckets that are configured to allow access to anyone on the internet or other AWS accounts, including accounts outside of your organization. For more information, see <u>Using Access Analyzer for Amazon S3</u> .	December 2, 2019
<u>S3 Replication Time Control (S3 RTC)</u>	S3 Replication Time Control (S3 RTC) replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes. For more information, see <u>Replicating objects using S3 Replication Time Control (S3 RTC)</u> .	November 20, 2019
<u>Same-Region Replication</u>	You can use Same-Region Replication (SRR) to copy objects across Amazon S3 buckets in the same AWS Region. For information about both Cross-Region Replication (CRR) and Same-Region Replication, see <u>Replication</u> .	September 18, 2019
<u>Cross-Region Replication support for S3 Object Lock</u>	Cross-Region Replication now supports Object Lock. For more information, see <u>What does Amazon S3 Replicate?</u> .	May 28, 2019

[S3 Batch Operations](#)

By using S3 Batch Operations, you can perform large-scale Batch Operations on Amazon S3 objects. S3 Batch Operations can run a single operation on lists of objects that you specify. A single job can perform the specified operation on billions of objects containing exabytes of data. For more information, see [Performing S3 Batch Operations](#).

April 30, 2019

[Asia Pacific \(Hong Kong\) Region](#)

Amazon S3 is now available in the Asia Pacific (Hong Kong) Region. For more information about Amazon S3 Regions and endpoints, see [Regions and endpoints](#) in the *AWS General Reference*.

April 24, 2019

[Added a new field to the server access logs](#)

Amazon S3 added the following new field to the server access logs: Transport Layer Security (TLS) version. For more information, see [Server access log format](#).

March 28, 2019

[New archive storage class](#)

Amazon S3 now offers a new archive storage class, S3 Glacier Deep Archive (DEEP_ARCHIVE), for storing rarely accessed objects. For more information, see [Storage Classes](#).

March 27, 2019

<u>Added new fields to the server access logs</u>	Amazon S3 added the following new fields to the server access logs: Host Id, Signature Version, Cipher Suite, Authentication Type, and Host Header. For more information, see <u>Server access log format</u> .	March 5, 2019
<u>Support for Parquet-formatted Amazon S3 Inventory files</u>	Amazon S3 now supports the <u>Apache Parquet (Parquet)</u> format in addition to the <u>Apache optimized row columnar (ORC)</u> and comma-separated values (CSV) file formats for inventory output files. For more information, see <u>Inventory</u> .	December 4, 2018
<u>S3 Object Lock</u>	Amazon S3 now offers Object Lock functionality that provides Write Once Read Many (WORM) protections for Amazon S3 objects. For more information, see <u>Locking Objects</u> .	November 26, 2018
<u>Restore speed upgrade</u>	Using Amazon S3 restore speed upgrade, you can change the speed of a restoration from the S3 Glacier Flexible Retrieval storage class to a faster speed while the restoration is in progress. For more information, see <u>Restoring Archived Objects</u> .	November 26, 2018

Restore Event Notifications

Amazon S3 Event Notifications now support initiation and completion events when restoring objects from the S3 Glacier Flexible Retrieval storage class. For more information, see [Event Notifications](#).

November 26, 2018

[PUT directly to the S3 Glacier Flexible Retrieval storage class](#)

The Amazon S3 PUT operation now supports specifying S3 Glacier Flexible Retrieval as the storage class when creating objects. Previously, you had to transition objects to the S3 Glacier Flexible Retrieval storage class from another Amazon S3 storage class. Also, when using S3 Cross-Region Replication (CRR), you can now specify S3 Glacier Flexible Retrieval as the storage class for replicated objects. For more information about the S3 Glacier Flexible Retrieval storage class, see [Storage Classes](#). For more information about specifying the storage class for replicated objects, [Replication Configuration Overview](#). For more information about the direct PUT to S3 Glacier Flexible Retrieval REST API changes, see [Document History: PUT directly to S3 Glacier Flexible Retrieval](#).

November 26, 2018

<u>New storage class</u>	Amazon S3 now offers a new storage class named S3 Intelligent-Tiering (INTELLIGENT_TIERING) that is designed for long-lived data with changing or unknown access patterns. For more information, see <u>Storage Classes</u> .	November 26, 2018
<u>Amazon S3 Block Public Access</u>	Amazon S3 now includes the ability to block public access to buckets and objects on a per-bucket or account-wide basis. For more information, see <u>Using Amazon S3 Block Public Access</u> .	November 15, 2018
<u>Filtering enhancements in Cross-Region Replication (CRR) rules</u>	In a CRR rule configuration, you can specify an object filter to choose a subset of objects to apply the rule to. Previously, you could filter only on an object key prefix. In this release, you can filter on an object key prefix, one or more object tags, or both. For more information, see <u>CRR Setup: Replication Configuration Overview</u> .	September 19, 2018

<u>New Amazon S3 Select features</u>	Amazon S3 Select now supports Apache Parquet input, queries on nested JSON objects, and two new Amazon CloudWatch monitoring metrics (<code>SelectScannedBytes</code> and <code>SelectReturnedBytes</code>).	September 5, 2018
<u>Updates now available over RSS</u>	You can now subscribe to an RSS feed to receive notifications about updates to the <i>Amazon S3 User Guide</i> .	June 19, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon S3 User Guide* before June 19, 2018.

Change	Description	Date
Code examples update	<p>Code examples updated:</p> <ul style="list-style-type: none">• C#—Updated all of the examples to use the task-based asynchronous pattern. For more information, see Amazon Web Services Asynchronous APIs for .NET in the <i>AWS SDK for .NET Developer Guide</i>. Code examples are now compliant with version 3 of the AWS SDK for .NET.• Java—Updated all of the examples to use the client builder model. For more information about the client builder model, see Creating Service Clients.•	April 30, 2018

Change	Description	Date
	<p>PHP—Updated all of the examples to use the AWS SDK for PHP 3.0. For more information about the AWS SDK for PHP 3.0, see AWS SDK for PHP.</p> <ul style="list-style-type: none">Ruby—Updated example code so that the examples work with the AWS SDK for Ruby version 3.	
Amazon S3 now reports S3 Glacier Flexible Retrieval and ONEZONE_IA storage classes to Amazon CloudWatch Logs storage metrics	<p>In addition to reporting actual bytes, these storage metrics include per-object overhead bytes for applicable storage classes (ONEZONE_IA , STANDARD_IA , and S3 Glacier Flexible Retrieval):</p> <ul style="list-style-type: none">For ONEZONE_IA and STANDARD_IA storage class objects, Amazon S3 reports objects smaller than 128 KB as 128 KB. For more information, see Understanding and managing Amazon S3 storage classes.For S3 Glacier Flexible Retrieval storage class objects, the storage metrics report the following overheads:<ul style="list-style-type: none">A 32 KB per-object overhead, charged at S3 Glacier Flexible Retrieval storage class pricingAn 8 KB per-object overhead, charged at STANDARD storage class pricing <p>For more information, see Transitioning objects using Amazon S3 Lifecycle.</p> <p>For more information about storage metrics, see Monitoring metrics with Amazon CloudWatch.</p>	April 30, 2018

Change	Description	Date
New storage class	<p>Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes.</p>	April 4, 2018
Amazon S3 Select	<p>Amazon S3 now supports retrieving object content based on an SQL expression. For more information, see Querying data in place with Amazon S3 Select.</p>	April 4, 2018
Asia Pacific (Osaka-Local) Region	<p>Amazon S3 is now available in the Asia Pacific (Osaka-Local) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the AWS General Reference.</p>	February 12, 2018
	⚠ Important <p>You can use the Asia Pacific (Osaka-Local) Region only in conjunction with the Asia Pacific (Tokyo) Region. To request access to Asia Pacific (Osaka-Local) Region, contact your sales representative.</p>	
Amazon S3 Inventory creation timestamp	<p>Amazon S3 Inventory now includes a timestamp of the date and start time of the creation of the Amazon S3 Inventory report. You can use the timestamp to determine changes in your Amazon S3 storage from the start time of when the inventory report was generated.</p>	January 16, 2018
Europe (Paris) Region	<p>Amazon S3 is now available in the Europe (Paris) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the AWS General Reference.</p>	December 18, 2017

Change	Description	Date
China (Ningxia) Region	Amazon S3 is now available in the China (Ningxia) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	November 29, 2017
Support for ORC-formatted Amazon S3 Inventory files	Amazon S3 now supports the Apache optimized row columnar (ORC) format in addition to comma-separated values (CSV) file format for inventory output files. Also, you can now query Amazon S3 inventory using standard SQL by using Amazon Athena, Amazon Redshift Spectrum, and other tools such as Presto , Apache Hive , and Apache Spark . For more information, see Cataloging and analyzing your data with S3 Inventory .	November 17, 2017
Default encryption for S3 buckets	Amazon S3 default encryption provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The objects are encrypted using server-side encryption with either Amazon S3 managed keys (SSE-S3) or AWS managed keys (SSE-KMS). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets .	November 06, 2017
Encryption status in Amazon S3 Inventory	Amazon S3 now supports including encryption status in Amazon S3 Inventory so you can see how your objects are encrypted at rest for compliance auditing or other purposes. You can also configure to encrypt Amazon S3 Inventory with server-side encryption (SSE) or SSE-KMS so that all inventory files are encrypted accordingly. For more information, see Cataloging and analyzing your data with S3 Inventory .	November 06, 2017

Change	Description	Date
Cross-Region Replication (CRR) enhancements	<p>Cross-Region Replication now supports the following:</p> <ul style="list-style-type: none">• In a cross-account scenario, you can add a CRR configuration to change replica ownership to the AWS account that owns the destination bucket. For more information, see Changing the replica owner.• By default, Amazon S3 does not replicate objects in your source bucket that are created using server-side encryption using keys stored in AWS KMS. In your CRR configuration, you can now direct Amazon S3 to replicate these objects. For more information, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).	November 06, 2017
Europe (London) Region	Amazon S3 is now available in the Europe (London) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	December 13, 2016
Canada (Central) Region	Amazon S3 is now available in the Canada (Central) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	December 8, 2016

Change	Description	Date
Object tagging	<p>Amazon S3 now supports object tagging. Object tagging enables you to categorize storage. Object key name prefixes also enable you to categorize storage, object tagging adds another dimension to it.</p> <p>There are added benefits tagging offers. These include:</p> <ul style="list-style-type: none"> • Object tags enable fine-grained access control of permissions (for example, you could grant an IAM user permissions to read-only objects with specific tags). • Fine-grained control in specifying lifecycle configuration. You can specify tags to select a subset of objects to which lifecycle rule applies. • If you have Cross-Region Replication (CRR) configured, Amazon S3 can replicate the tags. You must grant necessary permission to the IAM role created for Amazon S3 to assume to replicate objects on your behalf. • You can also customize CloudWatch metrics and CloudTrail events to display information by specific tag filters. <p>For more information, see Categorizing your objects using tags.</p>	November 29, 2016
Amazon S3 Lifecycle now supports tag-based filters	Amazon S3 now supports tag-based filtering in lifecycle configuration. You can now specify lifecycle rules in which you can specify a key prefix, one or more object tags, or a combination of both to select a subset of objects to which the lifecycle rule applies. For more information, see Managing the lifecycle of objects .	November 29, 2016

Change	Description	Date
CloudWatch request metrics for buckets	<p>Amazon S3 now supports CloudWatch metrics for requests made on buckets. When you enable these metrics for a bucket, the metrics report at 1-minute intervals. You can also configure which objects in a bucket will report these request metrics. For more information, see Monitoring metrics with Amazon CloudWatch.</p>	November 29, 2016
Amazon S3 Inventory	<p>Amazon S3 now supports storage inventory. Amazon S3 Inventory provides a flat-file output of your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or a shared prefix (that is, objects that have names that begin with a common string).</p> <p>For more information, see Cataloging and analyzing your data with S3 Inventory.</p>	November 29, 2016
Amazon S3 Analytics – Storage Class Analysis	<p>The new Amazon S3 analytics – storage class analysis feature observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. This feature also includes a detailed daily analysis of your storage usage at the specified bucket, prefix, or tag level that you can export to an S3 bucket.</p>	November 29, 2016
New Expedited and Bulk data retrievals when restoring archived objects from Amazon Glacier	<p>Amazon S3 now supports Expedited and Bulk data retrievals in addition to Standard retrievals when restoring objects archived to Amazon Glacier. For more information, see Restoring an archived object.</p>	November 21, 2016

Change	Description	Date
CloudTrail object logging	CloudTrail supports logging Amazon S3 object level API operations such as <code>GetObject</code> , <code>PutObject</code> , and <code>DeleteObject</code> . You can configure your event selectors to log object level API operations. For more information, see Logging Amazon S3 API calls using AWS CloudTrail .	November 21, 2016
US East (Ohio) Region	Amazon S3 is now available in the US East (Ohio) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	October 17, 2016
IPv6 support for Amazon S3 Transfer Acceleration	Amazon S3 now supports Internet Protocol version 6 (IPv6) for Amazon S3 Transfer Acceleration. You can connect to Amazon S3 over IPv6 by using the new dual-stack for Transfer Acceleration endpoint. For more information, see Getting started with Amazon S3 Transfer Acceleration .	October 6, 2016
IPv6 support	Amazon S3 now supports Internet Protocol version 6 (IPv6). You can access Amazon S3 over IPv6 by using dual-stack endpoints. For more information, see Making requests to Amazon S3 over IPv6 in the <i>Amazon S3 API Reference</i> .	August 11, 2016
Asia Pacific (Mumbai) Region	Amazon S3 is now available in the Asia Pacific (Mumbai) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	June 27, 2016

Change	Description	Date
Amazon S3 Transfer Acceleration	<p>Amazon S3 Transfer Acceleration enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration takes advantage of Amazon CloudFront globally distributed edge locations.</p> <p>For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.</p>	April 19, 2016
Lifecycle support to remove expired object delete markers	Lifecycle configuration Expiration action now allows you to direct Amazon S3 to remove expired object delete markers in a/ versioned bucket. For more information, see Elements to describe lifecycle actions .	March 16, 2016

Change	Description	Date
Bucket lifecycle configuration now supports action to stop incomplete multipart uploads	<p>Bucket lifecycle configuration now supports the <code>AbortIncompleteMultipartUpload</code> action that you can use to direct Amazon S3 to stop multipart uploads that don't complete within a specified number of days after being initiated. When a multipart upload becomes eligible for a stop operation, Amazon S3 deletes any uploaded parts and stops the multipart upload.</p> <p>For conceptual information, see the following topics in the <i>Amazon S3 User Guide</i>:</p> <ul style="list-style-type: none">• Aborting a multipart upload• Elements to describe lifecycle actions <p>The following API operations have been updated to support the new action:</p> <ul style="list-style-type: none">• PUT Bucket lifecycle – The XML configuration now allows you to specify the <code>AbortIncompleteMultipartUpload</code> action in a lifecycle configuration rule.• List Parts and Initiate Multipart Upload – Both of these API operations now return two additional response headers (<code>x-amz-abort-date</code>, and <code>x-amz-abort-rule-id</code>) if the bucket has a lifecycle rule that specifies the <code>AbortIncompleteMultipartUpload</code> action. These headers in the response indicate when the initiated multipart upload becomes eligible for a stop operation and which lifecycle rule is applicable.	March 16, 2016

Change	Description	Date
Asia Pacific (Seoul) Region	<p>Amazon S3 is now available in the Asia Pacific (Seoul) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the AWS General Reference.</p>	January 6, 2016
New condition key and a multipart upload change	<p>IAM policies now support an Amazon S3 <code>s3:x-amz-storage-class</code> condition key. For more information, see Bucket policy examples using condition keys.</p> <p>You no longer need to be the initiator of a multipart upload to upload parts and complete the upload. For more information, see Multipart upload API and permissions.</p>	December 14, 2015
Renamed the US Standard Region	<p>Changed the Region name string from "US Standard" to "US East (N. Virginia)." This is only a Region name update, there is no change in the functionality.</p>	December 11, 2015
New storage class	<p>Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes.</p> <p>Lifecycle configuration feature updates now allow you to transition objects to the STANDARD_IA storage class. For more information, see Managing the lifecycle of objects.</p> <p>Previously, the Cross-Region Replication feature used the storage class of the source object for object replicas. Now, when you configure Cross-Region Replication, you can specify a storage class for the object replica created in the destination bucket. For more information, see Replicating objects within and across Regions.</p>	September 16, 2015

Change	Description	Date
AWS CloudTrail integration	New AWS CloudTrail integration allows you to record Amazon S3 API activity in your S3 bucket. You can use CloudTrail to track S3 bucket creations or deletions, access control modifications, or lifecycle configuration changes. For more information, see Logging Amazon S3 API calls using AWS CloudTrail .	September 1, 2015
Bucket limit increase	Amazon S3 now supports bucket limit increases. By default, customers can create up to 100 buckets in their AWS account. Customers who need additional buckets can increase that limit by submitting a service limit increase. For information about how to increase your bucket limit, go to AWS service quotas in the AWS <i>General Reference</i> . For more information, see Using the AWS SDKs and General purpose bucket quotas, limitations, and restrictions .	August 4, 2015
Consistency model update	Amazon S3 now supports read-after-write consistency for new objects added to Amazon S3 in the US East (N. Virginia) Region. Prior to this update, all Regions except US East (N. Virginia) Region supported read-after-write consistency for new objects uploaded to Amazon S3. With this enhancement, Amazon S3 now supports read-after-write consistency in all Regions for new objects added to Amazon S3. Read-after-write consistency allows you to retrieve objects immediately after creation in Amazon S3. For more information, see Regions .	August 4, 2015
Event notifications	Amazon S3 Event Notifications have been updated to add notifications when objects are deleted and to add filtering on object names with prefix and suffix matching. For more information, see Amazon S3 Event Notifications .	July 28, 2015

Change	Description	Date
Amazon CloudWatch integration	<p>New Amazon CloudWatch integration allows you to monitor and set alarms on your Amazon S3 usage through CloudWatch metrics for Amazon S3. Supported metrics include total bytes for Standard storage, total bytes for Reduced-Redundancy Storage, and total number of objects for a given S3 bucket. For more information, see Monitoring metrics with Amazon CloudWatch.</p>	July 28, 2015
Support for deleting and emptying non-empty buckets	<p>Amazon S3 now supports deleting and emptying non-empty buckets. For more information, see Emptying a general purpose bucket.</p>	July 16, 2015
Bucket policies for Amazon VPC endpoints	<p>Amazon S3 has added support for bucket policies for virtual private cloud (VPC) (VPC) endpoints. You can use S3 bucket policies to control access to buckets from specific VPC endpoints, or specific VPCs. VPC endpoints are easy to configure, are highly reliable, and provide a secure connection to Amazon S3 without requiring a gateway or a NAT instance. For more information, see Controlling access from VPC endpoints with bucket policies.</p>	April 29, 2015
Event notifications	<p>Amazon S3 Event Notifications have been updated to support the switch to resource-based permissions for AWS Lambda functions. For more information, see Amazon S3 Event Notifications.</p>	April 9, 2015
Cross-Region Replication	<p>Amazon S3 now supports Cross-Region Replication. Cross-Region Replication is the automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see Replicating objects within and across Regions.</p>	March 24, 2015

Change	Description	Date
Event notifications	<p>Amazon S3 now supports new event types and destinations in a bucket notification configuration. Prior to this release, Amazon S3 supported only the <code>s3:ReducedRedundancyLostObject</code> event type and an Amazon SNS topic as the destination. For more information about the new event types, see Amazon S3 Event Notifications.</p>	November 13, 2014
Server-side encryption with customer-provided encryption keys	<p>Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)</p> <p>Amazon S3 now supports server-side encryption using AWS KMS. This feature allows you to manage the envelope key through AWS KMS, and Amazon S3 calls AWS KMS to access the envelope key within the permissions you set.</p> <p>For more information about server-side encryption with AWS KMS, see Protecting Data Using Server-Side Encryption with AWS Key Management Service.</p>	November 12, 2014
Europe (Frankfurt) Region	Amazon S3 is now available in the Europe (Frankfurt) Region.	October 23, 2014
Server-side encryption with customer-provided encryption keys	<p>Amazon S3 now supports server-side encryption using customer-provided encryption keys (SSE-C). Server-side encryption enables you to request Amazon S3 to encrypt your data at rest. When using SSE-C, Amazon S3 encrypts your objects with the custom encryption keys that you provide. Since Amazon S3 performs the encryption for you, you get the benefits of using your own encryption keys without the cost of writing or executing your own encryption code.</p> <p>For more information about SSE-C, see Server-Side Encryption (Using Customer-Provided Encryption Keys).</p>	June 12, 2014

Change	Description	Date
Lifecycle support for versioning	Prior to this release, lifecycle configuration was supported only on nonversioned buckets. Now you can configure lifecycle on both nonversioned and versioning-enabled buckets. For more information, see Managing the lifecycle of objects .	May 20, 2014
Access control topics revised	Revised Amazon S3 access control documentation. For more information, see Identity and Access Management for Amazon S3 .	April 15, 2014
Server access logging topic revised	Revised server access logging documentation. For more information, see Logging requests with server access logging .	November 26, 2013
.NET SDK samples updated to version 2.0	.NET SDK samples in this guide are now compliant to version 2.0.	November 26, 2013
SOAP Support Over HTTP deprecated	SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features will not be supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.	September 20, 2013
IAM policy variable support	<p>IAM policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based information from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy. For more information about policy variables, see IAM Policy Variables Overview in the <i>IAM User Guide</i>.</p> <p>For examples of policy variables in Amazon S3, see Identity-based policy examples for Amazon S3.</p>	April 3, 2013

Change	Description	Date
Console support for Requester Pays	<p>You can now configure your bucket for Requester Pays by using the Amazon S3 console. For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.</p>	December 31, 2012
Root domain support for website hosting	<p>Amazon S3 now supports hosting static websites at the root domain. Visitors to your website can access your site from their browser without specifying www in the web address (for example, they can use example.com instead of www.example.com). Many customers already host static websites on Amazon S3 that are accessible from a www subdomain (for example, www.example.com). Previously, to support root domain access, you needed to run your own web server to proxy root domain requests from browsers to your website on Amazon S3. Running a web server to proxy requests introduces additional costs, operational burden, and another potential point of failure. Now, you can take advantage of the high availability and durability of Amazon S3 for both www and root domain addresses. For more information, see Hosting a static website using Amazon S3.</p>	December 27, 2012
Console revision	<p>Amazon S3 console has been updated. The documentation topics that refer to the console have been revised accordingly.</p>	December 14, 2012

Change	Description	Date
Support for Archiving Data to Amazon Glacier	<p>Amazon S3 now supports a storage option that enables you to utilize Amazon Glacier's low-cost storage service for data archival. To archive objects, you define archival rules identifying objects and a time frame when you want Amazon S3 to archive these objects to Amazon Glacier. You can easily set the rules on a bucket using the Amazon S3 console or programmatically using the Amazon S3 API or AWS SDKs.</p> <p>For more information, see Managing the lifecycle of objects.</p>	November 13, 2012
Support for Website Page Redirects	<p>For a bucket that is configured as a website, Amazon S3 now supports redirecting a request for an object to another object in the same bucket or to an external URL. For more information, see (Optional) Configuring a webpage redirect.</p> <p>For information about hosting websites, see Hosting a static website using Amazon S3.</p>	October 4, 2012
Support for Cross-Origin Resource Sharing (CORS)	<p>Amazon S3 now supports Cross-Origin Resource Sharing (CORS). CORS defines a way in which client web applications that are loaded in one domain can interact with or access resources in a different domain. With CORS support in Amazon S3, you can build rich client-side web applications on top of Amazon S3 and selectively allow cross-domain access to your Amazon S3 resources. For more information, see Using cross-origin resource sharing (CORS).</p>	August 31, 2012
Support for Cost Allocation Tags	<p>Amazon S3 now supports cost allocation tagging, which allows you to label S3 buckets so you can more easily track their cost against projects or other criteria. For more information about using tagging for buckets, see Using cost allocation S3 bucket tags.</p>	August 21, 2012

Change	Description	Date
Support for MFA-protected API access in bucket policies	<p>Amazon S3 now supports MFA-protected API access, a feature that can enforce AWS Multi-Factor Authentication for an extra level of security when accessing your Amazon S3 resources. It is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, go to AWS Multi-Factor Authentication. You can now require MFA authentication for any requests to access your Amazon S3 resources.</p> <p>To enforce MFA authentication, Amazon S3 now supports the <code>aws:MultiFactorAuthAge</code> key in a bucket policy. For an example bucket policy, see Requiring MFA.</p>	July 10, 2012
Object Expiration support	You can use Object Expiration to schedule automatic removal of data after a configured time period. You set object expiration by adding lifecycle configuration to a bucket.	27 December 2011
New Region supported	Amazon S3 now supports the South America (São Paulo) Region. For more information, see Accessing an Amazon S3 general purpose bucket .	December 14, 2011
Multi-Object Delete	Amazon S3 now supports Multi-Object Delete API that enables you to delete multiple objects in a single request. With this feature, you can remove large numbers of objects from Amazon S3 more quickly than using multiple individual DELETE requests. For more information, see Deleting Amazon S3 objects .	December 7, 2011
New Region supported	Amazon S3 now supports the US West (Oregon) Region. For more information, see Buckets and Regions .	November 8, 2011
Documentation Update	Documentation bug fixes.	November 8, 2011

Change	Description	Date
Documentation Update	<p>In addition to documentation bug fixes, this release includes the following enhancements:</p> <ul style="list-style-type: none">• New server-side encryption sections using the AWS SDK for PHP and the AWS SDK for Ruby (see Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)).	October 17, 2011
Server-side encryption support	<p>Amazon S3 now supports server-side encryption. It enables you to request Amazon S3 to encrypt your data at rest, that is, encrypt your object data when Amazon S3 writes your data to disks in its data centers. In addition to REST API updates, the AWS SDK for Java and .NET provide necessary functionality to request server-side encryption. You can also request server-side encryption when uploading objects using the AWS Management Console. To learn more about data encryption, go to Using Data Encryption.</p>	October 4, 2011
Documentation Update	<p>In addition to documentation bug fixes, this release includes the following enhancements:</p> <ul style="list-style-type: none">• Added Ruby and PHP samples to the Making requests in the <i>Amazon S3 API Reference</i> section.• Added sections describing how to generate and use presigned URLs. For more information, see Sharing objects with presigned URLs and Sharing objects with presigned URLs.• Updated an existing section to introduce AWS Explorers for Eclipse and Visual Studio. For more information, see Developing with Amazon S3 using the AWS SDKs in the <i>Amazon S3 API Reference</i>.	September 22, 2011

Change	Description	Date
Support for sending requests using temporary security credentials	<p>In addition to using your AWS account and IAM user security credentials to send authenticated requests to Amazon S3, you can now send requests using temporary security credentials you obtain from AWS Identity and Access Management (IAM). You can use the AWS Security Token Service API or the AWS SDK wrapper libraries to request these temporary credentials from IAM. You can request these temporary security credentials for your own use or hand them out to federated users and applications. This feature enables you to manage your users outside AWS and provide them with temporary security credentials to access your AWS resources.</p> <p>For more information, see Making requests in the <i>Amazon S3 API Reference</i>.</p> <p>For more information about IAM support for temporary security credentials, see Temporary Security Credentials in the <i>IAM User Guide</i>.</p>	August 3, 2011
Multipart Upload API extended to enable copying objects up to 5 TB	<p>Prior to this release, Amazon S3 API supported copying objects of up to 5 GB in size. To enable copying objects larger than 5 GB, Amazon S3 now extends the multipart upload API with a new operation, <code>Upload Part (Copy)</code>. You can use this multipart upload operation to copy objects up to 5 TB in size. For more information, see Copying, moving, and renaming objects.</p> <p>For conceptual information about multipart upload API, see Uploading and copying objects using multipart upload in Amazon S3.</p>	June 21, 2011
SOAP API calls over HTTP disabled	To increase security, SOAP API calls over HTTP are disabled. Authenticated and anonymous SOAP requests must be sent to Amazon S3 using SSL.	June 6, 2011

Change	Description	Date
IAM enables cross-account delegation	<p>Previously, to access an Amazon S3 resource, an IAM user needed permissions from both the parent AWS account and the Amazon S3 resource owner. With cross-account access, the IAM user now only needs permission from the owner account. That is, If a resource owner grants access to an AWS account, the AWS account can now grant its IAM users access to these resources.</p> <p>For more information, see Creating a role to delegate permissions to an IAM user in the <i>IAM User Guide</i>.</p> <p>For more information on specifying principals in a bucket policy, see Principals for bucket policies.</p>	June 6, 2011
New link	This service's endpoint information is now located in the <i>AWS General Reference</i> . For more information, go to Regions and Endpoints in the AWS General Reference .	March 1, 2011
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, <code>http://mywebsite.com/subfolder</code>) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3 .	June 6, 2011

Change	Description	Date
<p>This service's endpoint information is now located in the <i>AWS General Reference</i>. For more information, go to Regions and Endpoints in the AWS General Reference.</p>	March 1, 2011	
Support for hosting static websites in Amazon S3	<p>Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, <code>http://mywebsite.com/subfolder</code>) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3.</p>	February 17, 2011
Response Header API Support	<p>The GET Object REST API now allows you to change the response headers of the REST GET Object request for each request. That is, you can alter object metadata in the response, without altering the object itself. For more information, see Downloading objects.</p>	January 14, 2011
Large object support	<p>Amazon S3 has increased the maximum size of an object you can store in an S3 bucket from 5 GB to 5 TB. If you are using the REST API, you can upload objects of up to 5 GB in a single PUT operation. For larger objects, you must use the Multipart Upload REST API to upload objects in parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3.</p>	December 9, 2010

Change	Description	Date
Multipart upload	Multipart upload enables faster, more flexible uploads into Amazon S3. It allows you to upload a single object as a set of parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3 .	November 10, 2010
Canonical ID support in bucket policies	You can now specify canonical IDs in bucket policies. For more information, see Principals for bucket policies	September 17, 2010
Amazon S3 works with IAM	This service now integrates with AWS Identity and Access Management (IAM). For more information, go to AWS services that work with IAM in the <i>IAM User Guide</i> .	September 2, 2010
Notifications	The Amazon S3 notifications feature enables you to configure a bucket so that Amazon S3 publishes a message to an Amazon Simple Notification Service (Amazon SNS) topic when Amazon S3 detects a key event on a bucket. For more information, see Setting Up Notification of Bucket Events .	July 14, 2010
Bucket policies	Bucket policies are an access management system that you use to set access permissions across buckets, objects, and sets of objects. This functionality supplements and in many cases replaces access control lists. For more information, see Bucket policies for Amazon S3 .	July 6, 2010
Path-style syntax available in all Regions	Amazon S3 now supports the path-style syntax for any bucket in the US Classic Region, or if the bucket is in the same Region as the endpoint of the request. For more information, see Virtual Hosting .	June 9, 2010
New endpoint for Europe (Ireland)	Amazon S3 now provides an endpoint for Europe (Ireland) : <code>http://s3-eu-west-1.amazonaws.com</code> .	June 9, 2010

Change	Description	Date
Console	You can now use Amazon S3 through the AWS Management Console. You can read about all of the Amazon S3 functionality in the console in the Amazon Simple Storage Service User Guide.	June 9, 2010
Reduced Redundancy	Amazon S3 now enables you to reduce your storage costs by storing objects in Amazon S3 with reduced redundancy. For more information, see Reduced Redundancy Storage .	May 12, 2010
New Region supported	Amazon S3 now supports the Asia Pacific (Singapore) Region. For more information, see Buckets and Regions .	April 28, 2010
Object Versioning	This release introduces object versioning. All objects now can have a key and a version. If you enable versioning for a bucket, Amazon S3 gives all objects added to a bucket a unique version ID. This feature enables you to recover from unintended overwrites and deletions. For more information, see Versioning and Using Versioning .	February 8, 2010
New Region supported	Amazon S3 now supports the US West (N. California) Region. The new endpoint for requests to this Region is <code>s3-us-west-1.amazonaws.com</code> . For more information, see Buckets and Regions .	December 2, 2009
AWS SDK for .NET	AWS now provides libraries, sample code, tutorials, and other resources for software developers who prefer to build applications using .NET language-specific API operations instead of REST or SOAP. These libraries provide basic functions (not included in the REST or SOAP APIs), such as request authentication, request retries, and error handling so that it's easier to get started. For more information about language-specific libraries and resources, see Developing with Amazon S3 using the AWS SDKs in the Amazon S3 API Reference .	November 11, 2009
